Good quality, comprehensive bionomic data capturing the ecology and behavior of different malaria vectors is challenging to collect. Nevertheless, considering evidence about the ecology of mosquitoes is crucial for predicting impact of vector control interventions. Mathematical models can be used to infer the likely impact of malaria interventions from entomological field data. With most vector control studies carried out in sub-Saharan Africa, most impact predictions are specific to African vectors, and these may not apply for settings with other vector species, leading to suboptimal policy guidelines for other geographical locations. Currently, there is no available tool which systematically incorporates field data and allows estimating location-specific intervention impact accordingly. We developed AnophelesModel, an online, open-access platform that quantifies the impact of vector control interventions according to mosquito species-specific bionomics and human behavior. AnophelesModel is based on a comprehensive, curated database of field entomological data from over 50 Anopheles species assembled from the Malaria Atlas Project and additional literature. Furthermore, the database contains patterns of human activity collected at 77 sites in 26 countries from Africa, Asia and Central America as well as vector control effectiveness estimated from experimental hut trial data. The considered interventions include indoor residual spraying, long-lasting insecticide-treated nets and house screening. Within AnophelesModel, the data are used to parameterize a discrete-time, state transition model of the mosquito feeding cycle and infer the location-specific impact of vector control on the vectorial capacity. Using AnophelesModel, we demonstrate how key implications for intervention impact change for various vectors across locations in Africa, Asia and Central America. Our platform can thus be used to make predictions about the key factors determining intervention impact according to human activity and vector-specific bionomics, guiding thinking towards more robust and efficient policy recommendations.

### DOES LARVAL HABITAT MODIFICATION AND MANIPULATION CONTROL MALARIA? FINDINGS FROM A SYSTEMATIC REVIEW

**Elisa Martello**<sup>1</sup>, Gowsika Yogeswaran<sup>1</sup>, Richard Reithinger<sup>2</sup>, Jo Leonardi-Bee<sup>1</sup>

<sup>1</sup>University of Nottingham, Nottingham, United Kingdom, <sup>2</sup>RTI International, Washington, DC, United States

Malaria continues to be a major public health problem. Although long-lasting insecticidal nets and indoor residual spraying of households with insecticide have proven highly effective, due to emerging and expanding insecticide resistance, there has been renewed interest in other vector control approaches, including larval source management (LSM). This systematic review summarises the effectiveness of larval habitat modification and manipulation on epidemiological and entomological outcomes. Intervention studies were identified from searches of six databases and other grey literature sources. Two authors independently screened studies, performed data extraction, and assessed the risk of bias. A narrative synthesis approach was used. GRADE was used to assess the certainty of the evidence for each intervention. A total of 13 controlled intervention studies were included, of which only four assessed epidemiological outcomes. There was very low evidence that using spillways across streams or floodgates on a dam reduce malaria parasite

prevalence and/or incidence. Also, there was low evidence that repairing and clearing of drains, cutting grasses and minor repairs reduces malaria parasite prevalence and/or incidence. Stronger certainty of evidence was seen for entomological outcomes, particularly relating to interventions based on frequent/intermediate clearing of grass and replenishing water in larval habitats, or the use of Napier grass for shading. Without epidemiological evidence or sufficient studies demonstrating that a significant reduction in vector densities translates to reduced disease, it is currently difficult to provide firm recommendations for the use of habitat manipulation/modification to control malaria.

### RESTING BEHAVIOR OF MALARIA VECTORS IN GHANA AND ITS IMPLICATION ON VECTOR CONTROL

**Aku Obeng Forson<sup>1</sup>**, Isaac A. Hinne<sup>2</sup>, Isaac Kwame Sraku<sup>3</sup>, Abdul Rahim Mohammed<sup>1</sup>, Simon K. Attah<sup>2</sup>, Yaw Asare Afrane<sup>1</sup>

<sup>1</sup>Department of Medical Laboratory Science, School of Biomedical and Allied Health Sciences, University of Ghana, Korle-Bu, Accra, Ghana., Accra, Ghana, <sup>2</sup>Department of Medical Microbiology, University of Ghana Medical School, University of Ghana, Korle-Bu, Accra, Ghana., Accra, Ghana, <sup>3</sup>Department of Medical Microbiology, University of Ghana Medical School, University of Ghana, Korle-Bu, Accra, Ghana, Accra, Ghana

There is widespread use of long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS) to control the density of malaria transmitting mosquitoes in Ghana. An understanding of the interactions between increased insecticide resistance and resting behaviour patterns of mosquitoes is important for an effective vector control programme. Mosquitoes were sampled during the dry and rainy seasons of 2019 from 3 ecological landscapes in Ghana, namely, Sahel savannah (Kpalsogou, Pagaza, Libga), Coastal savannah (Ada Foah) and Forest (Konongo) zones. PCR based molecular techniques was used to determine the species, knockdown resistance mutation (L1014F), G119S Ace-1 mutation, host blood meal and sporozoite infection in field collected mosquitoes. The study found 90% of vectors were *Anopheles gambiae* s. l. and the dominant sibling species was *An. coluzzii* (63%), followed by *An. gambiae* s. s. (27%), *An. arabiensis* (9%) and *An. melas* (1%). The frequency of *kdr* west (L1014F) mutation for mosquitoes resting indoors was 0.90 and 0.84 for outdoors collection in the Sahel savannah zone. However, in the Forest zone, the frequency of *kdr* mutation was 0.9 in outdoor resting and 0.79 indoor resting mosquitoes. The frequency of Ace-1 mutation was higher in mosquitoes resting outdoors (0.50) than indoors (0.38) in the coastal zone. However, similar Ace-1 mutation was detected in outdoor and indoor resting mosquitoes from the Sahel savannah (0.39 vs. 0.36). Outdoor resting mosquitoes had a higher (67.5%) human blood index (HBI) than indoor (67.0%) resting mosquitoes in the Sahel savannah. However, in the Coastal zone, the HBI for indoor resting mosquitoes was 66.7% and 50% for outdoor resting mosquitoes. Overall, the sporozoite rates was high in indoor resting *An. coluzzii* from the Sahel savannah (5.0%) and Forest (2.5%) zones. These results underline the difficulties of controlling malaria vectors resting and biting outdoors using the current interventions. Continuous monitoring of resting behavior of mosquitoes and the implementation of new vector control interventions that will target outdoor resting vectors are urgently needed in Ghana.

### CHARACTERIZATION OF ANOPHELES SPECIES TEMPORAL COMPOSITIONS AND BIONOMIC CHARACTERISTICS IN BANDARBAN, BANGLADESH

**Isabella Rodriguez**

University of Notre Dame, Notre Dame, IN, United States

With over 10% of the population of Bangladesh at risk of contracting malaria, it is imperative that we have a better understanding of mosquito drivers of the disease with malaria elimination on the agenda. This study sought to characterize temporal and spatial species compositions and behaviors throughout the rainy season towards understanding

present gaps in transmission that result in residual malaria transmission. *Anopheles* mosquitoes were sampled from four villages in malaria-endemic Bandarbandistrict, Bangladesh, from May through October, 2018. Sampling methods used included CDC-Light traps (CDC-LT), human landing catches (HLC), and pyrethrum spray catches (PSC). Species identification of female specimens was conducted both morphologically as well as molecularly - using ITS2 and *Co1* sequences. A total of 5376 mosquitoes were collected belonging to 17 species - *Anopheles vagus* was the dominant species (39.7%) followed by *An. nivipes* (12.5%). Other species identified included *An. baimaii*, *An. campestris*, *An. dissidens*, *An. jamesii*, *An. jeyporensis*, *An. karwari*, *An. kochi*, *An. maculatus*, *An. peditaeniatus*, *An. philippinensis*, *An. sawadwongporni*, *An. splendidus*, *An. subpictus* (Forms A and B) and *An. varuna*. The months following peak rainfall in June had the highest *Anopheles* biomass. Outdoor catches were usually higher than indoor catches at all four sites. A large variation in species-specific biting behaviors demonstrates a complex vector ecology with *An. vagus* demonstrated the highest endophily (95% of indoor resting mosquitoes) as well as the highest anthropophagy. This study points to the primary vector at these sites being *An. vagus* with contributions to disease transmission from other species. Gaps in protection with indoor-based interventions include vectors and humans overlapping in the early evening and outdoors. Targeting *An. vagus* indoor resting behavior with non-pyrethroid-based indoor residual spraying (IRS) may be effective against this vector. Other interventions targeting transmission that occurs outside the scope of LLINs and IRS are required with malaria elimination being the goal.

0744

### PHYSICAL DURABILITY MONITORING AND USE ASSESSMENT OF INSECTICIDE TREATED NETS IN MALI OVER A THREE-YEAR PERIOD

**Moussa Bm Cisse<sup>1</sup>**, Ibrahim Traore<sup>1</sup>, Lansana Sangare<sup>1</sup>, Yacouba Dansoko<sup>1</sup>, Alice Dembele<sup>1</sup>, Lazeni Konate<sup>1</sup>, Jean Marie Sanou<sup>1</sup>, Samah Sissoko<sup>2</sup>, Abdourhamane Dicko<sup>2</sup>, Libasse Gadiaga<sup>3</sup>, Richard Oxborough<sup>3</sup>, Jules Mihigo<sup>4</sup>, Aliou Diallo<sup>4</sup>, Celia Jane Woodfill<sup>4</sup>, Erin Eckert<sup>5</sup>, Paula Marcet<sup>6</sup>, Michael D. Green<sup>6</sup>, Ousmane Koita<sup>1</sup>

<sup>1</sup>Laboratoire de Biologie Moleculaire Appliquee / Universite des Sciences des Techniques et des Technologies de Bamako (LBMA/USTTB), Bamako, Mali, <sup>2</sup>Programme National de Lutte Contre le Paludisme, Bamako, Mali, <sup>3</sup>PMI VectorLink Project, Bamako, Mali, <sup>4</sup>President Malaria Initiative USAID, Bamako, Mali, <sup>5</sup>International Development Group/ RTI International, Washington, DC, United States, <sup>6</sup>Entomology Branch, US Centers for Disease Control, Atlanta, GA, United States

In Mali, insecticide treated nets (ITNs) are distributed through regional mass campaigns and through routine health services to pregnant women and infants. In 2018, the ITN national coverage was 95% (one ITN for every two persons) in 2018. Both net durability and the "average useful life" of a net are critical factors for determining the frequency at which nets need to be replaced and the types of nets to be procured. The objectives of this study were to: 1) assess the physical durability of deltamethrin based ITNs (Yorkool and PermaNet 2.0) in two sites, 2) compare their durability and 3) identify major determinants of net performance. The study was conducted in Kenieba and Kita districts which have similar malaria prevalence profiles. Cohorts of 461 ITNs (Yorkool) in Kenieba and 515 ITNs (PermaNet 2.0) in Kita were identified for monitoring with evaluations carried out at 6, 12, 24 and 36-months after a mass net distribution carried out in the area in December 2017. Physical durability monitoring was performed by taking into account the rate of net loss (attrition), the physical condition of surviving nets which was measured by the WHO standardized proportionate hole index (pHI) and the proportion of nets in good condition (pHI < 64) after three years. At the 36 months post-distribution evaluation, 245 ITNs in Kenieba and 193 ITNs in Kita were active. Attrition due to wear and tear was higher in Kenieba (44.8%) than in Kita (22.3%) ( $p=0.0187$ ), with tears being the main type of damage at both sites: 70% in Kenieba and 59% in Kita. The proportion of nets in good condition was lower in Kenieba (33%) than in Kita (63%) ( $p=0.0125$ ). The proportion of nets surviving in good condition was lower

in Kenieba (25%) than in Kita (58%) ( $p=0.002$ ). The median survival was 2.1 years [1.82-2.61] in Kenieba (Yorkool) and 3.4 years [2.67-5.04] in Kita (Permanet 2.0). The reasons for the significantly lower performance of Yorkool nets in Kenieba could be associated with product specifications, as PermaNet 2.0 has a thicker fabric of 100 denier polyester compared to 75 denier for Yorkool. Socio-cultural differences between the districts could have an impact and remain to be assessed.

## DEFINING A VECTOR CONTROL PRODUCT FOR THE BUILT ENVIRONMENT

Eleanore D. Sternberg<sup>1</sup>, Melinda P. Hadi<sup>2</sup>

<sup>1</sup>Vestergaard Sarl / Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Vestergaard Sarl, Lausanne, Switzerland

The risk of malaria is greatly influenced by the built environment; for example, house modifications such as metal roofs, ceilings, closed eaves, well-fitted doors, and screened windows can reduce the risk of malaria in households. Combining these features with targeted insecticide treatment may produce an even greater protective effect, by killing mosquitoes as they attempt to enter a house. Because these modifications cover a broad set of interventions, it can be difficult to define targets for product development and routes to market for new products. One tool to help guide the process is a target product profile (TPP). TPPs define the desired characteristics of a public health product, such as a new vaccine or insecticide-treated bed net, which helps address product development issues and prevent late-stage development failures. Understanding need and demand is essential for developing a TPP. To better understand demand for a screening product for the built environment, we conducted interviews with malaria control experts in six countries: Cameroon, Democratic Republic of the Congo, Ghana, Guinea, Nigeria, and Zambia. The survey sought to explore questions such as: 1. What is the level of interest for an insecticidal screen product (e.g. window screen)? 2. What drives interest in such a product? 3. Who would use such a product? 4. How important is a WHO recommendation for product adoption? 5. What are the expected technical and operational challenges? Respondents were generally interested in a screen product, particularly window screening. They felt that screening could be effective for vector-borne disease control and serve as a passive tool to deploy in areas with poor bed net usage. However, they also voiced concerns around cost and durability, and how households could acquire and install such a product. Whilst preliminary, the survey does demonstrate many recurrent themes in ongoing discussions around vector control and the built environment. We intend it as a launching point for further discussion with key stakeholders, and further development of a TPP for a screen product.

## RAPID AGEING AND SPECIES IDENTIFICATION OF NATURAL MOSQUITOES FOR MALARIA SURVEILLANCE

Doreen Josen Siria<sup>1</sup>, Roger Sanou<sup>2</sup>, Joshua Mitton<sup>3</sup>, Emmanuel Mwanga<sup>1</sup>, Abdoulaye Niang<sup>4</sup>, Paul Johnson<sup>5</sup>, Geraldine Foster<sup>6</sup>, Klaas Wynne<sup>7</sup>, Roderick Murray-Smith<sup>3</sup>, Abdoulaye Diabaté<sup>2</sup>, Fredros O. Okumu<sup>1</sup>, Heather M. Ferguson<sup>5</sup>, Mario González-Jiménez<sup>7</sup>, Simon A. Babayan<sup>5</sup>, Francesco Baldini<sup>5</sup>

<sup>1</sup>Environmental Health & Ecological Sciences Department, Ifakara Health Institute, Ifakara, Morogoro, United Republic of Tanzania, <sup>2</sup>Department of Medical Biology and Public Health, Institut de Recherche en Science de la Santé (IRSS), Bobo-Dioulasso, Burkina Faso, <sup>3</sup>School of Computing Science, University of Glasgow, Glasgow, United Kingdom, <sup>4</sup>University Nazi Boni de Bobo-Dioulasso, Bobo-Dioulasso, Burkina Faso, <sup>5</sup>Institute of Biodiversity Animal Health and Comparative Medicine, University of Glasgow, Glasgow, United Kingdom,

<sup>6</sup>Department of Vector Biology, Liverpool School of Tropical Medicine, Liverpool, UK, Liverpool, United Kingdom, <sup>7</sup>School of Chemistry, University of Glasgow, Glasgow, United Kingdom

Vector surveillance is essential to monitor and optimize adult mosquito control to prevent vector-borne diseases. Specifically, accurate and high-resolution estimation of both the mosquito abundance of morphological identical species and their longevity are essential for the assessment of the impact of vector control measures. Up to date no simple and precise method allows measuring these mosquito traits. The current tools in use are expensive and time-consuming. So, our new approach underway development is based on the amount of light absorbed by the different molecules of the mosquito cuticle through mid-infrared spectroscopy (MIRS), which changes between different mosquitoes species and during ageing. By applying convolutional neural networks to MIRS spectra, we have been able to predict with an unprecedented accuracy of up to 95% the age and species of lab and semi-field mosquitoes *Anopheles gambiae*, *An. coluzzii* and *An. arabiensis* from Bobo-Dioulasso, Burkina Faso and Ifakara, Tanzania. To account for the genetic and ecological variation, mosquitoes were collected from the field and then reared under lab standard conditions and in semi-field facilities. We then validated our model on wild mosquito species. First, we collected wild mosquitoes from different villages and their gonotrophic cycles assessed upon dissection and microscopic analysis of the ovaries, then measured by MIRS. Here we will present the age and species prediction model of wild mosquitoes based on convolutional neural networks. This new approach is easy-to-use, cost-effective, robust and high-throughput and presents several advantages by predicting simultaneously the age and species which could be of great value in vector surveillance programmes.

## A PROSPECTIVE MICRO-COSTING LARVAL SOURCE MANAGEMENT TOOL TO INFORM DECISION MAKING IN TANZANIA

Sophie Diarra, Denis Kailembo, Branwen Owen, Emilie Pothin  
Swiss Tropical and Public Health Institute, Basel, Switzerland

In the face of stagnating malaria budgets, only the most cost-effective interventions should ideally be implemented. However, cost-effectiveness estimates rest on accurate costing, a challenging activity when interventions have not yet been deployed in a given setting. Here, we aim to prospectively cost microbial larval source management for prospective deployment in Tanzania. We developed a micro-costing model to evaluate economic and financial costs associated with a microbial larval source management intervention in low and very low transmission areas. We used budgeting data from an infield intervention together with global guidance and the literature to inform economic and financial costing models. Costs were stratified based on uni-modal and bi-modal rainfall patterns. Resource use and costs were derived for the following sub-activities: micro-planning, quantification and procurement of larvicide, training and capacity building, implementation and monitoring and evaluation. Sensitivity analysis was used to explore how uncertainty in key parameters, such as the cost of larvicide, number of spray cycles, area and number of breeding sites, affected costs. Larvicide procurement accounted for 50% of the total costs, human resource including training and supervision accounted for 21%. Estimated financial unit costs of microbial larval-source management were US\$2.45 per person protected per year. Results were highly sensitive to the unit cost of the larvicide and staff payments. Standardized prospective costing tools offer a methodological framework that can be used to evaluate the financial and economic viability of malaria interventions at different scales. This costing tool demonstrates that larval source management is a low-cost vector control method which can supplement malaria control efforts. Costing frameworks like this help to better plan for implementation in specific settings, such as Tanzania, and can be adapted to different epidemiological and health system contexts that may consider implementing larval source management.

## HABITAT CHARACTERIZATION AND LARVAL ABUNDANCE OF ANOPHELES FUNESTUS IN A HIGHLAND AND LOWLAND SITE IN WESTERN KENYA

Isaiah Debrah<sup>1</sup>, Yaw Afrane<sup>1</sup>, Linda Amoah<sup>2</sup>, Harrysone Atieli<sup>3</sup>, Andrews Githeko<sup>4</sup>, Guiyun Yan<sup>5</sup>

<sup>1</sup>University of Ghana, Accra, Ghana, <sup>2</sup>Noguchi Memorial Institute for Medical Research, University of Ghana, Accra, Ghana, <sup>3</sup>International Center for Excellence Malaria Research, Tom Mboya University College, Kenya, Homabay, Kenya, <sup>4</sup>Center for Global Health Research, Kisumu, Kenya, <sup>5</sup>Program in Public Health, College of Health Sciences, University of California at Irvine, Irvine, CA, United States

*Anopheles funestus* is a major Afrotropical vector of human malaria. In the last few years, there have been reports of the resurgence of this vector in western Kenya after the introduction of insecticide-treated nets. This might be influencing malaria transmission in western Kenya. However, there is limited study on the larval ecology of this efficient primary vector. A larval survey was carried out in Kombewa in lowland and Bungoma in the highland of western Kenya from November 2019 to December 2020. All potential mosquito breeding habitats were identified, characterized, georeferenced and carefully examined for the presence of mosquito larvae and predators using the standard dippers technique and 10L bucket. The larvae were morphologically identified and confirmed using PCR. In all, 151 mosquito aquatic habitats were assessed. Of this, 58/71 (82%, 95%, CI, 0.73-0.91) were found in Kombewa and 62/80 (78%, 95%, CI, 0.68-0.87,) in Bungoma were positive for mosquito larvae. A total of 3,193 mosquito larvae were sampled and *An. funestus* larvae constitute 38% (1224/3,193). Bungoma recorded a higher number of *An. funestus* larvae (85%, 95%, CI, 8.722- 17.15) than Kombewa (15%, 95%, CI, 1.33- 3.91). Fifty-nine percent (59%), 35% and 5% of *An. funestus* larvae co-exist with *An. gambiae s.l.*, *Culex spp* and *An. coustani* in the same habitats. *An. funestus* breeds in a wide range of habitats with man-made ponds having the highest abundance of larvae. Typically, *An. funestus* breeds in a permanent and semi-permanent aquatic habitat with or without aquatic vegetation, slow-moving/disturbed or stagnant water that is either clear, opaque, cloudy or brownish near human habitations. Multiple regression analysis and principal component analysis identified the distance to the nearby house as the key environmental factors associated with the abundance of *An. funestus* larvae. This study serves as a guide to the control of aquatic stages of *An. funestus* and other mosquito species using larval source management or larviciding to complement the existing vector control tools.

## THE INTERPRETATION OF EXPERIMENTAL TRIAL DATA FOR EVALUATION OF INDOOR VECTOR CONTROL INTERVENTIONS AGAINST MALARIA

Joseph D. Challenger<sup>1</sup>, Corine Ngufor<sup>2</sup>, Raphael N'Guessan<sup>2</sup>, Thomas S. Churcher<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Experimental hut trials are the most important entomological assay for assessing the efficacy of anti-mosquito interventions used in the home. These assays are being increasingly used to evaluate new products as resistance to pyrethroid insecticide spreads and new insecticide treated nets (ITNs), indoor residual sprays, spatial repellents and attractive toxic sugar baits are developed. As several sources of variation are present in the assay and complexity is introduced due to the use of wild mosquitoes, the interpretation of hut trial data can be somewhat unclear and there is the potential for considerable measurement error. Product development or prioritisation of interventions often relies on relatively modest differences in mosquito mortality or blood-feeding inhibition. Though these differences appear statistically significant when the data is aggregated, as large numbers of mosquitoes are collected, they may not necessarily mean that different interventions have an underlying different efficacy, even if

the products were compared side by side in an experimental hut trial. The talk draws on a meta-analysis of 135 experimental hut trials to show how results from different sites should be interpreted. Using data from previous hut trials to understand the level of variation typically present in the assay, we utilise simulation-based methods to guide our work. For example, with a commonly used trial design, analyses indicate that the advantage that pyrethroid-piperonyl butoxide ITNs over standard pyrethroid-only ITNs can vary by up to 29% mortality in the same trial. The work highlights the minimum set of results that need to be presented to allow different results to be accurately compared. Implications for comparison of products, policy and the prioritisation of different vector control tools are discussed.

## MOSQUITOCIDAL CONCENTRATION OF IVERMECTIN OVER SIX MONTHS THROUGH A LONG-LASTING FORMULATION: TOWARD A SUSTAINABLE CONTROL OF MALARIA VECTORS IN A ONE-HEALTH APPROACH WITH THE HELP OF PERIDOMESTIC ANIMALS?

Sié Hermann Pooda<sup>1</sup>, Lamidi Zela<sup>1</sup>, Nicolas Moiroux<sup>2</sup>, Christophe Roberge<sup>3</sup>, Anne-Laure Courjaud<sup>3</sup>, Marie-Sophie Martina<sup>3</sup>, Jean-Baptiste Rayaissé<sup>4</sup>, Roch K. Dabiré<sup>5</sup>, Karine Mouline<sup>2</sup>

<sup>1</sup>Centre International de Recherche Développement sur l'Elevage en zone Subhumide -Université de Dédougou, Bobo-Dioulasso, Burkina Faso, <sup>2</sup>Institut de Recherche pour le Développement, Montpellier, France, <sup>3</sup>MedinCell, Jacou, France, <sup>4</sup>Centre International de Recherche Développement sur l'Elevage en zone Subhumide, Bobo-Dioulasso, Burkina Faso, <sup>5</sup>Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso

In malaria endemic areas, because humans are protected by bednets, peridomestic animals represent an alternative blood source for *Plasmodium* vectors, allowing residual transmission of the parasite. Previous studies show that ivermectin (IVM) treatments of *Anopheles* hosts provoke systemic insecticidal effects. This is therefore seen as an alternative to complement existing malaria control tools, albeit with the strong limitation of the poor remanence of the product, which represents a clear limit toward a mass implementation. The ANIVERMATE project was designed to evaluate the killing effect of a new formulation of IVM, using the Bepo® technology, on wild *A. coluzzii* females. Twenty-one calves were used as mosquito hosts for this 3-arms design study (control, classical formulation Ivomec-D® (monthly injections of 0,4 mg/kg) and Bepo®-IVM (one injection of 2,4 mg/kg)). The Bepo®-IVM has been designed to target at least the LC50 plasma concentration of IVM over 6 months. 15 000 *A. coluzzii* females were allowed to feed directly on the calves' skin at different time points after the hosts treatments. Mosquito survival was assessed over 30 days post feeding. As expected, IVM concentrations in the hosts treated with the Bepo®-IVM were lower and steadier than when using Ivomec-D®, with a significant mosquitocidal activity measured for up to 6 months. The efficacy using the Ivomec-D® was variable, depending on the time elapsed from the treatment, and reached concentrations below the LC50 on the last week of each month. By comparison, the Bepo®-IVM released IVM concentrations remained above the LC50 during the whole study. The entomological data will feed a model expected to show the benefit of Bepo®-IVM formulation for significantly reducing Malaria transmission. In addition, the potential use of a long lasting IVM treatments in peridomestic animals has been studied in the fields, where we examined IVM behaviour in the dung and in local soils as well as deleterious effects of the molecule on non-targeted coprophilic fauna, that are essential to ecosystem's health and productivity (see companion abstract by Heinrich *et al.*)

<sup>1</sup>Abt Associates, PMI VectorLink Project, Bogota, Colombia, <sup>2</sup>Secretaría Departamental de Salud del Cauca, Popayan, Colombia, <sup>3</sup>Abt Associates, PMI VectorLink Project, Rockville, MD, United States, <sup>4</sup>Grupo de Entomología, Subdirección de Investigación Científica y Tecnológica, Instituto Nacional de Salud, Bogota, Colombia, <sup>5</sup>Grupo de Entomología, Laboratorio Nacional de Referencia, Instituto Nacional de Salud, Bogota, Colombia, <sup>6</sup>Grupo Endemo-epidémicas, Subdirección de Enfermedades Transmisibles, Ministerio de Salud y la Protección Social, Bogota, Colombia, <sup>7</sup>Bureau for Latin America and the Caribbean, United States Agency for International Development, DC, United States, <sup>8</sup>U.S. President's Malaria Initiative, United States Agency for International Development, DC, United States, <sup>9</sup>U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States

Malaria vector control in the Americas depends on insecticide-treated nets (ITNs) and indoor residual spraying (IRS) of insecticide. However, there is limited evidence regarding the effectiveness of these tools against neotropical malaria vectors that exhibit host-seeking behaviors distinct from those observed in Africa. While the Americas have achieved reductions in malaria transmission, important foci remain despite the widespread use of ITNs and IRS. We are conducting a two-armed cluster-randomized trial to determine the entomological impact of ITNs and IRS in Colombia, where *Anopheles albimanus* is the primary vector. The trial began in February 2021 in Cauca department, on the Pacific coast of Colombia, in the municipalities of Guapi and Timbiquí. The study was designed to detect a 40% reduction in indoor host-seeking *Anopheles* spp. with 80% power, comparing the IRS and ITN arms. As such, the study required 20 clusters per arm, sampling four houses per cluster for the primary indicator (indoor and outdoor human landing catches, HLCs), for a total of 160 houses measured monthly. Clusters were randomly allocated to receive either ITNs (alpha-cypermethrin) or IRS (deltamethrin), implemented by the Colombian Ministry of Health. In addition to HLCs, mosquito resting density, parasite inoculation rates, and insecticide susceptibility are also being monitored. Finally, qualitative household KAP surveys, combined with human blood sampling to measure antibodies to mosquito salivary antigens are being conducted to better understand the impacts of the interventions. At baseline, 18,256 *Anopheles* spp. were collected throughout the night in both indoor and outdoor HLCs, with a peak of activity between 18:00 and 22:00 hours. When tested for insecticide resistance, the *Anopheles* spp. were susceptible to both deltamethrin and alpha-cypermethrin using CDC bottle bioassays. Entomological data collection will be ongoing for 18-months post-intervention. Results from this study will provide evidence for the entomological impact of ITNs and IRS in a malaria transmission setting in the Americas and will highlight gaps in use of the current tools.

### NITISINONE AS A POTENTIAL ALTERNATIVE ECTOPARASITIC DRUG FOR A COMPLEMENTARY MALARIA VECTOR CONTROL STRATEGY

Anna Elizabeth Trett, Lee Haines, Ghaith Aljayyousi, Alvaro Acosta-Serrano

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The residual transmission of malaria is driven by outdoor biting and insecticide resistant vectors. In the search for novel tools that target the current challenges facing malaria elimination, repurposing ivermectin as an endectocide and complementary tool for vector control has

been prominent. The tyrosinemia drug, nitisinone, is selectively toxic to blood-feeding arthropods, inhibiting the essential tyrosine metabolism that follows bloodmeal ingestion. Nitisinone is a promising candidate for an ectoparasitic drug, owing to its favourable pharmacokinetic/ pharmacodynamic (PK/PD) properties. Drug-spiked blood meals were fed to *Anopheles gambiae* in standard membrane feeding assays in a direct comparison between the drugs. A Cox regression survival analysis assessed mortality. Proportional hazard ratios were fitted to a non-linear squares model and PK/PD modelling simulated mosquitocidal activity over time. Monte Carlo population simulations were applied to dosing regimens to attain clinically meaningful comparisons. Nitisinone demonstrated a longer lasting mosquitocidal effect than ivermectin at relevant dosing regimens (3x300µg/kg IVM, 3x1mg/kg NTBC). At a modest dose, nitisinone maintained a superior mosquitocidal effect for one week longer than a high dose of ivermectin (19 days, 12 days). Nitisinone was superior to ivermectin at both low and single dosing regimens, which is important from a clinical safety and logistical perspective, respectively. Although the lethal concentration (LC50) for ivermectin was comparatively lower than nitisinone (15.66ng/mL, 136ng/mL), the PK profile of nitisinone means that higher blood concentrations can be attained and remain above the LC50 for longer. Our work presents initial results of a potential ectoparasitic drug that is comparative to ivermectin as a complementary vector control tool. Even when dosed at a tenth of the recommended regimen, a mosquitocidal effect was predicted for a week. It is important to preserve the existing efficacy of ivermectin. In exploring other compounds, we can alleviate a reliance on a sole eligible compound for this strategy of vector control.

Insecticides with a different mode of action are urgently needed to counter resistance in mosquitoes. A new meta-diamide insecticide for vector control, broflanilide (TENEBENAL™), was evaluated in northern Tanzania. We present the potential of this insecticide as an addition to the arsenal of IRS products needed for rotational use to maintain both control of malaria and resistance management of malaria-transmitting mosquitoes. Bottle bioassays indicated that broflanilide was effective against both susceptible and mosquito strains with multiple resistance mechanisms, demonstrating an absence of cross resistance between broflanilide and pyrethroids. Two consecutive experimental hut trials were conducted; the first evaluating the efficacy of three concentrations using a prototype formulation of broflanilide, and the second trial evaluating an improved formulation; VECTRON™ T500. The experimental hut trial showed a dosage-mortality response of broflanilide and 3-8 months of residual activity, with longer activity on concrete than mud. The second trial with VECTRON™ T500 showed prolonged residual efficacy to 5-6 months on mud, and high mosquito mortality for the full duration of the trial on concrete. Results with free-flying, wild *Anopheles arabiensis* echoed the mortality trend shown in cone assays, with the highest dose inducing the highest mortality and the improved formulation showing increased mortality rates. No blood-feeding inhibition or insecticide-induced exiting effects were observed. Following on from these promising results in the experimental hut studies, a community study in northern Tanzania with broflanilide was initiated in February 2021 with approximately 2000 households.

## REDUCTION IN MALARIA CASES AND ANNUAL PARASITE INCIDENCE AFTER REINTRODUCTION OF INDOOR RESIDUAL SPRAYING IN ESCUINTLA, GUATEMALA

Ligia M. Deaz-Morales<sup>1</sup>, Manica E. Barrientos Juarez<sup>1</sup>, Rodrigo A. Flores Sanchez<sup>2</sup>, Abraham Arnez Matias<sup>3</sup>, Melissa Wiles<sup>3</sup>, Justin Lana<sup>4</sup>, Daragh A. Gibson<sup>5</sup>

<sup>1</sup>Guatemalan Ministry of Public Health and Social Assistance, National Vector-Borne Disease Program, Guatemala City, Guatemala, <sup>2</sup>Guatemalan Ministry of Public Health and Social Assistance, Health Area of Escuintla Vector-Borne Disease Program, Escuintla, Guatemala, <sup>3</sup>Clinton Health Access Initiative, Guatemala Office, Guatemala City, Guatemala, <sup>4</sup>Clinton Health Access Initiative, Panama Office, Panama City, Panama, <sup>5</sup>Clinton Health Access Initiative, Boston Office, Boston, MA, United States

The department of Escuintla, Guatemala, is an important malaria endemic region, accounting for an average of 60% (50-70%) of the country's cases from 2013-2019. However, just 29% of Guatemala's cases were reported from the department last year coinciding with Escuintla's fourth straight year of case declines. In 2017, the National Vector-Borne Disease Program reintroduced indoor residual spraying (IRS) in high burden localities of Escuintla as a strategy to accelerate toward malaria elimination. This was done in conjunction with ongoing surveillance and case management strengthening activities and continued distribution of long-lasting insecticidal nets in endemic localities. IRS spray rounds were conducted at the beginning of the malaria high transmission season (defined as epidemiological weeks 40 to 18) in 1 (2017), 10 (2018), and 5 (2019) highly endemic localities. IRS coverage averaged >80% each year. We examined the impact of IRS on the reduction of malaria cases during the high transmission season and on annual parasite incidence (API) in the areas receiving IRS. We calculated the percent reduction from baseline (2016-2017 season) for each subsequent season after IRS was introduced. The total number of cases during the high transmission season in 2016-2017 (before IRS reintroduction) was 737 cases, compared to 646 (2017-2018 season), 346 (2018-2019 season), and 82 (2019-2020 season), reflecting a 12.3%, 53.1%, and 88.9% reduction in total cases in IRS localities when compared to the baseline, respectively. Because not all localities received three spray rounds, separate grouped analyses were conducted dependent on the total number of rounds received. Results for a subset of four localities receiving two spray rounds during consecutive high transmission seasons demonstrated an average API of 176.2 in 2018 (before IRS reintroduction), 106.2 in 2019, and 14.8 for 2020. These results suggest that the introduction of IRS in targeted, high-risk areas as part of an integrated and strengthened malaria elimination strategy contributed to Escuintla's 88% decline in total cases since 2017.

## WHICH TRAP IS BEST? ALTERNATIVES TO HUMAN LANDING CATCHES FOR MALARIA VECTOR SURVEILLANCE: A META-ANALYSIS

Jordan Eckert<sup>1</sup>, Seun Oladipupo<sup>1</sup>, Yifan Wang<sup>1</sup>, ShanShan Jiang<sup>1</sup>, Vivek Patil<sup>1</sup>, Benjamin A. McKenzie<sup>2</sup>, Sarah Zohdy<sup>3</sup>

<sup>1</sup>Auburn University, Auburn, AL, United States, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

Human landing catches (HLCs) are an entomological collection technique in which humans are used as attractants to capture medically relevant host-seeking mosquitoes. This method is considered the gold standard in malaria vector surveillance as it provides metrics such as human biting rate, and entomological inoculation rate (EIR). Despite the high-resolution data obtained from HLCs, the use of this method has been a topic of debate for decades mainly due to safety concerns for the collectors. Many alternatives to HLCs have been proposed; however, to date, no quantitative review of studies comparing HLCs to alternative trapping methods has been conducted. Here, we present a meta-analysis of published literature

on HLCs and alternative trapping methods for outdoor *Anopheles* spp. collections. We identified 17 studies comprising 59 comparisons representing 16 countries. Using data from these studies, we conducted a meta-analysis comparing treatment effects for each study (Hedges' G). Three moderators were used: mosquito (*An. gambiae* s.l., *An. funestus* s.l., and *Anopheles* spp.), trap type, and sub-trap classification (biological, chemical, physical, etc.). Our analysis showed that outdoor HLCs did not perform statistically better than any of the alternative trap types, although there were differences among the sub-traps including specifically between physical/chemical traps and biological, chemical, and physical traps alone. Traps with humans as attractants were the only sub-trap type to capture significantly more mosquitoes than HLCs ( $g = -0.3940$ ). Alternative trapping methods captured significantly more *An. gambiae* s.l., primary vectors, when compared to HLCs ( $g = -1.8516$ ). These results suggest that there is no significant difference between alternative trapping methods and outdoor HLCs for *Anopheles* collections and that these methods can be considered comparable. However, human-baited traps may be superior for the collection of *An. gambiae* s.l. Regional decisions about the use of HLCs for outdoor mosquito collection methods should consider factors such as target vector species and access to alternative trapping methods.

## IMPROVING INDOOR RESIDUAL SPRAYING DEPLOYMENT THROUGH A SPATIAL DECISION SUPPORT SYSTEM

Olivier Tresor Donfack<sup>1</sup>, Liberato Motobe Vaz<sup>1</sup>, Lucas Ondo<sup>1</sup>, Jose Antonio Mba Nlang<sup>1</sup>, Emily Hilton<sup>2</sup>, Jeremias Nzamio Mba Eyono<sup>1</sup>, Marcos Mbulito Iyanga<sup>1</sup>, Restituto Mba Avue<sup>1</sup>, Carlos A. Indoor residual spraying (IRS) has been implemented yearly on Bioko Island since 2004. IRS is expensive due to the costs of insecticide and the workforce needed to deliver the activity in a limited time frame. Robust deployment and monitoring strategies are needed to ensure optimal productivity and homogenous coverage across deployment units. The Bioko Island Malaria Elimination Project (BIMEP) developed a robust spatial decision support system (SDSS) that comprises a household mapping system, a server-based data collection platform, and real-time data access through live dashboards. In 2021, IRS was aimed at ~46,000 households across Bioko Island. The SDSS was used to cluster 100 x 100m map sectors into three equal deployment units. Map sectors within these clusters were grouped into equal size workloads taking into consideration accessibility and distance to cover in a given day by fieldworkers. One workload was given to a team of three spray operators and one community mobilizer at a given time, defining a deployment. To avoid stalling of productivity and over or under-spraying, feedback was provided daily to instruct field teams to prioritize map sectors with large denominators and/or high numbers of households remaining to spray to achieve optimal coverage. Secondary spraying visits were oriented towards map sectors with low IRS refusal rates. Once the target coverage was achieved in a map sector, the latter was eliminated from the workload, and the teams were prompted to exit and move on to other map sectors. After two months of spraying, 30% of the target coverage has been achieved with a team of 102 spray operators, spraying on average 4.7 households per sprayer per day, above the anticipated 3.7 and higher than the historical average for all previous spray rounds. Spray coverage was homogeneous across map sectors. Using a spatial, data-driven approach to optimize IRS will ensure optimal coverage and productivity as well as distributive equity, substantially improving the protection of the population and saving critical resources.

<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>PATH, Kampala, Uganda, <sup>3</sup>PATH, Seattle, WA, United States, <sup>4</sup>National Malaria Control Program, Ministry of Health, Maputo, Mozambique, <sup>5</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>6</sup>Rwanda Biomedical Centre Malaria and Other Parasitic Diseases Division, Ministry of Health, Kigali, Rwanda, <sup>7</sup>National Malaria Elimination Programme, Federal Ministry of Health, Abuja, Nigeria, <sup>8</sup>Ibolda Health International, Abuja, Nigeria, <sup>9</sup>PATH, Maputo, Mozambique, <sup>10</sup>Rwanda Biomedical Center, Rwanda, Rwanda, <sup>11</sup>IVCC, Liverpool, United Kingdom

Dual active ingredient insecticide-treated bed nets (ITNs) that contain more than one active ingredient (AI) and are effective against pyrethroid-resistant mosquitoes were recently distributed as part of mass distribution campaigns in Burkina Faso, Mozambique, Nigeria, and Rwanda. Interceptor® G2 (IG2) (BASF) ITNs were distributed in all four countries, and Royal Guard® (RG) (Disease Control Technologies) ITNs were distributed in Mozambique and Nigeria. Each campaign also included standard pyrethroid-only ITNs and ITNs containing the insecticide synergist piperonyl butoxide (PBO). As part of the New Nets Project, observational studies are underway in 16 districts across the 4 countries to determine the effectiveness and cost effectiveness of IG2, Royal Guard, and PBO ITNs compared to pyrethroid-only ITNs. Surveillance data from each country's health management information system were used to monitor trends in malaria case incidence across all age groups. Cases represented patients who sought care at public health facilities or from community health workers and tested positive for malaria by rapid diagnostic test and/or microscopy. Monthly malaria incidence was calculated by dividing the total number of positive malaria tests in each district by its corresponding population. Baseline malaria incidence rates using monthly incidence from the 12 months prior to each country's mass distribution campaign varied across countries and districts. Incidence rates up to one year post-distribution will be presented for each study district. Interim results from these routine data analyses can help inform country- and global-level decision makers on the effectiveness of different ITNs across a wide range of transmission settings and are critical in establishing calculations of cases averted for cost-effectiveness analyses. These preliminary epidemiological outcomes, showing the diversity in study sites, represent only one year of net life; more complete analyses with two years post-distribution data using a difference in difference approach are forthcoming.

## RESCUE THERAPY FOR ALVEOLAR ECHINOCOCCOSIS PATIENTS WITH BENZIMIDAZOLE TREATMENT FAILURE OR INTOLERANCE WITH LIPOSOMAL AMPHOTERICIN B

**Sanne Burkert**, Lynn Peters, Johannes Bloehdorn, Beate Grüner  
Ulm University Hospital, Ulm, Germany

Although curative resection is the treatment of choice for alveolar echinococcosis (AE), in most cases complete resection is impracticable due to extended involvement of critical anatomic structures. Benzimidazole treatment (BMZT) is the only available medical treatment approved in such cases, but may not be tolerated or insufficient. Thus, new drugs are urgently needed. Amphotericin B treatment (AMBT) has been used with success in such desperate situations. We report long-term follow-up data from 8 patients with AMBT at our centre who were diagnosed with unresectable AE and BMZT intolerance or treatment failure. Initial AMBT loading phase of 2 weeks was followed by 1-3 applications per week,

depending on response. Close monitoring was conducted for the first month and afterwards every 3 months. Responses were confirmed by clinical and serological response, as well as PET-CT scan. All patients had complex, disseminated disease manifestation with pulmonary, cardiac, vertebral, peritoneal and cerebral manifestations. Patients showed intolerance (n=4) and progression (n=4) under BMZT. Age at diagnosis ranged from 29-58 years and AMBT was initiated 1-25 years after diagnosis. With AMBT, 4 patients achieved stable disease (SD), of which 3 are still on therapy after 0.5, 1.5 and 13 years, respectively. One patient received curatively intended surgery under AMBT and treatment response has yet to be confirmed. The other two patients died after having had achieved SD for 4 months and 3 years, but AMBT had to be discontinued due to ileus or renal toxicity, respectively. One patient had shown only a partial remission for 17 months and achieved SD with alternative treatment. Treatment response of the last patient has yet to be evaluated. Side effects under AMBT were mostly manageable, however deteriorating renal function prompted the halt of AMBT in one patient. Salvage AMBT might be a valuable treatment option in cases of BMZT failure and can induce persistent disease control, although with potentially significant side effects, high treatment costs and the need for repeated intravenous therapy.

## A NOVEL MULTIPLEX REAL-TIME PCR ASSAY FOR THE MOLECULAR DIAGNOSIS OF METACESTODE INFECTIONS IN HUMANS

**Alexander Oberli**, Lavinia Furrer, Bruno Gottstein, Pascal Bittel  
Institute for Infectious Diseases, Bern, Switzerland

For the clinical outcome of larval cestodiasis in humans such as neurocysticercosis (NCC), cystic echinococcosis (CE) and alveolar echinococcosis (AE), fast therapeutic treatment based on early diagnosis at the initial stage of infection is key. Despite remarkable development of imaging technologies and serology for the diagnostic identification of invasive cestodiasis, a reliable high-throughput molecular method on biopsy or cytology specimens would ensure a more rapid species identification. This holds specifically true for diagnosing NCC, CE and AE in patients with unusual imaging data and/or negative serology due to immunosuppression, or diagnosing rare taeniid species. A broad variety of PCR protocols for the detection and differentiation of taeniid species have been published. However, most approaches are based on conventional PCR techniques and either require gel electrophoresis, an additional sequencing step or are limited to certain *Echinococcus* or *Taenia* species, taxa or genotypes. In the present study a quadruplex real-time PCR has been established which allows the differentiation of *Echinococcus granulosus sensu lato* (*s.l.*), *E. multilocularis* and *Taenia spp.* but also the detection of an internal control in a single processing step. Subsequent Sanger sequencing of *E. granulosus s.l.* and *Taenia spp.* amplicons further allows the differentiation of all *Echinococcus* and *Taenia* species including recently reported human infecting species such as *T. crassiceps*, *T. serialis*, *T. martis* and *Versteria sp.* This simple, fast and reliable multiplex real-time PCR has been successfully assessed for the specific detection of *E. granulosus sensu lato* (*s.l.*), *E. multilocularis* and a broad spectrum of *Taenia spp.* cyst fluids and fine-needle biopsies of clinical and veterinarian cases. All reference samples were from clinical cases well documented upon imaging, serological and parasitological/morphological means. To our knowledge, this is the first report of a quadruplex real-time PCR, which can be routinely used in a clinical microbiology lab on biopsy or cytology specimens for the detection of *E. granulosus s.l.*, *E. multilocularis* and *Taenia spp.*

### CORRECTION OF THE SELECTION BIAS IN THE ESTIMATION OF CYSTIC ECHINOCOCCOSIS PREVALENCE IN COMMUNITY SURVEYS

**Oswaldo G. Espinoza-Hurtado**<sup>1</sup>, Erick A. Chacón-Montalvan<sup>2</sup>, Raul Enriquez<sup>1</sup>, Cesar Sedano<sup>1</sup>, Percy Soto-Becerra<sup>1</sup>, Karina Bardales<sup>1</sup>, Luis Tello<sup>1</sup>, Hector H. García<sup>1</sup>, Saul Santivanez<sup>3</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Lancaster University, Lancaster, United Kingdom, <sup>3</sup>Universidad Nacional del Centro del Perú, Huancayo, Peru

Cystic echinococcosis (CE) is a zoonotic disease caused by the larval stage of the dog's parasite *echinococcus granulosus*. Epidemiological surveys performed in endemic areas of Peru reported prevalence values between 5% and 10%; however, the majority of them have a potential selection bias produced by the location of the homes in the city and their proximity to the place where the ultrasound evaluation is performed resulting in an underestimation of the real prevalence. One approach that have been used by ecology to correct this bias is the use of the spatial distribution of each individual at the moment they had selected to the sample. We performed a study to determine the prevalence of CE in Corpacancha, a highly endemic village located in Peruvian central highlands. Based on the function of sample intensity is equal to the population function intensity multiplied by a constant plus a function that depends on space, we determine that each observation doesn't have the same probability to be chosen at the sample. Therefore, in order to obtain an unbiased value of the prevalence, we fit a weighted model considering the spatial effect and other covariates that have been considered as a risk factor; in this model the weights are based on the sampling effect. Using the traditional method to estimate the prevalence (based on binomial distribution likelihood), the prevalence of CE in Corpacancha was 24.1% (95% CI: 18.9% - 29.3%); however, after adjusting this by the spatial distribution we observed a prevalence of 26.9% (95% CI: 19.6% - 34.2%). The main advantage of this methodology is that allows to correct the underestimated prevalence without increasing the sampling coverage. Additionally, it also allows the correction of risk at a spatial level through a correction factor that is mathematically equivalent to the value of the Odd Ratio of the disease between sample and population. Finally, this model makes it possible to extrapolate the results obtained in a biased sample to the entire population.

### ASSOCIATION OF HYDATID CYST VOLUME AND THE DEVELOPMENT OF PREOPERATIVE COMPLICATIONS IN PEOPLE WITH HYDATIDOSIS TREATED IN TWO PERUVIAN CITIES DURING 2000 - 2011

**Sandra Zeña-Nañez**<sup>1</sup>, Saul Santivañez Salazar<sup>1</sup>, Maria Valcarcel<sup>2</sup>, Maira Arce<sup>3</sup>, Luis Tello<sup>3</sup>, Diego Valencia<sup>3</sup>, Hector H. Garcia<sup>4</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Department of Surgery, Hospital Nacional Dos de Mayo, Lima, Peru, <sup>3</sup>Instituto Peruano de Parasitología Clínica y Experimental, Lima, Peru, <sup>4</sup>School of Sciences, Department of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru

Human cystic echinococcosis (CE) is a chronic zoonotic disease caused by the larval stage of *Echinococcus granulosus* that is characterized by the development of a cystic lesion in the organ involved such as liver or lungs. Infected subjects remain asymptomatic during several years until the cyst is enough large or develop a complication to produce symptoms. Several studies reported clinical characteristics of the disease as well as cyst characteristics; however there is not clear if the organ involved, morphological characteristics such as size, or vicinity with other cystic lesions are risk factors to develop cyst's complications. We performed a cross-sectional study in a cohort of subjects surgically treated between 2000 to 2011; using a bivariate and multiple analysis with a generalized linear model with Poisson family of robust variances and log linkage links. From a total of 714 subjects, more than half of them were female

(53.8%), the average age was 27.5 years ( $\pm 18.6$ ). Three hundred forty one presented liver involvement (47.8%) and the majority of them were CE1 stage (30.8%). Regarding lung cysts, it was more common to be in the right lung (56.3%), the total volume of cyst(s) ranged from 4.2 to 24268.4 mm<sup>3</sup>. It was observed that the average total volume of cysts in the liver was 1392.3mm<sup>3</sup> (4.2 - 24268.5), in the right lung it was 486.3mm<sup>3</sup> (6.7 - 3783.7) and in the left lung it was 557.4mm<sup>3</sup> (5.0 - 5575.3). There were 380 people (53.6%) with complicated cyst, where 227 were due to infection (59.7%) and 153 due to rupture (40.3%). In the multiple analysis it was observed that the left lung (PR: 1.29, CI95% 1.06-1.56) and right lung (PR: 1.30, CI95% 1.08-1.58) presented a higher prevalence of complication compared to the liver, both associations were statistically significant. Based on this findings, we conclude that the total volume of cysts has different characteristics according to the organ affected and also the presence of complication, suggesting the importance of performing lung evaluation during the epidemiological surveys in order to determine lung cystic lesion before being complicated.

### CAROTID PORCINE MODEL OF NEUROCYSTICERCOSIS: ASSESSING THE LINK BETWEEN INJECTION DOSE WITH CNS INFECTION RATES AND SERUM ANTIGEN DYNAMICS

**Ana Vargas-Calla**<sup>1</sup>, Gianfranco Arroyo<sup>1</sup>, Luz Toribio<sup>1</sup>, Nancy Chile<sup>1</sup>, Yesenia Castillo<sup>1</sup>, Juan F. Calcina<sup>2</sup>, Javier A. Bustos<sup>1</sup>, Robert Gilman<sup>3</sup>, Seth O'Neal<sup>4</sup>, Armando E. Gonzalez<sup>2</sup>, Hector H. Garcia<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>3</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>4</sup>Portland State University, Portland, OR, United States

Animal models in neurocysticercosis (NCC) allow a better understanding of the immunopathogenesis, host-parasite interactions, and disease progression in the central nervous system (CNS), and are also useful for assessing novel therapies. The pig is the ideal model for NCC as is the natural intermediate host of *Taenia solium* and closely resembles human pathology. Oral infection models require a high dose of eggs to produce NCC resulting in low CNS infection rates and poor reproducibility. Carotid injection of activated *T. solium* oncospheres in pigs overcomes these problems and provides a more feasible and consistent NCC model. We assessed the effects of oncosphere dose on infection outcomes and antigen dynamics in the carotid pig model. Twenty-nine piglets were infected via carotid injection of activated oncospheres (2500, 5000, and 10000). Pig sera were collected at days 0, 7, 14, 30, 50, 70, 100, 130 and 150 (necropsy). At necropsy, viable and degenerated cysts were recorded in the CNS and pig muscles. Antigen detection (Ag-ratios) was assessed using a sandwich Ag-ELISA assay. A panel of sera from 8 pigs orally infected with a *T. solium* gravid proglottid was used as a comparison group. NCC was achieved in 21/29 pigs (72%), with higher infection rates at higher doses (4/9 [44%], 9/11 [82%] and 8/9 [89%] for 2500, 5000, and 10000 oncospheres,  $p=0.038$ ). All CNS cysts were viable, whereas viable and degenerated cysts were found in muscles. Degenerated cysts were more frequent in pigs in the lower dose group (mean 57.7%, 6% and 9.1% for the 2,500, 5,000 and 10,000 oncosphere groups,  $p=0.020$ ). At day 14 Ag-ratios increased substantially in all groups, more in pigs that received 5000 and 10000 oncospheres. Ag-ratios in NCC pigs remained higher and not different between 5000 and 10000 oncosphere groups, reaching plateau levels at day 30 until necropsy (mean Ag-ratio: 59.2 and mean Ag-ratio: 52.7,  $p=0.812$ ). Ag-ratios over time in the high oncosphere groups were similar to those observed in orally infected pigs. Intracarotid doses of at least 5000 oncospheres provide high NCC rates and antigen dynamics similar to the oral model, providing an appropriate model for NCC.

### EXPLORING SOURCES OF FALSE-POSITIVE URINE CYSTAG SCREENING RESULTS IN A REGION ENDEMIC TO *TAENIA SOLIUM*

**Esperanza Zagal<sup>1</sup>**, Jessica Kramarz<sup>2</sup>, Michelle Beam<sup>1</sup>, Lauralee Fernandez<sup>1</sup>, Percy Vilchez<sup>2</sup>, Ricardo Gamboa<sup>3</sup>, Claudio Muro<sup>3</sup>, Yessenia Castillo<sup>3</sup>, Hector H. Garcia<sup>4</sup>, Seth E. O'Neal<sup>1</sup>, For the Cysticercosis Working Group in Peru<sup>5</sup>

<sup>1</sup>School of Public Health, Oregon Health & Science University -- Portland State University, Portland, OR, United States, <sup>2</sup>School of Public Health, Oregon Health & Science University -- Portland State University, Portland, OR, United States, <sup>3</sup>Centro de Salud Global, Universidad Peruana Cayetano Heredia, Tumbes, Peru, <sup>4</sup>Centro de Salud Global, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>5</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

Cysticercosis is an infection by the metacystode stage of the *Taenia solium* tapeworm. When infection involves the central nervous system, the disease is called neurocysticercosis (NCC), and when cysts or cyst membranes invade the subarachnoid spaces, it is called subarachnoid neurocysticercosis (SANCC), an aggressive form of the disease with poor prognosis. We are evaluating early detection and medical intervention for SANCC using a population screening approach by testing for high levels of cysticercosis antigen (cystAg) excreted in urine, using an ELISA with Peruvian monoclonal antibodies (TsW8/ TsW5). A positive urine screen result, however, requires magnetic resonance imaging (MRI) of the brain for definitive diagnosis of NCC, including SANCC. Approximately 75% of individuals with high levels of urinary cystAg do not have cysts detectable by MRI. The objective of this study is to evaluate potential sources of high cystAg levels in the absence of NCC. In this cross-sectional study, we are enrolling consecutively 30 individuals with high urine cystAg (optical density ratio  $\geq 3$ ) and no evidence of NCC on brain MRI, to investigate other potential sources of urine cystAg. Procedures include computed tomography (CT) without contrast of the head, chest, abdomen, and proximal limbs to evaluate for the presence of *T. solium* cysticercosis of the skeletal muscles, as well as other larval cestode infection (e.g. *Echinococcus* sp.) of the lungs, liver, and abdominal cavity. We also examine the skin for subcutaneous cysts. We use Western Blot to evaluate for the presence of antibodies against other larval *Taenia* cestodes known to infect humans including *Echinococcus* sp. and *T. multiceps*. We will report frequency and proportion of findings for all exams. Characterizing the reasons for false positive results is important for improving the performance of the assay and interpretation of its results.

### PROCESS MAPPING TO UNDERSTAND THE STEPS REQUIRED TO IMPLEMENT A CONTROL PROGRAM FOR CYSTICERCOSIS IN RURAL PERU

**Lisset M. Dumet<sup>1</sup>**, Angela G. Spencer<sup>1</sup>, Ruth Atto<sup>2</sup>, Percy Vilchez<sup>2</sup>, Vanessa Cruz<sup>2</sup>, Brenda Beltran<sup>1</sup>, Javier Bustos<sup>3</sup>, Hector H. Garcia<sup>4</sup>, Patricia J. Garcia<sup>5</sup>, Seth O'Neal<sup>1</sup>, Sara Gimbel<sup>6</sup>, for the Cysticercosis Working Group in Peru<sup>7</sup>

<sup>1</sup>Oregon Health & Science University-Portland State University School of Public Health, Portland, OR, United States, <sup>2</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>Department of Microbiology, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>4</sup>Center for Global Health - Tumbes and Department of Microbiology, Universidad Peruana Cayetano Heredia, and Cysticercosis Unit, Instituto Nacional de Ciencias Neurológicas, Lima, Peru, <sup>5</sup>School of Public Health, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>6</sup>Department of Global Health & Department of Child, Family and Population Health Nursing, University of Washington, Seattle, WA, United States, <sup>7</sup>Center for Global Health Tumbes, Tumbes, Peru

Ring treatment is a strategy to control cysticercosis that is efficacious when delivered by research teams. We are using implementation science tools to transfer ring treatment to the public health system in Northern

Peru. Process mapping is a system engineering and quality improvement tool used in health care settings to break down complex processes into sequenced steps, identify efficiencies, and streamline work. Our objective was to develop process maps to facilitate early stages of ring treatment implementation. The Systems Analysis and Improvement Approach guided our process mapping activities. We collected examples of existing protocols and procedures documents that have been applied in other infectious diseases in Peru and designed a prototype for community control of cysticercosis. We are conducting interviews and walk-through exercises with health system staff to detail each step of ring treatment, from community case identification and verification of *T. solium* infection to the presumptive treatment of humans/people/community members with niclosamide in 100-meter 'rings', and follow-up. We use Visio software to display our final process maps. We will present the steps to develop a process map in collaboration with stakeholders from the health system and provide recommendations for training staff and conducting fieldwork to build the process map flow chart. We will include examples of completed process maps in the poster. It will serve as a guide for applying process mapping when the processes are not well standardized but need to be established, in low-resource settings. Quality improvement tools, such as process mapping, can be applied in health care and community health settings with low resources to implement and scale-up evidence-based interventions, conserve resources, and establish sustainable control strategies/processes.

### DESCRIBING VARIABILITY OF URINE CYSTICERCOSIS ANTIGEN EXCRETION IN RURAL PERU, A REGION ENDEMIC TO *TAENIA SOLIUM*

**Jessica Kramarz<sup>1</sup>**, Esperanza Zagal<sup>1</sup>, Michelle Beam<sup>1</sup>, Lauralee Fernandez<sup>1</sup>, Percy Vilchez<sup>2</sup>, Ricardo Gamboa<sup>2</sup>, Claudio Muro<sup>2</sup>, Yessenia Castillo<sup>1</sup>, Hector H. Garcia<sup>2</sup>, Seth O'Neal<sup>1</sup>, For the Cysticercosis Working Group in Peru<sup>3</sup>

Neurocysticercosis (NCC) is a central nervous system infection by the cestode *Taenia solium* that accounts for 30% of seizure disorders in endemic regions. We are currently validating a population screening approach to detect the most severe form of infection, subarachnoid NCC, to allow medical management in early disease stages. We collect urine samples in the community setting and test these for the presence of cysticercosis antigens (cystAg) using ELISA and a monoclonal antibody (mAb) set developed in Peru (TsW8/TsW5). Understanding the natural variability in cystAg levels over time is critical to establish optimal cutoff levels for a positive result, which will help limit false positive results leading to unnecessary neuroimaging for diagnostic confirmation. Our objective is to describe the short-term variability of urine cystAg excretion among individuals living in a region endemic to *T. solium*. We are conducting a prospective cohort including 200 participants across 3 strata of baseline cystAg levels (Strong positive: Optimal density ratio (ODR)  $\geq 3$ , n= 50; Weak positive: ODR  $\geq 1$  and  $<3$ , n=50; Negative: ODR  $<1$ , n=100) in Tumbes, Peru. We collect urine samples from each participant once every 6 hours for 24 hours, once daily for 7 days, and once weekly for 4 weeks. Samples are processed by ELISA using TsW8/TsW5 mAbs. We will report the results of multilevel mixed-effects linear regression to compare mean ODR and standard deviation across time intervals (day, week, month), overall and according to ODR group, while evaluate effects of age and sex. Understanding the variability of urine cystAg will inform optimal ODR screening thresholds and reduce the likelihood of false positives and unnecessary neuroimaging.

## INCIDENCE OF CYSTICERCOSIS ANTIGEN EXCRETION IN THE URINE IN A POPULATION ENDEMIC TO TAENIA SOLIUM IN NORTHERN PERU

Jessica Kramarz<sup>1</sup>, Esperanza Zagal<sup>1</sup>, Michelle Beam<sup>1</sup>, Lauralee Fernandez<sup>1</sup>, Percy Vilchez<sup>2</sup>, Ricardo Gamboa<sup>2</sup>, Claudio Muro<sup>2</sup>, Yesenia Castillo<sup>2</sup>, Hector H. <sup>2</sup>Centro de Salud Global, Universidad Peruana Cayetano Heredia, Tumbes, Peru, <sup>3</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

*Taenia solium* is a zoonotic cestode with a transmission cycle involving pigs as an intermediate host and humans as a definitive host. Infection of the human brain, neurocysticercosis (NCC), is a leading cause of epilepsy and other neurologic disease across many regions of Latin America, Africa, and Asia. NCC occurs when people ingest *T. solium* eggs passed in the feces of a human with an intestinal tapeworm. Although there have been many cross-sectional studies describing the prevalence of exposure and infection in human and pigs, few studies have described the incidence of exposure to *T. solium* eggs among humans in an endemic community setting. The objective of this study is to evaluate the cumulative incidence of cysticercosis antigen (cystAg) excretion in urine, a marker for prior exposure to *T. solium* eggs, and one indicator of the overall level of transmission in the community. As part of a large cross-sectional study to validate population urine screening for NCC, we collected 4017 urine samples in several rural villages in Piura, Peru, in March 2020. Days later, Peru entered national lockdown due to COVID-19 restrictions, forcing us to return 9 months later to recollect these samples for their original screening purposes. Both sample sets were stored frozen at -20C, including paired sets from 3759 participants sampled at both time points. We are currently processing these paired urine sets by ELISA, using Peruvian monoclonal antibodies (TsW8/TsW5), to evaluate for the presence of cystAg. Results are characterized as strong positive (Optical density ratio (ODR)  $\geq 3$ ), weak positive (ODR  $\geq 1$  &  $< 3$ ), and negative (ODR  $< 1$ ). We will report the cumulative incidence of conversion of results between categories, as well as risk factors for both conversion and persistence of positive results. We will discuss the implications of our results for public health control and prevention.

## ASSESSING THE EFFECT OF COMBINED THERAPY WITH ALBENDAZOLE PLUS PRAZIQUANTEL VERSUS ALBENDAZOLE MONOTHERAPY IN TWO DOSES ON LIVER TRANSAMINASES IN PATIENTS WITH VIABLE PARENCHYMAL NEUROCYSTICERCOSIS

Gianfranco Arroyo<sup>1</sup>, Silvana Diaz-Mancilla<sup>1</sup>, Andres G. Lescano<sup>1</sup>, Javier A. Bustos<sup>1</sup>, Isidro Gonzales<sup>2</sup>, Herbert Saavedra<sup>2</sup>, John Horton<sup>3</sup>, Armando E. Gonzalez<sup>1</sup>, Robert H. Gilman<sup>4</sup>, Seth O'Neal<sup>5</sup>, Hector H. Garcia<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Instituto Nacional de Ciencias Neurologicas, Lima, Peru, <sup>3</sup>Tropical Projects, Hitchin, United Kingdom, <sup>4</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>5</sup>Oregon Health & Science University-Portland State University, Portland, OR, United States

Combined albendazole (ABZ) plus praziquantel (PZQ) is more effective for viable parenchymal neurocysticercosis (NCC) in comparison with ABZ monotherapy. ABZ therapy may induce elevation of liver transaminases, and is unclear whether this elevation is even greater when combining ABZ+PZQ, which may lead to temporary discontinuation of treatment. This study assessed whether elevation of liver transaminases (alanine aminotransferase [ALT] and aspartate aminotransferase [AST], U/L) from baseline to days 4, 7, 11 and 30 was associated with different therapy schemes in parenchymal NCC using data from two trials in patients who received 10 days of standard ABZ (15mg/kg/d), increased ABZ (22.5mg/kg/d) or standard ABZ plus PZQ (50mg/kg/d). We compared the

proportions of patients whose transaminases increased from baseline to follow-up between groups. Maximum differences ( $\Delta_{max}$ ) of liver transaminases were calculated by subtracting the highest measurement at follow-up with the measurement at baseline. Regression coefficients of  $\Delta_{max}$  values between therapy schemes were estimated in linear regression models adjusted by type of anti-epileptic drug, age and sex. The proportion of patients with elevated ALT levels from baseline to follow-up was statistically lower in the combined ABZ+PZQ group versus increased ABZ (35/47 [74.5%] and 27/29 [93%],  $p=0.041$ ), but not different with standard ABZ (41/47 [87%,  $p=0.116$ ). The regression model showed significantly lower  $\Delta_{max}$  ALT values in the combined ABZ+PZQ group versus standard ABZ ( $B=-30.9$  U/L,  $p<0.001$ ) and increased ABZ ( $B=-58.2$ ,  $p=0.020$ ). The proportion of patients with increased AST levels from baseline to follow-up was also lower in the combined ABZ+PZQ group (28/47 [60%]) versus standard ABZ (37/47 [70%,  $p=0.044$ ) and increased ABZ (23/29 [79%],  $p=0.075$ ), and the regression also showed lower  $\Delta_{max}$  AST values in the combined ABZ+PZQ group versus standard ABZ ( $B=-14.7$  U/L,  $p<0.001$ ) and increased ABZ ( $B=-27$  U/L,  $p=0.010$ ). The likelihood and magnitude of liver transaminases elevation increases following antiparasitic treatment in NCC and are lower when combining ABZ+PZQ instead of ABZ monotherapy

0768

## COMPARISON OF TWO MONOCLONAL ANTIBODY BASED AGELISA ASSAYS FOR ASSESSING THE DYNAMICS OF CIRCULATING ANTIGENS IN PIGS EXPERIMENTALLY INFECTED WITH TAENIA SOLIUM CYSTICERCOSIS

Luz Milagros Toribio<sup>1</sup>, Gianfranco Arroyo<sup>1</sup>, Percy Soto-Becerra<sup>1</sup>, Javier Bustos<sup>1</sup>, Yesenia Castillo<sup>1</sup>, Robert H. Gilman<sup>2</sup>, Seth O'Neal<sup>3</sup>, Armando E. Gonzalez<sup>4</sup>, Pierre Dorny<sup>5</sup>, Hector H. Garcia<sup>1</sup>

<sup>1</sup>Center for Global Health, San Martin De Porres, Peru, <sup>2</sup>Department of International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>School of Public Health, Oregon Health & Science University-Portland State University, Portland, OR, United States, <sup>4</sup>School of Veterinary Medicine, Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>5</sup>Department of Biomedical Sciences, Institute of Tropical Medicine, Antwerp, Belgium

Antigen dynamics in *Taenia solium* cysticercosis reflect the processes during infection as well as host-parasite interactions and can be properly assessed in the pig model. The reference assay for antigen detection is the B158/B60 Ag ELISA assay detecting excretory/secretory products of *Taenia saginata* cysts, but also detecting *T. solium* cysticercosis antigens due to cross-reaction. Our group has previously developed 22 moAbs against *T. solium*, of which two (TsW8/TsW5) can detect antigen in serum or urine samples. This study compares the performance of our novel anti-*T. solium* (TsW8/TsW5) moAbs in a sandwich Ag-ELISA format versus B158/B60 Ag-ELISA assay for assessing antigen dynamics in experimental porcine cysticercosis using a panel of sera collected at days 0, 7, 14, 21, 28, 42, 56, 70 and 90 in pigs infected with *T. solium* eggs by oral route. Mean optical density (OD) readings at different follow-up time-points were compared between Ag-ELISA assays, and correlations between cyst burden and antigen OD readings for each assay were calculated using the Spearman rank correlation coefficient. Antigen dynamics showed similar performance between Ag-ELISA assays with no decline in OD readings in pigs positive at necropsy. At baseline and at day 7, mean antigen OD readings were low ( $< 1$ ) and not different between assays. Mean antigen OD readings increased at day 14, being slightly higher when using TsW8/TsW5 moAbs compared to B158/B60 moAbs (mean OD: 1.07, and mean OD: 0.90,  $p=0.014$ ), and reached a plateau at day 28 onwards with no statistical differences between assays (mean OD: 1.80 and mean OD: 1.87 at day 90,  $p=0.382$ ). Viable cyst burden had a stronger correlation with antigen OD readings measured with the TsW8/TsW5 moAbs ( $r=0.87$ ,  $p<0.001$ ) compared to antigen OD readings measured with the B158/B60 moAbs ( $r=0.75$ ,  $p=0.003$ ). Our findings showed a similar performance between both Ag-ELISA assays for assessing antigen dynamics in

experimentally infected pigs, with an apparent higher avidity of our moAbs TsW8/TsW5 to detect living cysts, providing a promising tool for studying host-parasite interactions.

### VALIDATED NON-LOCAL PARAMETRIZATION OF AN AGENT-BASED MODEL TO REPRESENT LOCAL-SCALE TAENIA SOLIUM TRANSMISSION IN RURAL VILLAGES OF AN ENDEMIC AREA IN NORTHWEST PERU

Francesco Pizzitutti<sup>1</sup>, Gabrielle Bonnet<sup>2</sup>, Eloy Gonzales-Gustavson<sup>3</sup>, Sarah Gabriel<sup>4</sup>, William K. Pan<sup>5</sup>, Ian W. Pray<sup>6</sup>, Armando E. Gonzalez<sup>7</sup>, Hector H. Garcia<sup>8</sup>, Seth O'Neal<sup>6</sup>, for the Cysticercosis Working Group in Peru<sup>9</sup>

<sup>1</sup>Independent consultant with OHSU university, Rome, Italy, <sup>2</sup>Independent consultant with OHSU university, Toulouse, France, <sup>3</sup>Tropical and Highlands Veterinary Research Institute, Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>4</sup>Faculty of Veterinary Medicine, Ghent University, Ghent, Belgium, <sup>5</sup>Duke Global Health Institute, Duke University, Durham, NC, United States, <sup>6</sup>School of Public Health, Oregon Health & Science University -- Portland State University, Portland, OR, United States, <sup>7</sup>Center for Global Health-Tumbes, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>8</sup>Centro de Salud Global, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>9</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

*Taenia solium* is an important cause of epilepsy and economic loss in many rural areas of the world. Although there has been some progress in developing and testing interventions to control and eliminate transmission, optimal strategies are yet to be defined. Validated models that simulate transmission and interventions within regions may guide design and evaluation of the most effective strategies to control or eliminate *T. solium*. Our objective was to develop a new version of CystiAgents, an Agent Based Model of local-scale *T. solium* transmission, that does not rely on local calibration of every modeled village. Based in MASON with in-house Java coding, the model covers relevant aspects of *T. solium* transmission, including processes of pig and human infection, spatial distribution of human and pig populations in several endemic villages in northwest Peru, pork production within villages for human consumption, and movement of humans and pigs in an out of simulated villages. We applied a new approach to model calibration, based on approximate Bayesian computation, in which model outputs are fit simultaneously to observed prevalences of human taeniasis and pig cysticercosis for several endemic villages. Despite large underlying variance associated with empirical measurement of *T. solium* epidemiological data, the calibrated model reproduces observed prevalences with acceptable precision, not only for empirical data of villages used to calibrate the model, but also for empirical data from villages not included in the calibration process. The calibrated model can be successfully transferred to accurately simulate transmission in other villages within the same region. We plan to use CystiAgents with non-local calibrated model parametrization, as a universal tool to conduct *in silico* experiments to guide design and optimization of *T. solium* control and elimination interventions for northwest Peru.

### SUBARACHNOID NEUROCYSTICERCOSIS

Cesar G. Berto, Christina M. Coyle

Jacobi Medical Center, Bronx, NY, United States

Subarachnoid neurocysticercosis (SANCC) is the most serious form of neurocysticercosis; its clinical manifestations vary depending on the location, size and host response. Cysticercus antigen detection is useful for diagnosis and assessment of activity. Calcification has been reported after treatment but its frequency and clinical implications have not yet been elucidated. We report the baseline characteristics of patients with SANCC, frequency of calcification at presentation and after treatment, and correlation with cysticercosis antigen in a non-endemic region. Methods: We reviewed the symptoms, imaging and serology of patients with SANCC who presented to Jacobi Medical Center, New York City. Cysticercosis

antigen by ELISA was measured in serum and cerebrospinal fluid (CSF) at CDC. 91 patients with SANCC were included; 34 patients had exclusive SANCC, 44 patients had SANCC and parenchymal disease, 4 patients had SANCC and intraventricular disease, and 9 patients had involvement of all 3 spaces. The most common location was sylvian fissure alone (37.4%), followed by basilar alone (28.6%), sylvian and basilar (25.3%), cisterna magna (1.1%), interhemispheric (1.1%) and spinal (6.6%). Thirty-four patients (37.4%) had calcified SANCC at presentation. Seventy patients (76.9%) were assessed to have symptoms due to subarachnoid disease; headache was the most common symptom (81.4%). Of them, 32 patients had intracranial hypertension (45.7%). Less common presentations included seizures (15.7%), spinal symptoms (15.7%), aseptic meningitis (10%), and vascular complications (7.1%). Delay in diagnosis was noticed in 41 patients (58.6%). Among asymptomatic patients, 22.8% had concomitant spinal disease. The cysticercus antigen in serum and CSF was positive in 49 patients (59.8%) and 21 patients (38.2%). The most common presentations of SANCC are headache and intracranial hypertension. Concomitant spinal involvement is common. A third of patients had calcifications at presentation. Calcifications were associated with enhancement; further studies are needed to assess its significance.

### EVALUATING THE ROLE OF CORRALS AND INSECTS IN THE TRANSMISSION OF PORCINE CYSTICERCOSIS: A COHORT STUDY

Eloy Gonzales-Gustavson<sup>1</sup>, I. W. Pray<sup>2</sup>, Ricardo Gamboa<sup>3</sup>, Claudio Muro<sup>3</sup>, Percy Vilchez<sup>3</sup>, R. H. Flecker<sup>4</sup>, H. H. Garcia<sup>5</sup>, A. E. Gonzalez<sup>6</sup>, S. E. O'Neal<sup>2</sup>, for the Cysticercosis Working Group in Peru<sup>7</sup>

<sup>1</sup>Universidad Nacional Mayor de San Marcos, Jauja, Peru, <sup>2</sup>School of Public Health, Oregon Health & Science University -- Portland State University, Portland, OR, United States, <sup>3</sup>Centro de Salud Global, Universidad Peruana Cayetano Heredia, Tumbes, Peru, <sup>4</sup>OHSU, Portland, OR, United States, <sup>5</sup>Centro de Salud Global, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>6</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>7</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

The widespread dispersion across endemic villages of pigs infected with cysticercosis, the low average cyst burden among infected pigs, and the low prevalence of taeniasis, all suggest that direct pig ingestion of human feces is not the only mode of transmission for *Taenia solium*. Alternate mechanisms of egg dispersal away human fecal depositions are likely to play an important role in transmission. Insects are known to transmit many cestode parasites, including those of the Taenidae family. Our objective was to evaluate the risk of porcine cysticercosis associated with exposure to human feces and to insects in an endemic community setting. We used a cluster-randomized cohort design to compare the risk of developing antibodies and infection among 120 seronegative piglets raised in either free-roaming (FR; exposed to human feces and insects), standard corral (SC; protected from human feces, exposed to insects), or netted corral environments (NC; protected from human feces and flying insects). We processed monthly blood samples by LLGP-EITB to detect antibodies and necropsied all pigs after 10 months to identify cysts. 64 piglets developed antibodies for a seroincidence (95% CI) of 0.07 (0.04 - 0.11), 0.08 (0.05 - 0.13) and 0.15 (0.11 - 0.22) cases per pig-month in NC, SC, and FR groups, respectively. The relative risk of seropositivity in FR vs. corralled pigs was similar in the first 2 months, then increased to 5.3x (3-6 months) and 8.7x (6+ months). Of 108 pigs necropsied, 15 had *T. solium* cysts (range 1-2387 cysts), all belonging to the FR group. Corrals were protective against infection but less so against seropositivity. Netted corrals, which did not completely exclude insects, did not provide added protection against seropositivity compared with standard corrals. Results suggests that flying insects do not play an important role in infection. Alternate routes, such as egg persistence in soil, water, or feed should be explored.

### RACINE SCALE EVALUATION FOR THE ANALYSIS OF EPILEPSY IN A RAT MODEL OF NEUROCYSTICERCOSIS

Karla Villalobos-Camizan<sup>1</sup>, Oscar P. Nizama-Salazar<sup>1</sup>, Oksana Huerta-Reyes<sup>1</sup>, Edson Bernal-Teran<sup>1</sup>, Lizbeth Fustamante<sup>1</sup>, Edith S. Malaga<sup>1</sup>, Cesar M. Gavidia<sup>2</sup>, Robert H. Gilman<sup>3</sup>, Manuela R. Verastegui<sup>1</sup>, Cysticercosis Working Group in Peru<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru, <sup>3</sup>Johns Hopkins University, Baltimore, MD, United States

Neurocysticercosis (NCC) is caused by larval stage of *Taenia solium* or cysticerci infecting the central nervous system and is the leading cause of acquired epilepsy and convulsive conditions worldwide. The Racine scale is a method used in experimental epilepsy animal models that characterizes seizures at different levels according to their severity. The optimal evaluation of seizures in rats with NCC, would help in the prevention and treatment of epileptogenesis. The behavior of 41 Holtzman rats with NCC (8 months post-infection) was recorded using cameras for 5 days. Subsequently, the presence of seizures was evaluated according to the Racine scale. For 41 rats with NCC, 95% developed some level of seizures. During the evaluation, 37 rats had multiple levels of seizures. It was found that level 2 (85%, nodding the head) is the predominant, followed by level 3 (83%; clonus of forelimb), level 1 (73%; movement of the mouth and face), level 4 (36%; breeding) and level 5 (13%; breeding, and fall). However, some behaviors, which were not included in the scale, were observed. Such as sudden jumps, fleeting runs, myoclonic spasms, and fusion of several levels at the same time. In conclusion, the Racine scale must be complemented and adapted for the evaluation of epilepsy in a rat model of neurocysticercosis, which will allow the evaluation of antiepileptic drugs in this NCC model.

### ADDRESSING ACUTE FEBRILE ILLNESS AMONG NON-SEVERE PATIENTS IN RIO DE JANEIRO, BRAZIL: A PROSPECTIVE STUDY

Jose Moreira<sup>1</sup>, Leticia Fernandez-Carballo<sup>2</sup>, Camille Escadafal<sup>2</sup>, Patricia Brasil<sup>1</sup>, Sabine Dittrich<sup>2</sup>, Andre M. Siqueira<sup>1</sup>

<sup>1</sup>Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, <sup>2</sup>Foundation for Innovative New Diagnostics, Geneva, Switzerland

Identifying etiologies of acute febrile illness (AFI) is challenging in settings with limited laboratory capacity. We aimed to describe the causes of AFI among non-severe patients presenting at the primary level in Rio de Janeiro when a Chikungunya (CHIKV) outbreak was taken place. We conducted a 10-month prospective AFI study in outpatient participants aged 2-65 years. Patients with fever (axillary temperature of 37.5° C or higher) for seven or fewer days were offered enrollment, and clinical, and laboratory data were gathered for consecutive participants. Blood cultures and rapid diagnostics tests (RDTs) were performed regardless of presentation. Others tests were performed only if specific signs or symptoms were present. Flavivirus infection was defined when concurrent Dengue (DENV) and Zika (ZIKV) ELISA antibodies were present, while DENV infection was when reactivity against DENV without ZIKV occurred. Logistic regression model determined predictors of laboratory-positive CHIKV (defined as CHIKV RT-PCR positive). Follow-up visits were conducted 14-28 days after the index visit. A total of 500 participants (median age 26 [15-41] years, 50.4% females) yielded 708 diagnoses, 49.8% of whom were multiple diagnoses. Systemic infection was the most frequent febrile syndrome (380/500, 76%), followed by acute respiratory infection (150/500, 30%) and urinary infection (18/500, 3.6%). The diagnosis most prevalent was CHIKV (284/500, 56.8%), followed by Flaviviruses (214/500, 42.8%), DENV (42/500, 8.4%), and viral upper respiratory infection (40/500, 8%). Etiology remained undetermined in 124 (25%). According to arboviruses RDT, 80% were exposed to an arbovirus, and the most prevalent was DENV (25.8%). Predictors of laboratory-positive CHIKV were the absence of cough, arthralgia, rash, temperature, and leucopenia. At

follow-up, 40% reported persistence of any symptoms. CHIKV-infected patients were more likely to experience persistent arthritis than CHIKV negative. Evidence of a viral process was found in almost 80%, and the practice of empirical antibiotic prescription in non-severe febrile patients should be reconsidered.

### ETIOLOGY OF FEBRILE NEUROLOGICAL SYNDROMES IN LOW- AND MIDDLE-INCOME COUNTRIES: RESULTS FROM THE FIEBRE STUDY

Fever is one of the most common symptoms leading to health care seeking and hospital admission worldwide. Neurological symptoms associated with fever are a major concern given the difficulty and expense in making a diagnosis, and the high mortality of infection related neurological syndromes. In low- and middle-income countries (LMICs), there is little preexisting knowledge regarding the underlying etiology and microbiology of febrile neurological syndromes to adequately guide their management beyond empirical broad-spectrum antimicrobial regimens. This analysis aims to provide a description of patients with fever and neurological symptoms in the FIEBRE (Febrile Illness Evaluation in a Broad Range of Endemicities) observational study. We present a subset of patients enrolled in FIEBRE with neurological signs and symptoms on presentation, in order to describe their clinical characterization, treatment, outcome, and final etiology. Child and adult in- and outpatients were recruited and systematically investigated in Mozambique, Malawi, Lao PDR and Zimbabwe from 2018 to 2021. Clinical description on presentation, treatment and outcome were recorded for each participant. Point-of-care tests (including blood culture, urine dipstick and culture, and HIV and malaria tests) were performed, and further samples were shipped to reference laboratories for gold standard testing for a broad range of infectious agents. Across all sites 4577/145 patients (13% of all inpatients and 1.7% outpatients) presented with at least one neurological sign or symptom. Of those, 71% had seizures, 22% impaired consciousness, and 13% neck stiffness. The majority (78%) received antibiotics. Central nervous system infection was suspected by clinicians at arrival in 55/457. We will present all laboratory diagnostic results stratified by age, site and clinical presentation, and an analysis of sub-group outcomes. Neurological symptoms on presentation are frequent among febrile inpatients in LMICs and antibiotics are widely prescribed. Detailed etiological diagnoses are crucial to better target the scarce therapeutic interventions available.

### RECONCILING IMPERATIVES. CLINICAL GUIDELINES AND THE ENACTMENT OF GOOD CARE IN LOWER-LEVEL HEALTH FACILITIES IN TORORO, UGANDA

Susan Nayiga<sup>1</sup>, Laurie Denyer Willis<sup>2</sup>, Sarah G. Staedke<sup>3</sup>, Clare IR Chandler<sup>3</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>The University of Edinburgh, Edinburgh, United Kingdom, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

In the face of rising threats of antimicrobial resistance, health workers are urged to reduce the unnecessary prescription of antimicrobials. Clinical guidelines emerge through evaluations of best practice – bundling clinical, technological and economic dimensions – and they create metrics through which to assess practice. On the global health stage, guidelines become a device through which to address complexities of care across multiple contexts; by altering the algorithm of a guideline in one setting, the number of antibiotic prescriptions could be reduced in another. Prescribing practice can then be benchmarked against the latest guidelines, a key tenet of antimicrobial stewardship programmes. Drawing on ethnographic data gathered in lower-level health care facilities in rural Eastern Uganda for 10 months between January and October 2020, extending previous work carried out over the past decade, we describe how clinical guidelines are translated and implemented in settings where resources are limited. In a context of scarcity where ‘care’ is characterized by delivery of medicines, and is constituted beyond these algorithmic outputs, we observed that clinical practice in lower-level health facilities in Nagongera, Tororo was shaped by patterns of resources, professional and patient expectations as much as by the written algorithms. For stewardship to care for patients as well as for medicines, a better understanding is required of clinical practice and expectations of care, in relation to and beyond the framework of the guidelines.

### PREVENTION, DIAGNOSIS AND MANAGEMENT OF PODOCONIOSIS; INTEGRATION INTO PRIMARY HEALTH CARE IN SOUTHERN NATIONS, NATIONALITIES, AND PEOPLE’S REGION (SNNPR), ETHIOPIA

Laura Donovan<sup>1</sup>, Tedila Habte<sup>2</sup>, Esey Batisso<sup>2</sup>, Fikre Seife<sup>3</sup>, Kevin Baker<sup>1</sup>

<sup>1</sup>Malaria Consortium, London, United Kingdom, <sup>2</sup>Malaria Consortium, Addis Ababa, Ethiopia, <sup>3</sup>Federal Ministry of Health, Disease Prevention and Control Directorate, Addis Ababa, Ethiopia

Podoconiosis is a non-infectious, neglected tropical disease (NTD) whose global burden is estimated to be about 4 million people, concentrated in the highland areas of tropical Africa, Central America and north-west India. Ethiopia bears the highest burden of podoconiosis globally, with more than 1.5 million people affected, causing detrimental economic, physical and social impact. The absence of diagnostic point-of-care tests, coupled with inadequate knowledge among healthcare providers, contributes to the under-reporting of podoconiosis cases in a context where funding is limited. However, the World Health Organization (WHO)’s 2021-2030 roadmap calls for greater integration and mainstreaming of NTD approaches into national health systems. Additionally, Ethiopia’s 2016-2020 NTD Master Plan listed podoconiosis as one of eight priority NTDs for integration into its primary healthcare (PHC) system. This study aimed to develop and pilot an evidence-based, multi-component intervention to strengthen and integrate podoconiosis detection, management and reporting into PHC in Ethiopia. In the formative research phase of the project, mapping and review of existing national guidelines was conducted to identify current gaps in the PHC system. Key informant interviews were held to elicit community perceptions of podoconiosis and barriers to care-seeking. A health system capacity assessment was conducted in a primary hospital, health centre and five health posts to assess gaps and identify requirements for integration. Stakeholders included community members with and without podoconiosis, health

extension workers, health workers and programme managers from national to district level. Results informed the design and validation of intervention materials and processes which were piloted for six months with end users across all levels of PHC system. Formative research and the evaluation of intervention feasibility, acceptability and implementation cost will be presented.

### BACTERIAL ILLNESS IN LIBERIAN CHILDREN UNDER FIVE YEARS

Symren Dhaliwal<sup>1</sup>, Sabahat Rahman<sup>1</sup>, Benetta Andrews<sup>2</sup>, Kimberly Burke<sup>1</sup>, Steven Hatch<sup>1</sup>, Patricia McQuilkin<sup>1</sup>

<sup>1</sup>University of Massachusetts, Worcester, MA, United States, <sup>2</sup>JFK Medical Center, Monrovia, Liberia

Fever without apparent source (FWAS) is one of the most common reasons why children seek urgent medical treatment across the world (1). When diagnostic microbiology became available in Monrovia in 2019, we undertook a study of children under 5 who were admitted to the hospital with acute febrile illness to determine possible etiologies of their fever. We conducted a prospective study of febrile illness in children admitted to a Liberian tertiary care center from May 2019-June 2020. Parental consent was obtained for children aged 6 mo to 5yr who presented with fever within 24 hours. Demographic and clinical information, CBC, blood culture, and malaria smears were obtained for every participant. Tests such as CXR, urine, throat and CSF cultures were conducted when clinically indicated. Study staff were trained on sterile technique using alcohol and povidone prior to venipuncture. Of the 220 children who were included in the study, 31 had positive blood cultures. Of these samples, 21 had positive blood cultures associated with skin contaminants: 19 coagulase negative *Staph spp.* (CoNS), 2 *Corynebacterium*, and *Enterococcus spp.* (1). Thus, the overall contamination rate seen in our study was 9.5% (21/220 patients). In performing a study on acute febrile illness in Liberian children, we noted a high rate of contaminated blood cultures. This rate of contamination greatly exceeds the 2-3% benchmark rate for incidental culture contamination that has been cited previously. This is similar to findings within pediatric populations in other African tertiary care centers such as in Nigeria (11%), and Kenya (8.8%). CoNS is the primary cause of BC contamination worldwide and contamination is typically higher in pediatric populations than adults. Blood culture contamination leads to inappropriate antibiotic use and increased cost. Patient care may suffer from misdiagnosis. Several studies have noted improved rates of blood culture contamination with education directed at scrupulous sterile technique. Such strategies will be important to pursue in countries where diagnostic microbiology is newly available, such as Liberia.

0778

### THE HEART OF THE MATTER: CARDIAC MANIFESTATIONS OF CHAGAS DISEASE AT A TROPICAL MEDICINE CLINIC IN BOSTON

Katherine Anne Reifler<sup>1</sup>, Samantha Hall<sup>2</sup>, Davidson H. Hamer<sup>2</sup>, Deepa Gopal<sup>3</sup>, Alyse Wheelock<sup>4</sup>, Alejandra Salazar<sup>5</sup>, Jim Gomes<sup>5</sup>, Natasha S. Hochberg<sup>4</sup>

<sup>1</sup>Boston Medical Center Department of Internal Medicine, Boston, MA, United States, <sup>2</sup>Boston University School of Public Health, Boston, MA, United States, <sup>3</sup>Boston Medical Center Section of Cardiology, Boston, MA, United States, <sup>4</sup>Boston Medical Center Section of Infectious Disease, Boston, MA, United States, <sup>5</sup>Boston Medical Center for Infectious Diseases, Boston, MA, United States

There are limited data about Chagas disease (CD) screening and cardiac manifestations of CD for people living in the United States. This study aimed to describe disease severity by American Heart Association (AHA) stage and Rassi mortality risk prediction score and cardiac medication management for patients with CD. This retrospective cohort analysis included patients with CD (diagnosed with two positive tests) identified through a community-based screening program of immigrants at a

local community health center and seen at a Boston tropical medicine clinic between January 2016-February 2021. We analyzed cardiac testing (electrocardiogram [EKG], echocardiogram, cardiac monitor, stress tests, and cardiac MRI) and medication management. Of the 63 patients, 34 (54%) were female, and the mean age was 45 years (range 22-73). Among the 4 patients who underwent cardiac MRI, 3 (75%) had late gadolinium enhancement findings suggestive of Chagas cardiomyopathy (CCM). Overall, 34 (54%) patients were AHA stage A (no EKG/echocardiographic changes), 22 (35%) were stage B1 (EKG or echocardiographic changes, normal ventricular function), 4 (6%) were stage B2 (ventricular dysfunction), and 2 (3%) were stage C (ventricular dysfunction and symptomatic heart failure). No patient was stage D (heart failure refractory to medical therapy) and 2 were unstageable due to limited data. The majority of patients (n=55, 87%) were in the low Rassi mortality risk category, 6 (10%) were intermediate risk, none were high risk, and 2 (3%) were unable to be risk stratified. After their cardiac workup, 4 patients were started on goal-directed therapy for heart failure, and 4 patients were started on anticoagulation (1=warfarin, 3=aspirin). Almost half of patients in our cohort had evidence of CCM and 10% had elevated 10-year mortality risk. We demonstrate that screening individuals from endemic countries in a community-based primary care setting identifies those at high risk and in need of medical therapy for cardiomyopathy.

0779

#### PREVALENCE AND FACTORS ASSOCIATED WITH HEART FAILURE IN HAITI: FINDINGS FROM A POPULATION-REPRESENTATIVE COHORT STUDY

**Nicholas L. Roberts**<sup>1</sup>, Miranda Metz<sup>1</sup>, Lily Yan<sup>1</sup>, Jean Lookens Pierre<sup>2</sup>, Vanessa Rouzier<sup>2</sup>, Justin Kingery<sup>1</sup>, Jean W. Pape<sup>2</sup>, Margaret McNairy<sup>1</sup>

<sup>1</sup>Weill Cornell Medicine, New York, NY, United States, <sup>2</sup>GHEKIO, Port-au-Prince, Haiti

Cardiovascular disease is the leading cause of mortality in Haiti and other low- and middle-income countries (LMICs). However, there is a scarcity of data on the epidemiology, etiologies and risk factors of heart failure (HF) in these areas, hampering our ability to devise preventive interventions and treatment guidelines. We conducted a population-representative cohort study of Haitian adults ≥18 years of age to estimate the prevalence of HF in Port-au-Prince, Haiti. Sociodemographic and clinical data, including echocardiography, electrocardiography, and blood pressure measurements were collected from March 2019 - April 2020. HF was defined as the simultaneous presence of at least 2 major Framingham HF criteria or 1 major criterion in conjunction with at least 2 minor criteria. Associated factors (age, sex, education, income, smoking, alcohol, hypertension, and BMI) were assessed using univariate logistic regression models. Of 1,420 participants, the prevalence of HF was 3.2% (N = 45). Of those with HF, 11 (24.4%) had a reduced ejection fraction of less than 50% and 34 (75.6%) had a preserved ejection fraction greater than 50%. 68.9% of participants with HF had concurrent hypertension. Importantly, 301 (21.9%) participants without HF had diastolic dysfunction on echocardiography. In participants ≥50 years of age (N = 289), the prevalence of hypertension, diastolic dysfunction, and HF was 75.3%, 58.6%, and 7.7%, respectively. Female sex, increased age, lower education levels, hypertension, and increased BMI were all significantly associated with increased rates of HF (p-value < 0.05). HF has been shown to be the most common cause of hospital admission in Haiti, and we report that the prevalence of HF in a population-representative sample was 3.2%, which doubles in those 50 years of age and older. The high prevalence of hypertension, diastolic dysfunction, and HF with preserved ejection fraction demonstrate that early interventions like hypertension management may greatly improve cardiovascular health and reduce long-term morbidity and mortality in Haiti and other LMICs.

#### BUILDING THE FULL CONTINUUM OF CLEFT CARE IN EL SALVADOR

**Kelsey Mumford**, Kaylee O'Connor, Raymond Harshbarger

*Dell Medical School at The University of Texas at Austin, Austin, TX, United States*

Six percent of all surgical procedures are performed in the poorest countries that are home to 1/3 of the world's population. Disparate rates of cleft palate malformation repairs are one example of an inequity that disproportionately affects low income nations. The goals of comprehensive cleft care include repair of the birth defect, achievement of normal speech, adequate breathing, and dental health, and facilitation of optimal psychosocial and developmental outcomes. These goals are accomplished in America through coordinated, multidisciplinary care, which is challenging to provide in a global context with limited resources and surgical training. Investing in craniofacial care in these nations will save lives, improve quality of life, and promote economic growth. We describe a model for providing such care developed in 2009 by an American Craniofacial Surgeon in El Salvador at Bloom Children's Hospital wherein the focus was to both provide medical care and improve surgical capability and expansion within the country. While efforts started with the traditional focus of performing cleft palate surgeries, the program was developed into a multidisciplinary effort to provide craniofacial surgical care year-round. This progress largely resulted from establishing partnerships with local stakeholders and providing culturally-sensitive care that garnered trust from the local community. This trust enabled the group to train local orthodontists and oral/plastic surgeons in cleft care, allowing for longitudinal and multidisciplinary care for patients to span the continuum of care. Over three years, services expanded to include speech therapy, 12 cases of Le Fort I surgeries, 12 cases of alveolar bone grafting, 4 cases of distraction osteogenesis, and 3 cases of bilateral sagittal split osteotomies. Through offering educational opportunities, such as craniofacial fellowship training in America, as well as providing equipment advancements for the hospital, El Salvador is on its way to having an independent and sustainable foundation with which to provide comprehensive, multidisciplinary craniofacial care administered by local providers.

0781

#### THE MAIN PATHOGENS CAUSING FEBRILE ILLNESS AND IMPLICATIONS FOR FEVER MANAGEMENT IN LAOS; RESULTS FROM THE FIEBRE STUDY

**Manophab Luangraj**<sup>1</sup>, Vilayouth Phimolsarnnousith<sup>1</sup>, Somvai Singhaxaiyaseng<sup>1</sup>, Khamfong Kanlaya<sup>1</sup>, Vilada Chansamouth<sup>1</sup>, Audrey Dubot-Pères<sup>2</sup>, Andrew Simpson<sup>1</sup>, Manivanh Vongsouvath<sup>1</sup>, Vengmon Davong<sup>1</sup>, Sham Lal<sup>3</sup>, Chrissy H. Roberts<sup>3</sup>, Heidi Hopkins<sup>3</sup>, David Mabey<sup>3</sup>, Paul N. Newton<sup>4</sup>, Elizabeth A. Ashley<sup>1</sup>, Mayfong Mayxay<sup>1</sup>

<sup>1</sup>Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit, Vientiane, Lao People's Democratic Republic, <sup>2</sup>Unité des Virus Émergents (UVE), Aix Marseille Univ, IRD 190, INSERM 1207, IHU Méditerranée Infection, 13005, Marseille, France, <sup>3</sup>Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom

Management of febrile illness in Laos typically relies on clinical assessment and empiric treatment, as laboratory confirmation is often not available, except malaria and dengue rapid tests. The standard empiric treatment of inpatients with sepsis or febrile illness in Laos is parenteral ceftriaxone. Vientiane Provincial Hospital in northern Laos was one site of the multicentre FIEBRE (Febrile Illness in a Broad Range of Endemicities) study which performed a comprehensive evaluation of the causes of febrile illness in inpatients and outpatients of all ages. We aimed to describe the leading pathogens diagnosed from FIEBRE patients recruited in Laos. Between October 2018 and October 2020, 1972 patients were enrolled. Laboratory testing included blood culture, malaria microscopy, molecular

or serological testing for histoplasma-antigen, PCR and serology for dengue, Zika, chikungunya, and JEV, PCR for respiratory pathogens, plus *Leptospira* and rickettsial serology (results awaited). Among 1972 patients, 135 (6.8%) had positive blood cultures. Of these, 17 (12.6%) grew *Burkholderia pseudomallei*, 8 (5.9%) *Escherichia coli* (4 ESBL positive), 7 (5.2%) *Staphylococcus aureus* (2 MRSA), 3 (2.2%) *Klebsiella pneumoniae*, 2 (1.5%) *Talaromyces marneffeii*, and 2 (1.5%) *Streptococcus pneumoniae*. None of our patients tested positive for malaria. From the first batch of testing, 5/382 (1.3%) samples were positive for Histoplasma-Ag. From 605 samples, 24 (3.9%) were positive for dengue. Of 669 pharyngeal samples, 218 (32.6%) tested positive for respiratory viruses. 1207 (61.4%) patients received antibiotics, of which 799 (66.2%) were cephalosporins. Our results reveal the leading infectious causes of febrile illness in rural Vientiane. Results to date show viruses accounted for most diagnoses, particularly respiratory viruses and dengue. Despite this, antimicrobial prescribing rates were high. While the diagnostic yield from blood cultures was low. We demonstrated melioidosis and ESBL-producing Enterobacterales are prevalent in this part of Laos, with important implications for empiric prescribing in severely ill patients with sepsis.

0782

### ACUTE FEBRILE ILLNESSES IN CHILDREN PRESENTING TO A TERTIARY HOSPITAL IN SOUTHERN ETHIOPIA: MANAGEMENT AND OUTCOMES

**Techalew Shimelis<sup>1</sup>**, Susana Vaz Nery<sup>1</sup>, Birkneh T. Tadesse<sup>2</sup>, Adam W. Bartlett<sup>1</sup>, Fitsum W. Belay<sup>2</sup>, Gill Schierhout<sup>3</sup>, Sabine Dittrich<sup>4</sup>, John A. Crump<sup>5</sup>, John M. Kaldor<sup>1</sup>

<sup>1</sup>Kirby Institute, University of New South Wales, Sydney, Australia, <sup>2</sup>College of Medicine and Health Sciences, Hawassa University, Hawassa, Ethiopia, <sup>3</sup>The George Institute for Global Health, University of New South Wales, Sydney, Australia, <sup>4</sup>Foundation for Innovative New Diagnostics, Geneva, Switzerland, <sup>5</sup>Centre for International Health, University of Otago, Dunedin, New Zealand

The management of febrile illnesses is challenging in settings where diagnostic laboratory facilities are limited. We conducted a longitudinal study in febrile children to assess the appropriateness and outcomes of their management. We consecutively enrolled febrile children aged 2 months and under 13 years presenting to Hawassa University Comprehensive Specialized Hospital from May 2018 through February 2019. Information was obtained from history-taking, physical examination, and laboratory investigations. Culture results available within one week of enrolment provided further guidance on diagnoses and management. Participants were managed based on available findings on day of enrolment. Outcome data were collected on days 7 ( $\pm 1$ ) and 14 ( $\pm 1$ ). The appropriateness of management was retrospectively evaluated in accordance with guidelines. Of 433 enrolled children, pneumonia and acute diarrhoea were diagnosed at presentation in 177 (40.9%) and 82 (18.9%), respectively. Urinary tract infection (UTI) was detected in 74 (18.4%) of 402 children. Antibacterial agents were prescribed to 360 (84.7%) of 425 children, but 36 (34%) of 106 children without an initial indication received inappropriate antibacterials. Antimalarial drugs were prescribed to 47 (11.1%) of 425 children, but 30 (7.3%) of 411 children with negative malaria microscopy received inappropriate antimalarials. Fever had resolved in 357 (89.7%) of 398 children at day 7 ( $\pm 1$ ), and in-hospital death within 7 days occurred in 9 (5.9%) of 153 admitted patients. Among children with pneumonia, being infants or underweight, and absence of vomiting were predictors of death or persisting fever at 7 days. Inappropriate use of antimalarials was associated with older age, presence of anaemia, absence of cough, and higher fevers, while inappropriate antibacterial prescriptions were more likely among infants and those without tachypnea. Our study underscores the need for improving the diagnostic support to properly guide management decision and enhance adherence by clinicians to treatment guidelines.

### PODOCONIOSIS INSTRUCTION IN NURSING CURRICULA IN UGANDA, RWANDA, AND KENYA

**Lilian Nantume Wampande<sup>1</sup>**, Lamek Mageto Nyabuga<sup>2</sup>, Kelly Fowler<sup>3</sup>, Ursin Bayisenge<sup>2</sup>, Janna M. Schurer<sup>2</sup>

<sup>1</sup>University of Global Health Equity, Kigali, Rwanda, Rwanda, <sup>2</sup>University of Global Health Equity, Kigali, Rwanda, <sup>3</sup>Tufts University, Boston, MA, United States

Podoconiosis is a chronic, disfiguring, and non-infectious type of elephantiasis that predominantly affects communities marginalized by poverty. Nurses play an important role in early detection and response in rural Africa. However, it is unclear whether they receive adequate training to effectively diagnose and manage this disease. This study aimed to characterize podoconiosis curricula at all post-secondary institutions offering nursing education in three endemic countries. Between July and September 2020, we conducted a cross-sectional quantitative survey of certificate (84), diploma (148) and degree (56) programs across Kenya, Rwanda, and Uganda. Measures focused on podoconiosis knowledge, quality/quantity of podoconiosis instruction, and barriers to podoconiosis education. In total, 109 individuals participated, providing information on 145 of 228 invited nursing schools (63.6%). Knowledge of podoconiosis was poor; 68.6% knew that podoconiosis was caused by contact with soil but 17.6% believed it was caused by mosquitoes. Podoconiosis-specific content was highest in diploma (54.2%), followed by degree (28.6%) and certificate (23.1%) programs. Perceptions towards quality and quantity of instruction varied, ranging from high satisfaction across certificate programs (87.5%) in Kenya to low satisfaction (33.3%) across degree programs in Rwanda. The importance of providing podoconiosis training was ranked high by 41.7% of participants. Exclusion from government curricula, rarity of disease and low faculty knowledge were cited as barriers to sufficient podoconiosis inclusion. This study identified widespread gaps in podoconiosis knowledge among nursing faculty in three East African countries as well as low inclusion in nursing curricula. Well-trained nurses can play a critical role in prevention by promoting simple and low cost measures such as WASH and footwear. Interventions to improve nurses' knowledge could include the development and free distribution of podoconiosis teaching materials, designed for integration into pre-existing courses.

0784

### FEASIBILITY OF COMMUNITY BASED EPILEPSY TREATMENT USING TRAINED COMMUNITY HEALTH WORKERS IN MALI: DATA OF THREE MONTHS FOLLOW UP

**Housseini Dolo<sup>1</sup>**, Fatoumata dite Nènè Konipo<sup>2</sup>, Mariam Daou<sup>3</sup>, Abdou Koita<sup>3</sup>, Birama Sangaré<sup>3</sup>, Harouna Koné<sup>2</sup>, Housseini D. Coulibaly<sup>2</sup>, Mohamed Kamaforo<sup>2</sup>, Moussa Sangaré<sup>2</sup>, Abdoul Fatao Diabaté<sup>2</sup>, Modibo Sangaré<sup>1</sup>, Siaka Yamoussa Coulibaly<sup>2</sup>, Salif Seriba Doumbia<sup>2</sup>, Youssoufa Maiga<sup>3</sup>, Yaya Ibrahim Coulibaly<sup>1</sup>, Seydou Doumbia<sup>1</sup>

<sup>1</sup>Faculty of Medicine and Odontostomatology, Bamako, Bamako, Mali, <sup>2</sup>Filariasis Research and Training Unit (FRTU), Bamako, Mali, <sup>3</sup>Teaching Hospital Gabriel Touré, Bamako, Mali, Bamako, Mali

In Mali, a prevalence study to identify persons with epilepsy (PWE) by an active research method using community health workers (CHWs) was conducted in six Health Districts (HD) in Kolokani, Kayes, Kénéba, Sikasso, Kadiolo and Tominian of two ecoclimatic zones of Mali. Following this study, a cohort of PWE treated with phenobarbital has been implemented to evaluate the feasibility of community-based epilepsy with CHWs. A closed cohort study started in September 2020 and running until August 2022 was implemented. PWE from previous prevalence study were selected and checked for their eligibility for phenobarbital treatment. We took in each HD the health area that had the highest number of confirmed cases of epilepsy during the prevalence study. All confirmed cases of epilepsy aged two years and above, not pregnant, not having absence seizures and not taking other antiepileptic drugs were included in the

study. In each health area, the CHWs were trained in the correct use of the follow-up booklet and how to administer the drug. Of a total of 181 patients selected, 90.61% (164/181) were eligible for the community-based epilepsy treatment. In the six HD, 36 CHWs were used, including 9 women. The majority of CHWs (47.22% (17/36) had between 11 and 15 years of experience. Most of the CHWs had a basic education level with 69.44% (25/36) for primary education level or Medersa (Arabic school) with 42.75% (56/131). During the inclusion phase, 18.29% (30/167) of the patients were seizure-free compared to 59.21% (90/152) at the three months follow up. Drowsiness was the main side effect reported with 44.44% (8/18). The mean duration between two seizures was significantly reduced from 74.39% (122/164) at inclusion to 25.66% (39/152) at the three months follow up. Dosage errors were the most frequent error caused by the patients with 61.90% (13/22). Among the difficulties reported by the CHWs, those related to a long distance were the most frequent with 89.29% (25/152). Our preliminary data showed that CHWs seem to be a good alternative for the therapeutic follow up of patients with epilepsy in community-based epilepsy treatment in resource limited settings.

## 0785

### A PROSPECTIVE COHORT STUDY OF CLINICAL CHARACTERISTICS, MANAGEMENT, AND OUTCOMES FOR ADOLESCENTS AND ADULTS WITH SEPSIS IN NORTHERN TANZANIA

**John P. Bonnewell<sup>1</sup>**, John A. Crump<sup>1</sup>, Francis M. Sakita<sup>2</sup>, Julian T. Hertz<sup>1</sup>, Joseph R. Egger<sup>3</sup>, Kajiru G. Kilonzo<sup>2</sup>, Venance P. Maro<sup>2</sup>, Matthew P. Rubach<sup>1</sup>

<sup>1</sup>Duke University Medical Center, Durham, NC, United States, <sup>2</sup>Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, <sup>3</sup>Duke Global Health Institute, Durham, NC, United States

Despite a high burden of sepsis in sub-Saharan Africa (sSA), clinical data for sepsis in adolescents and adults are limited. We sought to describe sepsis clinical characteristics, management, severity scores, and their associations with outcomes in a prospective cohort of adolescents and adults at Kilimanjaro Christian Medical Centre, Moshi, Tanzania from September 2019-March 2020. We enrolled participants using a modified Sepsis-2 definition, which excluded the white blood cell criterion due to lack of routine availability, and we collected data on demographics, clinical characteristics, severity indicators, and management, with an emphasis on hours 0-6 after arrival to the Emergency Department. Poisson regression was performed to estimate incidence rate ratios (IRR) and 95% confidence intervals (95%CI) between demographics, clinical factors, and severity scores, and our primary outcome of in-hospital death. There were 86 participants included in our analysis, of whom median (IQR) age was 46.5 (32-60) years, 27 (31.4%) were female, 13 (15.3%) self-reported HIV infection, and 25 (29.1%) died in-hospital. Clinical factors associated with an increased rate of inpatient death included: inability to drink unassisted, IRR 3.75 (95%CI 1.66-8.49), requirement for oxygen supplementation, 2.39 (1.07-5.32), and altered mentation, defined as status other than alert on the Alert-Verbal-Pain-Unresponsive scale, 3.63 (1.38-7.07). Rate of in-hospital death was increased for participants with a quick Sequential Organ Failure Assessment (qSOFA) score  $\geq 2$ , IRR 3.12 (95%CI 1.38-7.07), and a Universal Vital Assessment (UVA) score  $> 4$ , 6.68 (2.15-20.71). Within 6 hours after arrival, 29 (33.7%) participants received antimicrobials and 49 (57.0%) received intravenous fluids. Neither intervention was associated with in-hospital outcome. Sepsis in northern Tanzania was associated with high in-hospital mortality. Further data on clinical factors, particularly management practices, and relationships to outcomes are needed to establish the highest-yield interventions suited to the unique characteristics of sepsis in sSA.

## 0786

### FIGHTING ADULT MORTALITY THROUGH ETIOLOGY OF FEVER STUDIES: DESCRIPTION OF HIGH MORTALITY IN AN ADULT INPATIENT POPULATION IN MOZAMBIQUE

**Justina Bramugy<sup>1</sup>**, Marta Valente<sup>2</sup>, Sham Lal<sup>3</sup>, Sara Ajanovic<sup>2</sup>, Oliver Baerenbold<sup>3</sup>, Heidi Hopkins<sup>3</sup>, David Mabey<sup>3</sup>, Quique Bassat<sup>4</sup>

<sup>1</sup>CISM-Centro de Investigacao em Saude de Manhica, Maputo Province, Mozambique, <sup>2</sup>Centro de Investigacao o em Saude de Manhica a and Instituto de Salud Global de Barcelona, Barcelona, Spain, <sup>3</sup>Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine (LSHTM), London, United Kingdom, <sup>4</sup>Centro de Investigacao em Saude de Manhica, Maputo, Mozambique. Instituto de Salud Global de Barcelona, ICREA, Pg. Lluas Companys 23, Pediatric Department, Hospital Sant Joan de Dieu, Barcelona, Spain

Fever is a common symptom leading to health care seeking and hospital admission in Africa. Mortality rates in febrile adult inpatients in Mozambique are high, and are associated with high underlying prevalence of co-morbidities like HIV and cardiovascular diseases, and delays in care-seeking. Better characterization of febrile teenage and adult patients in terms of clinical presentation, diagnostic laboratory findings, and outcomes may be important for a more evidence-based evaluation of current clinical management algorithms, with the aim of decreasing preventable mortality. The observational study "FIEBRE: Febrile illness evaluation in a broad range of endemicities" recruited febrile patients in Mozambique, Zimbabwe, Malawi and Lao PDR to identify infectious causes of fever and antimicrobial susceptibility of bacterial pathogens. Here we present mortality data from Mozambican adults enrolled from Jan 2019 to Feb 2021. Demographic, clinical and outcome data at enrolment and  $\geq 26$  days later were collected, and laboratory tests (blood culture, mycobacterial blood culture, urine dipstick and culture, malaria and HIV testing, serum cryptococcal antigen (CrAg) and urine lipoarabinomannan (uLAM)) were conducted on site. Samples were sent for centralized reference laboratory testing for other specific infectious pathogens. We enrolled 469 outpatient and 300 inpatient adults, with median age 33 years and majority female 529 (68.8%). Among inpatients 53 (17.7%) died within 28 days of enrolment, of which 36 (68%) were HIV-infected. Among HIV-infected inpatients 10% tested positive for uLAM and 7% were positive for CrAg. We will present the diagnostic profile of these patients, in comparison to survivors, with detailed characterization of co-morbidities and socio-demographic factors associated with deaths. Mortality among adult Mozambican inpatients with febrile illness is high, due in part to preventable and treatable opportunistic infections in the context of underlying HIV infection. Comprehensive strategies to address HIV infection at all stages (prevention, diagnosis and treatment) are needed to decrease mortality.

## 0787

### IMPROVING SURVEILLANCE AND MANAGEMENT OF MALARIA, DIARRHEA AND PNEUMONIA IN PRIVATE FACILITIES IN UGANDA

**Juliet Nakiganda<sup>1</sup>**, Alex Ogwal<sup>1</sup>, Deepa Pindolia<sup>2</sup>, Isaac Okiring<sup>1</sup>, Lorriane Kabunga<sup>1</sup>, Andrew Musoke<sup>1</sup>, Jimmy Opigo<sup>3</sup>, Robert Mugerwa<sup>3</sup>, Funlola Osinupebi<sup>2</sup>, Meley Woldeghebriel<sup>1</sup>

<sup>1</sup>Clinton Health Access Initiative, Kampala, Uganda, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>3</sup>National Malaria Control Program, Kampala, Uganda

In Uganda, more than 60% of the population seeks health care in the private sector as their first point of contact. The sector is characterized by poor quality and availability of malaria commodities, challenges with adherence to test results for malaria treatment, and lack of reporting. In 2018, there was a 6-month pilot of mTrac (a USSD based case self-reporting system previously used only in the public sector) for private sector malaria surveillance in 108 facilities in 3 districts which led to an increase in HMIS weekly reporting rates. In 2020, the MoH requested CHAI to assess the impact of scaling up mTrac while strengthening case

management in the private sector in another 4 districts. In September 2020, after a baseline assessment in 136 private clinics and drug shops to understand knowledge, practices, and reporting for malaria, pneumonia, and diarrhea, providers were trained on integrated management of childhood diseases as well as mTrac reporting. Data review meetings were conducted to identify testing, appropriate treatment, and reporting gaps reported through mTrac and followed by routine supportive supervision by district health teams. Testing and reporting rates reported through mTrac were monitored weekly to assess the impact of supervision visits implemented between October 2020-March 2021. Reporting rates showed trends closely linked with patterns of engagement and supportive supervision, i.e. dropping to 40% in between supervision, climbing up to above 88% (compared to baseline of 6%) following review meetings, on site mentorship and supportive supervision. Testing rates for malaria, as well as adherence to test results, increased from 76% to 90% between October 2020 and March 2021. Continuous follow up and refresher trainings through onsite mentorships and targeted supervision to underperforming private clinics and drug shops resulted in improvement in reporting rates as well as case & stock management practices. A key driver of the sustainability of this intervention will be the maintenance of continuous targeted support supervision visits as well as the quarterly data review meetings as per the study protocol.

### PUBLIC HEALTH INTERVENTION USING THE HEALTH BELIEF MODEL IMPROVES COVERAGE AND ACCEPTANCE TO IVERMECTIN MASS ADMINISTRATION

**Francis Adjei Osei**<sup>1</sup>, Sam Newton<sup>1</sup>, Dan Wolf Meyrowitsch<sup>2</sup>, Nicholas Karikari Mensah<sup>3</sup>, Evans Xorse Amuzu<sup>3</sup>, Isaac Nyamor<sup>1</sup>, Samuel Frimpong Odoom<sup>1</sup>, Suraj Yawnumah Abubakar<sup>3</sup>, Eugene Osei-Yeboah<sup>4</sup>, Mathias Dongyele<sup>1</sup>, Ernest Amanor<sup>1</sup>, Alfred Kwame Owusu<sup>3</sup>, Peter Furu<sup>2</sup>, Phans Oduro Sarpong<sup>1</sup>, Ellis Owusu-Dabo<sup>1</sup>

<sup>1</sup>*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*, <sup>2</sup>*University of Copenhagen, Copenhagen, Denmark*, <sup>3</sup>*Komfo Anokye Teaching Hospital, Kumasi, Ghana*, <sup>4</sup>*Ghana Health Service, Bolgatanga, Ghana*

Poor community awareness and social mobilization serve as a major barrier by increasing absenteeism and downplaying the relevance of the ivermectin mass distribution by community members. Inadequate awareness also creates confusion among community members especially when one intervention is mistaken for the other. We designed a targeted SBCC intervention with clearly defined and tailored messages of ivermectin MDA program targeting onchocerciasis in endemic communities. At baseline, 63.9% respondents did not receive ivermectin during the previous year (2019) MDA programme and more than half of them (53.3%) were not aware of the drug distribution. The communities that received the intervention at endline revealed a significantly higher increase in coverage (SATT=0.123, 95% CI=0.073, 0.173, p<0.001). At baseline, uptake rate of 91.0% was recorded. Post the intervention, there was an increase in the proportion of respondents who ingested the MDA drugs (ivermectin) from 91.0% to 95.45%. Previous uptake of MDA drugs (AOR=10.67; 95%CI: 5.59-20.38, p<0.001), Perceived benefit of MDA drug (AOR=4.13; 95%CI: 1.69-10.15, p<0.001) and being aware of the MDA programme (AOR=2.28; 95%CI: 1.00-5.02, p=0.049) was associated with improved receipt of ivermectin. The findings of this study reveal that SBCC intervention improves ivermectin coverage and uptake rate in mass drug administration. Further research with technological innovations which can enhance SBCC is recommended taking hind sight of the limitations of the study due to the COVID-19 pandemic.

### IMPLEMENTATION OF THE NATIONAL INTEGRATED HELMINTH CONTROL PROGRAM IN A PROVINCE IN WESTERN VISAYAS, THE PHILIPPINES: IMPLICATIONS IN THE COVID-19 PANDEMIC

**Antoinette Montelibano**<sup>1</sup>, Vicente Belizario<sup>2</sup>, Peter Veldkamp<sup>1</sup>, Judy Chang<sup>1</sup>

<sup>1</sup>*University of Pittsburgh School of Medicine, Pittsburgh, PA, United States*,

<sup>2</sup>*University of the Philippines - Manila, Manila, Philippines*

We performed qualitative semi-structured interviews of 14 individuals actively involved in the soil-transmitted helminth (STH) infection control program in Negros Occidental from different administrative divisions to determine how COVID-19 affected the program at various levels of implementation. Interviews were conducted from July to August 2020, audio-recorded, transcribed verbatim, and coded in an open inductive manner. Thematic analysis reveals that public health activities in the province were focused on detecting and controlling COVID-19. School-based deworming was suspended and the responsibility has been assumed by local government units through house-to-house or health center delivery; however, human resources are lacking as opposed to the education sector. There has been a large shift toward information and communications technology for continued operations. Advocacy continues online through websites and social media with a large emphasis on water, sanitation, and hygiene (WASH). The WASH component of the program has seen improvements as activities are in line with both COVID-19 and STH control and prevention. Communication has been challenging due to barriers such as lack of access to internet, cellular coverage or hardware, and the fear of exposure to the virus. Logistic support for preventive community activities like toilet construction continues to be underprovided, while financial and pharmaceutical resources for deworming are sufficient despite delays. Key informants agree that multi-sectoral collaboration, although lacking at the time, and integration with the activities of other programs are essential, especially when COVID-19-related. The STH control program implementation in Negros Occidental has been disrupted almost completely as public health efforts focus on COVID-19 and infection precautions such as social distancing and community quarantines are observed. As the country continues to face challenges in controlling the virus, there is a need to provide alternative and catch up strategies for NTD service delivery and build a new roadmap to accommodate the gaps identified by this study.

Neglected tropical diseases (NTDs) are a group of diseases targeted for control, elimination and eradication by the World Health Organization. Five NTDs use a strategy of mass drug administration (MDA) using preventive chemotherapy for all eligible people living in endemic areas. Certain populations, including nomadic and migrant mobile populations, may not be reached during drug distribution. Stopping infection transmission through MDA will not be possible as long as significant groups of untreated people remain. This study aims to understand the characteristics of nomadic and migrant populations and how to improve MDA drug coverage. We carried out a mixed methods study in two health districts of Mali. Research sites included internally displaced persons as a result of terrorist and ethnic violence. Data were collected through individual in-depth interviews (IDI), focus group discussions (FGD) and a questionnaire using a micro-narrative survey to capture the experiences and practices of nomads and migrants in relation to their participation in previous MDA rounds. A total of 1,067 people were included in the survey and 19 IDI and 10 FGD were done. Survey participants included 22.7% transhumants and 25.1% farmers. More than 50% said they had not participated in the last MDA campaign. Some participants said they missed the MDA in their home village because of their mobility. Others reported that they did not feel connected to the host districts: *We are not very convinced that these medicines are of any use to us. Even if we go there we would not be considered because we are not planned here.* The movements of these populations do not align with the MDA campaign in their district of origin. These populations do not feel connected to the communities they migrate to, further reducing their opportunities to take MDA treatment. This study suggests that nomadic and migrant populations may be missing multiple rounds of MDA, introducing an important barrier to eliminating some NTDs in Mali. Improved coverage to these populations could be achieved by understanding their movements and strengthening collaboration among stakeholders.

### IMPROVING NEGLECTED TROPICAL DISEASES (NTDS) SERVICES AND INTEGRATING INTO PRIMARY HEALTH CARE IN SOUTHERN NATIONS, NATIONALITIES, AND PEOPLE'S REGION (SNNPR), ETHIOPIA

**Tedila Habte**<sup>1</sup>, Laura Donovan<sup>2</sup>, Esey Batisso<sup>1</sup>, Fikre Seife<sup>3</sup>, Kevin Baker<sup>2</sup>

<sup>1</sup>Malaria Consortium, Addis Ababa, Ethiopia, <sup>2</sup>Malaria Consortium, LONDON, United Kingdom, <sup>3</sup>Federal Ministry of Health, Addis Ababa, Ethiopia

Neglected tropical diseases (NTDs) are a group of parasitic and bacterial infectious diseases that affect more than 1.5 billion of the world's population. Over 40% of the global NTD burden is concentrated in sub-Saharan Africa, and Ethiopia bears one of the highest burdens. Several NTDs are endemic in the country, including trachoma, schistosomiasis and lymphatic filariasis. Previous NTD control has focused on developing and distributing safe and effective drugs to affected populations, mainly through mass drug administration. However, the World Health Organization (WHO)'s 2021–2030 roadmap calls for greater integration and mainstreaming of NTD approaches into national health systems. Additionally, Ethiopia's 2016–2020 NTD Master Plan lists the integration of NTDs into its primary healthcare (PHC) system as a strategic objective. In 2017, Malaria Consortium conducted a small-scale pilot and based on the results, is now running a larger scale pilot. This study aimed to develop and pilot an intervention to strengthen and integrate NTD detection, management and reporting into PHC in Ethiopia. The project consisted of formative and intervention stages; in the formative stage, key informant interviews with different stakeholders aimed to understand current case management of NTDs, the impact of COVID-19 on NTD services and elicited perceptions of future system requirements. Twenty interviews were

conducted with community members, health extension workers, health workers and programme- and national-level stakeholders. A health system capacity assessment was conducted in a primary hospital, health centre and five health posts to assess health infrastructure gaps and identify requirements for NTD integration. Quantitative and qualitative results from the formative research informed the development of intervention materials and processes which were tested for 6 months across all levels of the health system. Results from both the formative research and intervention evaluation regarding feasibility, acceptability and implementation cost will be presented.

### PILOTING COVID-19 PREVENTION MEASURES DURING TRACHOMA SURVEYS IN THE DEMOCRATIC REPUBLIC OF CONGO

**Raymond Stewart**<sup>1</sup>, Pitchuona Awaca Uvon<sup>2</sup>, Felix Makangila<sup>2</sup>, Bonaventure F. Ngoyi<sup>1</sup>, Elie Matheranya<sup>1</sup>, Kathryn Crowley<sup>3</sup>, Amy Veinoglou<sup>3</sup>, Diana Lu<sup>3</sup>, Clara Burgert<sup>3</sup>, Margaret Baker<sup>3</sup>, Elizabeth Sutherland<sup>3</sup>, Aryc W. Mosher<sup>4</sup>, Penelope M. Smith<sup>4</sup>, Jeremiah M. Ngondi<sup>3</sup>

<sup>1</sup>RTI International, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Ministry of Health, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>RTI International, Washington DC, MD, United States, <sup>4</sup>USAID, Washington DC, MD, United States

Eye examination during trachoma surveys requires close person to person contact thus appropriate measures are needed to mitigate potential risk of COVID-19 spread. We report on methods and results piloting COVID-19 preventive measures during trachoma surveys in DRC. Before surveys, COVID-19 risk assessment of community spread was done and deemed to be low. Standard operating procedures (SOPs) were developed on COVID-19 prevention, including: PCR-based testing of surveyors for SARS-Cov2; daily COVID-19 symptoms check for surveyors; COVID-19 symptoms screen for survey participants; physical distancing during travel, training and fieldwork; face masks for surveyors and survey participants; integrated loupe-face shields (in addition to face masks) for graders; and gloves and alcohol hand sanitizing gel for graders. In a sub-sample of households, supervisors assessed compliance of preventive measures using a checklist of observations and interviewed household heads on acceptability of COVID-19 preventive measures. A focus group discussion (FGD) was done with surveyors to obtain feedback on COVID-19 preventive measures. A total of 79 households participated in the supervisor observations and household feedback. Compliance of COVID-19 preventive measures was high across 11 observations (range 87% to 100% of households). Majority of households agreed that: COVID-19 precautions were appropriate (100%); they felt safe, during survey (99%); and they would participate in survey again with same precautions (100%). Few households (5%) had concerns with potential risk of COVID-19. FGD found that integrated loupe/face shields: were easy to use and comfortable to wear; did not interfere with examination for trachoma signs; there were no difficulties disinfecting face shields between households; and the loupe/face shield assembly held firmly together. This pilot showed that the SOPs on COVID-19 prevention measures were practical and provided additional protection for both survey teams and communities. Based on this successful pilot, surveys were expanded to cover other areas of DRC where COVID-19 risk is deemed to be low.

### PRE-INTERVENTION PHASE IDENTIFICATION OF CHALLENGES AFFECTING UPTAKE OF ONCHOCERCIASIS AND LYMPHATIC FILARIASIS PREVENTIVE CHEMOTHERAPY AMONG PEOPLE WITH DISABILITIES IN EJIGBO AND ORIADE LOCAL GOVERNMENT AREA, OSUN STATE, NIGERIA

**Olabanji A. Surakat**<sup>1</sup>, Monsuru A. Adeleke<sup>2</sup>, Sammy O. Sam-Wobo<sup>3</sup>, Uwem F. Ekpo<sup>4</sup>, Muhammed Rufai<sup>2</sup>, Olusola Ogunmola<sup>5</sup>

<sup>1</sup>Department of Zoology, Faculty of Basic and Applied Sciences, Osun State University, Osogbo., Osogbo, Nigeria, <sup>2</sup>Department of Zoology, Faculty of Basic and Applied Sciences, Osun State University, Osogbo. Osun State University, Osogbo., Osogbo, Nigeria, <sup>3</sup>Department of Pure and Applied Zoology, College of Biosciences, Federal University of Agriculture, Abeokuta, Abeokuta, Nigeria, <sup>4</sup>Department of Pure and Applied Zoology, College of Biosciences, Federal University of Agriculture, Abeokuta, Abeokuta, Nigeria, <sup>5</sup>South West Zonal Coordinator, NTD Unit, Department of Public Health, Federal Ministry of Health, Abuja, Nigeria., Abuja, Nigeria

Preventive chemotherapy using ivermectin and albendazole is the main thrust of controlling and eliminating onchocerciasis and lymphatic filariasis in Nigeria. This study evaluated factors affecting accessibility and uptake of these medicines among people with disabilities (PWDs) and selected community members in eight hard-to-reach areas of Ejigbo and Oriade Local Government Areas of Osun State, Nigeria. The study was conducted at the pre-intervention stage of the annual treatment. A total of two hundred and twenty (220) PWDs, community stakeholders, and key informants participated in Focus Group Discussions to determine their community needs. Problems identified at the pre-intervention stage are presented as follows; need to compile and update household registers by the CDDs to include a column for PWDs. Emphasis on training for community Health Educators and CDDs to increase sensitization and mobilization using appropriate IEC materials 67.3% ( $\chi^2$  12.082, df 3,  $p$  0.003), need to improve sensitization and advocacy visits to leaders of the PWDs groups to ensure inclusion 87% ( $\chi^2$  02.041, df 6,  $p$  0.042). Also, a subset 31% ( $\chi^2$  23.115, df 3,  $p$  0.000) of the persistent refusers of the medicines among the PWDs believed that the medicines are only suited for women and are of no use to them, while the remaining advocated for a special treatment day to cater for their peculiarities. In general, there is the need to increase the number of CDDs who will be engaged to follow up PWDs who may have missed treatment during the treatment rounds. There is a need for increased and concerted efforts targeted at treatment to suit the peculiarity of this marginalized group. This will ensure equitable access to health services for all without leaving anyone behind.

### GAPS OF NEGLECTED TROPICAL DISEASES KNOWLEDGE AFTER MASS DRUG ADMINISTRATION INTERRUPTION IN BURKINA FASO

**Noubar Clarisse Dah**<sup>1</sup>, Eric Nebié<sup>1</sup>, Ouhohiré Millogo<sup>1</sup>, Idrissa Kouanda<sup>1</sup>, Mariam Seynou<sup>1</sup>, Mamadou Bountogo<sup>1</sup>, Matilibou Guira<sup>2</sup>, Pascal Zabre<sup>1</sup>, Edoh Eddie Agbanouvi-Agassi<sup>3</sup>, Aristide Ouédraogo<sup>1</sup>, Issouf Traore<sup>1</sup>, Ali Sié<sup>1</sup>

<sup>1</sup>Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso, <sup>2</sup>Programme d'Appui au Développement Sanitaire, Ouagadougou, Burkina Faso, <sup>3</sup>West African Health Organization, Bobo-Dioulasso, Burkina Faso

The burden of Neglected Tropical Diseases (NTDs) remains high in developing countries with over one billion people being at risk. Despite the joint efforts for NTDs control through high coverages mass drug administration campaigns and case management, several Sub-Saharan countries are failing to reach the target of NTDs elimination. Possible causes for the persistence of these diseases include socio-cultural factors, namely knowledge and attitudes. Innovative and collaborative approaches have been initiated to accelerate the elimination of selected prioritized NTDs in Burkina Faso, Mali and Niger through the Malaria/Neglected Tropical Diseases control project. We assessed the gaps of knowledge relative to NTDs among the children aged 9-14 years in Burkina Faso. An electronic

lot quality assurance sampling survey (LQAS) was conducted in 2020 in 15 eligible districts for mass drug administration against at least one prioritized NTDs in Burkina Faso. Overall, 266 participants children aged from 9 to 14 were interviewed in each district using standardized LQAS survey questionnaire. Soil-transmitted helminthiasis, trachoma, onchocerciasis schistosomiasis and lymphatic filariasis were known by 59.77%, 25.56%, 17.29%, 35.90% and 45.49% of the participants respectively. School and parents were the main sources of information about NTDs. The main symptoms of schistosomiasis and soil-transmitted helminthiasis were known by 87.97% and 84.96% of participants respectively. NTDs routes of transmission were known by 14.42%, 53.96%, 29.6%, 28.10%, and 13.04% of participants for schistosomiasis, soil-transmitted helminthiasis, trachoma, lymphatic filariasis and onchocerciasis, respectively. School-aged children had insufficient knowledge about NTDs particularly for the NTDs for which MDA was interrupted. There is a need to strengthen sensitization and improve schools' managers' involvement in NTDs control. The inclusion of NTDs in schools' curricula might be a winning approach.

0795

### OVERCOMING COVID-19 THREAT TO CONDUCT LYMPHATIC FILARIASIS TRANSMISSION ASSESSMENT SURVEYS IN 36 HEALTH DISTRICTS IN CAMEROON

Biholong Benjamin<sup>1</sup>, Ebene Clarisse<sup>1</sup>, Georges NKO'Ayissi<sup>2</sup>, Julie Akame<sup>3</sup>, **Patrick Mbia**<sup>3</sup>, Carine Fokam<sup>3</sup>, Ismael Teta<sup>3</sup>, Michel Hendji Yoya<sup>3</sup>, Benoit Dembele<sup>4</sup>, Patricia Houck<sup>5</sup>, Jennifer Magalong<sup>6</sup>, Achille Kabore<sup>6</sup>, Yaobi Zhang<sup>5</sup>, Steven D. Reid<sup>5</sup>, Angela Weaver<sup>5</sup>

<sup>1</sup>Ministry of Public Health, PNLO, Yaounde, Cameroon, <sup>2</sup>Ministry of Public Health, NTD Coordination Unit, Yaounde, Cameroon, <sup>3</sup>Helen Keller International, Yaounde, Cameroon, <sup>4</sup>Helen Keller International, Regional Office for Africa, Dakar, Senegal, <sup>5</sup>Helen Keller International, New York, NY, United States, <sup>6</sup>Family Health International 360, Washington DC, MD, United States

Cameroon declared its first COVID-19 case on March 6, 2020. The national government then instated COVID-19 control measures, including mass gathering bans and school closures. Following the issuance of updated World Health Organization guidance on safe resumption of field-based NTD activities in July 2020, the National NTD Program (NTDP) undertook a risk assessment of NTD activities. Based on this assessment, the NTDP resumed NTD field activities. Here we describe the restart and implementation of the lymphatic filariasis transmission assessment survey 2 (TAS2) in 36 health districts (HDs), grouped into 13 evaluation units (EUs), in the context of the COVID-19 pandemic. The NTDP worked with partners to conduct a risk assessment and then developed standard operating procedures (SOP) for MDA and DSAs in the COVID-19 context, and also received support from partners for COVID-19 preventive measures, such as handwashing stations, bleach, water containers, soaps and hand sanitizers, alcohol, masks, and for production of social mobilization materials. Training sites selection considered larger space for physical distancing of 2 meters between participants. All supervisors, laboratory technicians and drivers were screened by COVID-19 test prior to traveling to the field for data collection. Three community mobilizers per cluster, instead of one, enforced social distancing and managed crowd control. Teams and participants were required to comply with systematic mask-wearing, handwashing before entering survey testing areas, use of a new pair of gloves for each child, survey-site access strictly reserved for enrolled children, and bleach to disinfect the survey testing area before and after teams' work. To mitigate rumors about testing or COVID-19, administrative, traditional, and religious authorities were involved in community sensitization. All 13 EUs achieved the minimum sample size required and all selected clusters were visited, indicating that the TAS2 was implemented successfully and that mitigation measures were accepted by the surveyors and the community.

## MASS DRUG ADMINISTRATION FOR SCHISTOSOMIASIS IN SIERRA LEONE IN THE CONTEXT OF COVID-19

Ibrahim Kargbo Labour<sup>1</sup>, Habib I. Kamara<sup>2</sup>, Abdul Conteh<sup>1</sup>, Victoria Redwood-Sawyer<sup>2</sup>, Mohamed S. Bah<sup>2</sup>, Gandi Kallon<sup>2</sup>, **Mustapha Sonnie<sup>2</sup>**, Mary H. Hodges<sup>2</sup>, Patricia Houck<sup>3</sup>, Benoit Dembele<sup>4</sup>, Sarah Craciunoiu<sup>5</sup>, Achille Kabore<sup>5</sup>, Yaobi Zhang<sup>3</sup>, Steven D. Reid<sup>3</sup>, Angela Weaver<sup>3</sup>

<sup>1</sup>*Neglected Tropical Diseases Program, Ministry of Health and Sanitation, Freetown, Sierra Leone*, <sup>2</sup>*Helen Keller International, Freetown, Sierra Leone*, <sup>3</sup>*Helen Keller International, New York, NY, United States*, <sup>4</sup>*Helen Keller International, Regional Office for Africa, Dakar, Senegal*, <sup>5</sup>*Family Health International 360, Washington, DC, United States*

In 2008, baseline mapping for schistosomiasis (SCH) was conducted in 16 districts of Sierra Leone, where prevalence was found to be high (>50%) in five and moderate (between 10% and 50%) in four districts. Mass drug administration (MDA) with praziquantel (PZQ) started in 2009 and impact assessments in 2016 showed a reduction in overall prevalence from 42.2% to 20.4%, no district had high prevalence, and only 2.0% of infections were moderate or high intensity. MDA schedules were adjusted per World Health Organization (WHO) guidelines. In March 2020, WHO declared the COVID-19 pandemic and recommended postponing field-based NTD activities, like MDA. Preparations were already complete for the SCH MDA in nine districts, but the government postponed the campaign following the WHO announcement. The government limited public gatherings and closed all schools. The SCH MDA was deferred to October 2020, following WHO recommendations, and schools had reopened. The MDA was modified to include a risk assessment, contingency plans and standard operational procedures. Trainings were held in smaller, socially distanced sessions, and included handwashing and mask wearing. Enhanced community engagement included the identification of negative influences on social media on MDA compliance and targeted 'push-backs' to build trust in the health sector. PICO videos were translated in five local languages to increase health worker and public awareness of the SCH campaign and COVID-19 safety. A supervisory checklist was adapted to capture compliance with COVID-19 prevention measures during the MDA. MDA data showed that 84.5% (678,929/803,437) of school-aged children received PZQ (range 76.1-97.5%). Impacts of COVID-19 on the MDA included initial delay, misinformation through social media even to remote communities and NTD staff reassignment to COVID-19 surveillance. Some parents were reluctant to send children to school or allow them in the MDA. Careful messaging emphasized safety measures and informed health workers and communities on adverse events so they were not mistaken for COVID-19 symptoms, which enabled effective coverage in all nine districts.

0797

## CONTEXTUAL FACTORS ASSOCIATED WITH EPIDEMIOLOGICAL COVERAGE DURING MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS ACROSS TEN WEST AFRICAN COUNTRIES

**Brian B. Fuller<sup>1</sup>**, Andres Martinez<sup>2</sup>, Caleb Parker<sup>2</sup>, Vance Harris<sup>1</sup>, Anna Phillips<sup>2</sup>, Steven D. Reid<sup>1</sup>, Ernest Mensah<sup>2</sup>, Angela Weaver<sup>1</sup>, Diana Stukel<sup>2</sup>

<sup>1</sup>*Helen Keller International, New York, NY, United States*, <sup>2</sup>*Family Health International 360, Washington, DC, United States*

Effective mass drug administration (MDA) is the cornerstone of the elimination of lymphatic filariasis (LF) and a critical component in combatting all neglected tropical diseases (NTD) for which preventative chemotherapy is recommended. Although MDA coverage is the essential metric of any MDA's success, trends in coverage are rarely investigated systematically and informal anecdotes often blend assumptions with evidence. Coverage evaluation surveys can provide some explanation of coverage trends but have limited external validity and rely on questions the lay public can answer (e.g., a respondent's own behavior and

demographics) leaving more macro-level trends unexplored. As a result, national NTD programs are only partially equipped to explain past MDA performance, be it high or low, and make informed programmatic decisions for the future. Here we present a regression analysis of reported epidemiological coverage (proportion of those at risk who are treated) from 3,875 district-level LF MDA campaigns across ten West African countries from January 2009-June 2021 (analysis ongoing). Coverage to date averaged 72.7% (24.5 – 121.0, SD 16.1) amongst 647 health districts, each having conducted between one and twelve (mean 5.9) rounds of LF MDA. Using a hierarchical linear model (HLM) to account for variation between districts and countries, we examined the relationship between each MDA's coverage rate and contextual factors relevant to its date and/or location including rainfall, temperature, road access, Ramadan, population density, reported social unrest, COVID-19, and the number of previous rounds of MDA. Key findings include an estimate of COVID-19's relationship to coverage as well as that of rainfall and temperature, both with implications for climate change.

0798

## COMPLIANCE WITH COVID-19 PREVENTIVE AND BARRIER MEASURES DURING RECENT MDA AND DSA IN SIX ACT | WEST COUNTRIES

**Benoit Dembele<sup>1</sup>**, Angel Weng<sup>2</sup>, Brian Fuller<sup>2</sup>, Elisabeth Chop<sup>2</sup>, Dieudonne Nare<sup>3</sup>, Lucien Mano<sup>3</sup>, Patrick Mbia<sup>4</sup>, Carine Fokam Tagne<sup>4</sup>, Lamine Lamah<sup>5</sup>, Abdoul Karim Camara<sup>5</sup>, Modibo Keita<sup>6</sup>, Boubacar Guindo<sup>6</sup>, Sita Hamadou<sup>7</sup>, Mounkaila Issoufou<sup>7</sup>, Habib Kamara<sup>8</sup>, Patricia Houck<sup>2</sup>, Cleo Stern<sup>2</sup>, Achille Kabore<sup>9</sup>, Katherine A. Sanchez<sup>2</sup>, Fatou Gueye<sup>2</sup>, Steven D. Reid<sup>2</sup>, Yaobi Zhang<sup>1</sup>, Angela Weaver<sup>2</sup>

<sup>1</sup>*Helen Keller International, Regional Office for Africa, Dakar, Senegal*, <sup>2</sup>*Helen Keller International, New York, NY, United States*, <sup>3</sup>*Helen Keller International, Ouagadougou, Burkina Faso*, <sup>4</sup>*Helen Keller International, Yaounde, Cameroon*, <sup>5</sup>*Helen Keller International, Conakry, Guinea*, <sup>6</sup>*Helen Keller International, Bamako, Mali*, <sup>7</sup>*Helen Keller International, Niamey, Niger*, <sup>8</sup>*Helen Keller International, Freetown, Sierra Leone*, <sup>9</sup>*Family Health International 360, Washington, DC, United States*

In March 2020, the World Health Organization (WHO) declared COVID-19 a pandemic, prompting governments to implement measures, such as closing borders, mandating masks and limiting public gatherings. In July 2020, WHO issued new guidance recommending countries conduct a risk assessment and develop a risk mitigation plan prior to resuming neglected tropical disease (NTD) activities. Burkina Faso, Cameroon, Guinea, Mali, Niger and Sierra Leone restarted NTD activities with support from USAID's Act to End NTDs | West Program, following risk mitigation steps and donor approval. To monitor COVID-19 risk mitigation plan in the field, Act | West developed COVID-19 Supervisors Checklists for mass drug administration (MDA) and disease-specific assessments (DSA). Participating supervisors completed one MDA checklist per community drug distributor (CDD) team, observing their performance during a single interaction with MDA participants. For DSAs, supervisors completed one checklist per site. A total of 329 MDA checklists were completed. MDA strategies included door-to-door (282), fixed point (27) or school-based (18) distribution. CDDs wore masks (91.7%) more than MDA participants (48.1%). Handwashing or hand sanitizer was used by 71.4% of participants, and 94.6% of CDDs did not touch the participants when giving the drug. Physical distancing (two meters) between participants and CDDs was maintained in 84.1% of households. Willingness to participate in MDA was high among both participants (95.7%) and CDDs (97.3%). A total of 100 DSA checklists were completed. Masks were worn by 57.0% of participants and 99.0% of surveyors. All DSA sites had hand sanitizers and 98.0% had a handwashing facility with soap. Physical distancing was maintained in 92.9% of sites, and crowd control measures were implemented at 99.0% of sites. Results from both MDA and DSA checklists indicate compliance with COVID-19 preventive and barrier measures was high, except mask-wearing among participants. The willingness of the countries to adopt these measures indicates the commitment of the national governments and partners to safely continue the fight against NTDs.

0799

### INVESTIGATION PRELIMINARY REPORT: RIFT VALLEY FEVER OUTBREAK IN FATICK, SENEGAL, 2020

Ibrahima Mamby Keita<sup>1</sup>, Medoune Badiane<sup>2</sup>, Yamar Ba<sup>3</sup>, Tenning Diome<sup>4</sup>, Diogoye Dione<sup>5</sup>, Ndate Dia<sup>6</sup>, Daba Ndour<sup>1</sup>, Abdoulaye Sam<sup>1</sup>, Boly Diop<sup>1</sup>, Bassirou Sarr<sup>5</sup>, Amady Deme<sup>7</sup>, Idrissa Ndiaye<sup>5</sup>, Ibrahima Dieme<sup>7</sup>, Gabriel Massene Senghor<sup>5</sup>, Abib Ndiaye<sup>7</sup>

<sup>1</sup>Ministry of Health and Social Action, Dakar, Senegal, <sup>2</sup>Ministry of Breeding and Animal Production, Dakar, Senegal, <sup>3</sup>Pasteur Institut of Dakar, Dakar, Senegal, <sup>4</sup>Human Health Facility of Ndiaye Ndiaye, Fatick, Senegal, <sup>5</sup>Fatick Health District, Fatick, Senegal, <sup>6</sup>Departmental Service of Breeding and Animal Productions, Fatick, Senegal, <sup>7</sup>Medical Region of Fatick, Fatick, Senegal

Located in central-western Senegal, Fatick Health District is a pastoralist area and covers 40 Facilities including *Ndiaye Ndiaye* from where an RVF case was confirmed when an outbreak is noted in a border country and an epizootic in the north of Senegal. Indeed we were alerted on 10-08-2020, during the 41st epidemiological week (EW). Thus we had to investigate immediately this RVF outbreak. A cross-sectional study, respecting ethical considerations and one health approach, was conducted and followed by a riposte from 10-29-2020 in Fatick. In fact, the data management needed: observation, literature reviews, interviews, rolling and picking logistics, multidisciplinary team, other investigation tools as Biogents Sentinel, laptops, etc. And this, from data collection to results presentation. The investigation found, according to Senegalese adapted WHO's case definitions, RVF outbreak in Fatick with already two human cases in 40th and 42nd EW, and one animal case in 44th EW. Among human cases, 19.8 percent consulted at the 42nd EW, 89 percent complained of headaches versus 34 percent of asthenia. The age group most affected was between 25 and 50 years old with women predominance, 38 percent were students, 32 percent housewives, 8 percent shopkeepers. Dakar and Touba for 31 percent were the most visited cities through travel in the last 15 days and the most facilities were *Ndiaye Ndiaye* for 35 percent then *Peulga* for 20 percent versus *Emetteur* for 2 percent which was less visited. Regarding animal cases spread over 5 herds, 40 were sampled of which 35 percent were less than a year old, 67.5 percent females, 95 percent ovines, and 32.5 percent local breed. Finally, the entomological and environmental surveys showed 33 percent of vector species identified were competent, including *Culex quinquefasciatus*, 139 ticks collected from livestock, and an ecological environment favorable to RVF. The risk assessment placed Fatick in the orange zone. Results prove the importance of community-based surveillance and one health approach response to public health emergencies.

### EGYPTIAN FRUIT BATS ROUSETTUS AEGYPTIACUS ARE RESERVOIRS OF CCAMPYLOBACTER COLI EXPRESSING ANTIMICROBIAL RESISTANCE GENES

Ebere Roseann Agusi, Benschak John Audu, Daniel Geoffrey ThankGod, Dennis Kabantiyok, Mark Samson, Adeyinka Adedeji, Amos Rimfa, Clement Meseko

National Veterinary Research Institute, Vom, Vom, Nigeria

Many infectious diseases in human including campylobacteriosis are directly attributed to wildlife sources at the human-animal interface and these poses increasing threat to public health. Interactions between humans and animals have also led to acquisition of antimicrobial resistance (AMR) genes in pathogens that are transmitted from animals to humans in shared environments. Emerging AMR from wildlife reservoirs especially bats is underestimated yet contributes to the pattern of antimicrobial resistance in nature. In this study, a total of 51 freshly voided bat guano were randomly collected in a zoological garden and analysed. The process was humane and without the need for invasive procedure after obtaining necessary permit from the park authority. Following microbial culture and isolation, 13 (25.5%) *Campylobacter* isolates were obtained. Molecular

identification using specie specific PCR technique revealed all the strains obtained by isolation to be *Campylobacter coli*. The predominant extended spectrum beta-lactamase (ESBL) genes were bla<sub>CTXM</sub> (31%) and bla<sub>SHV</sub> (31%). Beta-lactam are commonly used antibiotics and resistance to these can hamper their effectiveness in chemotherapy of infectious diseases. This investigation determined the presence of *Campylobacter coli* and elucidate AMR genes in a colony of *Rousettus aegyptiacus* at a zoological park in Jos Nigeria. We showed that bats are carriers of zoonotic bacteria pathogens with antimicrobial resistant genes. The potential for human transmission including zoo workers and tourists through contact with feces, food contamination and aerosols in the environment is of public health concern. It is therefore important to implement interventions including enlightenment, hygiene and biosecurity at the human-wildlife interface especially in places where contact with bats is inevitable.

### USING A ONE HEALTH SYSTEMS ASSESSMENT TOOL TO STRENGTHEN ZONOTIC DISEASE OUTBREAK RESPONSE IN LIBYA

Lauren N. Miller, Alexander G. Linder, Claire J. Standley, Erin M. Sorrell

Georgetown University, Washington, DC, United States

Communication and coordination among national disease surveillance and response networks are vital in ensuring the timely response to emerging infectious diseases. Libya, however, faces a number of challenges due to recurrent political and social conflicts that have weakened public and animal health systems infrastructure and disrupted rapid detection, surveillance and response efforts throughout the country. Our study aim is to determine whether resources to develop vertical programs can be leveraged to build sustainable One Health laboratory and surveillance networks for priority zoonoses. In collaboration with the Libyan National Centre for Disease Control (NCDC) and the National Centre for Animal Health (NCAH), we deployed our One Health Systems Assessment for Priority Zoonoses (OH-SAPZ) tool to map the existing laboratory and surveillance networks for detecting and reporting priority zoonotic diseases. The tool helps identify nodes of communication, coordination and decision-making where health and veterinary sectors intersect, as well as priorities and gaps that limit information-sharing for action. Working with officials at the national and subnational level, we selected five zoonoses as case studies to map Libya's current response capacity and determine overlaps and gaps in communication and coordination across the surveillance and laboratory sectors. Our major findings indicate a strong desire for and commitment to multi-sectoral coordination for zoonoses detection and response across public health and veterinary sectors. Nevertheless, rapid disease surveillance and detection in Libya is heavily impacted by the ongoing national security crises and the diminished workforce and resources available. Therefore, assessing The current coordination and communication between implicated health sectors can assist in determining areas for improvement and target actions. We anticipate this project will result in the formal creation of One Health rapid response teams composed of personnel from both NCDC and NCAH, responsible for coordinated management of zoonotic disease outbreaks in the country.

### ENVIRONMENTAL CONTAMINATION WITH FASCIOLA EGGS PASSED IN LIVESTOCK STOOL IS ASSOCIATED WITH HUMAN INFECTIONS IN THE ANTA PROVINCE OF CUSCO, PERU

Melinda B. Tanabe<sup>1</sup>, John Prochaska<sup>1</sup>, Maria Luisa Morales<sup>2</sup>, Martha Lopez<sup>2</sup>, Miguel M. Cabada<sup>1</sup>

<sup>1</sup>University of Texas Medical Branch, Galveston, TX, United States, <sup>2</sup>Cusco Branch – Tropical Medicine Institute, Universidad Peruana Cayetano Heredia, Cusco, Peru

Fascioliasis is an emergent infectious disease but little is known about the dynamics transmission. We hypothesized that environmental

contamination with *Fasciola* eggs passed in livestock stool is associated with human fascioliasis. We analyzed data from a cross-sectional study among children aged 3-16 years old in 3 districts of the Anta Province in the Cusco region of Peru. Three stool specimens were collected from each child and livestock samples around the children's residence were collected and analyzed using microscopy for *Fasciola* eggs. Each sample was geographically tagged. A total of 2070 children were enrolled, 49.5% were female, the average age was 9.1 ( $\pm$  3.5) years, and the *Fasciola* prevalence was 7.2%. The most common district of residence was Anta (50.8%). Stool from 2627 livestock was collected. *Fasciola* prevalence in livestock stool was 31.3% with the highest prevalence in the Ancahuasi (45.1%) and Anta (44.4%) districts. Donkey stool had the highest prevalence of *Fasciola* (60.4%), followed by sheep (40.31%) and cattle (32.2%). The logistic regression analysis showed no association between infected children in a residence and finding livestock stool with *Fasciola* eggs in a 50 m, 100 m, and 200 m radius. A significant association was found between having infected children in a residence and finding cattle stool infected with *Fasciola* in a 50 m (OR 1.46, 95%CI 1.12-1.9,  $p=0.005$ ), 100 m (OR 1.23, 95%CI 1.04-1.46,  $p=0.018$ ) and 200 m (OR 1.1, 95%CI 1.00-1.22,  $p=0.041$ ) radius around the residence. The median distance to a positive animal stool from a residence with infected children was 40.7 m (IQR=86.7) compared to 237.9 m (IQR=448.7) from a non-infected residence ( $p<0.0001$ ). The need for large-scale analysis to understand the dynamics of infection is imperative, as strategies for infection control are urgently needed.

0803

#### DETECTION OF THE SIMULTANEOUS PRESENCE OF SPECIFIC ANTIBODIES TO CAUSATIVE AGENTS OF PORCINE REPRODUCTIVE AND RESPIRATORY SYNDROME, CIRCOVIRUS INFECTION, TESCHEN DISEASE, AND AUJESZKY'S DISEASE IN WILD BOARS

Mykola Sytiuk<sup>1</sup>, Megan W. Howard<sup>2</sup>

<sup>1</sup>Institute of Veterinary Medicine of the NAAS, Kyiv, Ukraine, <sup>2</sup>Battelle, Columbus, OH, United States

Wild pigs play an important role in the maintenance and circulation of viruses that affect domestic pigs. The distribution of viruses in wild pigs is thus an important One Health issue because the causative agent of Aujeszky's disease can infect humans (animal care staff). Using Elisa, we screened wild boar blood sera (6,840 samples) and detected the presence of antibodies to: Aujeszky's disease virus - 15.04%, Teschen disease virus - 19.94%, porcine circovirus infection (PCV type 2) - 31.51%, porcine reproductive and respiratory syndrome (PRRS) viruses - 2.38%. In 455 (6.68 %) blood sera, the simultaneous presence of antibodies to these diseases was detected in the following distribution: to two pathogens (Aujeszky's disease and Teschen disease - 119 (1.75%), Aujeszky's disease and PCV type 2 - 145 (2.13%), Aujeszky's disease and PRRS - 14 (0.21%), Teschen disease and PCV type 2 - 133 (1.95%), PCV type 2 and PRRS - 28 (0.41 %); simultaneously to three pathogens (Aujeszky's disease, Teschen disease and PCV type 2 - 7 (0.1%), Aujeszky's disease, PCV type 2, and PRRS - 2 (0.03 %). The obtained new serological data confirm the spread of these viral diseases in the wild boar population and do not exclude their associative course and may pose a threat to the pig industry and to the health of people.

0804

#### A ONE HEALTH PERSPECTIVE ON THE PREVALENCE OF PARALYTIC SHELLFISH TOXINS AND ITS IMPACT ON ALASKA NATIVE SUBSISTENCE

Savannah Miller

Emory University, Atlanta, GA, United States

Subsistence practices are imperative to many Alaska Natives, providing traditional and cultural meaning while serving societal and dietary needs. Potential threats to the security of subsistence foods such as shellfish includes the increased occurrences of harmful algal blooms (HABs)

in southeast Alaska. The dinoflagellate genus *Alexandrium* produces saxitoxins which can bioaccumulate in shellfish, making the shellfish toxic to humans after consumption, a condition referred to as paralytic shellfish poisoning (PSP). A One Health perspective on this issue acknowledges the interconnectedness of Alaska Native health, shellfish, HABs, and climate change. The purpose of this study was to analyze biotoxin data collected from 2017-2019 by six tribal partners of the Southeast Alaska Tribal Ocean Research (SEATOR) group to establish paralytic shellfish toxin profiles for community locations. For the six locations included in the study, descriptive statistics were calculated and graphs showing trends in shellfish toxin levels over time were created. Receptor Binding Assay was used to detect paralytic shellfish toxins in samples from select locations. It was hypothesized that shellfish toxin levels would exceed the regulatory limit for safe consumption at 80 $\mu$ g/100 g in non-summer months in addition to the expected spikes in toxin levels in summer months. It was also hypothesized that toxin levels would vary across the six locations samples were collected from. A total of 786 shellfish samples from these sites were analyzed and it was found that 51.0% of samples above the regulatory limit were in non-summer months. The data also suggest the prevalence of biotoxins in shellfish differs across the six locations, with Petersburg having no samples above the limit while Juneau presented the highest overall toxin level with 40.9% of all samples above the limit. Identifying the prevalence of toxins in areas of shellfish harvest can help inform communities on the safety of this subsistence resource, identify potential prevention strategies, and protect Alaska Native health.

0805

#### A ONE HEALTH APPROACH TO DESCRIBE THE PREVALENCE OF METHICILLIN-RESISTANT STAPHYLOCOCCUS AUREUS COLONIZING LIVESTOCK FARMERS, LIVESTOCK AND LIVESTOCK PRODUCTS IN SOUTHERN SRI LANKA

M. R. P. Kurukulasoorya<sup>1</sup>, L. Gayani Tillekeratne<sup>2</sup>, Weerasinghe M. D. G. B. Wijayarathne<sup>3</sup>, Champica K. Bodinayake<sup>3</sup>, U. H. B. Y. Dilshan<sup>1</sup>, A. Dharshan de Silva<sup>4</sup>, Bradley P. Nicholson<sup>2</sup>, Truls Østbye<sup>2</sup>, Christopher W. Woods<sup>2</sup>, A. De S. Nagahawatte<sup>3</sup>

<sup>1</sup>Duke-Ruhuna Research Centre, Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka, <sup>2</sup>Duke University, Durham, NC, United States, <sup>3</sup>Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka, <sup>4</sup>Faculty of Medicine, General Sir John Kotelawala Defence University, Ratmalana, Sri Lanka

Methicillin-resistant *Staphylococcus aureus* (MRSA) is a pervasive multidrug-resistant pathogen which causes life-threatening infections in humans and animals. Based on genotypic and antibiotic susceptibility patterns, MRSA is classified as community-associated (CA), healthcare-associated (HA) and livestock-associated (LA). Being a zoonotic pathogen, LA-MRSA strains can be transmitted to humans via direct contact with animals, environmental contamination, and eating or handling contaminated livestock products. This study describes the *S. aureus* and MRSA colonization prevalence in livestock farmers, livestock and livestock products in the Southern Province of Sri Lanka using the One Health approach. From November 2020 to March 2021, nasal swabs were collected from farm personnel who had direct contact with livestock, as well as from randomly selected livestock (cattle, buffalo, pig, goat and poultry) in the respective farms. At least one livestock product (milk, meat or egg) was also collected from all farms. Standard microbiological testing and antibiotic susceptibility testing using Kirby Bauer disc diffusion were used to isolate *S. aureus* and identify MRSA. Nasal swabs were collected from 71 farmers, who were mostly male (65, 85%) and had a median age of 39 (21-63) years. A total of 22 (30%) farmers were colonized with *S. aureus*. Of them, 7 (9.8%) were colonized with MRSA. Nasal swabs were collected from 70 livestock animals (cattle-40%, pig-37%, goat-14% and poultry-9%). Of those, 19 (27.2%) were colonized with *S. aureus* (cattle-42%, goat-31% and pig-26%). None of the *S. aureus* isolates was identified as being MRSA. Among 35 livestock products tested (milk-60%, egg-25% and meat-14%), 10 (29%) showed the presence of *S. aureus* (milk-60% and meat-40%). MRSA was not isolated. MRSA was isolated from farmers, but not from the livestock and livestock products. However, the presence of *S. aureus* at a considerable level in livestock and livestock

products suggests the potential for transmission to humans. Continued surveillance of farmers and livestock is needed to detect whether LA-MRSA exists and to describe zoonotic transmission.

0806

### HUMAN-ANIMAL INTERACTIONS TO ASSESS RISK OF EMERGING INFECTIOUS DISEASES IN KENEMA DISTRICT SIERRA LEONE: FINDINGS FROM A 2010 HOUSEHOLD SURVEY

**Kate A. Nelson<sup>1</sup>**, James Bangura<sup>2</sup>, Richard O. Fonnies<sup>2</sup>, Augustine Goba<sup>2</sup>, Frederique Jacqueroiz<sup>3</sup>, Lansana D. Kanneh<sup>2</sup>, Kande Kargbo<sup>2</sup>, Sheik Humarr Khan<sup>2</sup>, James T. Koninga<sup>2</sup>, Shelby Lloyd<sup>4</sup>, Sushryia Rath<sup>4</sup>, Megan Saunders<sup>4</sup>, Ashlea Winfield<sup>4</sup>, Lina M. Moses<sup>4</sup>, Daniel G. Bausch<sup>5</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>Kenema Government Hospital, Kenema, Sierra Leone, <sup>3</sup>Tulane School of Public Health and Tropical Medicine; University Hospital of Geneva, New Orleans, LA, United States, <sup>4</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>5</sup>UK Public Health Rapid Support Team, Public Health England/London School of Hygiene & Tropical Medicine, London, United Kingdom

Most emerging infectious diseases have zoonotic origins. Understanding the relationships between human behavior and animal exposure in a given community is essential to understanding spillover events and taking steps to prevent them. In 2010 we conducted a pilot survey of 260 persons in Kenema District, Sierra Leone to characterize human-animal interactions. The population surveyed was a convenience sample of: Kenema town residents (n=100); three rural villages within close proximity to Kenema town (n=112); and purposively-selected hunters residing in surrounding areas (n=48). A total of 89% of participants reported someone in the household with a febrile illness in the past year. Participants reported a wide variety of animal interactions, including physical contact with rodents (93%), bats (23%), wild birds (75%), and monkeys (48%). Contact occurred both intentionally through farming and hunting and unintentionally through contact or bites from household pests. A total of 83% participants raised animals for food or sale. Behaviors and interactions varied by location, with animal exposures generally higher in rural villages than in Kenema town. For example, 80% of households in the rural villages reported the presence of bats in the household in the past year, compared to only 36% in Kenema town. Preparing or eating certain animals such as mongooses and wild birds was also more common in the villages (>95%) than in Kenema town (<50%). Hunting or opportunistic catching was reported by 43% of participants in the villages. Of particular interest was the high frequency of exposure to rodents, given Kenema District is endemic for the rodent-borne disease Lassa fever, and to bats, the putative reservoir of Ebola virus, considering that Kenema is within a few 100 kilometers of the sites where Bombali ebolavirus was first reported in 2018 and Ebola virus epidemics began in neighboring Guinea in 2013 and 2021. Pilot surveys such as this are relatively rapidly and inexpensively conducted and could help assess specific human-animal interactions to develop localized surveillance and prevention efforts.

0807

### SEROPREVALENCE AGAINST VIRUS AND ZOOLOGICAL PARASITIC DISEASES IN SLOTHS OF WESTERN PANAMA

**Rita Juliet Corrales**, Vanessa Pineda, Yamilka Diaz, Yanneth Pitti, Jean Paul Carrera, Liseth Saenz, Maria Chen, Sandra Lopez-verges, Azael Saldana

Gorgas Memorial Institute of Health, Panama, Panama

Panama has played an important role in the discovery and control of emerging zoonotic diseases with impact on public health. These etiological agents involve different reservoirs with potential to cause outbreaks, such as sloths *Choloepus spp.* and *Bradypus spp.* involved in the transmission of parasitic agents *Trypanosoma cruzi*, *Trypanosoma rangeli*, *Leishmania panamensis*. Despite the isolation of *T. cruzi*, *T. rangeli* and arboviruses

as *Oropouche*, *Punta Toro group virus (PTV)*, *Uti virus* in the 1980s, the current status of these mammals and their role as a reservoir in Panama is unknown. This descriptive study aims to determine the current seroprevalence against arboviruses and parasites with epizootic potential in 50 sloths captured in rural areas of the province of West Panama endemic for Chagas, Leishmaniasis and Dengue. To detect neutralizing antibodies against arboviruses: *PTV*, *Madariaga (MADV)*, *Mayaro (MAYV)*, *Venezuelan Equine Encephalitis (VEEV)*, *Una (UNAV BT 1495)*, *Chikungunya (CHIKV)*, *Yellow Fever (YFV)*, *Dengue serotype 2 (DENV-2)* and *Pan Sloth 149* and *D50* viruses of genus *Orbivirus*, plaque neutralization assay as used. To determine the presence of antibodies against *T. cruzi*, *L. panamensis*, *T. rangeli*, Western Blot was used. If present, antibodies in sloth serum detect proteins of the parasites, and then were detected by a mouse secondary antibody anti sloth IgM and IgG, which in turn, binds to a commercial anti mouse antibody conjugated with peroxidase. As anti sloth antibody is not available commercially, we proceeded to immunize CFW mice using full immunoglobulin protein, the heavy chain and the light chain. Preliminary results indicate that 8% of the sloth sera have neutralizing antibodies for *VEEV*, while all were negative for *UNAV*, *MAYV*, *CHIKV*. The development of polyclonal mouse anti IgM and IgG antibodies from sloths was standardized, observing 100% recognition against both light and heavy chains. We aim to provide data on the presence of zoonotic viruses and parasites with emerging potential in sloths in the province of West Panama that is under increasing deforestation and urbanization, a risk factor for emergence.

0808

### CAUSE OF ACUTE RESPIRATORY INFECTION IN NORTHERN LAOS

**Koukeo Phommason**

Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit, Vientiane Capital, Lao People's Democratic Republic

With the advent of highly sensitive real-time PCR, a diversity of pathogens are identified from the nasopharyngeal swabs of patients with acute respiratory infections (ARIs). However, the detection of micro-organisms in the upper respiratory tract does not necessarily mean that they were the cause. We conducted a matched case-control study, nested in a large fever aetiology project, to facilitate the determination of the aetiology of ARI in hospitalised patients in northern Laos. Consenting febrile patients of any age admitted to Xiengkhuang Provincial Hospital were included in the case-control study if they had an ARI presentation ( $\geq$  one of: cough, rhinorrhoea, nasal congestion, sore throat, difficulty breathing or abnormal chest auscultation). One control for each included case, matched by sex, age and village of residence, was recruited within 2 weeks of patient enrolment if they did not have fever and ARI presentation. Nasopharyngeal swabs were collected from participants and tested for 33 pathogens by probe-based multiplex real-time (RT)-PCR (FastTrack Diagnostics Respiratory pathogen 33 kit). Attributable fraction of illness for a given microorganism was calculated by comparing results between patients and controls ( $=100 * [OR-1]/OR$ ). Between 24<sup>th</sup> June 2019 and 24<sup>th</sup> June 2020, 205 ARI patients and 205 matching controls were recruited. After excluding 8 pairs due to age mismatch, 197 pairs remained in the analysis. Males were predominant with sex ratio 109:88 and children <5 years old accounted for 56% of participants. At least one potential pathogen was detected in 172 (87%) patients and 175(89%) controls. 17.8% of all ARI cases were attributable to influenza B, 17.2% to influenza A, 7.5% to human metapneumovirus, and 6.5% to respiratory syncytial virus (RSV). Determining aetiology of ARI remains challenging. Among hospitalised Lao ARI patients presenting at a provincial hospital in northern Laos, most were attributed to a viral cause, particularly influenza A, influenza B, human metapneumovirus, or

0809

### RESPIRATORY SYNCYTIAL VIRUS-ASSOCIATED MORTALITY AMONG YOUNG INFANTS IN KARACHI, PAKISTAN: A PROSPECTIVE POST-MORTEM SURVEILLANCE STUDY

Abdul Momin Kazi<sup>1</sup>, Obianuju G. Aguolo<sup>2</sup>, Waliyah Mughis<sup>1</sup>, Nazia Ahsan<sup>1</sup>, Saima Jamal<sup>1</sup>, Ayub Khan<sup>1</sup>, Inci Yildirim<sup>2</sup>, Hanya Qureshi<sup>2</sup>, Fauzia A. Malik<sup>2</sup>, Saad B. Omer<sup>2</sup>

<sup>1</sup>Aga Khan University, Karachi, Pakistan, <sup>2</sup>Yale University, New Haven, CT, United States

Respiratory syncytial virus (RSV) is a significant cause of infant morbidity and mortality globally, and a potential target for maternal immunization strategies. However, data on the role of RSV in young infant deaths in developing countries is limited. We conducted a community-based mortality surveillance from August 2018 to March 2020 for infants  $\leq 6$  months old in Karachi, Pakistan. Nasopharyngeal swabs from deceased infants were tested (RT-PCR) for presence of RSV. We collected 490 nasopharyngeal specimens from 1,280 eligible infant deaths. Verbal autopsy was conducted to identify respiratory cases and controls. We calculated odds of RSV-associated mortality with 95% confidence intervals (CI) and used multivariable logistic regression to evaluate associations. There were 377/490 live births, of which 14 (3.7%) were RSV positive. Most deaths occurred at age 0-3 months (88.1%) or 0-28 days (67.4%), in the community (50.1%), and 64.3% (9/14) of RSV positive cases were captured during RSV high season. RSV infection was more likely to be detected among deceased infants with respiratory illness versus no respiratory illness (odds ratio (OR): 5.2; CI: 1.2-23.7) and during high RSV season versus low RSV season (OR: 4.4, CI: 1.4-13.3). In the multivariable logistic regression analysis, having respiratory symptoms during fatal illness (OR: 6.6; CI: 1.3-32.5), RSV seasonality (OR: 6.1; CI: 1.8-20.4), and age (neonatal versus post-neonates) (OR: 9.2; CI: 2.6-33.1) were significant predictors of RSV-associated mortality. RSV has a significant mortality burden in early infancy, in Karachi, Pakistan. Age, RSV seasonality, and respiratory symptoms/illness during fatal disease were significant predictors of RSV-associated mortality in young infants.

0810

### DETECTION OF RESPIRATORY PATHOGENS USING MULTIPLEX TAQMAN ARRAY CARD AMONG STILLBIRTHS AND UNDER-FIVE DEATHS IN EASTERN ETHIOPIA

Mussie Adhanom

Hararghe Health Research, Haramaya University, Harar Town, Ethiopia

Respiratory infections are an important cause of morbidity and mortality in lower income countries like Ethiopia. The Child Health and Mortality Prevention Surveillance (CHAMPS) network has adapted a custom multiplex real-time PCR 384-well microfluidic array, TaqMan Array Cards (TACs), to identify multiple pathogenic microorganisms. The aim of this study is to identify potential respiratory pathogens in post-mortem samples among stillbirths and under-five deaths. Among children aged  $< 5$  years in Harar/Kersa, Eastern Ethiopia, we examined postmortem specimens of lung tissue (all deaths) and nasopharyngeal/oropharyngeal (NP/OP) swabs (deaths in liveborn children only). We used the TAC panel for detection of 46 respiratory pathogens. Total nucleic acid (DNA and RNA) were extracted using Qiagen EZ1 DSP Virus Kit and the TAC runs were performed using reverse transcriptase real-time PCR on the QuantStudio 7 Flex real-time PCR system. A total of 137 deaths were investigated; 73 (53%) were stillbirths. Among 64 deaths in live-born children, 50 (78%) lung tissue samples and 59 (92%) NP/OP swabs contained nucleic acid of one or more organisms; a total of 358 pathogen-specific target detections were identified from lung tissue (36%) and NP/OP swab (64%). These consisted of bacteria (81.6%), viruses (17%) and fungi (1.4%). Bacteria detected included *K. pneumoniae* (24%), *A. baumannii* (12%), *S. aureus* (9.2%), *M. catarrhalis* (7.8%) and *H. influenzae* (7.5%). Among viral detections, Rhinovirus (6.4%) was most commonly detected, followed by Human Cytomegalovirus (3.1%), and Measles virus (1.7%). Among stillbirths, 20% of lung tissue samples processed were positive for a pathogen; only

18 pathogen-specific targets were detected. Two-thirds (61%) of those detected were *A. baumannii*, Human Cytomegalovirus and *P. aeruginosa*. Bacteria were commonly detected as potential respiratory pathogens among post-mortem respiratory specimens from recently deceased children aged  $< 5$  years. The TAC multi-pathogen detection platform provided an efficient laboratory method to detect a variety of infectious organisms.

0811

### RESPIRATORY VIRUSES DETECTED AMONG SEVERE ACUTE RESPIRATORY INFECTION IN-HOSPITAL DEATH CASES DURING FIRST YEAR OF COVID-19 PANDEMIC IN BANGLADESH

Md Ariful Islam<sup>1</sup>, Md Zakiul Hassan<sup>1</sup>, Zubair Akhtar<sup>1</sup>, Mohammad Abdul Aleem<sup>1</sup>, Syeda Mah-E- Muneer<sup>1</sup>, Md Kaousar Ahmmad<sup>1</sup>, Mustafizur Rahman<sup>1</sup>, Mohammed Ziaur Rahman<sup>1</sup>, Kamal Hossain<sup>1</sup>, M. Salim uzzaman<sup>2</sup>, Tahmina Shirin<sup>2</sup>, Fahmida Chowdhury<sup>1</sup>

<sup>1</sup>icddr, Dhaka, Bangladesh, <sup>2</sup>Institute of Epidemiology, Disease Control and Research, Dhaka, Bangladesh

Severe acute respiratory infection (SARI) is one of the leading causes of morbidity and mortality globally with an extreme peak during this COVID-19 pandemic. We aim to describe the respiratory viral pathogens detected from SARI patients who died in-hospital. During March 2020 - February 2021, we collected surveillance data of SARI associated in-hospital death cases utilizing the national hospital-based influenza surveillance (HBIS) platform at nine tertiary level hospitals in Bangladesh. Surveillance physicians prospectively identified inpatients meeting WHO-SARI case definition. Oro- and nasopharyngeal swabs were collected from these patients and tested for a panel of respiratory viruses including influenza virus, SARS-CoV-2, respiratory syncytial virus (RSV), human metapneumovirus (HMPV), human parainfluenza viruses (HPIV 1,2,3) and adenoviruses by rRT-PCR. We conducted descriptive analyses to describe the proportions of different respiratory viral pathogens among these SARI deaths. There were 122 (5%) in-hospital deaths among 2,408 SARI inpatients. The median age of the SARI death cases was 55 years (IQR: 1.5 - 65 years) and 71% of the death cases were male. Of them, 49 (40%) had respiratory viral etiology. The highest proportion of virus detection was for SARS-CoV-2 (25%, 31) followed by HPIV (2%, 3), influenza (2%, 2), RSV (2%, 2) and HMPV (2%, 2). Viral co-infections were detected in 9 (7%) death cases. Four death cases were co-infected with SARS-CoV-2 and adenovirus, 3 with HPIV and adenovirus, 1 with RSV and adenovirus and 1 with SARS-CoV-2, adenovirus and RSV. Fifty-one percent of the death cases (25/49) having a viral etiology had at least one co-morbid condition. Death cases aged  $\geq 40$  years were most commonly infected with SARS-CoV-2 (39%, 29/75). Respiratory viruses were detected in one-third of SARI inpatients who died in-hospital during first year of COVID-19 pandemic in Bangladesh. Highest rate of virus detection was due to SARS-CoV-2. Vaccination against SARS-CoV-2 and non-pharmaceutical interventions such as social distancing, hand hygiene and wearing face masks might contribute to reduction of SARI mortality.

0812

### EASY ACCESS TO MODS CULTURE: EVALUATION OF DEHYDRATED MEDIA

Joseline Rodriguez<sup>1</sup>, Roberto Alcantara<sup>2</sup>, Robert H. Gilman<sup>3</sup>, David Moore<sup>4</sup>, Ricardo Antiparra<sup>1</sup>, Mirko Zimic<sup>1</sup>, Patricia Sheen<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Peruana de Ciencias Aplicadas, Lima, Peru, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Tuberculosis (TB) is still one of the leading causes of death from infectious diseases in low- and middle-income countries (LMIC). Efficient diagnosis is crucial for TB control. Molecular tests show important advantages (i.e. short response time, and high sensitivity/specificity). However, they are not nationwide applied in LMIC. Culture-based methods remain a low-cost

option but with longer response times ( $\geq 24$  days). The MODS culture is a low-cost assay with a mean response time of 10 days and a sensitivity/specificity of more than 90%. However, its implementation is limited in LMIC due to the low accessibility to culture supplies required for the enriched medium. Here, two dehydrated 7H9-OAD based media were evaluated: a powder-component blended media (BM) (not sterilized), and a sterile lyophilized liquid media (LM). Catalase, PANTA mixture, and gamma irradiation were evaluated for BM and LM variants. Culture performance was compared with the MODS standard medium (MM) using *M. tuberculosis* (MTB) isolates and 26 positive acid-fast smear sputum samples. Bacterial growth was reported as CFU/mL and growth-well percentage (GW%). Analysis with MTB isolates showed that catalase promotes bacterial growth regardless of the type of media. PANTA and gamma irradiation were evaluated to prevent culture contamination; however, both combined reduce bacterial growth significantly ( $P < 0.05$ ) in all media variants. In contrast, gamma irradiation does not reduce bacterial growth. Overall, no important difference was observed in CFU/mL between the evaluated media and MM. Three variant media were selected for sputum samples screening (irradiated LM, non-irradiated BM, and irradiated BM). A median positivity day of  $6 \pm 5$  days was observed, regardless of the type of media. The non-irradiated BM showed high contamination (30% samples). No significant difference ( $P = 0.47$ ) was observed when GW% was compared between irradiated BM (100%), and LM (100%) with MM. In conclusion, the preliminary results show that these two variant media have a similar performance to the standard MODS medium, aiming their incorporation in a high-accessible MTB diagnostic kit.

#### GLYCOSYLATED HEMOGLOBIN DYNAMICS PRE AND POST TUBERCULOSIS TREATMENT DIFFERENTIALLY IDENTIFY DIABETES RANGE GLYCEMIA IN DHAKA, BANGLADESH

**Yosra M. Alkabab<sup>1</sup>**, Samanta Biswas<sup>2</sup>, Shahriar Ahmed<sup>3</sup>, Sayera Banu<sup>2</sup>, Scott Heysell<sup>1</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>icddr, Dhaka, Bangladesh, <sup>3</sup>icddr, Dhaka, Bangladesh

In recent non-pandemic periods, tuberculosis (TB) has been the leading killer worldwide from a single infectious disease. Patients with DM are three times more likely to develop active TB, have accelerated progression of TB disease and poor treatment outcomes. However, data are limited regarding glycemic dynamics from TB diagnosis through treatment and single glycemic measurements at treatment initiation may inaccurately diagnose DM or mischaracterize DM severity. We aimed to conduct a prospective study of glycemia dynamics in response to TB treatment measured point-of-care glycosylated hemoglobin (HbA1c) in patients presenting to TB screening centers in Dhaka, Bangladesh to determine the prevalence and risk factors of new DM prior to and at the end of TB treatment. Total of 429 adults with active TB infection were enrolled from October '18 to July '19 and divided into three groups based on initial HbA1c range: normoglycemic, prediabetes and DM group. DM was diagnosed in 158 (37%), of which 14% were newly diagnosed DM by HbA1c despite normal random blood sugar testing. At end of treatment, we found 14 (6%) additional patients from the normoglycemia and prediabetes groups had HbA1c level in the diabetic range  $> 6.5\%$ , thus increasing the prevalence of DM to 39%. The number needed to screen to diagnose one new case of DM prior to TB treatment was 5.7 and was 16 when repeating at the end of treatment in the subgroup without DM at treatment initiation. Weight gain  $> 5\%$  at end of treatment significantly increased the risk of diabetic range glycemia in patients who had normoglycemia or prediabetes at TB treatment initiation (OR 5.66, 95% CI 1.23-26.04,  $p < 0.05$ ). In conclusion, point-of-care HbA1c testing for undiagnosed DM prior to and at the end of TB treatment found a high prevalence of prediabetes and DM, including a proportion that was found only at the end of treatment and more commonly in people with higher percentage of weight gain. Further longitudinal research is needed to understand the effects of TB disease and treatment on insulin resistance, impacted immune pathways, and long-term DM complications.

0814

#### TUBERCULOSIS CARE SERVICES AMIDST THE EBOLA VIRUS DISEASE EPIDEMIC (2014-2015) IN LIBERIA: TIME SERIES-ANALYSES FOR 2013-2017

**Keith L. Gray**, Wahdae-mai Harmon-Gray

Ministry of Health, Monrovia, Liberia

Tuberculosis is a major public health problem in Liberia. To estimate the magnitude of the impact of the EVD outbreak and establish trends of TB care services in Liberia, we conducted an interrupted time-series analysis, using five years of routinely collected health information system data. We analyzed three TB care services indicators before, during, and after the EVD outbreak from January 2013 to December 2017. We used a segmented linear regression model to generate estimates and predictions for trends in services over three time periods. We found that the number of presumptive TB cases significantly declined at the start of the EVD outbreak with an estimated loss of 3222 cases ( $p = 0.014$ , 95%CI: -5691, -752). There was also an estimated loss of 709 cases per quarter post-EVD ( $p = 0.032$ , 95%CI: -1346, -71). The proportion of smear-positive to presumptive cases increased by 1.45% over the post-EVD period ( $p = 0.011$ , 95%CI: 0.38%, 2.5%). The proportion of treatment success to TB cases evaluated also increased significantly by 3.3% quarterly over the post-EVD period ( $p = 0.013$ , 95%CI: 0.82%, 5.79%). These findings suggest that the EVD outbreak (2014-2015) negatively affected TB care services with a decline in the number of presumptive cases. While the numbers of presumptive cases continue to decline, there has been an improvement in case ascertainment and successful treatment outcomes of TB cases evaluated. Health care delivery needs to be maintained in future outbreaks to sustain chronic infectious disease services, and the national TB control program needs newer strategies to maintain post-EVD progress and address current gaps in control activities.

0815

#### TUBERCULOSIS INCIDENCE AND ASSOCIATED FACTORS AMONG HOUSEHOLD CONTACTS OF TUBERCULOSIS PATIENTS IN THE 100 MILLION BRAZILIAN COHORT

**Priscila Pinto<sup>1</sup>**, Camila Teixeira<sup>1</sup>, Maria Ichihara<sup>1</sup>, Mauro Sanchez<sup>2</sup>, Mauricio Barreto<sup>1</sup>, Julia Pescarini<sup>3</sup>

<sup>1</sup>Centre for Data and Knowledge Integration for Health (CIDACS), Salvador, Brazil, <sup>2</sup>University of Brasilia, Brasilia, Brazil, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Using the '100 Million Brazilian Cohort', we estimated the incidence of Tuberculosis (TB) in a group of 92,153 household contacts of TB patients and investigated the factors related to this occurrence. The 100 Million Brazilian Cohort comprises individual socioeconomic and demographic data on over 114 million individuals and their applying for social benefits in Brazil (2001-2015) linked to nationwide mortality data (2001-2015) and TB registries (2006-2013). We selected new applicants to the cohort between January 1, 2006, and December 31, 2013. We defined the first case of TB in each household as the primary case. All household contacts were followed up from the date of diagnosis of the primary case until the detection of a subsequent case, the end of the cohort or death, whichever date comes first. Then we compared the demographic, socioeconomic and the primary case clinical characteristics of household contacts that did or did not develop TB subsequently to the exposure with a primary case using multilevel mixed-effects logistic regression model allowing for the municipality- and household-level random effects. We studied 92,153 household contacts of 32,504 primary cases. Household contacts were young (mean age= 18.8 years [sd=17.6] and woman (53.6%). During the eight years of follow-up (median=2.5 years), the incidence rate of TB among household contacts was 523.5 (95% CI=496.6-551.9) per 100,000 person-years at risk and 817.1 (95% CI=692.3-964.3) per 100,000 person-years at risk among children younger than 5-years. Sixty percent of cases were detected within one year after the detection of the primary case. Household contacts of primary cases with pulmonary TB had higher odds of developing the disease (OR=3.01; 95% CI=2.32-3.90). The high

incidence of TB among household contacts and the high number of cases detected after the first year of follow-up suggests the need to strengthen contacts tracing policies in Brazil that, along with chemoprophylaxis for latent TB, is key to reach TB control.

0816

### THE IMPACT OF COVID-19 ON THE CIRCULATION OF RESPIRATORY VIRUSES AMONG UNITED STATES MILITARY BENEFICIARIES AT A MEDICAL TREATMENT FACILITY IN HAWAII

**Zakariae Bram**, Timothy S. Horseman, Rachael L. Downham, Lindsey L. O'Neal, Catherine F. Uyehara, Viseth Ngauy, Jonathan A. D'Ambrozio, Alexander K. Kayatani

*Tripler Army Medical Center, Tripler AMC, HI, United States*

Viral respiratory tract infections are a leading cause of morbidity worldwide. Hawaii implemented significant public health measures to include travel restrictions, mask-mandate, stay-at-home orders, and mandatory pre-travel testing to limit transmission, resulting in one of the lowest COVID-19 rates in the nation. This study aimed to evaluate the prevalence and etiology of respiratory viral infections during the ongoing COVID-19 pandemic among military health system beneficiaries on Oahu, HI and the impact of public health measures on viral transmission and circulation on the island. We retrospectively analyzed respiratory viral specimens collected from FilmArray BioFire or Cepheid GeneXpert Infinity tests from January 2020 to February 2021 at our institution. Patient demographic, specimen information, and encounter data were extracted from the electronic medical record. Descriptive statistics were calculated for the demographic characteristics and respiratory viruses detected. A total of 5,656 respiratory viral panels (BioFire and Cepheid) were performed during the study period with 983 positive specimens identified including 50 co-infections. Among the positive tests the most common pathogen detected was influenza A (40.1%), followed by rhinovirus (35.3%), influenza B (12.6%), adenovirus (6.3%), and RSV (6.1%). Viral distribution differed strongly with age. Circulation of respiratory viruses other than rhinovirus/enterovirus and adenovirus largely disappeared after SARS-CoV-2 onset and decreased activity continued throughout the study period. Public health mitigation measures, environmental persistence of rhinovirus/enterovirus and adenovirus, and viral interactions could all be drivers of this observation. The nature of how these viruses are transmitted, severity of disease, functional status of infected patients, and age of the population affected may have contribute to the distribution of pathogens identified. Further research is warranted to explore the prevalence, clinical presentation, and strain type among the respiratory viral pathogens and their impact on public health policies.

0817

### "PEOPLE LISTEN MORE TO WHAT ACTORS SAY": A QUALITATIVE STUDY OF TUBERCULOSIS-RELATED KNOWLEDGE, BEHAVIORS, STIGMA, AND POTENTIAL INTERVENTIONS IN PUDUCHERRY, INDIA

Lora Sabin<sup>1</sup>, Mahalakshmy T<sup>2</sup>, **Madeline E. Carwile**<sup>1</sup>, Senbagavalli Prakash Babu<sup>2</sup>, Selby Knudsen<sup>3</sup>, Jessie Stephens<sup>1</sup>, Priyanka Fernandes<sup>4</sup>, Chelsie Cintron<sup>3</sup>, C. Robert Horsburgh, Jr.<sup>1</sup>, Padmini Salgame<sup>5</sup>, Jerrold J. Ellner<sup>5</sup>, Sonali Sarkar<sup>2</sup>, Natasha S. Hochberg<sup>3</sup>

<sup>1</sup>*Boston University School of Public Health, Boston, MA, United States*,

<sup>2</sup>*Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India*,

<sup>3</sup>*Boston University School of Medicine, Boston, MA, United States*,

<sup>4</sup>*University of California, Los Angeles, CA, United States*,

<sup>5</sup>*Rutgers New Jersey Medical School, Newark, NJ, United States*

To capitalize on advances in tuberculosis (TB) diagnostics and therapeutics, and maximize the likelihood of the best TB outcomes, it is critical that people living with active TB (PLWATB) engage in care. One major challenge is stigma, which occurs when PLWATB experience discrimination or rejection due to their disease status; this can lead to delays in diagnosis and treatment. Understanding TB stigma is particularly important in India,

which shoulders a quarter of the worldwide TB burden. We aimed to understand TB stigma (anticipated, enacted, and internalized) and collect views on potential interventions to reduce stigma from PLWATB, their household members (HHM), and other key stakeholders in Puducherry and Tamil Nadu, India. We conducted 47 in-depth interviews (IDI) with PLWATB (n=23) and their HHM (n=24), and eight focus group discussions (FGD): two each with PLWATB, HHM, healthcare workers, and key informants, such as community leaders and outreach workers. A total of 54 individuals participated in the FGDs. Overall, 38 (80.9%) of IDI participants reported misconceptions about TB transmission, though most (70.2%) were aware that TB is curable. Participants reported high levels of anticipated stigma; 59.6% of PLWATB chose to hide their disease to avoid stigma in their community. They also reported experiencing enacted stigma from community members (e.g. neighbors), employers, and healthcare workers (who were often described as "scolding"). Participants suggested many interventions, including celebrity advocacy (to raise awareness through social media) and school-based programs to increase community knowledge and reduce enacted stigma. They also supported interventions to reduce internalized stigma among PLWATB, including support groups and counseling. These findings have the potential to inform future interventions to reduce TB-related stigma in India, which could increase engagement in care and result in higher TB treatment success.

0818

### SYMPTOMATIC GIARDIA LAMBLIA INFECTIONS IN NICARAGUA, EPIDEMIOLOGY AND IMPACT ON THE GROWTH OF YOUNG CHILDREN DURING THE FIRST THREE YEARS OF LIFE

**Lester Gutierrez**<sup>1</sup>, Patricia Blandan<sup>1</sup>, Yaoska Reyes<sup>1</sup>, Fredman Gonzalez<sup>1</sup>, Christian Toval-Ruiz<sup>1</sup>, Nadja Vielot<sup>2</sup>, Filemon Bucardo<sup>1</sup>, Luther Bartelt<sup>2</sup>, Sylvia Becker-Dreps<sup>2</sup>, Samuel Vilchez<sup>1</sup>

<sup>1</sup>*National Autonomous University of Nicaragua, Leon, Nicaragua*,

<sup>2</sup>*University of North Carolina, Chapel Hill, NC, United States*

*Giardia lamblia* infections cause a high burden of disease in children in low- and middle-income countries. Between June 2017 and July 2018, we enrolled 444 infants from León, Nicaragua in a population-based birth cohort. Clinical and epidemiological, socioeconomic and anthropometric data were collected monthly, while household surveillance for acute gastroenteritis (AGE) was done weekly. Here we present preliminary data on analysis of *Giardia lamblia* during the first 36 months of life of 184 infants, including parasites detected by optical microscopy of wet mounts or qPCR. The one hundred and eighty-four children experienced 340 AGE episodes, where *G. lamblia* was detected in 25 (7.35%) AGE stool samples. Children with AGE episodes in which *G. lamblia* was detected were significantly less likely to receive care in primary care settings as compared to AGE episodes due to other etiologies ( $p=0.01$ , OR: 0.2, 95% CI: 0.07, 0.8), even when microscopy results were available to families. Similarly, children with *G. lamblia* were less likely to receive zinc supplementation ( $p=0.13$ , OR: 0.4, 95% CI: 0.1, 1.3). In the first year of life, *G. lamblia* was detected in 2.04% (4/196) of AGE stools. By age two, frequency of detection increased to 9.82% (11/112). While by age three, *G. lamblia* was detected in almost 1/3 of AGE stools 31.25% (10/32). The LAZ score decreased after 3 months ( $\Delta LAZ$ : -0.40), at 2 years ( $\Delta LAZ$ : -0.32) and 3 years ( $\Delta LAZ$ : -0.84) after a *G. lamblia* episode. A similar pattern was observed for difference in WAZ after 3 months ( $\Delta WAZ$ : -0.28), at 2 years ( $\Delta WAZ$ : -0.32) and 3 years ( $\Delta WAZ$ : -0.13). Comparing *Giardia lamblia* and other AGE etiologies, Reduction in WAZ at 3 months post-episode greater in children with *Giardia Lamblia* as compared to children AGE of another etiology ( $p=0.021$ ). In summary, we observed a negative impact on  $\Delta LAZ$  and  $\Delta WAZ$  after an AGE episode associated with *Giardia lamblia*.

0819

### CONTRIBUTION TO THE EPIDEMIOLOGICAL STUDY OF TOXOPLASMOSIS IN BEEF HANDLERS IN SLAUGHTERHOUSES ON THE ATLANTIC COAST OF COLOMBIA

Linda M. Chams, Alberto S. Mestra, Carlos J. Castro

Grupo de Investigaciones Microbiológicas y Biomédicas de Cardoba (GIMBIC)-Universidad de Cardoba, Montería, Colombia

*Toxoplasma gondii* infections are very common in humans and food animals. Raw beef may contain viable *T. gondii* tissue cysts and therefore handling them may pose a risk of *T. gondii* infection to slaughterhouse workers. 686 serological tests were carried out that represented the universe of the existing population in 16 municipal slaughterhouses belonging to the seven departments of the Atlantic coast of Colombia, with the aim of determining the prevalence of reactors for *T. gondii*, using indirect hemagglutination technique (IHA) and determine the relationship between the seroreaction found with the degree of risk and the work time of the handler in the slaughter process. The serological study revealed a general prevalence of 77.69% (range: 66.3 - 99.6%) that exceeds the figures of 40.0 - 50.0% indicated for humans worldwide. In particular, prevalences were found according to departments, corresponding to: Córdoba (78.9%), Sucre (83.1%), Bolívar (78.9%), Atlántico (0.8%), Magdalena (70.7%), Cesar (75.0%) and Guajira (74.3%). The interpretation of the serological reaction showed a trend for high titers (greater than and equal to 1: 1280) (33.8%) and lower values for intermediate titers (Range: 1: 320 - 1: 640) (27.8%) and low (Range: 1:80 - 1: 160) (16.0%). The relationship of seropositivity for working times of less than 4 years, 4 -8 years and older than 8 years, did not show statistical significance, unlike the marked significance ( $p < 0.05$ ) for the seroreaction relationship - risk grade III (viscera wash). The prevalence found, when relating it in a large proportion to handlers with high-risk trades and with titles equal to or greater than 1: 1280, added to the unwanted hygienic-locative conditions, the lack of education, little professional supervision and inadequate protection of operators, requires epidemiological surveillance for the population studied.

0820

### A FIRST REPORT ON EXPERIENCE IN MANAGING INFANTS WITH CONGENITAL TOXOPLASMOSIS IN ETHIOPIA: A REVIEW OF EVALUATION AND TREATMENT IN RESOURCE-LIMITED SETTINGS

Tinsae Alemayehu<sup>1</sup>, Selamawit Assefa<sup>2</sup>, Solomie Jebessa Deribessa<sup>3</sup>, Semienew Ambachew<sup>4</sup>

<sup>1</sup>St. Paul's hospital millennium medical college, Addis Ababa, Ethiopia, <sup>2</sup>Lancet hospital, Addis Ababa, Ethiopia, <sup>3</sup>St. Paul's hospital millennium medic college, Addis Ababa, Ethiopia, <sup>4</sup>Addis Ababa University, Addis Ababa, Ethiopia

Congenital toxoplasmosis is a major sequela of untreated primary maternal infection. With or without symptoms, untreated infections eventually lead to multiple neurologic complications. Despite the high *Toxoplasma gondii* seroprevalence in the Ethiopian population, there are no reports of newborns diagnosed and treated for congenital toxoplasmosis. The clinical presentation, evaluation, and management of three infants diagnosed with congenital toxoplasmosis in our clinic are described. Two were symptomatic at birth. All three had confirmed diagnoses using *Toxoplasma* serologic tests. Two completed their treatment with one infant developing complications of strabismus and seizure disorder. There is little experience in managing congenital toxoplasmosis in Ethiopia due to constraints in diagnostics and therapy. The description of this first such report underscores the need for risk assessment and evaluation during antenatal care to obtain favorable fetal outcomes.

0821

### MULTIPLEX ANTIBODY BEAD ASSAY DETECTS EARLY AND PERSISTENT CHRONIC BABESIA MICROTI INFECTIONS IN BLOOD DONORS

Scott Meredith<sup>1</sup>, Ankit Puri<sup>1</sup>, Victoria Majam<sup>1</sup>, Laura Tonnetti<sup>2</sup>, Susan Stramer<sup>2</sup>, Sanjai Kumar<sup>1</sup>

<sup>1</sup>Food and Drug Administration, Silver Spring, MD, United States, <sup>2</sup>American Red Cross, Rockville, MD, United States

*Babesia microti*, a major causative agent of human babesiosis, represents an emerging public health concern in United States and globally. In the US, the number of reported cases of babesiosis nearly doubled between 2011 and 2018. Our goal was to develop a test to effectively detect window period cases (prior to seroconversion) and persistent chronic infections. To this end, we developed a multiplex assay using the Luminex bead-based platform for detection of antibody specific for four immunodominant *B. microti* antigens that we identified previously—BmSERA, BmPiβS, BmMCFRP1, and BmBAHCS. Assay sensitivity and specificity were determined in plasma samples collected from blood donors as part of an investigational study by the American Red Cross. Plasma samples were stratified based on the results of *B. microti* detection assays (IFA and PCR). BmBAHCS was the most sensitive antigen in detecting *B. microti*-specific antibody in donor plasma samples tested so far. BmBAHCS-coated beads (single antigen) yielded positive results with 98% (54/55) of IFA+ samples. Multiple-antigen coated beads (all four antigens) were less sensitive compared to IFA, detecting 87% (151/174) of IFA+ samples. On the other hand, multiple antigen-coated beads detected 46% (6/13) of PCR+ window period cases that were not detected by IFA, whereas BmBAHCS-coated beads detected 16.7% (2/12) of window period cases. Thus, our single antigen assay is comparable to IFA in identifying *B. microti*-exposed blood donors, and the four antigen combination improves detection of early antibody responses undetected by IFA. Additional development is required, but this test could potentially be adapted as a high throughput multiplex antibody bead assay to identify *B. microti* exposed individuals in endemic areas.

0822

### UNEXPECTED CONSEQUENCES OF A PANDEMIC ON CRYPTOSPORIDIOSIS INFECTIONS IN NEW YORK STATE

Kimberly Mergen, Susan Madison-Antenucci

NYSDOH, Albany, NY, United States

Cryptosporidiosis is an infectious disease transmitted through the fecal oral route and is caused by the pathogenic parasite, *Cryptosporidium*. *Cryptosporidium* infections can be contracted by drinking or contact with contaminated water, eating contaminated food, or through fomites. We examined whether novel Coronavirus 2020 guidelines of decreased human contact and social gatherings might have impacted cryptosporidiosis infections. Since most *Cryptosporidium* specimens are submitted during the summer months when travel, gatherings and outdoor activities are highest we focused on cases received between May and September. The *Cryptosporidium* species was determined for specimens that were PCR positive. Results showed that *C. parvum* infections, which are mainly acquired through agricultural influences, slightly decreased between 2019 and 2020 but were not significantly different. However, there was a significant decrease in *C. hominis* infections ( $p < 0.0053$ ) which are typically spread from human-to-human, and a significant increase in infections from *Cryptosporidium* sp. found in the environment ( $p < 0.0001$ ). For infections caused by species other than *C. parvum* and *C. hominis*, the most common was *Cryptosporidium* chipmunk genotype for both 2019 and 2020, with 7 and 29 cases respectively. Other identified species include *C. ubiquitum*, *C. felis*, and *Cryptosporidium* skunk genotype. When demographics of patients were examined for both years, spatial and temporal information suggests that human-to-human transmission of *Cryptosporidium* sp. typically found in the environment was unlikely. This

data suggests that the 2020 guidelines for decreased human interaction likely contributed to the decreased human-to-human cryptosporidiosis infections.

0823

### THE EFFECT OF TEMPERATURE ON PERSISTENCE OF A SARS-COV-2 SURROGATE ON MEAT PRODUCTS

Emily S. Bailey<sup>1</sup>, Mark D. Sobsey<sup>2</sup>

<sup>1</sup>Texas Tech Health Sciences Center, Lubbock, TX, United States, <sup>2</sup>The University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

COVID-19, the disease caused by Severe Acute Respiratory Syndrome Coronavirus 2 (SARS-CoV-2) was declared a pandemic by the World Health Organization (WHO) in March 2020. Multiple pathways of SARS-CoV-2 transmission have been examined and the role of contaminated foods as a source of SARS-CoV-2 exposure has been suggested. As many cases of SARS-CoV-2 have been linked to meat processing plants, it may be that slaughterhouse workers or meat processing plant procedures transfer viral particles during meat processing, storage or transport. Because of the potential for contamination of foods such as fish, meat and poultry, the goal of this study was to evaluate the survival of a lipid enveloped RNA bacteriophage, phi 6, as a surrogate for SARS-CoV-2 survival under various meat and fish cold storage conditions over 60 days.

0824

### FECAL CONTAMINATION IN CHILD PLAY SPACES AND ON CHILD HANDS IS ASSOCIATED WITH SUBSEQUENT ADVERSE CHILD DEVELOPMENTAL OUTCOMES IN RURAL DEMOCRATIC REPUBLIC OF THE CONGO (REDUCE PROGRAM)

Christine Marie George<sup>1</sup>, Alves Birindwa<sup>2</sup>, Sarah Beck<sup>3</sup>, Timothy Julian<sup>3</sup>, Jennifer Kuhl<sup>1</sup>, Camille Williams<sup>1</sup>, Nicole Coglianesi<sup>2</sup>, Elizabeth Thomas<sup>1</sup>, Sarah Bauler<sup>2</sup>, Ruthly Francois<sup>1</sup>, Angela Ng<sup>1</sup>, Amani Sanvura Presence<sup>2</sup>, Bisimwa Rusanga Jean Claude<sup>2</sup>, Fahmida Tofail<sup>4</sup>, Jamie Perin<sup>1</sup>, Patrick Mirindi<sup>2</sup>, Lucien Bisimwa Cirhuza<sup>2</sup>

<sup>1</sup>Johns Hopkins School of Public Health, Baltimore, MD, United States, <sup>2</sup>Food for the Hungry, Phoenix, AZ, United States, <sup>3</sup>Department of Environmental Microbiology, Swiss Federal Institute of Aquatic Science and Technology (EAWAG), Zurich, Switzerland, <sup>4</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

The objective of the Reducing Enteropathy, Undernutrition, and Contamination in the Environment (REDUCE) program is to identify exposure pathways to fecal pathogens that are significant contributors to morbidity among young children in the Democratic Republic of the Congo (DRC), and on developing and evaluating scalable interventions to reduce fecal contamination from these pathways. This prospective cohort study of 270 children under 5 years of age was conducted in rural South Kivu, DRC to investigate the association between *Escherichia coli* in hand rinse, soil, food, object, surface, stored-water, and water-source samples and child developmental outcomes. Child developmental outcomes were assessed by communication, fine motor, gross motor, personal social, problem solving, and combined scores measured by the Extended Ages and Stages Questionnaire (EASQ) at a 6 month follow-up. Children with *E.coli* present in the soil in their play spaces had significantly lower combined EASQ z scores (coefficient: -0.38 (95% Confidence Intervals (CI): -0.73, -0.03)). *E.coli* on children's hands was associated with lower communication EASQ z scores (-0.37 (95% CI: -0.10, -0.01)), and *E.coli* in stored drinking water was associated with lower gross motor EASQ z scores (-0.40 (95% CI: -0.68, -0.12)). In the REDUCE cohort study, *E.coli* in child play spaces, on children's hands, and in stored-drinking water was associated with lower developmental outcomes (communication, gross motor, fine motor, and problem solving skills). These results demonstrate the need for interventions to reduce fecal contamination in the household environment to protect the health of susceptible pediatric populations in rural DRC.

0825

### ACCESS TO WATER SANITATION AND HYGIENE FACILITIES AT PRIMARY HEALTH CARE CENTERS IMPACTING MOTHER'S PARTICIPATION IN A GROUP SESSION: EXPERIENCES FROM RINEW-G STUDY IN BANGLADESH

Tania Jahir<sup>1</sup>, Mahbubur Rahman<sup>1</sup>, Elli Leontisini<sup>2</sup>, Farzana Yeasmin<sup>1</sup>, Peter J Winch<sup>2</sup>

<sup>1</sup>icddr, Dhaka, Bangladesh, <sup>2</sup>John Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

There are many interrelated ways to improve child cognitive development and growth such as good nutrition, clean home environment, and parent's interacting positively with their children. We integrated maternal and child nutrition, maternal mental health, water, sanitation, hygiene and reduction of lead exposure with child stimulation to learn about the best ways to deliver the intervention package. The intervention was delivered from mid 2019 by the government frontline health workers in Chatmohar sub district of northern central Bangladesh. This package offered 24 sessions to the mother-baby group and four sessions to pregnant women. Sessions were delivered by the health workers in the sub-district health complex, union health and family welfare centers and community clinics. We conducted 12 interviews and four focus groups with pregnant and lactating mothers and explored the facilitators and difficulties to participate in the group sessions. We also conducted spot checks to examine WASH situation in all (n=44) health care facilities. Mothers reported that due to lack of functional toilets for visitors' use, after attending 1 or 2 sessions, many of them did not attend any subsequent sessions. Lack of water for both drinking and toilet use was another reason for them to leave the sessions earlier. Mothers faced problems with cleaning up if their babies defecated or vomited during the sessions. Spot checks revealed that 84% of the facilities had functional toilets but only for staff use, only 30% had drinking water facility, and 20% had handwashing provision with soap and water. Findings suggested that, improved water, sanitation and hygiene facilities is one of the important pre-conditions to increase mothers' participations in the group sessions in the health care centers. Improvement of WASH facilities could increase participation and acceptance when integrated intervention or other interventions delivered through group sessions.

### EPIDEMIOLOGIC FEATURES OF ACUTE PEDIATRIC DIARRHEA IN MANAGUA, NICARAGUA FROM 2011 TO 2019

Jose Victor Zambrana<sup>1</sup>, Fausto Bustos Carrillo<sup>1</sup>, Sergio Ojeda<sup>2</sup>, Brenda Lopez<sup>2</sup>, Krista Latta<sup>3</sup>, Amy Schiller<sup>3</sup>, Guillermina Kuan<sup>4</sup>, Aubree Gordon<sup>3</sup>, Arthur Reingold<sup>5</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, <sup>2</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>3</sup>Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, MI, United States, <sup>4</sup>Centro de Salud Socrates Flores Vivas, Ministry of Health, Managua, Nicaragua, <sup>5</sup>Division of Epidemiology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States

Diarrhea remains a leading cause of death in children in low- and middle-income countries, including Nicaragua, but little is known about diarrhea incidence in cohort settings in Central America. The purpose of this study was to determine the incidence, risk factors, long-term trends, and seasonality of diarrhea in children aged 2-14 years old in Managua, Nicaragua, as the population underwent a demographic transition. From 2011 to 2019, we examined medically attended diarrheal episodes among 6,485 children who participated in a long-term prospective cohort study and presented for care in the study primary care facility. We performed a longitudinal analysis considering time-varying variables and intra-subject correlation. In addition, we analyzed the weekly incidence of diarrhea, applying seasonal trend decomposition to extract secular and seasonal patterns. The overall incidence rate of medically attended diarrhea was 156 per 1,000 (95% CI: 152 - 161). We observed a slight increase in the

incidence of diarrhea between 2011 and 2019. Age was the strongest predictor of the risk of diarrhea, and the incidence increased with every additional hour without running water supply per day in the household. Diarrhea in Managua behaved seasonally, with high peaks each year between May and July. Despite reductions in childhood mortality since 1990 in Nicaragua, diarrheal disease remains a major problem in Managua.

0827

### FECAL CONTAMINATION ON THE HOUSEHOLD COMPOUND AND IN WATER SOURCES ARE ASSOCIATED WITH SUBSEQUENT DIARRHEA IN YOUNG CHILDREN IN URBAN BANGLADESH (CHOB17 PROGRAM)

**Tahmina Parvin**<sup>1</sup>, Elizabeth D. Thomas<sup>2</sup>, Md. Sazzadul Islam Bhuyian<sup>1</sup>, Ismat Minhaj Uddin<sup>1</sup>, M. Tasdik Hasan<sup>1</sup>, Zillur Rahman<sup>1</sup>, Indrajeet Barman<sup>1</sup>, Fatema Zohura<sup>1</sup>, Jahed Masud<sup>1</sup>, Marzia Sultana<sup>1</sup>, Anne Westin<sup>2</sup>, Fatema-Tuz Johura<sup>1</sup>, Shirajum Monira<sup>1</sup>, Shwapon Kumar Biswas<sup>1</sup>, David A. Sack<sup>2</sup>, Jamie Perin<sup>2</sup>, Munirul Alam<sup>1</sup>, Christine Marie George<sup>2</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Johns Hopkins School of Public Health, Baltimore, MD, United States

A prospective cohort study was conducted to investigate the environmental and individual-level risk factors for diarrheal disease among 884 children under 5 years of age in slum areas of Dhaka, Bangladesh. Caregiver reports were collected on sociodemographic factors and hygiene behaviors. Diarrhea surveillance data was collected monthly based on caregiver-reported diarrhea for children in the past two weeks during the 12-month study period. Unannounced spot checks of the household compound were performed at 1, 3, 6, 9 and 12 months after enrollment to check for the presence of feces (animal or human), presence of animals in the child's sleeping space, assess child and caregiver hands for the presence of dirt, and to collect samples of the household's source and stored drinking water. Children with feces found on the household compound during spot checks had a significantly higher odds of diarrhea (Odds Ratio: 1.71; 95% Confidence Interval: 1.23, 2.38). Children residing in households with >100 colony forming units (CFU)/ 100 mL *E. coli* in source drinking water had a significantly higher odds of diarrhea (OR: 1.43; 95% CI: 1.06, 1.92). The presence of feces on the household compound and source drinking water with >100 CFU/ 100 mL *E. coli* were significant risk factors for diarrheal disease for children <5 years of age in slum areas of Dhaka, Bangladesh. These findings demonstrate the urgent need for comprehensive interventions to reduce fecal contamination on the household compound to protect the health of susceptible pediatric populations.

### EFFECTS OF A SCHOOL WATER, SANITATION, AND HYGIENE INTERVENTION ON CHILDREN'S NUTRITION, HYDRATION, HEALTH LITERACY, AND HANDWASHING: A MULTI-ARM CLUSTER-RANDOMIZED CONTROLLED TRIAL IN MANILA, PHILIPPINES

**Stephanie O. Sangalang**<sup>1</sup>, Zheina Ottong<sup>2</sup>, Allen Lemence<sup>2</sup>, Shelley Medina<sup>2</sup>, Shyrill Mariano<sup>3</sup>, Nelissa Prado<sup>2</sup>, Patricia Singson<sup>4</sup>, Mylene Cayetano<sup>5</sup>, Christian Borgemeister<sup>1</sup>, Thomas Kistemann<sup>6</sup>

<sup>1</sup>Center for Development Research, University of Bonn, Bonn, Germany, <sup>2</sup>University of the Philippines, Diliman, Quezon City, Philippines, <sup>3</sup>Marine Science Institute, University of the Philippines, Diliman, Quezon City, Philippines, <sup>4</sup>Ateneo de Manila University, Quezon City, Philippines, <sup>5</sup>Institute of Environmental Science and Meteorology, University of the Philippines, Diliman, Quezon City, Philippines, <sup>6</sup>Institute for Hygiene and Public Health and Center for Development Research, University of Bonn, Bonn, Germany

Inadequate water, sanitation, and hygiene (WaSH) threatens the health of millions of children globally. Urban poor children suffer from disease

due to inadequate school WaSH facilities and health education programs. But evidence is limited about which types of interventions are most effective in improving children's health in tropical megacities. Our study aimed to evaluate the impacts of a school-based WaSH intervention on children's nutrition, hydration, hygiene-related health literacy (HL), and handwashing (HW) in Metro Manila, Philippines. We conducted a cluster-randomized controlled trial in 15 public schools, assigning two schools to the control group (CG) and randomizing 13 schools to 1 of 3 intervention groups (IGs), IGA, IGB, and IGC, which received low-, medium-, and high-intensity health education, respectively. The intervention consisted of WaSH workshops for teachers, health education for children, hygiene supplies, and WaSH facilities repairs. We measured nutrition status via anthropometry; dehydration via urine test strips; HL via questionnaire; HW via observation. Our sample was 756 and 701 children at baseline and end-line (8 months later), respectively (retention rate ~93%). We used intention-to-treat analysis. At end-line, compared to the CG, IGA and IGC had significantly lower odds ratios (OR) for obesity and overweight, respectively. The intervention had no significant effects on stunting or thinness prevalence. Compared to the CG, IGB and IGC had significantly lower risks of dehydration. Compared to the CG, IGB had a greater knowledge of using HW to prevent infection. IGC had a significantly higher OR for observed HW after using the toilet/urinal. We conclude that the intervention reduced the risks of over-nutrition and dehydration and improved HL and HW. But focusing only on schools without addressing household WaSH may not be enough to reduce stunting and thinness risks. We are currently conducting sensitivity analyses and will present those results during the conference. Findings from our trial may be helpful for future WaSH interventions aimed at improving children's health in other tropical megacities.

### HOSPITALS IN DHAKA AND DISCHARGE OF WASTEWATER WITH HIGH SARS-COV-2 VIRAL RNA GENETIC LOADINGS: AN ASSESSMENT OF POTENTIAL ENVIRONMENTAL HEALTH RISK

**Nuhu Amin**<sup>1</sup>, Rehnuma Haque<sup>1</sup>, Md. Ziaur Rahman<sup>1</sup>, Mohammed Ziaur Rahman<sup>1</sup>, Zahid Hayat Mahmud<sup>1</sup>, Rezaul Hasan<sup>1</sup>, Supriya Sarker<sup>2</sup>, Nargis Akter<sup>3</sup>, Dara Johnston<sup>3</sup>, Mahbubur Rahman<sup>1</sup>, Prosun Bhattacharya<sup>4</sup>

<sup>1</sup>icddr, Dhaka, Bangladesh, <sup>2</sup>Directorate General of Health Services (DGHS), Dhaka, Bangladesh, <sup>3</sup>UNICEF, Dhaka, Bangladesh, <sup>4</sup>KTH Royal Institute of Technology, Stockholm, Sweden

Hospitals in low-and middle-income countries are frequently the center of epidemics and emerging infectious diseases. Significant health hazards result due to lack of systematic monitoring of wastewater (WW) discharges from hospitals containing a significant load of pathogens. We conducted a cross-sectional study to explore the WW management in Dhaka hospitals and analyzed the genetic materials of SARS-CoV-2 viral RNA discharged with the hospital WWs to the environment during COVID-19 pandemic between September 2020-January 2021. We selected 4 COVID and 2 non-COVID hospitals and conducted spot checks of the sanitation systems to explore availability of WW treatment facilities, and containments and collected 90 WW effluent samples (68 from COVID and 22 from non-COVID hospitals) and analyzed them for SARS-CoV-2 viral RNA gene copies using RT-PCR. Among 6 hospitals, no hospital had a WW treatment facility; 2 hospitals (1 COVID and 1 non-COVID) had containments (anaerobic baffled reactor); and 3 (2 COVID and 1 non-COVID) discharged WW effluents directly to environment. Average number of toilet users were 972/day (range:500-2272) in COVID and 3268/day (range:3063-3472) in non-COVID hospitals. All samples were positive with *E.coli*, with mean log<sub>10</sub> concentrations=7.1/100mL. Overall, 67%(n/N=60/90) of samples were positive with SARS-CoV-2 viral RNA [66%(45/68) in COVID and 68%(15/22) in non-COVID] in selected hospitals. In COVID hospitals, highest SARS-CoV-2 viral RNA copies (18214 copies/mL; range:13-18214 copies/mL) were detected, and in non-COVID hospital 1829 copies/mL (range:30-1829 copies/mL) were detected from the WW effluents. The prevalence of the genetic materials of SARS-CoV-2 in both hospitals are however independent of the number of admitted

patients. High concentrations of *E.coli* and genetic loading of SARS-CoV-2 viral RNA were discharging through the hospital WW without treatment in the ambient water bodies of Dhaka, contributing to significant health hazards to neighboring communities. Appropriate technologies should be adopted by the hospitals for WW treatment to reduce growing health risk to the environment.

## 0830

### "NON-PSEUDOMONAS" SWIMMERS' EAR, A CONDITION UNFAMILIAR TO MOST CLINICIANS

Don W. Kannagara, Dhyanes Pandya

St Luke's University Health network, Warren Campus, Phillipsburg, NJ, United States

Most cases of swimmers' ear are due to exposure to *Pseudomonas aeruginosa* found in fresh water. But other environmental, fresh or brackish water and salt water associated organisms may be responsible for some cases. Multiple species of salt water vibrios (*Vibrio alginolyticus*, *V. cholerae*, *V. fluvialis*, *V. cincinnatiensis*, *V. parahaemolyticus*), fresh or brackish water *Aeromonas* species (*Aeromonas caviae*, *Aeromonas hydrophila*, *Aeromonas veronii*, *Aeromonas* sp.) and *Achromobacter* are the most frequently reported "non-*Pseudomonas*" species. Most reports of vibrio caused otitis externa are from coastal areas. All the reported swimmers' ear bacteria appear to be motile. In a study of clinical cases of infections due to *Achromobacter xylosoxidans* and *Stenotrophomonas maltophilia*, we found 23 cases of ear infections due to these 2 environmental organisms. Age range was 4-87 with 14 males and 10 females. Ten were children. Some had started swimming lessons recently. Most otitis externa was treated with ciprofloxacin ear drops. Antibiotic susceptibilities of these 2 organisms differ significantly from *Pseudomonas*, vibrios and *Aeromonas* that are usually susceptible to quinolones, aminoglycosides, and other anti-*Pseudomonas* agents. Only 25% *Achromobacter* isolates were susceptible to ciprofloxacin with very poor susceptibility to gentamicin (5%) and aztreonam (1%). Most active drug for *Achromobacter* was meropenem (95%). All *Stenotrophomonas* were susceptible to trimethoprim/sulphamethoxazole. Patients with persistent or recurrent infections would benefit from antibiotic changes based on susceptibilities.

## 0831

### BIOACTIVITY OF FOUR NIGERIAN WILD MUSHROOMS AGAINST SOME TYPED CLINICAL ISOLATES

Janet Olubukola Olaitan<sup>1</sup>, Mobolaji A. Titilawo<sup>1</sup>, Abidemi O. Faseun<sup>1</sup>, Sunday B. Akinde<sup>1</sup>, Olu Odeyemi<sup>2</sup>

<sup>1</sup>Osun State University, Osogbo, Nigeria, <sup>2</sup>Obafemi Awolowo University, Ile-Ife, Nigeria

This study aimed at investigating the antimicrobial activity of some wild Nigerian mushrooms against selected typed clinical isolates. We collected wild mushrooms from an integrated organic farm in Ilesa, Southwest Nigeria. Crude methanolic extract of *Lentinus squarrosulus* Mont., *Termitomyces robustus* (Beeli) R. Heim, *Trametes ochracea* (Pers.) Gilb. & Ryarden and *Xylaria hypoxylon* (L.) Grev. were screened singly and in different combinations for bioactivity against the selected bacterial and yeast isolates. The minimum inhibitory concentration (MIC) and chemical constituents of the extracts were studied following standard procedures. Overall, we obtained a total of 16 mushrooms belonging to 14 genera. The extracts showed varied clearance zones against at least one of the eight bacteria, and one yeast isolates tested when applied singly with the antimicrobial inhibitory zone ranging from 7.2 mm to 20.0 mm in *Staphylococcus aureus* (*T. ochracea* extract) and *Pseudomonas aeruginosa* (*L. squarrosulus* extract) respectively. Furthermore, the MIC ranged from 2.09 to 16.75 mg/mL. When combined, the blends were active against some Gram-negative bacteria (*Escherichia coli*, *Pseudomonas aeruginosa* and *Proteus mirabilis*) but inactive against the Gram-positive bacteria and yeast. Except for *X. hypoxylon*, other extracts contained saponins, tannins and terpenoids. Our findings revealed that the wild mushrooms

are potential antimicrobial agents against the tested isolates. Further development of the bioactive compounds into antimicrobial drugs is advocated.

## 0832

### CORE MICROBIOME OF MALNOURISHED CHILDREN WITH ENVIRONMENTAL ENTERIC DYSFUNCTION

Najeeha Talat Iqbal<sup>1</sup>, Robert Chen<sup>2</sup>, Nicholas Griffin<sup>3</sup>, Safina Abdul Razzak<sup>1</sup>, Kamran Sadiq<sup>1</sup>, Junaid Iqbal<sup>1</sup>, Aneeta Hotwani<sup>1</sup>, Najeeb Rahman<sup>1</sup>, Fayaz Umran<sup>1</sup>, Sheraz Ahmed<sup>1</sup>, Sana Syed<sup>4</sup>, Sean Moore<sup>4</sup>, Barratt Michael<sup>5</sup>, Gordon Jeffrey<sup>5</sup>, Asad Ali<sup>1</sup>

<sup>1</sup>Aga Khan University, Karachi, Pakistan, <sup>2</sup>Washington University St.Louis, St. Louis, MO, United States, <sup>3</sup>Washington University St.Louis, St.Louis, MO, United States, <sup>4</sup>University of Virginia, Charlottesville, VA, United States, <sup>5</sup>University Of Washington, St. Louis, MO, United States

Environmental Enteric Dysfunction (EED) is a subclinical acquired syndrome of altered gut function and poor absorptive capacity whose etiology is unknown. EED is postulated to be an important contributor to linear growth faltering in early childhood. The role of upper gastrointestinal (GI) bacterial communities in the pathophysiology of EED is poorly defined due to a paucity of studies where there has been direct collection of proximal small intestinal biological samples from undernourished children. In a two-year longitudinal follow-up study, we obtained duodenal aspirates and fecal samples from a subset of undernourished children (n=43) who underwent esophagogastroduodenoscopy for growth failure refractory to nutritional interventions. We analyzed duodenal and fecal microbiota composition from cases and fecal microbiota from age-matched healthy controls by performing amplicon sequencing on the V4-16S rRNA gene. All reads were processed using DADA2 and analyzed using the Bioconductor software packages 'Microbiome' and 'phyloseq'. We discovered a 'core' group of eight upper-intestinal bacterial amplicon sequence variants (ASVs) that were detected at >0.01% relative abundance in at least 80% of the aspirate samples, with *Streptococcus anginosus* being the most prevalent, followed by *Gemella haemolysans* and other *Streptococcus* species. A group of 12 bacterial ASVs with relative abundances >0.01% were detected in >50% of all fecal samples from both cases and healthy growing children. The top three taxa were *Escherichia-Shigella* sp., *Bifidobacterium breve* and a *Streptococcus* sp. In age-matched fecal specimens sampled monthly from healthy controls, we detected a high abundance of *Bifidobacterium* species in greater than 90% of samples. These observations provide a starting point for follow-up studies designed to examine the contributions of the small intestinal microbiota more directly to the pathogenesis of EED, including analyses that correlate the absolute abundances of the shared ('core') group taxa identified in the duodenal microbiota of subjects with EED with features of gene expression in duodenal mucosa.

## 0833

### THE CRUCIAL ROLE OF ECONOMIC EVALUATIONS TO ASSESS THE IMPACT OF WATER, SANITATION AND HYGIENE ON REDUCING SCHISTOSOMIASIS BURDEN IN UGANDA

Sergi Alonso<sup>1</sup>, Eva Janouskova<sup>2</sup>, Emma McIntosh<sup>3</sup>, Joaquin Prada<sup>2</sup>, Poppy Lambertson<sup>4</sup>

<sup>1</sup>Institute of Biodiversity, Animal Health & Comparative Medicine, University of Glasgow, Glasgow, United Kingdom, <sup>2</sup>University of Surrey, Guildford, United Kingdom, <sup>3</sup>Health Economics & Health Technology Assessment, University of Glasgow, Glasgow, United Kingdom, <sup>4</sup>Institute of Biodiversity, Animal Health & Comparative Medicine, University of Glasgow, Glasgow, United Kingdom

Schistosomiasis is a debilitating disease caused by parasitic worms with over 240 million people infected. Individuals acquire infections when contacting contaminated fresh water through daily activities, such as fishing or bathing, and transmit it in areas with inadequate sanitation. This is the case in Uganda where, after a decade of mass drug administration (MDA), mean infection intensity is higher than at baseline in high endemic

areas. The WHO estimates that the potential reduction in schistosomiasis burden due to improvements in water, sanitation and hygiene (WASH) can reach 60-70%, and that they could hold the key to eliminating the disease. A recent discrete choice experiment in Uganda informed about the popularity of different WASH practices, infrastructure improvements and behavioural changes. We are using these data, combined with primary data from previous studies, to assess which combination of WASH interventions, on top of bi-annual MDA, is the most cost-effective to reduce schistosomiasis transmission in Mayuge (Uganda). We are building a Markov model to characterise the risk of schistosomiasis infection among the population of Mayuge during their lifetime, and follow a societal perspective to calculate the expected lifetime costs and benefits associated with each intervention. The WASH interventions aim at: (1) improving sanitation and reducing infection risk to others, such as public latrines and open defaecation fines; and (2) improving water access and reducing infection risk to oneself, mainly water sources for domestic chores and/or drinking and water access points. We will, then, compare them and calculate incremental cost-effectiveness ratios, as the 'extra cost per disability-adjusted life-year (DALY) averted', to decide which combination of interventions is the most cost-effective in these settings. This project will improve our understanding of WASH and will inform on the most cost-effective interventions needed to achieve schistosomiasis elimination. It focuses on using novel mathematical modelling tools to inform policy-makers on popular and sustainable WASH to complement MDA.

0834

### WORLD HEALTH ORGANIZATION - HOUSEHOLD WATER TREATMENT TECHNOLOGY AND MICROBIAL LOG-REDUCTION VALUES

Gouthami Rao<sup>1</sup>, Emma Wells<sup>2</sup>, Karl Linden<sup>2</sup>, Joe Brown<sup>1</sup>

<sup>1</sup>University of North Carolina - Chapel Hill, Chapel Hill, NC, United States,

<sup>2</sup>University of Colorado Boulder, Boulder, CO, United States

Practitioners and researchers use household water treatment technology microbial removal ratings as a key tool and benchmark to assess innovative technologies in low-and-middle income countries. The current World Health Organization Drinking Water Quality Guidelines includes a log-reduction value (LRV) table based on bacteria, virus, and protozoa categories by household water technologies. Our team worked closely with WHO to update the current table to be included in the next (i.e., fifth) edition. We implemented a systematic, replicable, peer-literature review. Literature searches were conducted from 1997-2021 using a standardized search string query for target databases. Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) best practices were followed for the review. Subject-matter experts were gathered in December 2020 to assess missing literature and discuss reported LRVs. Preliminary results included mean LRVs and 95% confidence intervals [CI] across bacteria (B), virus (V), and protozoa (P) categories for chlorination (n=21; B= 3.3 [2.5—4.1], V= 3.1 [1.9—4.2]), filtration (n=20; B= 3.5 [2.5—4.4], V= 2.9 [1.9—3.8], P= 3.0 [0.40—5.6]), coagulation/disinfection (n=6; B= 7.4 [6.5—8.4], V= 3.3 [-1.3—7.9], P= 3.1 [2.2—4.1]), solar (n=54; B= 4.2 [3.7—4.7], V= 2.9 [2.2—5.6], P= 3.3 [2.2—4.4]), UV (n=19; B= 4.3 [3.3—5.2], V= 2.7 [2.0—3.3], P= 2.7 [1.7—3.7]), and thermal water treatment (n=9; B= 1.8 [1.0—2.6]). Data was further disaggregated between field and lab-based studies. Updated LRVs indicate a variety of effective household water treatment options, but limitations exist based on technology performance, microbial target, and lab vs. field-based studies. Practitioners and researchers can use the updated microbial LRVs as a future benchmark, assessment of novel technologies, and international standard for household water treatment technologies.

0835

### USING CHOICE MODELLING TO IDENTIFY POPULAR AND AFFORDABLE ALTERNATIVE INTERVENTIONS FOR SCHISTOSOMIASIS IN UGANDA

Keila Meginnis<sup>1</sup>, Nick Hanley<sup>2</sup>, Lazaaro Mujumbusi<sup>2</sup>, Lucy Pickering<sup>2</sup>, Poppy Lambertson<sup>2</sup>

<sup>1</sup>University of Stirling, Glasgow, United Kingdom, <sup>2</sup>University of Glasgow, Glasgow, United Kingdom

Schistosomiasis is caused by a vector-borne parasite, commonly found in low- and middle-income countries. People become infected by direct contact with contaminated water, through activities such as bathing and fishing. Water becomes contaminated when human waste is not adequately contained. We elicit community preferences towards alternative water access, sanitation and hygiene interventions that would reduce individuals' risk of contracting, or transmitting, *Schistosoma mansoni*. We administered a discrete choice experiment to understand community preferences for improved WASH interventions. We compared interventions that target behaviours that put oneself at higher risk versus behaviours that mainly put others at risk. We used two payment vehicles to quantify what individuals are willing to give up in time and/or labour. Key findings indicate that new sources of potable water and fines on open defecation are the highest valued interventions. A large portion of our sample ignored the payment vehicles, which is key for policy analysis.

0836

### WATER TREATMENT BEHAVIOR AND SOCIAL NORMS AMONG WOMEN LIVING WITH YOUNG CHILDREN IN RURAL UGANDA

Jessica M. Perkins<sup>1</sup>, Bernard Kakuhikire<sup>2</sup>, Charles Baguma<sup>2</sup>, Raphael Abayateye<sup>3</sup>, Meredith Meadows<sup>1</sup>, Justin D. Rasmussen<sup>4</sup>, Emily N. Satinsky<sup>5</sup>, David R. Bangsberg<sup>6</sup>, Alexander C. Tsai<sup>5</sup>

<sup>1</sup>Vanderbilt University, Nashville, TN, United States, <sup>2</sup>Mbarara University of Science and Technology, Mbarara, Uganda, <sup>3</sup>Vanderbilt University School of Medicine, Nashville, TN, United States, <sup>4</sup>Duke University, Durham, NC, United States, <sup>5</sup>Massachusetts General Hospital, Boston, MA, United States, <sup>6</sup>Oregon Health and Science University - Portland State University of Public Health, Portland, OR, United States

Many households worldwide need to treat drinking water to prevent infection. Perceived norms of others' water treatment practices may influence individuals' personal water treatment use. This study assesses personal water treatment use and perceived peer norms among all women living with children under five years old in a water insecure setting in rural Uganda. We used data from women who were part of a whole-population study of 8 villages in Rwampara District, southwest Uganda. We recorded participants' self-reported household water treatment practice, the self-reported water treatment practice by participants' neighbors (within 0.2km) who were also study participants, and participant's perceptions about water treatment practice by most women living with young children in their village. A multivariable Poisson regression model estimated the association between individual water treatment practice and perceived peer norms, adjusting for neighbor behavior, perceived water source quality, having had diarrhea recently, and socioeconomic and demographic factors. Of 274 participants (78% response rate), 225 (82%) reported taking action to make their household drinking water safer, and 49 (18%) reported taking no action. Most [218 (80%)] reported boiling water. Across villages, the prevalence of participants who treated their drinking water ranged from 73-89%. Treating water to make it safer was the population norm in every village among women living with young children. However, 129 (47%) participants mistakenly thought most other women with young children in their village did not take any action to make household drinking water safer. Participants who misperceived the norm were less likely themselves to treat their household drinking water (adjusted relative risk = 0.81.67; 95% CI 1.68-0.97, p-value = 0.018), adjusting for other factors. Boiling household water to make it safe in this

setting is common. Future research should assess whether communicating accurate norms about water treatment practice can encourage greater uptake of water treatment practices.

0837

### DETERMINATION OF GROUNDWATER QUALITY IN AND AROUND KWAME NKURUMAH UNIVERSITY OF SCIENCE AND TECHNOLOGY (KNUST), KUMASI, GHANA

James Deke

*Kumasi Centre for Collaborative Research in Tropical Medicine, Kumasi, Ghana*

In recent times, there has been a tremendous pressure on the provision of potable water to individuals due to a global increase in human population. The availability and accessibility of potable water has therefore become a critical and urgent problem worldwide, especially in developing countries. Groundwater is one of the major sources of potable water readily available and accessible to individuals, however, periodical monitoring is key to ensure groundwater is potable for consumption. To this end, this study was conducted at the Kwame Nkrumah University of Science and Technology (KNUST) and its environs between January and March, 2019 to determine the quality of groundwater accessed by students in various residences. Groundwater was sampled from eight residences each from two different sites namely Zone A (on-campus) and Zone B (off-campus). Groundwater sampled from the selected residential sites were analyzed for total hardness, pH and concentrations of cadmium (Cd) and lead (Pb). The results indicated that the total hardness of water obtained from the various residential sites (28.13 mg/L,  $\pm$  9.21) were far below WHO's standard, 500 mg/L ( $p < 0.05$ ). In addition, only five (all on-campus) residences had the pH of groundwater falling within the WHO standard for pH of water (6.5-8.5). There were considerably high concentration of lead (Pb) in all the water samples obtained (0.28 mg/L  $\pm$  0.16), way above WHO standard of 0.01 mg/L ( $p < 0.05$ ), which is of great health concern. The concentration of cadmium (Cd) was below detection level (BDL) for all the residential sites. In conclusion, there is the need for regular monitoring of groundwater accessed by residents in the study area to ensure compliance with standards given the increase in population in the study area.

0838

### QUANTIFYING THE CONTRIBUTION OF LOW-DENSITY AND ASYMPTOMATIC INFECTIONS TO PLASMODIUM VIVAX TRANSMISSION IN THE AMAZON

Marcelo U. Ferreira<sup>1</sup>, Rodrigo M. Corder<sup>1</sup>, Igor C. Johansen<sup>1</sup>, Johanna H. Kattenberg<sup>2</sup>, Marta Moreno<sup>3</sup>, Angel Rosas-Aguirre<sup>4</sup>, Jan E. Conn<sup>5</sup>, Dionicia Gamboa<sup>6</sup>, Alejandro Llanos-Cuentas<sup>6</sup>, Anna Rosanas-Urgell<sup>2</sup>, Joseph M. Vinetz<sup>7</sup>

<sup>1</sup>University of São Paulo, São Paulo, Brazil, <sup>2</sup>Institute of Tropical Medicine, Antwerp, Belgium, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Université Catholique de Louvain, Brussels, Belgium, <sup>5</sup>State University of New York, Albany, NY, United States, <sup>6</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>7</sup>Yale School of Medicine, New Haven, CT, United States

Low-density and asymptomatic *Plasmodium vivax* infections remain largely undetected by malaria control programs in the Amazon. Quantifying their relative contribution to onward transmission is critical for designing regional strategies for malaria elimination. We did a systematic review and pooled analysis of individual data from population-based surveys that measured *P. vivax* prevalence by both microscopy and polymerase chain reaction (PCR). We modeled the relationship between parasite density and infectiousness to mosquitos using membrane feeding assay data. We examined: (1) how malaria transmission intensity and age relate to the proportion of *P. vivax* infections that are subpatent and asymptomatic, and (2) how parasite density relates to the risk of clinical manifestations and *P. vivax* transmission to mosquitoes in the Amazon. Seventy-nine pairs of prevalence measurements from Brazil, Peru, and French Guiana were

analyzed. PCR detected 5-fold more infections than microscopy, with similar microscopy detection rate (mean, 28%) in high and low prevalence settings. Asymptomatic and subpatent infections predominated over symptomatic and patent infections across all age groups in six studies with individual-level data. We used parasitemia measurements by quantitative PCR to characterize site-specific and age-dependent parasite density thresholds above which most *P. vivax* infections were symptomatic. We estimate that parasite carriers missed by microscopy are the source of only 12% to 24% of mosquito infections, while asymptomatic carriers contribute 27% to 79% of community-wide *P. vivax* transmission. In conclusion, microscopy may suffice to identify the infectious reservoir of *P. vivax* to be targeted by active case detection across the Amazon.

0839

### USING SOURCE OF INFECTION DATA TO TARGET MALARIA ELIMINATION IN THAILAND

Prayuth Sudathip<sup>1</sup>, Sathapana Naowarat<sup>2</sup>, Suravadee Kitchakarn<sup>1</sup>, Chalita Suttiwong<sup>1</sup>, Darin Areechokchai<sup>1</sup>, Chantana Padungtod<sup>1</sup>, Deyer Gopinath<sup>3</sup>, Niparueradee Pinyajeerapat<sup>4</sup>, David Sintasath<sup>4</sup>, Jui A. Shah<sup>2</sup>

<sup>1</sup>Division of Vector Borne Diseases, Department of Disease Control, Ministry of Public Health, Thailand, Nonthaburi, Thailand, <sup>2</sup>Inform Asia: USAID's Health Research Program, RTI International, Bangkok, Thailand, <sup>3</sup>World Health Organization, Nonthaburi, Thailand, <sup>4</sup>U.S. President's Malaria Initiative, United States Agency for International Development (USAID), Regional Development Mission for Asia, Bangkok, Thailand

With the adoption of its National Malaria Elimination Strategy in 2016, Thailand's national malaria program enhanced its long-standing case investigation efforts. The revised process continues to collect minimal essential data on human movement and travel history but adds details on source of infections. As incidence further declines, Thailand is assessing these data to understand their utility in identifying remaining hotspots and reservoirs that may impede elimination. This study examined routine surveillance data from fiscal years 2016 through 2020 for associations between source of infections and at-risk populations. Among 50,178 confirmed cases recorded in the national database, 34,189 (68.1%) had a case investigation form with complete travel history on file and were included in the analyses. Source of infection was categorized as home (no travel outside of focus or to forested/agricultural areas; 56.5%), outside (domestic travel either outside of focus or to forested/agricultural areas; 28.2%), or imported (travel outside of the country; 15.3%). Over the study period, home transmission decreased dramatically (66.0%), whereas outside and imported cases saw smaller absolute gains. Among patients with outside infections, for which fewer interventions are effective, 53.7% reported an overnight forest stay and 44.3% an overnight farm stay. Outside transmission was associated with young adult and adult groups (15-59 years), males, non-Thai migrants, and mixed species infections ( $p < 0.01$ ). Although incomplete data was a challenge at the start of the study period, 90.8% of case investigations were completed for the final year, showing great improvement in reporting. The results align with other surveillance and research findings on key populations prone to outside transmission, validating the utility of source of infection data. Implementers are optimistic that improved case investigation processes, and perhaps refined data highlighting the most useful details on source of infections, will support the program in protecting at-risk groups and in targeting its strategies for elimination and prevention of reintroduction.

Gold miners are currently a key reservoir for malaria in the Guiana shield, with a risk of emergence of antimalarial resistance linked to improper use of artemisinin-based combination therapy (ACT). The remoteness of the mines, and regulatory as well as political issues hinders their access to health care. A large-scale operational research called Malakit was hence implemented at the French Guiana (FG)-Brazil and FG-Suriname borders in order to improve access to malaria testing and treatment in illegal gold mining areas in the Amazon forest. This operational research evaluated the efficacy of a combination of training and distribution of kits for self-diagnosis and self-treatment to gold-miners, at strategic border staging areas. Evaluation relied on questionnaires at inclusion and follow-up visits, and cross-sectional pre/post studies. The primary outcome was the proportion of participants of reporting the proper use of the ACT after a malaria diagnosis and the secondary outcomes assessed the use of the kit and the impact on malaria prevalence. From April 2018 to March 2020, 3,733 persons participated in the Malakit intervention. Of the 631 participants who attended a follow-up, 223 reported having used a malakit: 71.7% [65.8-77.7] had used it correctly. Among the 1,098 participants of the pre/post studies, the odds-ratio of using both a test and treatment (using a malakit or turning to the healthcare system) was 1.8 (IC95% [1.1-3.0]) after the intervention relative to pre-intervention. Treatment adherence was higher when the patient reported receiving care in a health center (91% [89-94]) or using a malakit (81% [67-96]) than with unregulated self-medication (65% [60-70]) (OR=5.4 [3.7-7.8]). The Malakit project would have increased the decline in malaria prevalence in the region by 47%. This innovative international project showed that people with low educational level can manage their malaria symptoms from diagnosis to treatment with appropriate training tools, and change their behavior. This new malaria control strategy could be transferred to other regions facing similar situation.

### EFFECTIVENESS AND COST-EFFECTIVENESS OF REACTIVE, TARGETED INDOOR RESIDUAL SPRAYING FOR MALARIA CONTROL IN LOW-TRANSMISSION SETTINGS: A CLUSTER-RANDOMISED, NON-INFERIORITY TRIAL IN SOUTH AFRICA

**David Bath**<sup>1</sup>, Jackie Cook<sup>1</sup>, John Govere<sup>2</sup>, TIRS Trial Team<sup>3</sup>, Maureen Coetzee<sup>4</sup>, Catherine Pitt<sup>1</sup>, Immo Kleinschmidt<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>University of the Witwatersrand, Johannesburg, South Africa, <sup>3</sup>University of the Witwatersrand, Johannesburg, United Kingdom

Increasing insecticide costs and constrained malaria budgets could make universal vector control strategies, such as indoor residual spraying (IRS), unsustainable in low-transmission settings. We investigated the effectiveness and cost-effectiveness of a reactive, targeted IRS strategy. This cluster-randomised, open-label, non-inferiority trial compared reactive, targeted IRS with standard IRS practice in northeastern South Africa over two malaria seasons (2015-17). In standard IRS clusters, programme

managers conducted annual mass spray campaigns prioritising areas using historical data, expert opinion, and other factors. In targeted IRS clusters, only houses of index cases (identified through passive surveillance) and their immediate neighbours were sprayed. The non-inferiority margin was 1 case per 1000 person-years. Health service costs of real-world implementation were modelled from primary and secondary data. Incremental costs per disability-adjusted life-year (DALY) were estimated and deterministic and probabilistic sensitivity analyses conducted. Malaria incidence was 0.95 per 1000 person-years (95% CI 0.58 to 1.32) in the standard IRS group and 1.05 per 1000 person-years (0.72 to 1.38) in the targeted IRS group, corresponding to a rate difference of 0.10 per 1000 person-years (-0.38 to 0.59), demonstrating non-inferiority for targeted IRS. Per additional DALY incurred, targeted IRS saved US\$7845 (2902 to 64 907), giving a 94-98% probability that switching to targeted IRS would be cost-effective relative to plausible cost-effectiveness thresholds for South Africa (\$2637 to \$3557 per DALY averted). Depending on the threshold used, targeted IRS would remain cost-effective at incidences of less than 2.0-2.7 per 1000 person-years. Findings were robust to plausible variation in other parameters. Targeted IRS was non-inferior, safe, less costly, and cost-effective compared with standard IRS in this very-low-transmission setting. Saved resources could be reallocated to other malaria control and elimination activities.

<sup>1</sup>Malaria Research and Training Centre, Faculty of Pharmacy and Faculty of Medicine and Dentistry, University of Sciences Techniques and Technologies of Bamako, Bamako, Mali, <sup>2</sup>Department of Infection Biology, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Department of Medical Microbiology and Radboud Center for Infectious Diseases, Radboud University Medical Center, University of Nijmegen, Nijmegen, Netherlands, <sup>4</sup>Department of Pharmacy and Radboud Center for Infectious Diseases, Radboud University Medical Center, University of Nijmegen, Nijmegen, Netherlands, <sup>5</sup>MRC International Statistics and Epidemiology Group, London School of Hygiene & Tropical Medicine, London, United Kingdom

Achieving malaria elimination may depend on the transmission-blocking capabilities of anti-malarial drugs. The World Health Organization (WHO) recommends that a single low dose (SLD) of primaquine (PQ) be added to artemisinin combination therapy (ACT) to reduce *P. falciparum* transmission. The transmission blocking efficacy of ACTs alone is unclear. We aimed to determine i) the effectiveness of pyronaridine-artesunate (PA) and dihydroartemisinin-piperazine (DP) with and without 0.25mg/kg PQ for reducing transmission to mosquitoes, and ii) the detectability of gametocyte derived HRP2 protein following treatment. We conducted a four-arm, single-blind, randomised clinical trial at the Ouelessebougu Clinical Research Unit of the Malaria Research and Training Centre (MRTC) of the University of Bamako, Mali. Participants were male and non-pregnant females aged 5-50 years with asymptomatic *P. falciparum* mono-infection and gametocyte carriage (n=100). Allocation to four treatment groups (PA, PA+PQ, DP, and DP+PQ) was randomised in a 1:1:1:1 ratio. Individuals were followed for up to 49 days post-treatment with regular blood sampling and mosquito feeding assays. Before treatment, 66% (66/100) of individuals were infectious to mosquitoes, infecting an average of 15.8% mosquitoes (IQR 5.41-31.94). In infectious individuals the median percent reduction in mosquito infection rate after 48 hours

was 100% (IQR 100-100) in the PA+PQ (n=18) and DP+PQ (n=15), arms, compared to -8.7% (IQR -54.8-93.2) and 50.4% (IQR 13.8-70.9) in the PA (n=17) and DP arms (n=16) respectively. Individuals continued to infect mosquitoes up to 28 days after PA and DP treatment without PQ. Gametocyte density measures, sex ratio, and the detectability of PfHRP2 protein by standard RDT, ultra-sensitive RDT (uRDT), and quantitative assays were also analysed. Our data strongly support the use of SLD PQ as an effective supplement to PA for blocking *P. falciparum* transmission, may have implications for uRDT based parasite surveillance, and are of immediate relevance to areas aiming to eliminate malaria or constrain the spread of drug resistant parasites strains.

Botswana reoriented its malaria program towards elimination in 2010. Between 2013 and 2016, 78% of the 1532 locally infected cases were focalized within three districts in Northern Botswana. However, the surveillance system had gaps that hindered a full understanding of the geographic limits and drivers of transmission. To address these surveillance gaps, the National Malaria Programme (NMP) and Clinton Health Access Initiative (CHAI) conducted a household parasite survey comprising 7459 individuals from 5503 households during the peak transmission season from February to April 2018 in Okavango, Ngami and Chobe districts. In each household, a structured questionnaire was administered and two individuals (one >5 years and one ≤5 years of age) were randomly selected to receive a malaria Rapid Diagnostic Test (RDT), and provide blood spots on filter paper for quantitative polymerase chain reaction (qPCR) and ELISA serology testing. Out of the 7227 samples, only five (0.07%) tested positive by RDT, four of which were confirmed to be positive by qPCR. Three additional low-level infections were detected by qPCR. Preliminary serology results indicate that 954/7227 (13%) participant samples were seropositive based on a cutoff determined by a finite mixture regression model. Controlling for age and vector control, unemployed individuals were significantly less likely to be seronegative than those who reported working in agriculture or forestry (OR=0.37, p=0.002). Overall, only 33 out of 1721 (<2%) of the under 5 year old participants were seropositive, with 4% with moderate antibody response (>0.5 OD), suggesting low recent infections. Both qPCR positives and recent past infections were focalized to areas where the surveillance system also detected relatively high local cases and confirmed findings from routine data that cases declined over time and that farmers have the most exposure. These similarities indicate that the surveillance system is strong enough to inform malaria elimination. The results of the survey are being used to target health promotion activities to at-risk groups, and to improve targeting and uptake of vector control.

<sup>1</sup>SADC Malaria Elimination 8, Windhoek, Namibia, <sup>2</sup>University of California, San Francisco, San Francisco, CA, United States, <sup>3</sup>Angola National Malaria Programme, Luanda, Angola, <sup>4</sup>University of Botswana, Gaborone, Botswana, <sup>5</sup>Centro de Investigação em Saúde de Manhiça, Mozambique, <sup>6</sup>Manhica, Mozambique, <sup>7</sup>University of Namibia, Windhoek, Namibia, <sup>8</sup>South Africa Medical Research Council, Cape Town, South Africa, <sup>9</sup>National Institute for Communicable Diseases, Johannesburg, South Africa, <sup>10</sup>Zambia National Malaria Programme, Lusaka, Zambia, <sup>11</sup>Zimbabwe National Malaria Programme, Harare, Zimbabwe

The SADC Malaria Elimination Eight (E8) is a coordinated, eight-country initiative in Southern Africa aiming to achieve malaria elimination by 2030. Countries that have reduced malaria to low levels face the challenge of persistent importation from neighbouring countries with higher rates of malaria infection. In 2017, the E8, in collaboration with National Malaria Control Programs (NMCPs) established 46 border health facilities on 5 key international borders between E8 countries. These services aimed to improve access to timely diagnosis and treatment of malaria for border communities and mobile and migrant populations (MMPs) who frequently cross the border. To evaluate the impact of these facilities, a quasi-experimental, non-randomized, matched comparison of seven pairs of sites (intervention and control) in was conducted in the four low-burden, so-called frontline countries. In second-line countries, cross-sectional surveys of border residents living near border post were carried out. Studies in second-line countries were descriptive and showed that there were reasonably high levels (>70%) of timely treatment-seeking and access to diagnosis when experiencing fever and that all those who did test positive for malaria reported receiving treatment. However, up to 40% in some settings did not receive a blood test when experiencing fever. Residents reported good access to healthcare in terms of distance and time to facility. Although residents reported access to IRS and LLINs, a proportion of households did not own any nets, even in sites where this was the primary form of vector control. Knowledge about malaria symptoms and prevention was high and bed nets were overwhelmingly regarded as an effective method of preventing malaria. Border residents travelled frequently both within their own country and across borders; sometimes to seek healthcare. Results identified a gap in the provision of malaria prevention for travelers who often slept outside whilst travelling without any protection against mosquitoes. Studies in front line countries will provide an analytical comparison between intervention and control sites.

Despite intense study, yellow fever (YF) is poorly understood in humans. Previous studies reinforced the occurrence of late-relapsing hepatitis as a possible late clinical manifestation of YF, with the persistence of symptoms (fatigue, weakness, and jaundice) and slightly abnormal levels of liver and renal injury markers. During the YF 2017-2018 outbreak in Brazil, 302 confirmed YF cases were admitted to Hospital Eduardo de Menezes (HEM), Belo Horizonte, Brazil. Following discharge, patients were advised to return at 15-, 30-, 45- and 60-days post symptom onset (DPS) for clinical and laboratory examination and serum sample collection. For the first two visits, the patients presented with normal or slightly elevated liver and renal enzymes and did not report any signs or symptoms related to YF. However, from 30 up to 60 DPS, 12% of patients (n=38) exhibited a rebound of elevated transaminase (>500IU/L) and bilirubin levels. The patients showed general clinical worsening: a majority reporting myalgia (92%), arthralgia (92%), weakness (61%), headache (24%), and jaundice (24%). Eight patients needed to be re-hospitalized. Serum samples collected during follow-up were tested by RT-qPCR and were all negative. Other etiologies of hepatitis were ruled out by PCR or serology, including dengue, Zika, chikungunya, hepatitis A, B, C, HIV, and other viruses that can cause hepatitis. Tests for autoimmune hepatitis were also performed and were negative. Univariate analysis of risk ratios did not identify any significant demographic, clinical, or image exams risk factors for late-relapsing hepatitis after YF (LHep-YF) present during the acute (inpatient) phase of YF. AST and ALT values during LHep-YF were higher in the group that presented this clinical picture than in the other group (P=0.003). These results provide new data on the clinical course of YF and highlight the need for extended patient follow-up. Further studies to investigate the viral persistence and immune responses causing LHep-YF are needed.

0846

#### **INFECTION WITH CHIKUNGUNYA VIRUS CONFERS CROSS-PROTECTIVE NEUTRALIZING ANTIBODIES AND MEMORY B-CELLS THAT REMAIN IN CIRCULATION FOR DECADES FOLLOWING NATURAL INFECTION IN BOTH ENDEMIC AND NON-ENDEMIC TRANSMISSION SETTINGS**

**Zoe L. Lyski<sup>1</sup>**, John M. Powers<sup>2</sup>, Chad D. Nix<sup>1</sup>, Brian Booty<sup>3</sup>, Luisa I. Alvarado<sup>4</sup>, Rachel M. Rodriguez<sup>4</sup>, Vanessa Rivera-Amill<sup>4</sup>, Daniel N. Streblow<sup>2</sup>, William B. Messer<sup>1</sup>

<sup>2</sup>Vaccine and Gene Therapy Institute, Oregon Health & Science University, Beaverton, OR, United States, <sup>3</sup>Oregon Clinical and Translational Research Institute (OCTRI), Portland, OR, United States, <sup>4</sup>Ponce Health Sciences University, Ponce, PR, United States

Chikungunya virus (CHIKV) a mosquito-borne alphavirus, is an important viral pathogen that causes acute febrile illness often with arthralgia than can persist for months to years, posing a significant public health risk. Here we describe the antibody-mediated immune response following CHIKV infection, upon which, naïve host B-cells expand, produce, and secrete CHIKV-specific antibodies (Abs) that recognize viral antigens, namely structural proteins E1 and E2. After viral clearance, some of these B-cells become long-lived plasma cells (LLPC) which constitutively secrete CHIKV-Abs, while others become CHIKV-specific memory B cells (MBCs) that remain in circulation, quiescent, but poised to respond and expand on repeat infection. This MBC "founder" population is expected to play a critical role in broader alphavirus immunity that is established following repeat exposure. Using a panel of 15 convalescent immune samples collected 1 to 24 years post infection from endemic (n=5) and non-endemic (n=7) subjects with suspected or confirmed CHIKV infection, 50% neutralization titers were determined against a panel of alphaviruses, including the Semliki Forest complex, CHIKV, Mayaro (MAYV), Ross River Virus (RRV), Una (UNAV) and Venezuelan Equine Encephalitis virus (VEEV), part of the VEEV complex. To determine MBC frequency, peripheral blood mononuclear cells (PBMCs) from CHIKV immune donors were evaluated by

limiting dilution assay, where PBMCs are serially diluted and stimulated to become Ab-secreting cells. The resulting Abs are assessed for homotypic and heterotypic-specificity by ELISA using whole CHIKV and MAYV. Using these approaches, we identified neutralizing Abs and long-lived MBCs with broad potency against members of the Semliki Forest complex, however cross-neutralization did not extend to the VEEV complex, suggesting that broadly protective Abs may be complex restricted. Subsequent experiments seek to identify the predominant epitope responsible for this cross protection in both LLPC and MBC populations. These results will provide insight into the MBC founder population following alphavirus infection.

0847

#### **LONG-TERM SEQUELAE OF CHIKUNGUNYA AMONG CHILDREN AND ADULTS IN MANAGUA, NICARAGUA, 2014-2018**

**Colin Warnes<sup>1</sup>**, Fausto A. Bustos Carrillo<sup>1</sup>, Brenda Lopez Mercado<sup>2</sup>, Sergio Ojeda<sup>2</sup>, Angel Balmaseda<sup>2</sup>, Guillermina Kuan<sup>3</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, <sup>2</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>3</sup>Centro de Salud Socrates Flores Vivas, Ministry of Health, Managua, Nicaragua

Chikungunya virus (CHIKV) infections cause debilitating arthritis in many symptomatic individuals, often presenting as acute, self-limited pain but occasionally manifesting as chronic arthralgia for months or years post-infection. Relatively little is known about pediatric chikungunya, how the disease differs between children and adults, and the relationship between longitudinal antibody titers and the risk of chronic arthralgia. To characterize the long-term sequelae of chikungunya, we recruited 782 patients (0-9 years old [y/o], 294; 10-15 y/o, 310; 16-21 y/o, 51; 22-35 y/o, 57; 35+ y/o, 53) with rRT-PCR-confirmed symptomatic CHIKV infections in Managua, Nicaragua, during two sequential chikungunya epidemics (2014, 2015). Participants were followed up at 15 days and 1, 3, 6, 12, and 18 months post-illness, and we analyzed longitudinal clinical data from 2014 to 2018. Participants were tested for anti-CHIKV IgM antibodies, and anti-CHIKV antibody titers of pediatric patients were measured annually by CHIKV inhibition ELISA (iELISA). Multivariable analysis indicated that individuals 35+ y/o had the highest odds of pain, relative to the baseline group of ages 10-15 (odds ratio (OR) 7.5, 95% CI: 4.6-12.3, p-value <0.001), and males had lower odds of pain than females (OR 0.6, 0.5-0.9, p-value = 0.004). For both children and adults, pain was most commonly localized in the legs (29.2%), followed by hands (22.5%) and torso (14.4%). Compared to the 10-15 y/o group, 0-9 y/o children had significantly lower odds of wrist pain (OR 0.5, 0.3-0.8, p-value = 0.006) while patients 15+ y/o had significantly higher odds of pain. Individuals younger than 15 years had a higher prevalence of chronic (>3 months) than acute (6 days-3 months) pain; the opposite trend was observed among adults. Further, we observed that higher iELISA antibody titers and positive convalescent IgM tests correlated with a higher risk of arthralgia, suggesting a potential relationship between antibody titer levels and disease severity. In sum, differences in the presentation of pain were observed across age, sex, and antibody titers in our longitudinal chikungunya cohort.

0848

#### **CHIKUNGUNYA: PHASE 3 CLINICAL DEVELOPMENT OF A SINGLE-SHOT LIVE-ATTENUATED VACCINE**

**Juan-Carlos Jaramillo**, Martina Schneider, Marivic Narciso, Romana Hochreiter, Annegret Bitzer, Robert Mader, Katrin Dubischar, Oliver Zoihs, Nina Wressnigg, Susanne Eder-Lingelbach Valneva Austria GMBH, Vienna, Austria

Chikungunya is a mosquito-transmitted outbreak disease with potentially debilitating consequences and no available causative treatments or preventative vaccines. VLA1553 is a live-attenuated chikungunya virus (CHIKV) vaccine candidate designed for active immunization as a

prophylactic measure for travelers to endemic areas or areas at risk for an upcoming outbreak, as well as for the general population living in endemic regions. A double-blinded, multicenter randomized, pivotal phase 3 study enrolling approximately 4,060 adult volunteers randomized in a 3:1 ratio to receive the live-attenuated CHIKV vaccine candidate VLA1553 or placebo is currently ongoing (NCT04546724). VLA1553 or placebo were administered as a single intramuscular immunization. The primary objective of the study is to evaluate the immunogenicity and safety of VLA1553 28 days after immunization. Subjects in this study were stratified into two age strata from 18 to 64 years and 65 years of age or above. Immunogenicity evaluations include the seroprotection rate as primary endpoint. This seroprotection rate is based on neutralizing CHIKV antibody titers higher than a surrogate threshold of protection agreed with the FDA. To date, recruitment is completed and 4,131 volunteers have been vaccinated. The study is progressing and primary endpoint analysis on immunogenicity up to Day 29 will be available mid 2021.

0849

### LONG-TERM SAFETY AND IMMUNOGENICITY OF CHIKUNGUNYA VIRUS-LIKE PARTICLE VACCINE IN CHIKUNGUNYA SEROPOSITIVE INDIVIDUALS

Roshan Ramanathan<sup>1</sup>, Julie Ledgerwood<sup>2</sup>, Emily Coates<sup>2</sup>, Jason Mendy<sup>1</sup>, Lisa Bedell<sup>1</sup>, Jason Richardson<sup>1</sup>, Ranjini Prithviraj<sup>1</sup>, Sarah Royalty Tredo<sup>1</sup>, Kelly L. Warfield<sup>1</sup>, Chris Cabell<sup>1</sup>

<sup>1</sup>Emergent BioSolutions, Gaithersburg, MD, United States, <sup>2</sup>Vaccine Research Center, NIAID, NIH, Bethesda, MD, United States

Chikungunya virus (CHIKV) causes acute febrile illness accompanied by debilitating joint pain that may progress to chronic manifestations including arthralgia. Since outbreaks on the Indian subcontinent in 2005 and 2006, the geographic distribution of CHIKV has expanded to >100 countries. A safe, effective vaccine with durable protection against chikungunya disease is urgently needed. The long-term safety and immunogenicity of an investigational chikungunya virus-like particle (CHIKV VLP) vaccine in individuals with pre-existing CHIKV immunity who live in CHIKV-endemic areas is unknown. VRC704 was a multi-center, randomized, placebo-controlled, double-blind Phase 2 study to evaluate the safety and immunogenicity of a two-dose regimen of CHIKV VLP vaccine (CHKVLP059; 20 µg CHIKV VLP administered by intramuscular injection 28 days apart) in healthy adults 18-60 years of age in the Caribbean (N=400). Study criteria required that subjects were seronegative. Despite screening negative via IgG/IgM ELISA at the time of inclusion, 39 CHIKV VLP vaccine and 43 placebo recipients from sites in Haiti and the Dominican Republic were retrospectively found to have pre-vaccination CHIKV neutralizing antibodies at the time of enrollment. This study is a post-hoc analysis comparing the safety and immunogenicity of CHIKV VLP vaccine to placebo in these seropositive subjects for 72 weeks post-vaccination. Two CHIKV VLP vaccine recipients and one placebo recipient had serious adverse events (SAEs) during the 72-week follow-up period which were considered unrelated to vaccination. Unsolicited AEs were monitored for 4 weeks after each dose; no difference was seen between the CHIKV VLP vaccine and placebo groups. Baseline seropositive vaccine recipients had a geometric mean titer (GMT) of approximately 2000 at baseline with 3.7 and 4.2 geometric mean fold rises (GMFR) at 4 weeks after the first dose and 12 weeks after the second dose, respectively. The GMFR remained >3 for 72 weeks post-vaccination. These data support further evaluation of long-term safety and immunogenicity of the CHIKV VLP vaccine in individuals with pre-existing immunity to CHIKV.

0850

### MODELING THE KINETICS AND DURABILITY OF THE HUMORAL RESPONSE TO A CHIKUNGUNYA VIRUS-LIKE PARTICLE VACCINE

Steven Stoddard<sup>1</sup>, Lisa Bedell<sup>1</sup>, Jason Richardson<sup>1</sup>, Jason Mendy<sup>1</sup>, Spencer Stonier<sup>1</sup>, Stefan Metz<sup>1</sup>, Lo Vang<sup>1</sup>, Ravi Anantha<sup>1</sup>, James McCarty<sup>2</sup>, Sanduli Fernando<sup>1</sup>, Ranjini Prithviraj<sup>1</sup>, Roshan Ramanathan<sup>1</sup>

<sup>1</sup>Emergent BioSolutions, Gaithersburg, MD, United States, <sup>2</sup>Stanford University, Stanford, CA, United States

Chikungunya is a globally recognized infectious disease transmitted by *Aedes* mosquitoes. It causes disruptive epidemics of febrile illness characterized by acute symptoms such as incapacitating joint pain. Long-term chronic symptoms including arthralgia are common. Using data from two Phase 2 immunogenicity studies in populations based in the United States and Caribbean, we model antibody levels after immunization with a chikungunya virus-like particle (VLP) vaccine to characterize kinetics and duration of the humoral immune response. Depending on the study, blood samples were taken at roughly weekly intervals through Week 8 and at additional timepoints through 2 years post-immunization. Neutralizing antibody titers were determined using a luciferase-based virus neutralization assay and measured with a stringent 80% cutoff (NT<sub>80</sub>). We use time series analyses to evaluate variability in the magnitude of the neutralizing response, and mechanistic modeling to estimate parameters associated with the humoral immune response and to estimate the long-term durability of antibodies. Neutralizing antibody titers were available from 528 study participants receiving at least one dose of vaccine. The induced neutralizing antibody response was rapid, with up to 80% of study participants mounting at least a 4-fold rise in neutralizing antibody titers by 1 week, and 89-100% by 3 weeks post-immunization. Antibody titers subsided by week 26 but stabilized ≥4-fold above baseline in ~80-90% of vaccinees through 104 weeks of follow-up. There was a ~6% drop in geometric mean titer (GMT) between weeks 78 and 104. The magnitude of response varied by dose and dosing regimen, though kinetics remained similar. A single alum-adsjuvanted dose induced a >80% rise in >80% of recipients by 1 week and the highest neutralizing antibody response at 26 weeks. The rapid immune response after a single dose of the VLP vaccine would support its utility for travelers to chikungunya affected regions and outbreak response. Ongoing modeling will further characterize the long-term antibody dynamics to estimate the duration of immunity and the timing of revaccination.

### SCALE UP OF JAPANESE ENCEPHALITIS VACCINATION IN IMMUNIZATION PROGRAM OF BIHAR AMIDST COVID-19 PANDEMIC IN 2020 IN INDIA, THROUGH EFFECTIVE PARTNERSHIPS

Dr. Satyabrata Routray<sup>1</sup>, Dr. Padmalochan Biswal<sup>1</sup>, Dr. Siddhartha Dutta<sup>2</sup>, Dr. NK Sinha<sup>3</sup>, Shyamashree Das<sup>4</sup>

<sup>1</sup>PATH, New Delhi, India, <sup>2</sup>PATH, Patna, India, <sup>3</sup>Govt. of Bihar, Patna, India, <sup>4</sup>BMGF, New Delhi, India

Bihar which is the third populous State of India has been witnessing Japanese Encephalitis outbreaks regularly since 2005. The most effective immunization strategy implemented in JE endemic areas is a one-time campaign targeting children (1-15 years), followed by integration of JE vaccine into routine immunization program, for the new cohort. In late 2019, decision was taken by Bihar state to undertake JE vaccination campaign in 14 newly identified JE endemic districts in State and PATH was envisaged to provide technical assistance in planning and implementation of these campaigns to the government. JE vaccination campaign launched in January 2020 in two districts initially, was staggered due to COVID-19 pandemic. Campaign was resumed in a phased manner in other 9 districts from June 2020. PATH with support from Bill & Melinda Gates Foundation provided technical assistance to state Govt. at multiple levels, in training 262 medical officers and ~ 24,000 health workers via online platform and

classroom sessions, maintaining COVID appropriate safety protocols. In the backdrop of school shut down due to pandemic, leveraged routine immunization platform for mobilizing eligible children for JE vaccination. Over the next few months due to worsening pandemic situation, affecting health workers and burdening the health system, progress of JE campaign was hindered. Coverage achieved was 73% by November 2020, that was ramped-up, through special staggered initiatives under state program officer, supported by PATH project team. Initiatives like prioritization of low performing pockets, line-listing of unvaccinated children, liaising with related government departments (e.g., education, social welfare and rural development) were adopted to accelerate mobilization of eligible children to nearest vaccination sites. Vaccination campaign in 11 districts was completed in January 2021 with net coverage of >90 % where > 9 MM children were vaccinated alongside COVID response, underway. Effective coordination, close collaboration with all partners and stakeholders and using RI platform has helped in achieving the desired JE Vaccination coverage.

### ROLE OF PLASMODIUM FALCIPARUM KELCH 13 PROTEIN MUTATIONS AND FALCIPAIN 2A HAPLOTYPES IN ARTEMISININ RESISTANCE

Faiza Siddiqui<sup>1</sup>, Rachasak Boonhok<sup>1</sup>, Mynthia Cabrera<sup>2</sup>, Huguette Gaelle Ngassa Mbenda<sup>1</sup>, Meilian Wang<sup>3</sup>, Hui Min<sup>1</sup>, Xiaoying Liang<sup>1</sup>, Junling Qin<sup>1</sup>, Xiaotong Zhu<sup>3</sup>, Jun Miao<sup>1</sup>, Yaming Cao<sup>3</sup>, Liwang Cui<sup>1</sup>

Mutations in the *Plasmodium falciparum* Kelch 13 (PfK13) protein are associated with artemisinin resistance. PfK13 is essential for asexual erythrocytic development, but its function is not known. We tagged the PfK13 protein with green fluorescent protein in *P. falciparum* to study its expression and localization in asexual and sexual stages. We used a new antibody against PfK13 to show that the PfK13 protein is expressed ubiquitously in both asexual erythrocytic stages and gametocytes and is localized in punctate structures, partially overlapping an endoplasmic reticulum marker. We introduced into the 3D7 strain four PfK13 mutations (F446I, N458Y, C469Y, and F495L) identified in parasites from the China-Myanmar border area and characterized the *in vitro* artemisinin response phenotypes of the mutants. We found that all the parasites with the introduced PfK13 mutations showed higher survival rates in the ring-stage survival assay (RSA) than the wild-type (WT) control, but only parasites with N458Y displayed a significantly higher RSA value (26.3%) than the WT control. After these PfK13 mutations were reverted back to the WT in field parasite isolates, all revertant parasites except those with the C469Y mutation showed significantly lower RSA values than their respective parental isolates. Although the 3D7 parasites with introduced F446I, the predominant PfK13 mutation in northern Myanmar, did not show significantly higher RSA values than the WT, they had prolonged ring-stage development and showed very little fitness cost in *in vitro* culture competition assays. In comparison, parasites with the N458Y mutations also had a prolonged ring stage and showed upregulated resistance pathways in response to artemisinin, but this mutation produced a significant fitness cost, potentially leading to their lower prevalence in the Greater Mekong subregion.

0853

### THE IMPORTANCE OF THE PARASITE PROTEASOME IN ARTEMISININ RESPONSE

Melissa Rosenthal, Caroline Ng

University of Nebraska Medical Center, Omaha, NE, United States

Artemisinin (ART)-based combination therapies (ACTs), the recommended first-line treatment for *falciparum* malaria, are largely responsible for the nearly 50% decline in malaria-related deaths in the last two decades. Alarming, resistance to ACTs is widespread in Southeast Asia (SEA), and

has been detected in greater Asia, Africa, and South America. The most prevalent ART-resistance conferring kelch 13 (K13) haplotype in SEA is C580Y. ART causes widespread protein damage in parasites, resulting in accumulation of ubiquitinated proteins which are then degraded by the parasite proteasome. We hypothesized that the proteasome is critical for parasite ART-response and mutations that decrease proteasome catalytic activity reduce the ability of parasites to recover following ART-induced protein damage. We have previously generated  $\beta 2$  and  $\beta 5$  proteasome mutants in Cam3.11 strain parasites of Cambodian origin that express K13<sup>C580Y</sup>. In response to dihydroartemisinin (DHA), these proteasome mutants exhibit decreased  $\beta 2$  and  $\beta 5$  catalytic activity. In addition, relative to their parent, DHA-treated  $\beta 2$  proteasome mutants display increased accumulation of K48-linked ubiquitinated polypeptides and increased activation of the unfolded protein response, signifying a reduced capacity to restore proteostasis. Lastly, we observe that  $\beta 2$  proteasome mutants display increased sensitivity to DHA and the related endoperoxide OZ439. This increase in sensitivity was observed not only at early ring stages, where ART resistance is classically observed, but also at trophozoite stages and in asynchronous cultures. The sensitivity throughout the intraerythrocytic development is likely due to the necessity of the parasite proteasome throughout its lifecycle. These data demonstrate the importance of the parasite proteasome in response to endoperoxides.

### ASSESSING FEASIBILITY OF A STRATEGY DEPLOYING MULTIPLE FIRST-LINES ARTEMISININ-BASED COMBINATION THERAPIES FOR UNCOMPLICATED MALARIA IN THE HEALTH DISTRICT OF KAYA, BURKINA FASO

Jean Moïse Tanga Kabore<sup>1</sup>, Mahamadou Siribié<sup>1</sup>, Denise Hien<sup>1</sup>, Issiaka Soulama<sup>1</sup>, Yacouba Nombre<sup>1</sup>, Frederic Dianda<sup>2</sup>, Benjamin Sombié<sup>1</sup>, Nouhoun Barry<sup>1</sup>, Gauthier Tougri<sup>2</sup>, Adama Baguïya<sup>3</sup>, B. Alfred Tiono<sup>1</sup>, Christian Burri<sup>4</sup>, André-Marie Tchouatié<sup>5</sup>, Sodiomon Bienvenu Sirima<sup>1</sup>

<sup>1</sup>Groupe de Recherche Action en Santé (GRAS), Ouagadougou, Burkina Faso, <sup>2</sup>Programme National de Lutte contre le Paludisme, Ministère de la Santé, Ouagadougou, Burkina Faso, <sup>3</sup>Institut de Recherche en Sciences de la Santé, Ouagadougou, Burkina Faso, <sup>4</sup>Swiss Tropical & Public Health Institute, Basel, Switzerland, <sup>5</sup>Medicines for Malaria Venture (MMV), Geneva, Switzerland

The emergence and spread of resistance to artemisinin derivatives is a serious threat to malaria control. Thus, the development of new strategies to rapidly mitigate this threat is crucial. This study aimed at assessing for the first time in a structured way, the feasibility of deploying simultaneously three artemisinin-based combination therapies (ACTs) at health facility (HF) level for the management of uncomplicated malaria cases in Burkina Faso, with the hypothesis that this strategy is feasible and can be successfully managed by health workers (HWs). For this pilot, the MFT strategy consisted of segmenting the populations in three groups and allocating one ACT to each. Malaria patients under 5 years received pyronaridine-artesunate, 5 years and above, dihydroartemisinin-piperazine, and pregnant women, artemether-lumefantrine (AL), respectively at HF level. The community case management of malaria continued with no change using AL. Over 12 months from December 2019 to December 2020, MFT was deployed in 40 public primary HF of Kaya health district. All HWs (278) and drug store managers (50) were trained before initiating the deployment of MFT. A monitoring plan was implemented. HF-based survey, interviews (27) and focus group discussions (10) were carried out as part of the evaluation of MFT deployment. 182,247 and 4,955 malaria cases were seen at HF and community level respectively and treated with ACTs. No serious adverse drug reaction was reported. Of the 2018 suspected malaria cases randomly selected at HF level for records review, 44.8% and 4.7% of the cases were under 5 and pregnant women, respectively. 78.8% were tested for malaria and 98.3% of positive tests were treated. 81.9% of patients were assigned the correct treatment for their segment ( $p=0.002$ ). The overall HWs compliance level was 73.2 % and was associated with segments of the population ( $p<0.001$ ). Participants interviewed had a good knowledge

of the MFT implementation strategy and a favorable opinion. The pilot study showed that implementing a MFT strategy is operationally feasible and well accepted by the HWs. The scale-up of this MFT strategy could be considered.

0855

### MEASURING GROWTH, RESISTANCE, AND RECOVERY AFTER ARTEMISININ TREATMENT IN A SINGLE SEMI-HIGH-THROUGHPUT ASSAY

**Mackenzie A. Sievert**<sup>1</sup>, Douglas A. Shoue<sup>1</sup>, Lisa A. Checkley<sup>1</sup>, Puspendra S. Singh<sup>1</sup>, Katelyn M. Vendrely<sup>1</sup>, Zion Cassady<sup>1</sup>, Marina McDew-White<sup>2</sup>, François H. Nosten<sup>3</sup>, Timothy J. Anderson<sup>2</sup>, Michael T. Ferdig<sup>1</sup>

<sup>1</sup>Eck Institute for Global Health, University of Notre Dame, South Bend, IN, United States, <sup>2</sup>Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>3</sup>Centre for Tropical Medicine and Global Health, University of Oxford, Oxford, United Kingdom

Artemisinin (ART) resistance has spread throughout Southeast Asia and mutations in Kelch13, the molecular marker of ART resistance, have been identified in Africa. Effective *in vitro* assays for resistance are crucial for monitoring populations for the emergence and spread of resistance around the world. The Ring Stage Assay (RSA) is a time consuming and labor-intensive *in vitro* measure of resistance. Previously, we developed a modified RSA that improved correlation with patient clearance half-life and significantly reduced experimental noise and the labor intensiveness of RSA. This also allowed the higher throughput needed to quickly phenotype large numbers of parasites in less time. Here we report an extension and refinement of this assay to include measurements of parasite growth and parasite recovery after treatment with ART or other drugs. Growth is assayed by parasite multiplication rate using untreated control samples at 6h post-treatment and 96h post-treatment. Growth measures can reveal fitness defects and illuminate relationships between proliferation rates and drug resistance. Resistance is inferred at 120h as a differential between treated and untreated parasites in our assay; this is then combined with an additional 192h post-treatment sample to generate a recovery profile. This serves as a novel and complementary phenotype to resistance that quantifies a parasite's ability to tolerate drug exposure, a hallmark of parasite response to ART. Recovery from drug is a crucial step to evolving high level drug resistance. This trio of readouts offer a more comprehensive phenotypic assessment of clinical isolates and parasite progeny populations for the effects of ART, piperazine and other drugs.

### THE PLASMODIUM FALCIPARUM ELONGATION FACTOR 2 INHIBITOR M5717 IS EFFICACIOUS AGAINST MALARIA LIVER STAGE: A CONTROLLED LIVER-STAGE MALARIA INFECTION STUDY IN HEALTHY SUBJECTS

Vincent Kuiper<sup>1</sup>, Johan van de Plas<sup>2</sup>, Oezkan Yalkinoglu<sup>3</sup>, Aliona Tappert<sup>3</sup>, Xiaoyan Yin<sup>4</sup>, Deon Bezuidenhout<sup>3</sup>, Akash Khandelwal<sup>3</sup>, Justin Wilkins<sup>5</sup>, Ingrid Kamerling<sup>2</sup>, Meta Roestenberg<sup>1</sup>, Claude Oeuvray<sup>3</sup>, **Wilhelmina Bagchus**<sup>3</sup>

<sup>1</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Centre for Human Drug Research, Leiden, Netherlands, <sup>3</sup>Merck KGaA, Darmstadt, Germany, <sup>4</sup>EMD Serono, Boston, MA, United States, <sup>5</sup>Occams, Amsterdam, Netherlands

M5717 is an anti-malaria compound targeting PeEF2 and is *in vitro* equipotently active against all stages of the parasite. As such, M5717 has the potential to be developed in combination as single dose treatment for chemoprevention for malaria. M5717 was well tolerated up to a dose of 1800 mg in a previous Phase I single dose ascending study (SAD) and demonstrated anti-malarial activity in a blood stage controlled human malaria infection model. Now a Phase Ib, randomized, double blind, sequential, adaptive dose-finding study was performed in healthy male and female volunteers to evaluate the chemoprophylactic effect and

define an exposure-response relationship. Each participant was inoculated with 3200 sporozoites by direct venous inoculation and treated with M5717/placebo administered as an oral suspension two hours later. Blood parasitemia was measured by qPCR on a regular basis until reaching a threshold of  $\geq 100$  asexual Pf/mL, when subjects were treated with rescue medication (atovaquone/proguanil). PCR negative subjects received rescue medication at Day 28 after inoculation. The study included several cohorts and each cohort consisted of 1 to 3 groups of 4 subjects, of which 3 received M5717 free base and 1 received placebo. The first cohort included one group at the protocol defined dose of 200 mg. The dose and the number of groups in the subsequent cohorts were decided by a safety monitoring committee based on observed efficacy, pharmacokinetic (PK) parameters and variability. The initial cohorts followed a dose de-escalation pattern and the effect of doses ranging from 200 to 30 mg was evaluated. M5717 was well tolerated and the safety profile confirmed the data from the SAD study. Preliminary data showed that M5717 can provide full protection against malaria. PK evaluations will be performed to define the relevant parameter predicting liver stage efficacy. All together the data warrant further development of M5717 as part of a chemoprevention combination for malaria.

### A 2-PART STUDY TO EVALUATE THE ASEQUAL BLOOD STAGE ANTIMALARIAL ACTIVITY, AND THE TRANSMISSION BLOCKING ACTIVITY, OF A SINGLE ORAL DOSE OF TAFENOQUINE IN HEALTHY SUBJECTS EXPERIMENTALLY INFECTED WITH PLASMODIUM FALCIPARUM

**Bridget E. Barber**<sup>1</sup>, Rebecca Webster<sup>2</sup>, Louise Marquart<sup>2</sup>, Azrin Rahman<sup>2</sup>, Fiona Amante<sup>2</sup>, Hayley Mitchell<sup>2</sup>, Jeremy Gower<sup>2</sup>, Jenny Peters<sup>2</sup>, Juanita Heunis<sup>2</sup>, Helen Jennings<sup>2</sup>, Lynch Sean<sup>2</sup>, Pava Zuliema<sup>2</sup>, David Wesche<sup>3</sup>, Dennis Shanks<sup>4</sup>, Scott Miller<sup>5</sup>, James S. McCarthy<sup>6</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, ASHGROVE, Australia, <sup>2</sup>QIMR Berghofer Medical Research Institute, Herston, Australia, <sup>3</sup>Certara, Princeton, NJ, United States, <sup>4</sup>Australian Defence Force Malaria and Infectious Disease Institute, Enoggera, Australia, <sup>5</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States, <sup>6</sup>University of Melbourne, Parkville, Australia

Tafenoquine (TQ) is a long-acting 8-aminoquinolone that has activity against hepatic stage schizonts, and *Plasmodium vivax* hypnozoites, as well as less well-characterised activity against blood stage parasites and gametocytes. However, like primaquine, TQ causes haemolysis in G6PD deficient individuals when used at currently recommended doses, thereby limiting its use as a component of mass drug administration. To define the lowest effective dose of TQ, we have undertaken a 2-part study in healthy volunteers experimentally infected with blood-stage *P. falciparum* aiming to investigate the minimum single dose of TQ that would effectively clear blood-stage *P. falciparum* parasitemia (Part 1), and prevent transmission of *P. falciparum* to mosquitoes (Part 2). In Part 1, 4 participants were inoculated with *P. falciparum* and treated on day 8 with a single 300mg dose of TQ. Although parasite clearance occurred in all 4 participants, recrudescence parasitemia occurred in 3 (18, 26 and 28 days post TQ dosing) requiring treatment with artemether-lumefantrine (AL). Based on PK/PD modelling, in subsequent cohorts participants were treated with TQ 200mg (n=3), 400mg (n=2) or 600mg (n=3). None of the participants in the 200mg achieved complete parasite clearance, and all required treatment with AL. All participants in the 400mg or 600mg dose group achieved complete parasite clearance and did not recrudescence by day 46. PK/PD modelling is underway to define the PK/PD parameters necessary for prediction of the efficacious dose, and results will be presented. For part 2 of the study, participants will be inoculated with blood-stage *P. falciparum*, and treated on day 9 with piperazine to clear asexual parasitemia while allowing development of gametocytemia. TQ 50mg will be administered on day 24, with enriched membrane feeding assays conducted immediately before, and 1, 3 and 7 days post-TQ. The proportion of volunteers infective to mosquitoes (as measured by detection of oocysts and sporozoites) before and after TQ will be reported.

## ROSIGLITAZONE ADJUNCTIVE THERAPY FOR CHILDREN WITH SEVERE MALARIA

**Rosauro Varo<sup>1</sup>**, Valerie Crowley<sup>2</sup>, Antonio Siteo<sup>3</sup>, Marta Valente<sup>1</sup>, Sara Ajanovic<sup>1</sup>, Nuria Balanza<sup>1</sup>, Clara Erice<sup>2</sup>, Justina Bramugy<sup>3</sup>, Andrea Weckman<sup>2</sup>, Alfredo Mayor<sup>1</sup>, Kevin Kain<sup>2</sup>, Bassat Quique<sup>1</sup>

<sup>1</sup>Barcelona Institute for Global Health, Barcelona, Spain, <sup>2</sup>S. A. Rotman Laboratories, Sandra Rotman Centre for Global Health, University Health Network-Toronto General Hospital, Toronto, ON, Canada, <sup>3</sup>Centro de Investigação em Saúde de Manhiça, Manhiça, Mozambique

Despite the widespread use of effective anti-malarials, the case fatality rate of severe malaria (SM) remains unacceptably high. Adjunctive therapies that target the host response to malaria infection may decrease mortality over that of anti-malarial agents alone. Rosiglitazone, a peroxisome proliferator-activated receptor-gamma agonist, has been shown to act on pathways implicated in the pathogenesis of SM including reducing inflammation and enhancing endothelial stability, as determined by decreased levels of angiopoietin-2, a surrogate marker of malaria severity and mortality. To test the hypothesis that rosiglitazone plus IV artesunate would improve outcome in SM over IV artesunate alone, we conducted a randomized, double-blind placebo-controlled trial in a rural hospital in Manhiça, southern Mozambique. The primary objective was to determine whether supplemental rosiglitazone (0.045mg/kg/dose) twice daily for 4 days, in addition to standard of care anti-malarial treatment (IV artesunate), accelerates the rate of decline in angiopoietin-2 from admission levels in children with severe malaria compared to standard of care anti-malarial treatment plus placebo. We have previously determined the safety and tolerability of rosiglitazone in children with uncomplicated malaria before proceeding to examine its efficacy in children with SM. Children with SM were enrolled between March 2016 and December 2019. We screened 203 children for eligibility and 180 children were enrolled: 91 children were assigned to rosiglitazone and 89 to placebo (all received parenteral artesunate). 85 were females (47.2%) and 95 were males (52.8%). 141 out of 180 were younger than 5 years (78.3%) and 39 out of 180 were older than 5 years (21.6%). Secondary objectives included: comparing clinical outcomes between groups and quantifying the change in levels of biomarkers of disease severity and host response associated with endothelial activation, inflammation, coagulopathy, and neuro-protection. Analysis of primary and secondary objectives is currently underway. We will present the results of this adjunctive

0859

## EXPLORING COVID-19 DISEASE BURDEN THROUGH SEWAGE AND DRAINAGE SYSTEM OF DHAKA CITY, BANGLADESH

**Md Ziaur Rahman<sup>1</sup>**, Nuhu Amin<sup>1</sup>, Rehnuma Haque<sup>1</sup>, Golam Bashir Ahmed<sup>1</sup>, Mohammed Ziaur Rahman<sup>1</sup>, Zahid Hayat Mahmud<sup>1</sup>, Rezaul Hasan<sup>1</sup>, Nargis Akter<sup>2</sup>, Dara Johnston<sup>2</sup>, Md Alamgir Hossain<sup>3</sup>, MD Tahmidul Islam<sup>4</sup>, Christine L. Moe<sup>5</sup>, Mahbubur Rahman<sup>1</sup>, Prosun Bhattacharya<sup>4</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Water, Sanitation & Hygiene (WASH) section, UNICEF, Dhaka, Bangladesh, <sup>3</sup>Dhaka Water Supply & Sewerage Authority (DWASA), Dhaka, Bangladesh, <sup>4</sup>KTH Royal Institute of Technology, Stockholm, Sweden, <sup>5</sup>Rollins School of Public Health, Emory University, Atlanta, GA, United States

SARS-CoV-2 virus, the causative agent of COVID-19, is excreted in stool of both symptomatic and asymptomatic cases, and SARS-CoV-2 RNA can be detected in wastewater samples from the sewer system. Therefore, the concentration of SARS-CoV-2 RNA in wastewater can be used as a predictor of COVID-19 infection in specific catchment areas using wastewater-based epidemiology. Sewage lifting stations (SLS) and sewage treatment plants (STP) are important infrastructural components of the municipal sewage network of Dhaka city and are responsible for wastewater management for 20-25% of the population. Additionally, storm sewage pumping stations (SSPS) are a major part of the drainage

system where both SLS and SSPS receive wastewater and grey water from the community and pump them towards the STP and river. We conducted a cross-sectional study from October 2020 to April 2021 on 14 active SLS, four SSPS, and the STP of Dhaka city to explore developing an early warning system using SARS-CoV-2 viral load in wastewater to indicate trends in COVID-19 confirmed clinical cases through a wastewater surveillance system. A total of 42 sewage and drainage samples (28 SLS, 4 SSPS, 5 STP inlets and 5 STP outlets) were analyzed and quantified by RT-PCR. Overall, 48% (20/42) of samples were positive for SARS-CoV-2 RNA: 54% (15/28) of SLS samples, 75% (3/4) of SSPS samples, and 40% (2/5) of samples from the STP inlet were positive. The highest concentration of SARS-CoV-2 genome equivalent copies (GEC) were detected in SSPS samples [median=111 GEC/mL (range=47-482)]. Median viral load in SLS samples was 70 GEC/mL (range=12-140), and 25 GEC/mL (range=15-45) in STP samples. Pearson's correlation coefficient analysis suggested that concentration of GEC detected in wastewater was significantly correlated with the number of clinically reported cases in the corresponding catchment area of Dhaka city on the day of sample collection (P=0.058). This study suggests that wastewater surveillance could be a helpful tool in tracking the circulation and accumulation of SARS-CoV-2 in sewage and drainage systems and could complement clinical surveillance of the COVID-19 burden in Dhaka.

0860

## PREVALENCE OF CIRCULATING SARS-COV-2 IN WASTEWATER FROM NICARAGUA

**Evelin Martínez<sup>1</sup>**, Omar Zepeda<sup>1</sup>, Nancy Corea<sup>1</sup>, Edwing Centeno<sup>1</sup>, Yaoska Reyes<sup>1</sup>, Sylvia Becker-Dreps<sup>2</sup>, Johan Nordgren<sup>3</sup>, Filemón Bucardo<sup>1</sup>

<sup>1</sup>National Autonomous University of Nicaragua, León, Nicaragua,

<sup>2</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,

<sup>3</sup>Linköping University, Linköping, Sweden

Wastewater-based monitoring for SARS-CoV-2 by real-time PCR (RT-qPCR) is a useful tool for epidemic surveillance. In Nicaragua, the first COVID-19 case was reported on March 18, 2020. In this study, the levels of SARS-CoV-2 transmission at community level was investigated for 10 months (May 2020 - March 2021) by detection of SARS-CoV-2 genes in wastewater. Weekly samples (50ml) were collected in 2 of the 4 wastewater sedimentation treatment plants in León, designated as plant A and plant B. SARS-CoV-2 RNA was purified from 350 µL of clarified sewage samples, by using an in-house silica/guanidium thiocyanate method. The presence of the SARS-CoV-2 E-gene in the sewage RNA eluate was by RT-qPCR and confirmed with a secondary RT-qPCR for the RdRp gene. Following the first screening, all RNA eluates were diluted 1:100 and re-tested for possible presence of RT-PCR inhibitors. In both treatment plants, temperature ranged between 28.9 (SD: 1.5, Min: 28, Max: 34) and 30.3°C (SD: 1.7, Min: 25, Max: 36) and pH between 8 (SD: 0.2, Min: 8, Max: 9) and 10 (SD: 0.3, Min: 8, Max: 10). The weekly precipitation mean during the period of sampling was 50.4 mm (SD: 50.7, Min: 0, Max: 193) with the highest peak in the months of August and November. A total of 61.7% of the samples were positive in both plants, with 67.5% positive in plant A (mean Ct = 32.9, SD 2.2, Min: 28, Max: 38) and 56.1% in plant B (mean Ct = 34.08, SD: 0.936, Min: 33, Max: 36). There was a 80% correlation between E- and RdRp-gene detection, of notice the Ct values in the RdRp RT-qPCR were > 33. There was no correlation between SARS-CoV-2 detection and sewage's temperature, pH, or precipitation. This study shows that SARS-CoV-2 genes can be detected in sewage without the need of RNA concentration steps and the mean viral concentration was estimated to 7.59 log<sub>10</sub> genome equivalents/L (SD: 0.52, Min: 6.32, Max: 9.17), data differ with other studies that report lower viral concentration, suggesting high transmission of SARS-CoV-2 at community level.

### SPATIAL AND TEMPORAL PATTERNS OF SAPOVIRUS GASTROENTERITIS IN CHILDREN UNDER THREE YEARS OF AGE IN LEÓN, NICARAGUA

Christian Eduardo Toval-Ruiz<sup>1</sup>, Katerina Brandt<sup>2</sup>, Yaoska Reyes<sup>1</sup>, Lester Gutierrez<sup>1</sup>, Patricia Blandón<sup>1</sup>, Edwing Centeno<sup>1</sup>, Fredman González<sup>1</sup>, Samuel Vilchez<sup>1</sup>, Nadja Vielot<sup>2</sup>, Sylvia Becker-Dreps<sup>2</sup>, Filemón Bucardo<sup>1</sup>, Michael Emch<sup>2</sup>

<sup>1</sup>National Autonomous University of Nicaragua - León, León, Nicaragua,

<sup>2</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Sapovirus is a common cause of pediatric acute gastroenteritis but there is limited data about the incidence and environmental factors that facilitate transmission. We analyzed the spatial and temporal distribution of sapovirus gastroenteritis and measured the association with rainfall in a cohort of children (0-3 years of age) in León, Nicaragua. In a prospective cohort study, newborns received weekly household surveillance for gastroenteritis from 2017-2020. Diarrheal stool samples were examined using RT-qPCR testing for the presence of sapovirus. We used dwelling characteristics (construction of floor, wall, and ceiling, water source, sanitation, and overcrowding) and household income and education to create a poverty index (extremely poor, poor, and not poor). Participants' homes were georeferenced using Epicollect and to create maps showing the clusters density of sapovirus episodes using ArcGIS 10.7. Tropical Rainfall Measuring Mission Multi-Satellite Precipitation Analysis data from NASA were used to calculate average rainfall and extreme rainfall days by epidemiological week. Of 1,258 gastroenteritis episodes, 110 (8.74%) among 96 children were attributed to sapovirus during 3-year of surveillance. Sapovirus was more frequently observed in semi-urban areas with 57% of children living in families categorized as poor or extremely poor and neighborhood with low sanitation conditions. Sapovirus gastroenteritis was associated with rain, being more frequently detected at the beginning (June) and end (October) of the rainy season. Extreme rainfall in preceding weeks could predict sapovirus episodes; for instance, if extreme rainfall were observed at week 1, the probability (OR) of detecting sapovirus at week 3 was of 1.94 (95% CI [1.28,2.97]) and at week 4 was 2.04 (95% CI [1.32,3.23]) among children with observed gastroenteritis. Sapovirus was more frequently observed in semi-urban areas with high poverty index. Ecological and environmental factors, sanitation infrastructure, and seasonal climate should be further explored to understand how these conditions may affect disease progression over time.

### HIGH LEVELS OF EXTENDED SPECTRUM BETA-LACTAMASE (ESBL) CONTAMINATION ARE FOUND IN MALAWIAN HOUSEHOLDS WITH BASIC WATER, SANITATION AND HYGIENE (WASH) ACCESS

Derek Cocker<sup>1</sup>, Kondwani Chidziwisano<sup>2</sup>, Nicola Elviss<sup>3</sup>, Andrew C. Singer<sup>4</sup>, Tracy Morse<sup>5</sup>, Nicholas Feasey<sup>6</sup>

<sup>1</sup>Malawi-Liverpool Wellcome Trust Center, Blantyre, Malawi, <sup>2</sup>Centre for Water, Sanitation, Health and Appropriate Technology Development (WASHTEd), University of Malawi - The Polytechnic, Blantyre, Malawi,

<sup>3</sup>National Infection Service, Public Health England, London, United Kingdom, <sup>4</sup>NERC Centre for Ecology & Hydrology, Wallingford, United Kingdom, <sup>5</sup>Department of Civil and Environmental Engineering, University of Strathclyde, Glasgow, United Kingdom, <sup>6</sup>Liverpool School of Tropical Medicine (LSTM), Liverpool, United Kingdom

Low-middle income countries face the greatest burden of antimicrobial resistance (AMR), and WASH factors play an important role in the environmental dispersal and transmission of AMR. We recruited 300 households in urban, peri-urban and rural sites in southern Malawi between 2018-2020 and completed up to 4 visits at each household over a 6-month period. Samples of food, water, environment, co-located animal stool and human stool were taken at each household visit, to assess the prevalence and flux of ESBL bacteria in humans, animals and

the environment. The broader environment of each household was also sampled including drainage and river water. 11,719 samples were cultured, which identified a high prevalence of ESBL *E. coli* (18.0%), and ESBL *K. pneumoniae* (8.9%) in all sample types, from each site, especially river water (67.2%), human stool (41.7%) and animal stool (29.3%). Evaluation of water sanitation and hygiene practice (WASH) illustrated low availability of hand washing facilities at the households, poor animal waste management practices and high levels of interactions between humans and animals with the local riverine environment. In order to reduce transmission of ESBLs between the human, animal and environmental nexus, a one health approach is required which focusses on the need for human and animal faeces management and containment at household and community level to reduce the risk of more widespread environmental exposure. This should be complemented by both infrastructural and behavioural improvements in hygiene practices to reduce faecal oral transmission. Further genomic assessment of these samples will identify the interaction between human, animal and environmental compartments, their relationship to locally circulating clinical strains in blood stream infections and key ecological niches of AMR.

### CHILD MOUTHING OF SOIL AND CONTAMINATED FOMITES AND UNIMPROVED SANITATION ARE ASSOCIATED WITH SUBSEQUENT POOR CHILD DEVELOPMENTAL OUTCOMES IN URBAN BANGLADESH (CHOB17 PROGRAM)

Christine Marie George<sup>1</sup>, Tahmina Parvin<sup>2</sup>, Md. Sazzadul Islam Bhuyian<sup>2</sup>, Elizabeth D. Thomas<sup>1</sup>, Shirajum Monira<sup>2</sup>, Fatema Zohura<sup>2</sup>, M. Tasdik Hasan<sup>2</sup>, Jamie Perin<sup>1</sup>, Munirul Alam<sup>2</sup>, Fahmida Tofail<sup>2</sup>

<sup>1</sup>Johns Hopkins School of Public Health, Baltimore, MD, United States,

<sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh

Millions of young children annually in low and middle income countries are not meeting their developmental potential. Water, sanitation, and hygiene(WASH) program delivery presents a potential approach to improve child developmental outcomes by reducing enteric infections which can lead to malnutrition and poor child growth. This prospective cohort study of 224-children under 5-years was conducted in urban Dhaka, Bangladesh to investigate the association between household WASH infrastructure and behaviors and subsequent child developmental outcomes. Developmental outcomes were assessed by communication, fine motor, gross motor, personal social, problem solving, and combined developmental scores measured by the Extended Ages and Stages Questionnaire(EASQ) at a 12-month follow-up visit. Children who put soil in their mouth at the majority of surveillance visits had significantly lower combined EASQ Z scores(coefficient: -0.53 (95% Confidence Intervals (CI): -0.83, -0.22)) at the 12-month follow-up visit. Children who put visibly dirty objects in their mouths at the majority of visits had significantly lower combined EASQ Z scores(-0.50 (95% CI: -0.79, -0.22)). Children in households with unimproved sanitation had significantly lower combined EASQ Z scores(-0.63 (95% CI: -1.11, -0.16)). Children found to put soil and visibly dirty objects in their mouths at the majority of household visits, and those that resided in households using unimproved sanitation had lower subsequent cognitive developmental outcomes. These findings demonstrate the importance of interventions targeting child mouthing behaviors and sanitation infrastructure in households to reduce exposure to fecal pathogens and improve child cognitive developmental outcomes for susceptible pediatric populations.

## EXPLORING POOR WATER, SANITATION, AND HYGIENE AS FACTORS RELATED TO LEPROSY TRANSMISSION IN MINAS GERAIS, BRAZIL

**Tolulope R. Ojo-Akosile**<sup>1</sup>, Lorena B. de Oliveira<sup>2</sup>, Rosemary S. e Lima<sup>3</sup>, José A. Ferreira<sup>4</sup>, Julie A. Clennon<sup>5</sup>, Alexandre C. Branco<sup>6</sup>, Erica B. Magueta<sup>2</sup>, Maria Aparecida de Faria Grossi<sup>4</sup>, Lucia A. Fraga<sup>2</sup>, Jessica K. Fairley<sup>7</sup>

<sup>1</sup>Emory University, Rollins School of Public Health, Atlanta, GA, United States, <sup>2</sup>Universidade Federal de Juiz de Fora - Campus GV, Governador Valadares, Brazil, <sup>3</sup>Universidade Vale do Rio Doce, Governador Valadares, Brazil, <sup>4</sup>Faculdade da Saúde e Ecologia Humana, Vespasiano, Brazil, <sup>5</sup>Emory College of Arts and Sciences, Department of Environmental Sciences, Atlanta, GA, United States, <sup>6</sup>Centro de Referência em Doenças Endêmicas e Programas Especiais, Governador Valadares, Brazil, <sup>7</sup>Emory University School of Medicine, Atlanta, GA, United States

While leprosy is associated with poverty, it is not completely clear which factors, such as substandard and crowded housing conditions, unsafe drinking water, poor sanitation, or limited access to health care are driving this association. Given data suggesting that water and contaminated environments could be reservoirs for *Mycobacterium leprae* and that co-infections with water, sanitation, and hygiene (WASH)-associated helminths may increase susceptibility to leprosy, we aimed to explore the association of WASH factors with leprosy. A case-control study was conducted in the municipalities in and near Governador Valadares, Minas Gerais, Brazil, between June 2016-December 2018. Individuals ages three years or older were recruited as cases or community-matched controls. Cases were diagnosed by dermatologic experts with confirmatory skin slit smears for the bacillary index. Questionnaires were administered on socioeconomic status, education, occupation, and WASH factors. Descriptive and statistical analyses were conducted to identify WASH associations with leprosy. Seventy-nine cases of leprosy and 81 controls (non-household contacts) were recruited of which 52.5% were male. 75.2% (n=112) of the participants had piped water as their water source, 54.5% (n=85) acknowledged they did not treat water. Multivariate logistic regression revealed an association with larger household sizes with leprosy (aOR = 1.34; 95% CI 1.07, 1.68), and an unexpected positive association with the presence of a piped sewer system (aOR=4.67; 95% CI 1.51, 14.45). In a contrast, those with leprosy were less likely to have household plumbing (versus a well or unimproved sources) (aOR=0.39; 95% CI 0.13, 1.18) or to treat their water (aOR=0.52; 95% CI 0.25, 1.06), although these did not reach statistical significance. These associations suggest that WASH factors could be related to leprosy and supports other emerging research in this field. Still, there is a need for further research on the association of WASH and leprosy disease, more specifically the potential mechanisms of bacterium exposure and viability of *M. leprae* in the environment.

0865

## THE STATUS AND IMPACT OF WATER, SANITATION, AND HYGIENE RESOURCES ON SOIL TRANSMITTED HELMINTHS IN OGUN STATE, NIGERIA: AN IMPETUS FOR DEVELOPING A CROSS-SECTORAL FRAMEWORK

**Hammed O. Mogaji**<sup>1</sup>, Gabriel A. Dedeke<sup>1</sup>, Babatunde S. Bada<sup>1</sup>, Abass B. Adigun<sup>2</sup>, Monday E. Johnson<sup>3</sup>, Dorcas O. Adeaga<sup>4</sup>, Uwem F. Ekpo<sup>1</sup>

<sup>1</sup>Federal University of Agriculture, Abeokuta, Nigeria, <sup>2</sup>National Center for Remote Sensing, Jos, Nigeria, <sup>3</sup>United Nations Children's Fund, Abuja, Nigeria, <sup>4</sup>Rural Water Supply and Sanitation Agency, Abeokuta, Nigeria

The recent call on WASH implementers to maximize delivery of interventions for soil-transmitted helminths (STH) control or elimination requires the development of a cross-sectoral framework. To support such effort, there is need to document in real-time, the status of WASH resources and their impact on STH transmission. We therefore assessed the status of WASH and STH in 1,499 households across 33 spatially selected

communities in Ogun State, Nigeria where such data are lacking. We identified four sub-specific components of WASH and objectively assessed metrics related to availability, accessibility, functionality and adequacy using a newly developed scoring tool. Fresh stool samples were also collected from household members and examined for helminths ova using concentration method. Data obtained were used to estimate prevalence and odds of exposures. We found three most common STH species; *Ascaris lumbricoides* (AI - 13.6%), Hookworms (Hk - 4.6%) and *Trichuris trichiura* (Tt - 1.7%). The percentage of those who had access to improved water facilities within their household (76%) was higher compared to sanitation (46%) and handwashing facilities (11%). Personal hygiene metrics also showed that open defecation (48%), walking barefoot (32%), dirty fingernails (40.6%), pica (39%) and sucking fingernails (10%) were common. Furthermore, the availability of improved water source reduced the odds of Tt (OR=0.18), while access to any type of water facility within the household premises increased the odds of AI (OR=1.72), Tt (OR=4.43) and Hk (OR=1.92). Availability of handwashing facilities reduced the odds of AI (OR=0.35). There were no significant relationship between sanitation and STH prevalence. However, sucking of nails and open defecation increased the odds of AI (OR=2.63) and Hk (OR=3.87, OR=1.95) respectively. This study has identified provision of improved water, handwashing facilities and hygiene education as drivers of reduced STH transmission. We believe these results can guide state-wide WASH intervention delivery, even in resource challenged areas with the potential to maximize impact on STH control.

0866

## VECTOR COMPETENCE OF THE INVASIVE ASIAN LONGHORNED TICK, HAEMAPHYSALIS LONGICORNIS, FOR HEARTLAND VIRUS UNDER LABORATORY CONDITIONS

**Meghan E. Hermance**, Wilson R. Raney, Josiah B. Perry  
*University of South Alabama, Mobile, AL, United States*

The Asian Longhorned tick, *Haemaphysalis longicornis*, is native to eastern Asia but recently established populations in the United States where it continues to expand its geographic range. In its native range, *H. longicornis* is the main vector of the bandavirus, Severe Fever with Thrombocytopenia Syndrome virus (SFTSV). SFTSV is genetically closely related to Heartland virus (HRTV), an emerging North American tick-borne bandavirus that is increasing in human disease cases in the midwestern and southern United States since first reported in 2012. As the current geographic range and the predicted range expansion of invasive *H. longicornis* overlap considerably with human cases of HRTV, the objective for this study was to assess the ability of *H. longicornis* to maintain and transmit HRTV. In this study, adult female *H. longicornis* were microinjected in the anal pore with HRTV or media. Ticks were dissected at 14, 21, and 28 days post-injection (d.p.i.). At each time point, HRTV RNA was detected via qRT-PCR in the salivary glands and midguts of HRTV-injected ticks, and infectious virions were also detected in each tick. At 40 d.p.i., BALB/c mice were infested with 8 HRTV-injected *H. longicornis* females (1 tick per mouse), of which 5 ticks fed to repletion. Mice were monitored through 28 days post-tick attachment but did not display any clinical signs of disease. No HRTV RNA was detected in blood or terminal organs of mice exposed to HRTV-injected ticks; however, 4 of the 5 mice fed on by HRTV-injected ticks seroconverted, demonstrating host exposure to HRTV during tick feeding. The engorged female *H. longicornis* were maintained for oviposition. Transovarial and transstadial transmission of HRTV was demonstrated by detection of HRTV RNA in 100% of egg pools and larval pools, respectively. Together, these findings show that *H. longicornis* is a competent vector of HRTV. On-going studies are investigating whether non-viremic transmission of HRTV occurs between co-feeding invasive *H. longicornis* and native *Amblyomma americanum* ticks, as this could amplify transmission of HRTV in natural foci.

## A TRANSCRIPT CORRESPONDING TO A PREDICTED SECRETED PROTEIN AFFECTS FLAVIVIRUS INFECTION OF IXODES SCAPULARIS SALIVARY GLAND CULTURES

Jeffrey M. Grabowski<sup>1</sup>, Rebecca Rosenke, Daniel R. Long, Dana P. Scott, Marshall E. Bloom

Rocky Mountain Laboratories/NIAID/NIH, Hamilton, MT, United States

*Ixodes scapularis* transmits a number of pathogens, including the agent of Lyme disease and tick-borne flaviviruses (TBFVs). TBFV infections cause thousands of human encephalitis cases worldwide each year. In the US, confirmed human infections with TBFV Powassan virus (POWV) are increasing and have a fatality rate of 10-15%. In addition, Langat virus (LGTV) is often used as an experimental model TBFV of low neurovirulence. Elucidation of tick-virus interactions may inform countermeasures to reduce TBFV transmission. Understanding the functional effect of tick salivary gland transcripts in TBFV infection within tick organs is limited. Organ cultures are an excellent system for studying virus infection in individual tick organs, and RNAi methodology in tick organ cultures can identify selected tick transcripts as possible countermeasure targets. Through dsRNA-mediated RNAi transcript knockdown studies, a transcript corresponding to a predicted *I. scapularis* secreted protein (SecP) limited LGTV and POWV infection in salivary gland (SG) cultures from unfed female ticks. Because transfection of dsRNA corresponding to a SecP transcript reduced infectious LGTV and POWV replication, SecP is considered to be proviral. Additionally, *in situ* hybridization-localized SecP transcripts were observed in SG granular acini of unfed female ticks. Further investigation into the role of SecP in TBFV infection is currently underway. Complementary studies with TBFV-infected *I. scapularis* are being planned. This research approach defines a translational pipeline by which tick transcripts/proteins can be assayed as targets for TBFV countermeasures. This research was supported by the Intramural Research Program of the NIH, NIAID.

## SHREW RESERVOIR HOST FOR DEER TICK VIRUS

Heidi Goethert<sup>1</sup>, Thomas Mather<sup>2</sup>, Richard Johnson<sup>3</sup>, Sam Telford<sup>1</sup>

<sup>1</sup>Tufts University School of Veterinary Medicine, N. Grafton, MA, United States, <sup>2</sup>University of Rhode Island, Kingston, RI, United States, <sup>3</sup>Martha's Vineyard Tick Borne Illness Reduction Initiative, Martha's Vineyard, MA, United States

Deer tick virus (DTV) is a Powassan virus subtype found in eastern North America. It causes a severe severe meningoencephalitis and cases are increasingly reported where Lyme disease is endemic. Despite being described over 20 years ago, the enzootic cycle remains poorly studied. About 0.5%-5% of host seeking deer ticks, *Ixodes dammini*, are infected throughout their range. Because white-footed mice have long been considered to be the main host for subadult *I. dammini* as well as the reservoir for the agents of Lyme disease and babesiosis, these mice have been assumed to be the reservoir host for DTV. Serosurveys demonstrate that mice are exposed in nature, but definitive evidence (xenodiagnosis, virus isolation or detection by RT-PCR) has not been reported. We sought to identify the reservoir host of DTV using bloodmeal remnant analysis to directly detect the host upon which ticks had been infected. Infected host-seeking nymphal ticks likely acquired their infection while feeding on a viremic host as a larva. Accordingly, we screened host-seeking nymphs collected from 12 different sites in Massachusetts and Rhode Island from 2018-2020 and found 20 that were infected with DTV. Bloodmeal hosts were identified using our newly developed qPCR assay that targets mammalian retrotransposons of mouse, vole, bird, rabbit, shrew, squirrel/chipmunk or deer. The bloodmeal host was identified for 16 (80%) of the infected ticks; mice were not detected at all. Instead, shrews were identified from 65% of them. Furthermore, the general proportion of shrew-fed nymphs at a site was positively associated with the prevalence of DTV in ticks in a site ( $p=0.006$ ). We conclude that shrews are likely reservoir hosts for DTV.

## POPULATION-WIDE FALL IN SERIOUS BACTERIAL COMPLICATIONS FOLLOWING IVERMECTIN-BASED MASS DRUG ADMINISTRATION FOR SCABIES

Li Jun Thean<sup>1</sup>, Lucia Romani<sup>2</sup>, Daniel Engelman<sup>1</sup>, Handan Wand<sup>3</sup>, Adam Jenney<sup>4</sup>, Jyotishna Mani<sup>1</sup>, Jessica Paka<sup>1</sup>, Tuliana Cua<sup>1</sup>, Sera Taole<sup>1</sup>, Aalisha Sahukhan<sup>5</sup>, Mike Kama<sup>5</sup>, Meciusela Tuicakau<sup>5</sup>, Joseph Kado<sup>5</sup>, Matthew Parnaby<sup>1</sup>, Natalie Carvalho<sup>6</sup>, Margot Whitfeld<sup>7</sup>, John Kaldor<sup>3</sup>, Andrew Steer<sup>1</sup>

<sup>1</sup>Murdoch Children's Research Institute, Melbourne, Australia, <sup>2</sup>Kirby Institute, University of New South Wales, Sydney, Australia, <sup>3</sup>Kirby Institute, University of New South Wales, Sydney, Australia, <sup>4</sup>Fiji National University, Suva, Fiji, <sup>5</sup>Fiji Ministry of Health and Medical Services, Suva, Fiji, <sup>6</sup>School of Population and Global Health, University of Melbourne, Melbourne, Australia, <sup>7</sup>Department of Dermatology, St. Vincent's Hospital, Sydney, Australia

Scabies, with a global prevalence of 200 million people, is the predominant precipitant of impetigo in endemic settings. Impetigo can progress to serious bacterial complications including skin and soft tissue infections, invasive infections and post-infectious sequelae. Ivermectin-based mass drug administration (MDA) can significantly reduce scabies and impetigo prevalence in endemic settings. We aimed to ascertain the impact of this intervention on the serious bacterial complications of scabies. We conducted a before-after trial, administering MDA in Fiji's Northern Division (population: 131,914). We measured the incidence of hospital admissions with skin and soft tissue infections, invasive infections and post streptococcal sequelae over 12 months prior the intervention and compared this with the incidence over the 12 months post. We also compared the incidence of primary healthcare presentations with scabies and skin infections, and the prevalence of scabies and impetigo in the community before and after the intervention. The coverage of MDA achieved was 97% and 87% for the first and second doses respectively. The incidence of hospitalizations with skin and soft tissue infections fell by 17% in the year following the intervention (467.3 to 388.7 per 100,000 person-years, incidence rate ratio 0.83, 95% CI, 0.74 to 0.94;  $P=0.002$ ). There was a 21% decrease in presentations to primary healthcare with scabies and skin infections (108.3 to 89.2 per 1,000 person-years, IRR 0.79, 95% CI, 0.78 to 0.82). The prevalence of scabies fell from 14.2% to 7.7% (cluster-adjusted prevalence ratio 0.71; 95% CI, 0.28 to 1.17) and impetigo prevalence reduced from 15.3% to 6.1% (cluster-adjusted prevalence ratio 0.4; 95% CI, 0.18 to 0.86). The results of this study demonstrate the extended clinical and public health benefits of reducing scabies prevalence with ivermectin-based MDA through substantial reductions in serious bacterial complications and healthcare burden. Our findings support endemic settings and international health agencies towards prioritising scabies control.

## GENERATION OF TRANSFECTED BABESIA BOVIS EXPRESSING AN ANTI-TICK TOXIN TO CONTROL TICKS

hala Elsayed, Wendell Johnson, Carlos Suarez, Massaro Ueti  
Washington State University, Pullman, WA, United States

Ticks cause significant economic losses to livestock directly and through transmission of pathogens. Vaccines to control ticks or tick-borne pathogens are urgently needed. Bio-insecticides such as protein spider toxins have potential to reduce tick burdens if they can be efficiently delivered. We propose a novel approach for delivery of protein toxins based on expression by transfected *B. bovis* exclusively during tick specific stages of the parasite. In addition to killing ticks this would also confer protection against disease. Expression of the toxin gene at the appropriate time can be achieved if it is under the transcriptional control of a *B. bovis* tick-stage specific promoter. We first tested this model by generating stably transfected *B. bovis* parasites containing a constitutively expressed promoter and a previously identified *B. bovis* kinete specific promoter controlling the expression of green and red fluorescent proteins,

respectively. Successful expression of eGFP and RFP by the transfected parasites was confirmed by genotypic and phenotypic characterization. Comparison of the levels of expression of eGFP and RFP in blood stage *B. bovis* parasites developed in *in vitro* cultures showed significantly reduced activity of the kinete-specific promoter compared to the constitutive promoter. Future experiments using this transfected parasite line will be aimed at confirming the activity of the promoter in ticks. These studies suggest that this promoter is a viable candidate for developing vaccines based on transfected *B. bovis* strains with tick-stage specific expression, which could become a valuable tool in our arsenal for fighting ticks and tick-borne diseases.

0871

### ISOLATION OF HEARTLAND VIRUS IN FIELD-COLLECTED TICKS, GEORGIA

**Yamila Romer**<sup>1</sup>, Kayla Adcock<sup>2</sup>, Zhuoran Wei<sup>1</sup>, Daniel Mead<sup>3</sup>, Oscar Kirstein<sup>1</sup>, Steph Bellman<sup>1</sup>, Anne Piantadosi<sup>1</sup>, Uriel Kitron<sup>1</sup>, Gonzalo Vazquez Prokopec<sup>1</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>University of Georgia, Athens, GA, United States, <sup>3</sup>Georgia University, Athens, GA, United States

Heartland Virus (HRTV) is an emerging tick-borne arbovirus transmitted by *Amblyomma americanum* ticks, recently discovered, linked to more than 40 cases of moderately severe to fatal human disease across 9 US States. In Georgia, evidence of HRTV circulation dates to at least 2001, based on seroprevalence studies of white-tailed deer. A fatal human case from 2005 was identified retrospectively by the CDC. Here, we report the finding of HRTV infection in *A. americanum* ticks from Georgia. The study area was a rural landscape comprising 64 km<sup>2</sup> in central Georgia, where historical data indicated HRTV exposure in white-tailed deer. Questing adult and nymphal stages were collected by flagging. Ticks were identified to species morphologically and vialled in pools. RNA was extracted from pooled homogenates and screened using real-time PCR specific for HRTV. Isolation of the virus was attempted in Vero E6 cells using homogenates positive by PCR. A total of 6,398 ticks were collected from the study area in 2019 and grouped in 677 pools. Three pools of *A. americanum* (two adult pools and one nymph pool) were positive for HRTV by real-time PCR (0.4%). No other tick species (*Amblyomma maculatum*, *Dermacentor variabilis*, *Ixodes scapularis*) were found infected with HRTV. HRTV was successfully isolated in Vero E6 cells from 2 of the positive pools collected from 2 separate sites. The identity of each HRTV isolate was confirmed by whole-genome sequencing. The isolates were much more similar to one another than to the three other available HRTV genomes. It is common for tick-borne arboviruses, especially when their emergence or diagnosis is recent, that the occurrence of human disease is sporadic and often underdiagnosed. Unfortunately, little is known about HRTV eco-epidemiology, including their main reservoirs, seasonality of transmission, and drivers of population persistence. Our findings confirm the presence and persistence of HRTV in Georgia and represent the first isolate of HRTV in the southeastern US. Further work is needed to better assess the risk for human disease in the region.

0872

### OUTDOOR ACTIVITIES IN THE TIME OF COVID-19 AND ITS IMPLICATIONS FOR EXPOSURE TO TICK-BORNE DISEASES IN THE UNITED STATES

**Maria Pilar Fernandez**<sup>1</sup>, Gebbiena Bron<sup>2</sup>, Pallavi Kache<sup>3</sup>, Jean Tsao<sup>4</sup>, Lyric Bartholomay<sup>2</sup>, Mary Hayden<sup>5</sup>, Kacey Ernst<sup>6</sup>, Kevin Berry<sup>7</sup>, Maria Diuk-Wasser<sup>3</sup>

<sup>1</sup>Washington State University, Pullman, WA, United States, <sup>2</sup>University of Wisconsin-Madison, Madison, WI, United States, <sup>3</sup>Columbia University, New York, NY, United States, <sup>4</sup>Michigan State University, East Lansing,

MI, United States, <sup>5</sup>University of Colorado - Colorado Springs, Colorado Springs, CO, United States, <sup>6</sup>University of Arizona, Tucson, AZ, United States, <sup>7</sup>University of Alaska Anchorage, Anchorage, AK, United States

During the COVID-19 pandemic, governmental and individual responses to COVID-19 risk were focused on behavioral changes to reduce transmission, but inadvertent consequences of such behavioral changes are yet to be fully realized. Herein, we evaluated changes in people's outdoor activity patterns during the spring and summer of 2020 in the Northeast and Midwest United States by comparison with the same period in 2019. Because changes in outdoor activity patterns can lead to changes in vector-borne disease risk, we simultaneously assess changes in exposure to tick vectors, and its association with outdoor activities. We used longitudinal self-reported data collected from daily surveys available in The Tick App, a smartphone application designed to assess outdoor activity patterns in relation to tick exposures. The daily proportion of users reporting any type of outdoor activity, including peridomestic activities, increased by two-fold in 2020 vs. 2019, while recreational activities in green spaces decreased by 70%. Meanwhile, self-reported tick encounters significantly increased by 30% in 2020 compared to 2019, and were mainly associated with outdoor activities and living in a rural county. Changes in daily activity patterns were associated with statewide stay-at-home orders in 2020 and persisted despite increased out-of-home mobility measured at the county-level (i.e., Shelter-in-Place Index). By contrast, individual self-reported impacts on outdoor activities (any impact vs. no impact) were positively associated with the Shelter-in-Place Index and if the participant lived in an urban area. Obtaining granular information on activity patterns proved useful in gaining insights about potential changes in the risk of tick-borne disease exposure during 2020, associated with behavioral changes driven by COVID-19 pandemic. Our findings suggest that public health response should address competing hazards from COVID-19 related outdoor exposure and the increasing risk of tick- and other vector-borne diseases associated with increased outdoor activity.

0873

### LOIASIS-MEDIATED FILARIASIS TEST STRIP POSITIVITY IS STABLE OVER ONE YEAR

**Marla I. Hertz**<sup>1</sup>, Linda Djune-Yemeli<sup>2</sup>, Hugues C. Nana-Djeunga<sup>2</sup>, Jean Bopda<sup>2</sup>, Joseph Kamgno<sup>2</sup>, Philip J. Budge<sup>1</sup>

<sup>1</sup>Washington University in St Louis, St Louis, MO, United States, <sup>2</sup>Centre for Research on Filariasis and Other Tropical Diseases (CRFiMT), Yaounde, Cameroon

The Filariasis Test Strip (FTS) is an essential tool to monitor lymphatic filariasis (LF) elimination efforts. FTS cross-reactivity mediated by *Loa loa* circulating filarial antigens (*Loa*-CFAs) is an obstacle to LF elimination in coendemic regions. Cross-reactive FTS results correlate with increasing *L. loa* microfilaria (Mf) loads, and the protein profile of *Loa*-CFAs suggests FTS-positivity stems from intermittent release of *Loa*-CFAs from dying worms. To further characterize the nature of FTS cross-reactivity, we collected serial plasma samples from a cohort of individuals with high *L. loa* Mf loads (>20,000/mL) in the Okola health district in Cameroon, a region endemic for loiasis but not LF. Seventy (52%) of 135 individuals screened tested positive by FTS. Mf counts were higher among FTS-positive participants compared to the FTS-negative group (median 34,450 versus 10,180, p-value <0.0001 by unpaired t-test). All FTS-positive and 13 FTS-negative participants were followed quarterly for one year to better understand the temporal dynamics of antigenemia. The FTS status registered at baseline remained stable for 80% of the sixty-eight participants who attended all study visits. *Loa*-CFA levels were quantified by an ELISA using the FTS antibody AD12, or the Og4C3 antibody which recognizes the same AD12 core epitope. At baseline, 66 (90%) of the FTS-positive group and 12 (92%) of the FTS-negative group were AD12 ELISA positive, while 25% and 31% of the FTS-positive and FTS-negative groups, respectively, were Og4C3 ELISA positive. Neither baseline Mf counts, nor ELISA results were predictive of FTS status changes. The best predictor was the baseline FTS score, a semiquantitative measure of the amount of circulating antigen. Subjects who converted from FTS-positive

to negative, scored lower (score 1) than those who remained FTS-positive (score 2-3). These findings suggest that FTS cross-reactivity in loiasis patients with high Mf counts is relatively stable over time and stress the importance of developing more specific diagnostic assays to aid public health interventions for LF and loiasis.

0874

#### OPTIMIZED QPCR STRATEGY FOR THE MOLECULAR DETECTION OF ONCHOCERCA VOLVULUS IN BLACKFLIES

Jessica R. Grant<sup>1</sup>, Sasisekhar Bennuru<sup>2</sup>, Kerstin Fischer<sup>3</sup>, Peter U. Fischer<sup>3</sup>, Sara Lustigman<sup>4</sup>, Thomas B. Nutman<sup>2</sup>, Nils Pilotte<sup>1</sup>, Thomas R. Unnasch<sup>5</sup>, Steven A. Williams<sup>1</sup>

<sup>1</sup>Smith College, Northampton, MA, United States, <sup>2</sup>National Institutes of Health, Bethesda, MD, United States, <sup>3</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>4</sup>New York Blood Centre, New York, NY, United States, <sup>5</sup>University of South Florida, Tampa, FL, United States

Global elimination of onchocerciasis remains a lofty but realistic goal, yet there are obstacles that need to be addressed if the ambitions of the global health community are to be met. In this study, we address one such obstacle: the need for diagnostic tools of increased sensitivity and species-specificity that are both optimized and standardized. Current guidelines governing when to stop mass drug administration, and post-treatment surveillance strategies, include screening pools of the blackfly vector for the presence of infectious *Onchocerca volvulus* larvae. Molecular screening is non-invasive and cost effective, since large numbers of insects can be tested at once. However, as the prevalence of disease decreases, the sensitivity of the assay becomes more critical, as infrequent pathogen signal can be missed by sub-optimal detection strategies. A potential confounding factor, the bovine parasite *Onchocerca ochengi*, which is genetically similar to *O. volvulus*, can also be found in blackflies. We have tested 4 qPCR primer/probe combinations in 3 different laboratories and with different reagents to identify a screening approach with optimal sensitivity and specificity. The most sensitive assay targeted the *O. volvulus* O-150 repeat and has a limit of detection of 0.01 pg and consistently amplified as few as one *O. volvulus* L3 in a pool of 100 blackfly heads. However, this assay did cross amplify *O. ochengi* genomic DNA at high concentrations (>1 ng/μL). A qPCR assay with a mitochondrial target (ND5) had lower sensitivity but did not amplify *O. ochengi* DNA, even at concentrations up to 25 ng/μL. Thus, we have determined that using qPCR targeting O-150 for primary testing, followed with a confirmatory ND5 qPCR assay, will provide an optimal diagnostic for *O. volvulus* screening in areas of low endemicity. SOPs for DNA extraction and qPCR have been developed and optimized. Aiming to export this diagnostic tool for use in endemic locations, we have designed the assay to be shelf-stable, centrally produced, and easily shipped, allowing for increased standardization and reagent availability while minimizing logistical costs and challenges.

#### LYMPHATIC FILARIASIS ELIMINATION IN SAMOA: EVALUATING THE USE OF MOLECULAR XENOMONITORING AS A SURVEILLANCE TOOL

Brady McPherson<sup>1</sup>, Helen Mayfield<sup>2</sup>, Angus McLure<sup>3</sup>, Take Naseri<sup>4</sup>, Robert Thomsen<sup>4</sup>, Tautala Mauala<sup>5</sup>, Shaun Coutts<sup>3</sup>, Stephen Harfield<sup>3</sup>, Jessica Chellappah<sup>1</sup>, Donna MacKenzie<sup>1</sup>, Christina Hoare<sup>1</sup>, Joanne Kizu<sup>1</sup>, Jessica Guidotti<sup>2</sup>, Nils Pilotte<sup>6</sup>, Andrew Gonzales<sup>6</sup>, Steven Williams<sup>6</sup>, Katherine Gass<sup>7</sup>, Patricia Graves<sup>8</sup>, Colleen Lau<sup>2</sup>

<sup>1</sup>Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia, <sup>2</sup>University of Queensland, Brisbane, Australia, <sup>3</sup>Australian National University, Canberra, Australia, <sup>4</sup>Samoa Ministry of

Health, Apia, Samoa, <sup>5</sup>Samoa Red Cross, Apia, Samoa, <sup>6</sup>Smith College, Northampton, MA, United States, <sup>7</sup>Task Force for Global Health, Atlanta, GA, United States, <sup>8</sup>James Cook University, Cairns, Australia

The World Health Organization recently recommended triple-drug mass drug administration (ivermectin, diethylcarbamazine, albendazole: IDA) in areas with slow progress towards lymphatic filariasis (LF) elimination. Samoa distributed the first round of IDA in 2018. Antigen (Ag) prevalence was 4.0% (2.8-5.6%) in 2018, and 4.1% (2.8-5.9%) post-IDA in 2019. The 2019 'Surveillance and Monitoring to Eliminate Lymphatic Filariasis and Scabies from Samoa' project consisted of human and mosquito surveys to identify the best indicators for post-IDA surveillance. Delays in Ag clearance post-IDA limits its usefulness as an indicator in the immediate post-IDA period, and molecular xenomonitoring (MX) may be more sensitive in this setting. We compared estimated prevalence of mosquitoes containing *Wuchereria bancrofti* DNA pre- and post-IDA and investigated associations between PCR+ mosquitoes and Ag+ humans. Mosquitoes were collected from 35 villages using BG Sentinel traps and sorted into 9 categories: *Aedes polynesiensis* (main vector), *Ae. aegypti*, *Ae. albopictus*, *Ae. upolensis*, *Ae. (Finlaya) spp.*, other *Ae. spp.*, *Culex quinquefasciatus* and other *Culex spp.* Pools of ≤25 mosquitoes of each category were tested. Analyses were conducted for each category, 'all *Aedes*' and 'all species' using novel PoolTestR software that adjusts for sample hierarchical clustering. Of 2,638 pools (total 34,299 mosquitoes), 6.5% were PCR+. Pools with highest PCR-positivity were *Ae. polynesiensis* (14.1%) and *Ae. aegypti* (7.0%). Estimated infection prevalence in Samoa in 2019 was 0.8% for *Ae. polynesiensis*, 0.6% for *Ae. aegypti*, 0.6% for 'all *Aedes*' and 0.4% for 'all species', a reduction from 2018 (1.2%, 1.4% and 0.8%, respectively). 'All species' proved most sensitive for detecting villages with Ag+ humans, with PCR+ pools identified in 78.6% of these villages, compared to 67.9% for 'all *Aedes*' and 64.3% for *Ae. polynesiensis*. PCR+ *Ae. polynesiensis* pools provided the highest positive predictive value (81.8%) of villages with Ag-positive people. Our study provides promising evidence to support the value of MX (even using 'all species') in post-MDA surveillance.

#### ESTABLISHMENT AND VALIDATION OF A REAL-TIME PCR FOR ABSOLUTE QUANTIFICATION OF WOLBACHIA ENDOSYMBIONTS OF ONCHOCERCA VOLVULUS IN SAMPLES WITH VERY FEW TO A SINGLE MICROFILARIA

Stefan Schlabe<sup>1</sup>, Christine Laemmer<sup>2</sup>, Bettina Dubben<sup>2</sup>, Marianne Koschel<sup>2</sup>, Patricia J. Korir<sup>2</sup>, Marc P. Huebner<sup>2</sup>, Kenneth Pfarr<sup>2</sup>, Ute Klarmann-Schulz<sup>2</sup>, Achim Hoerauf<sup>2</sup>

<sup>1</sup>University Hospital Bonn, Department of Internal Medicine I, Bonn, Germany, <sup>2</sup>University Hospital Bonn, Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany

The neglected tropical disease Onchocerciasis (river blindness) affects 21 mio people in Sub-Saharan Africa and a few loci in Latin America. It is caused by the filarial nematode *Onchocerca volvulus* which lives in symbiosis with the Gram-negative bacteria *Wolbachia*. Targeting the endosymbiont *Wolbachia* using antibiotics leads to permanent sterilization of female worms and an adulticidal effect. The depletion of *Wolbachia* precedes the adulticidal effect. Quantifying *Wolbachia* after therapy is critical for clinical trials on antiwobachial regimens. The gold standard to assess *Wolbachia* depletion is histological examination of adult worms in subcutaneous nodules 20-27 months after treatment. A diagnostic tool for detecting *Wolbachia* depletion at an earlier time point in microfilariae (MF) would accelerate new antiwobachial drug clinical trials. Successful treatment will result in loss of MF, therefore the assay must work with few MF. We have established a real-time PCR (qPCR) for quantifying *Wolbachia* in *O. volvulus* MF that had migrated from skin biopsies. Reproducibility of the procedure was tested on *Litomosoides sigmodontis* MF in blood of infected mice. After counting MF with an inverse microscope, DNA was extracted using a modified protocol of the QiaAmp DNA Micro Kit protocol (Qiagen). *Wolbachia* were quantified by amplifying the single-copy gene *ftsZ* with specific primers and a Taqman® probe.

Reaction efficiency was determined by a 1:10 dilution series of plasmid containing the target sequence. For absolute quantification linearized plasmid standards and synthetic DNA fragments (gBlocks®) were used. The qPCR enabled reproducible *Wolbachia* quantification in isolated MF. The detection limit of the diagnostic tool was 1 MF. Detection of *ftsZ* in 1 MF was possible in 66.7% in field isolates and was 100% in DNA extracted from >2 MF. By using linearized plasmids the qPCR delivered an absolute quantification of *Wolbachia* endosymbionts per MF. The qPCR is reliable for quantifying *Wolbachia* in isolated MF from skin biopsies. Its establishment provides a tool for early treatment monitoring (≤6 months) of new antiwobachial treatments.

### HIGH-THROUGHPUT MOLECULAR XENOMONITORING USING AN AMPLICON SEQUENCING-BASED APPROACH TO PATHOGEN DISCOVERY

Nils Pilonne<sup>1</sup>, Samantha Schultz<sup>2</sup>, Steven A. Williams<sup>1</sup>

<sup>1</sup>Smith College, Northampton, MA, United States, <sup>2</sup>University of Massachusetts, Amherst, MA, United States

Molecular xenomonitoring (MX) is the molecular testing of vector insects for the presence of pathogen. In recent years, recognition of the utility of this approach has grown, resulting in its adaptation by various tropical disease control and elimination programs as a means of augmenting traditional monitoring and surveillance methods. However, the full potential of MX remains unrealized, as limitations to throughput of testing, vector capture, and cost of testing represent obstacles for many applications. In an attempt to mitigate these challenges, we have developed an amplicon sequencing-based approach to MX, which allows for high-throughput screening of large numbers of mosquito pools as part of a single next-generation sequencing (NGS) reaction. Employing a conserved 18S ribosomal sequence target and "blocking" primers, which prevent amplification of both mosquito and mammalian host sequences, this method allows for the amplification of all eukaryotic species harbored by the mosquito host. Amplification occurs in a universal fashion, meaning prior knowledge of potential targets is not required. In this manner, surveillance is integrated, providing a high-throughput, cost-minimized approach to the screening of mosquito pools, while enabling the identification of all eukaryotic pathogens present in the pools, whether or not they are vectored by the mosquitoes being tested. To demonstrate proof-of-concept for this approach, we screened 50 DNA extracts isolated from mosquito pools previously collected in Zanzibar as part of an unrelated study. NGS-based amplicon sequencing identified the presence of multiple pathogens, including the filarial pathogen *Wuchereria bancrofti*, the presence of which was confirmed in 24 samples using qPCR. Utilization of this technique should enable entire xenomonitoring studies to occur as part of a single NGS reaction. Testing of as many as 25,000 mosquitoes in a single sequencing run is possible, and at an estimated cost of under \$2,000 per study, a per-mosquito cost of \$0.08 is realized, with each mosquito screened for all eukaryotic pathogens present in the study's sample population.

### MOLECULAR DIAGNOSTICS FOR MONITORING HUMAN LYMPHATIC FILARIASIS USING CIRCULATING CELL-FREE NUCLEIC ACIDS IN BODY FLUIDS

Marisa Martinez Salazar, Thomas B. Nutman, Sasisekhar Bannuru

Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Detecting parasitic circulating cell free nucleic acids (ccfDNA/ccfRNA) in plasma is a promising approach for sensitive and specific detection of active helminth infection including *Wuchereria bancrofti* (Wb). Ccf nucleic acids, given their short half-lives, may be better biomarkers for assessing infection status than more traditional approaches (e.g., circulating antigen). To identify potential Wb RNA targets, we performed Plasma-RNAseq using

plasma from 10 Wb microfilaria-positive (mf-positive) individuals and 10 healthy blood bank individuals and used bioinformatic tools to ensure specificity. Six targets were identified that were specific to Wb and/or *Brugia malayi* (Bm), the causative agents of LF, and not found in *Loa loa* (Ll) or *Onchocerca volvulus* (Ov), closely related filarial parasites. These targets were compared to the previously described DNA-based targets WbLDR and WbTR1 using newly optimized qPCR assays. After optimizing primer/probe combinations using genomic DNA or RNA from Wb or Bm, we demonstrated that ccfDNA and ccfRNA can be detected in Wb-infected individuals. Because the DNA-based assays appeared to be more sensitive, we next assessed the utility of the most sensitive ccfDNA qPCR assay as a biomarker of active Wb infection. Thus, we extracted ccfDNA from 250 µl of plasma from individuals with Wb infection from India (n=19), Cook Islands (n=71), Mali (n=13), and Haiti (n=1) and Guyana (n=2). Of all the mf-positive individuals, 71 percent were positive for ccfDNA using WbTR1 qPCR; as expected endemic uninfected controls and those with *Mansonella perstans* and/or Ll were negative. To understand the kinetics of Wb-specific ccfDNA following treatment, we assessed ccfDNA longitudinally following definitive treatment. In a small number of patients we demonstrated, in time course analyses, that patients had undetectable levels within a year of definitive treatment. Results from different Wb treatment regimens are underway. Overall, ccfDNA/RNA detection in LF holds promise for assessment of infection and treatment response in Wb and Bm infection.

Implementation of an effective and targeted mass drug administration program against filarial worms needs an accurate identification and mapping of the distribution of these parasites. Molecular diagnostic methods like polymerase chain reaction (PCR) based techniques have shown high sensitivity to detect and distinguish parasites at low levels and even in people amicrofilaremic by microscopy. However, larger scale implementation over time remains a challenge for low-income countries because of logistical complexity and costs, including collection, transportation and preservation of biological samples and running of the analytical tests. To overcome these concerns, we developed a new approach based on the use of nucleic acids (NA) extracted from dried blood retained on used malaria rapid diagnostic (RDT) tests. People of all age groups were recruited during malaria indicator survey carried out in 2018 on Bioko Island (Equatorial Guinea). This yearly survey is based on a detailed questionnaire and includes malaria testing based on malaria RDT. RDTs were barcoded, stored at room temperature, NA was extracted from the roughly five microliter of venous blood retained followed by a multiplex qPCR assay to detect *Mansonella perstans*, *Loa loa* and a control human gene. We identified NA encoding for filarial worms among 254 (8.5%) of the 3214 RDTs screened. Prevalence of *M. perstans* and *L. loa* were 7.1% and 1.6%, respectively. Co-infections between *Plasmodium* spp and *M. perstans* were found in 35 (4.6 %) of 764 *Plasmodium* spp positive RDTs. Elderly male of the lowest socioeconomic quintile and living in rural areas of Bioko Island were affected most by *M. perstans* infection. Our study shows for that malaria RDTs stored at room temperature for around 6 months can be used as source for NA to detect other blood-dwelling pathogens.

### USE OF A NOVEL PLASMODIUM VIVAX CHIMERIC PROTEIN FOR MALARIA SEROSURVEILLANCE IN MULTI-SPECIES ENDEMIC COUNTRIES NEARING ELIMINATION

Jessica N. McCaffery<sup>1</sup>, Balwan Singh<sup>2</sup>, Douglas Nace<sup>3</sup>, Ashenafi Assefa<sup>3</sup>, Jimee Hwang<sup>2</sup>, Mateusz Plucinski<sup>2</sup>, Nidia Calvo<sup>4</sup>, Alberto Moreno<sup>1</sup>, Venkatachalam Udhayakumar<sup>2</sup>, Eric Rogier<sup>2</sup>

<sup>1</sup>Emory Vaccine Center, Yerkes National Primate Research Center, Emory University, Atlanta, GA, United States, <sup>2</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Ethiopian Public Health Institute, Addis Ababa, Ethiopia, <sup>4</sup>Instituto Costarricense de Investigación y Enseñanza en Nutrición y Salud (INCIENSA), Tres Rios, Costa Rica

Reliable estimates of malaria transmission are needed to achieve elimination targets. Detection of anti-malarial antibodies provide exposure history, but previous studies have relied largely on species-specific antigens. The use of pan-*Plasmodium* antigens in serological surveys could provide data for exposure to all *Plasmodium* species circulating in an area. We have recently described a chimeric protein based on *P. vivax* merozoite surface protein 1, designated *P. vivax* recombinant modular chimera based on MSP1 (PvRMC-MSP1), which includes five broadly recognized T cell epitopes, two T helper epitopes from the PvMSP1 33kD fragment, the PvMSP1 19kD fragment, and a (NANP)<sub>6</sub> sequence representing the central repeat of the *P. falciparum* circumsporozoite protein. PvRMC-MSP1 binds IgG from a majority of returning US travelers with PCR-confirmed malaria infection regardless of the infecting *Plasmodium* species. Using a multiplex bead-based assay, we present seroprevalence of anti-PvRMC-MSP1 IgG antibodies in population-based surveys using from Ethiopia (n=8,944) and Costa Rica (n=852) collected from household-based cross-sectional studies. Ethiopia is endemic for all four human malarial species, and Costa Rica is historically endemic for *P. vivax* but is nearing elimination. Seroconversion rates were calculated for both datasets and were determined to be 0.023 for PvMSP1 and 0.03 for PvRMC-MSP1 in Costa Rica. In Ethiopia, seroconversion rates were 0.044 for PvMSP1 and 0.106 for PvRMC-MSP1. Seroprevalence in Costa Rica was 41.5% for PvMSP1 and 46.7% for PvRMC-MSP1. In Ethiopia, seroprevalence of PvMSP1 was 20.6%, but was 34.5% for PvRMC-MSP1, and comparison of IgG levels showed higher titers to PvRMC-MSP1 when compared to PvMSP1 in both studies. In Ethiopia, the seroprevalence of PfMSP1-specific IgG antibodies was higher than that of PvRMC-MSP1 and PvMSP1 regardless of age, consistent with the relatively high predominance of *P. falciparum* infections in the region. Our data suggest that PvRMC-MSP1 may be able to detect both prior *P. falciparum* and *P. vivax* infections and display higher sensitivity in detecting past malaria exposure.

### FIELD ASSESSMENT OF QUANTITATIVE POINT-OF-CARE G6PD ACTIVITY ASSAY—KAMPONG SPEU, CAMBODIA, 2019-2020

Dean Sayre<sup>1</sup>, Lek Dysoley<sup>2</sup>, Sochea Phok<sup>3</sup>, Jean Popovici<sup>4</sup>, Michael C. <sup>1</sup>Epidemic Intelligence Service, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>National Center for Malaria Control, Parasitology and Entomology, Phnom Penh, Cambodia, <sup>3</sup>PSI Cambodia, Phnom Penh, Cambodia, <sup>4</sup>Institut Pasteur du Cambodge, Phnom Penh, Cambodia, <sup>5</sup>U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Phnom Penh, Cambodia, <sup>6</sup>U.S. President's Malaria Initiative, United States Agency for International Development, Phnom Penh, Cambodia, <sup>7</sup>PfPR Impact Malaria, Washington, DC, United States, <sup>8</sup>U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

Primaquine and tafenoquine remain the only effective drugs to eliminate the persistent liver stage of *Plasmodium vivax*, thereby providing radical cure for malaria. Both medications may also cause hemolytic anemia in individuals with glucose-6-phosphate dehydrogenase (G6PD) deficiency, a

common genetic disorder in many malaria endemic areas. Most methods for screening of G6PD deficiency require special laboratory equipment and can be costly or time-consuming. However, recent advances in G6PD point-of-care (POC) testing aim to improve access to radical cure by accurately identifying individuals at risk of hemolytic anemia secondary to primaquine or tafenoquine therapy. We conducted a clustered, cross-sectional community survey of 840 adults living in 30 villages in Kampong Speu Province, Cambodia to determine performance characteristics of the quantitative STANDARD™ G6PD (SD Biosensor, Suwon, Republic of Korea) POC assay in this population. G6PD activity and hemoglobin concentration in capillary blood were measured at the time and site of collection using the POC assay. Laboratory references for each participant were measured by spectrophotometry and hematology analysis of a corresponding venous specimen in EDTA within three days of collection. Using the nationally proposed G6PD activity threshold for primaquine administration in Cambodia of 6 Units/gram hemoglobin, field diagnosis of individuals with  $\leq 30\%$  median G6PD activity by spectrophotometry was 93% (85–100%) sensitive with a negative predictive value (NPV) of 99% (98–100%). Field diagnosis of individuals with  $\leq 70\%$  median G6PD activity was 65% (53–78%) sensitive with an NPV of 88% (81–94%). Areas under the curve by receiver operator curve analyses were 0.96 and 0.84, respectively. Though data collection on assay performance among febrile individuals presenting for care at health facilities is ongoing, these results suggest that this POC assay is capable of accurately identifying those at the highest risk of primaquine-induced hemolytic anemia.

### IMPACT OF MALARIA RAPID DIAGNOSTIC TESTS SCALE-UP ON ANTIBIOTIC PRESCRIBING AND MORTALITY IN SUB-SAHARAN AFRICA

Han Zhang, Jessica Cohen

Harvard University, Boston, MA, United States

The massive scale-up of malaria rapid diagnostic tests (RDTs) in sub-Saharan Africa over the past 10 years is believed to reduce antimalarial overuse and to improve febrile case management. Yet to date there have been no rigorous analysis on whether malaria RDTs scale-up diverts antimalarial overuse to other antimicrobials when test results are negative, especially antibiotics. To estimate the impact of RDTs on antibiotic and antimalarial use and the resulting health implications, we pair country-specific data from the annual operational reports and procurement records from two major donor agencies, the Presidential Malaria Initiative and the Global Fund, with a sample of 125,000 pediatric fever episodes from 42 national household surveys across 13 sub-Saharan Africa countries from 2009-2019. We exploit geographic variation in total number of RDTs distributed via the two donor agencies as an instrument for RDTs take-up. We find that the number of RDTs distributed from donor agencies predicts both blood test take-up at individual level and RDTs use at country level. We find that receiving RDTs increased antibiotic prescribing for febrile children, while antimalarial prescribing remained unchanged. We also examine the implications of receiving RDTs on all-cause mortality among febrile under-five children and find no statistically significant impact on all-cause mortality. However, our results show a large and statistically significant mortality reduction in lower respiratory tract infections concentrated in areas with low RDTs positivity rates. In contrast, respiratory disease mortality increased in areas with high RDTs positivity rates. These results provide the first large-scale causal evidence on the effect of RDTs scale up on the antibiotic prescribing and the resulting health implications in sub-Saharan Africa.

The most used *Plasmodium falciparum* rapid diagnostic tests (RDT) target the Histidine-Rich Protein 2 (HRP2) antigen. However, an increasing number of countries report parasites that carry *hpr2|hrp3* gene deletions, which makes them undetectable by these RDTs. Molecular surveillance of *hpr2|hrp3* deletions is thus crucial but proving the absence of a gene is difficult using conventional PCR techniques. We have developed a novel assay for deletion typing based on digital PCR (dPCR), a highly accurate method to quantify DNA. The assay was optimized on 2 digital PCR systems (BioRad QX200 and Qiagen QiaCuity). The latter allows detection of *hpr2|hrp3* deletions in a single tube. To compare the assay to conventional protocols relying on nested PCR (nPCR) and visualization of the product on gel, 248 samples from asymptomatic infections from western Kenya were screened in triplicate by dPCR and nPCR. For the nPCR, *msp2* was run as control, also in triplicate. Eight percent of samples had a band for *msp2* in all replicates, but no band for *hpr2* in any replicate. Thus, a prevalence of deletion of 8% was observed by nPCR. No deletions were observed by dPCR, indicating false negative results by nPCR. In addition, mixed infections with wild type and *hpr2* deleted parasites presented a challenge for surveillance, as the wild type parasite could mask the presence of the deletion. By dPCR, mixed infections were reliably detected when the proportion of parasites carrying the deletion is >40%. We screened 819 samples from Kenya (248), Tanzania (152), Ghana (98), Ecuador (54), Brazil (209), and southwestern Ethiopia (58) by dPCR. No deletions were observed in samples from Kenya, Ghana, and Tanzania. In Ethiopia 2.1% carried a *hpr2* deletion, and 76.9% *hrp3* deletions (2% *hpr2|hrp3* double deletion). In Brazil, 41% of samples carried *hpr2* deletions, and 53% *hrp3* deletions (39% *hpr2|hrp3* double deletions). In Ecuador, no *hpr2* deletions were observed, but 47% of samples carried *hrp3* deletions. In conclusion, dPCR allows for rapid and highly accurate typing of *hpr2|hrp3* deletions. The assay is currently being set up in Ethiopia for molecular surveillance of *hpr2|hrp3* deletions across Africa.

## THE NEAR-INFRARED SPECTROSCOPY TECHNIQUE CAN NON-INVASIVELY DETECT MALARIA PARASITES THROUGH THE SKIN OF MICE

**Maggy Sikulu-Lord**<sup>1</sup>, Anton Richard Lord<sup>2</sup>, Brendon Goh<sup>1</sup>, Jye Travis<sup>1</sup>, Geoffrey W. Birrell<sup>3</sup>, Marina Chavchich<sup>3</sup>, Ivor E. Harris<sup>3</sup>, Stephen McLeod-Robertson<sup>3</sup>, Anthony Kent<sup>3</sup>, Karin Vanbreda<sup>3</sup>, Michael D. Edstein<sup>3</sup>

<sup>1</sup>The University of Queensland, Brisbane, Australia, <sup>2</sup>Spectroscopy and Data Analysts, Brisbane, Australia, <sup>3</sup>Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia

The near-infrared spectroscopy (NIRS) technique has been applied in various studies to non-invasively predict mosquito age, species identity and to detect infections such as *Wolbachia*, Zika, Dengue and malaria in mosquitoes. Here, using a *Plasmodium berghei*-mouse model, we have demonstrated for the first time that NIRS can also non-invasively, through the skin detect and quantify malaria parasites in mice. The technique simply involves shining a beam of infrared light for approximately 5 seconds on a mouse body part, which partially penetrates the skin, and subsequently collecting a reflected spectral signature. Machine learning techniques were then applied on the spectral signatures to differentiate *P. berghei* infected from uninfected mice and to predict parasitaemia of infected mice. A total of 118 mice were used in this experiment. Half were randomly assigned to a control group (i.e. uninfected) and the remaining half to an infected group. The infected group was intraperitoneally injected with *P. berghei* infected red blood cells (RBC) while the control group were injected with uninfected mice RBC. All mice were scanned non-invasively with a NIR spectrometer at pre-parasite inoculation and again at 24, 48 and 72 h post inoculation. Two spectral signatures were collected from the ears, feet, groin and tail of each mouse at each time point. Models were built to differentiate infected from uninfected mice at each time point and to predict parasitaemia of the infected mice. The positive predictive rate (PPR) and negative predictive rate (NPR) of NIRS was 90% and 100% when parasitaemia levels were ≥2%. However, the PPR ranged from 40-55% and the NPR ranged from 47-75% at lower parasitaemia levels. Surprisingly, NIRS predicted parasitaemia values were consistent with microscopy results with parasitaemia ≥2%. The findings of this study are an important first step towards development of the NIRS technique for diagnosis of malaria in the field. If successful, NIRS will provide a non-invasive, reagent-free and rapid platform for screening hundreds of people per day in malaria endemic areas and guide malaria elimination strategies.

0885

## POTENTIAL APPLICATION OF THE HEMATOLOGY ANALYZER XN-31 PROTOTYPE IN A FIELD MALARIA SURVEILLANCE

**Wataru Kagaya**<sup>1</sup>, Ikki Takehara<sup>2</sup>, Kyoko Kurihara<sup>2</sup>, Gordon Okomo<sup>3</sup>, James Kongere<sup>1</sup>, Jesse Gitaka<sup>4</sup>, Akira Kaneko<sup>1</sup>

<sup>1</sup>Osaka City University, Osaka, Japan, <sup>2</sup>Sysmex corporation, Kobe, Japan, <sup>3</sup>Homa Bay County Government, Homa Bay, Kenya, <sup>4</sup>Mount Kenya University, Thika, Kenya

Early and accurate diagnosis is a key component in malaria control program. Microscopy is the current gold standard; however, it requires training of the examiner, and the results largely rely on the skill of the microscopists. Rapid diagnostic test (RDT) can be performed without training and much faster, but not quantitative. Moreover, recently false negative due to HPR2 deleted parasites are reported. XN-31 prototype (XN-31p), developed by Sysmex cooperation, is an automated hematology analyzer which enables assistance in malaria diagnosis. It can also provide the information of species differentiation and stage specific parasite counts. The machine has a system to analyze the whole blood sample in a minute without any sample preparation. Previous report evaluated this with venous blood samples. Here we test the applicability of this to capillary blood samples and evaluate the effect of sample storage time and temperature on the stability of results. 168 clinically malaria suspected

outpatients in Homa Bay County Referral hospital, Kenya were enrolled in the study. Capillary blood sample was collected from each participant together with venous blood sample. Both samples were tested for malaria with XN-31p, microscopy, RDT, and PCR. The measurement in XN-31p for capillary blood samples was repeated after 6 and 24 hours by storing the samples in room temperature or 4 degrees Celsius. The sensitivity and specificity of XN-31p with capillary blood sample against PCR were 85.7% and 100% respectively and were comparable to that of microscopy and RDT. There was no discordant result between venous blood sample and capillary blood sample in XN-31p. Parasitemia together with major complete blood count are stable under both room temperature and 4 degree even after 24 hours. The results showing the capillary blood samples can be used for this analyzer makes the diagnosis with XN-31p more practical. Furthermore, the stability of the results even under room temperature up to 24 hours gives us the option of transporting and measuring samples collected in a remote area and broaden the applicability of XN-31p not only in the hospital but also in the field survey.

<sup>1</sup>Eijkman Institute for Molecular Biology, Jakarta, Indonesia, <sup>2</sup>Institute Pasteur, Paris, France, <sup>3</sup>Eijkman-Oxford Clinical Research Unit, Jakarta, Indonesia, <sup>4</sup>Health Service, Army of the Republic of Indonesia, Jakarta, Indonesia, <sup>5</sup>Walter + Eliza Hall Institute, Melbourne, Australia

Distinguishing *Plasmodium vivax* primary infections from mosquito bites and relapse infections caused by re-activation of dormant hypnozoite parasites from a previous primary infection is not possible with current diagnostic tools. Serological markers of exposure to *P. vivax* infection and hypnozoite carriage have been previously identified using longitudinal data and developed into a diagnostic tool. This study aims to further validate this diagnostic tool follow-up of returning Indonesian soldiers from the malaria endemic area of southern Papua to the non-endemic area in East Java, Indonesia. Soldiers who were microscopically diagnosed as free of acute *P. vivax* infection voluntarily participated in the study. They were recruited a few weeks after returning to East Java and followed for 24 weeks. Blood samples were collected on the day of recruitment, during regular follow-up time points and at times of symptomatic relapses. Microscopy diagnosis was conducted on all samples. Serology with a Luminex assay for 19 markers was conducted in all enrollment samples and in a sub-sample of soldiers also in all follow-up samples. The diagnostic tool based on a machine learning Random Forest classification algorithm was used to classify the sero-status of samples during the previous 9 months. A total of 294 soldiers were enrolled in the study in December 2018, of which 24 relapsed during follow-up. Another 45 non-relapsing soldiers were detected by PCR and serology in Eijkman Institute for Molecular Biology, Jakarta. Soldiers who relapsed had higher median antibody titers for several of the biomarkers compared to those who did not relapse. The diagnostic tool had 75% sensitivity and 93% specificity at identifying future relapses using blood samples from recruitment day. Recurrent infections strongly boosted antibody titres both in sero-positive and initially sero-negative soldiers. This study demonstrates that serological markers can identify people at risk of *P. vivax* relapses.

Zika virus (ZIKV) infection is strongly associated with major birth defects and serious neurologic complications. A ZIKV vaccine is therefore an important global health priority. To this end, we developed a Zika purified inactivated vaccine (ZPIV) formulation containing 5µg of formalin inactivated Zika virus with 500µg aluminum hydroxide gel adjuvant. We recruited 75 subjects into three groups of 25 including a flavivirus naïve group, a Japanese encephalitis virus (JEV) vaccine (Ixiaro<sup>™</sup>) primed group and a yellow fever virus (YFV) vaccine (Sanofi 17D) primed group. Five subjects per group were randomly assigned to receive placebo. In the primed groups, subjects were given either JEV vaccine or YFV vaccine 72-96 days prior to receipt of experimental purified inactivated ZIKV vaccine. Subjects were given ZPIV in either two or three doses at days 0, 28 and 196-234. Vaccinations were well tolerated in all groups with only pain at the injection site occurring more frequently in vaccinated subjects than placebo recipients (65% vs 21%). An 88% seroconversion rate and geometric mean neutralizing antibody titer (GMT) of 100 was observed in the flavivirus naïve group 28 days following 2 doses of ZPIV. In the JEV and YFV primed groups the seroconversion rates (31% and 25%, respectively) and GMTs (11 and 5, respectively) were significantly lower at the same time point. All groups demonstrated a substantial boost following a third dose, with seroconversion rates of 100%, 90% and 60% and GMTs of 511, 174, and 79 for the flavivirus naïve, JEV primed, and YFV primed groups, respectively. This differential immune response is hypothesized to be secondary to biasing of the immune response towards shared non-neutralizing epitopes between ZIKV and JEV and YFV respectively, and is being further evaluated. Overall, ZPIV is a safe and immunogenic tool that represents a potentially effective countermeasure for ZIKV infection. However a third dose is likely necessary to achieve an adequately robust and durable immune response and significant immune interference may occur between related YFV and JEV vaccines.

### UNIQUE MICROBIAL SIGNATURES ASSOCIATED WITH ZIKA VIRUS INFECTION AND TEMPERATURE IN AEDES ALBOPICTUS AND IDENTIFICATION OF ANTIVIRAL PROPERTIES OF ELIZABETHKINGIA

Maria G. Onyango<sup>1</sup>, Rachel Lange<sup>1</sup>, Sean Bialosuknia<sup>1</sup>, Anne Payne<sup>1</sup>, Nicholas Mathias<sup>1</sup>, Aurelien Vigneron<sup>2</sup>, Dilip Nag<sup>1</sup>, Laura Kramer<sup>1</sup>, Alexander Ciota<sup>1</sup>

Vector-borne pathogens must survive and replicate in the hostile environment in the insect midgut before successful dissemination and transmission. The insect midgut bacteria can have a modulatory effect on their vectorial capacity. The relationship between infection, temperature and the mosquito gut microbiome are not well characterized. The goal of this study was to delineate the effect of Zika virus (ZIKV) infection and temperature variation on the microbial profile of *Aedes albopictus* mosquitoes. *Aedes albopictus* were reared at diurnal temperature of

day 28°C/ night 24°C and day 30°C/ night 26°C. Mosquitoes were given infectious blood meals with 8.3 log<sub>10</sub> PFU/ml ZIKV and 16S rRNA sequencing was performed on midguts at 7 days post infectious bloodmeal exposure. Our results demonstrate that blood feeding, infection and temperature broadly impact midgut microbial communities of *Ae. albopictus*. Further, unique microbes were associated with variable infection outcomes. Most notably, *Elizabethkingia*, a flavobacterium, was found to be associated with both blood digestion and ZIKV infection, particularly at lower temperatures. Subsequent studies demonstrated a negative correlation between ZIKV and *Elizabethkingia* in the midguts of *Ae. albopictus*. Further, *Elizabethkingia* was found to have broad-spectrum antiviral and antibacterial activity inhibiting the replication of *Zika virus* (ZIKV), *Dengue virus* (DENV) and *Chikungunya virus* (CHIKV) and *Escherichia coli* *in vitro* while significantly reducing the infection rates of *Ae. albopictus* for ZIKV *in vivo*. ZIKV and other mosquito-borne viruses remain major public health threats and lack FDA-approved medication or vaccine to treat or prevent them hence the need for alternative approaches that limit the transmission of the pathogens by the mosquito vector. Identification of a midgut microbe with a broad-spectrum antiviral activity could inform novel transmission barrier tools.

### CHIMERIC ZIKA VIRUSES CONTAINING STRUCTURAL PROTEIN GENES OF INSECT-SPECIFIC FLAVIVIRUSES CANNOT REPLICATE IN VERTEBRATE CELLS DUE TO ENTRY AND POST-TRANSLATIONAL RESTRICTIONS

Chandra Tangudu<sup>1</sup>, Jermilia Charles<sup>1</sup>, Daniel Nunez-Avellaneda<sup>1</sup>, Alissa Hargett<sup>1</sup>, Aaron Brault<sup>2</sup>, **Bradley Blitvich<sup>1</sup>**

<sup>1</sup>Iowa State University, Ames, IA, United States, <sup>2</sup>Centers for Disease Control and Prevention, Fort Collins, CO, United States

Long Pine Key virus (LPKV) and Lammi virus are insect-specific flaviviruses that phylogenetically affiliate with dual-host flaviviruses. The goal of this study was to provide insight into the genetic determinants that condition this host range restriction. Chimeras were initially created by replacing select regions of the Zika virus genome, including the pre-membrane and envelope protein (prM-E) genes, with the corresponding regions of the LPKV genome. Of the four chimeras produced, one (the prM-E swap) yielded virus that replicated in mosquito cells. Another chimeric virus with a mosquito replication-competent phenotype was created by inserting the prM-E genes of Lammi virus into a Zika virus genetic background. Vertebrate cells did not support the replication of either chimeric virus although trace to modest amounts of viral antigen were produced, consistent with suboptimal viral entry. These data suggest that dual-host affiliated insect-specific flaviviruses cannot replicate in vertebrate cells due to entry and post-translational restrictions.

### IMMUNE CORRELATES OF PROLONGED ZIKA VIRUS SHEDDING IN HUMAN SEMEN

**Megan B. Vogt<sup>1</sup>**, Erin M. McDonald<sup>2</sup>, Mark Delorey<sup>2</sup>, Paul S. Mead<sup>2</sup>, Sarah A. Hook<sup>2</sup>, Alison F. Hinckley<sup>2</sup>, Aaron C. Brault<sup>2</sup>, Nisha K. Duggal<sup>1</sup>

<sup>1</sup>Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, <sup>2</sup>Centers for Disease Control and Prevention National Center for Emerging and Zoonotic Infectious Diseases, Fort Collins, CO, United States

Zika virus (ZIKV) can cause significant birth defects following maternal infection and is the only flavivirus known to be sexually transmitted in humans. In a human cohort of ZIKV-infected symptomatic men that was established during the ZIKV pandemic, approximately 50% of the men shed viral RNA in their semen, with a prolonged duration of viral shedding in some individuals. Men shedding ZIKV RNA for over 3 months were classified as long-term shedders, and men with undetectable ZIKV RNA shedding were classified as short-term shedders. The mechanism behind prolonged shedding of ZIKV in semen is unknown; however, semen contains various cell populations and immune mediators which

may provide insights into the mechanism(s) of prolonged ZIKV shedding. Case reports from other groups suggest that ZIKV infection increases leukocyte populations and inflammatory cytokine concentrations in semen compared to healthy individuals. Here, we sought to identify changes in semen composition associated with prolonged seminal ZIKV shedding using semen samples from the ZIKV-infected cohort. We hypothesized that long-term shedders would have higher leukocyte counts and inflammatory cytokine concentrations in their semen than short-term shedders. In the first sample collected post-disease onset, leukocyte counts were significantly higher in the long-term shedders compared to the short-term shedders as assessed by flow cytometric analyses. Using Luminex assays, we observed a trend toward higher concentrations of inflammatory cytokines, specifically IL-6 and RANTES, in the semen of long-term shedders compared to the short-term shedders. Increased immune correlates in the semen of long-term shedders may indicate a persistent infection of the male reproductive tract. Future studies will investigate whether these changes in seminal composition are a response to prolonged viral infection in the male reproductive tract. Understanding the mechanisms behind sexual transmission of ZIKV will be crucial to limit ZIKV spread and prevent ZIKV-associated birth defects.

### MULTIPLE INTRODUCTIONS OF ZIKA VIRUS IN THE AMERICAS

**Carla N. Mavian<sup>1</sup>**, Massimiliano S. Tagliamonte<sup>1</sup>, Bernardo Garcia Carreras<sup>1</sup>, Ana I. Bento<sup>2</sup>, Taylor K. Paisie<sup>1</sup>, Simone Marini<sup>1</sup>, Derek A. Cummings<sup>1</sup>, John A. Lednicky<sup>1</sup>, J Glenn Morris Jr<sup>1</sup>, Marco Salemi<sup>1</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>Indiana University, Bloomington, IN, United States

Discovered in 1947 in the Zika forest, Uganda, Zika virus (ZIKV) remained mostly unnoticed before the epidemic in the Americas. Locally-transmitted infections were reported in French Polynesia and Easter Island in 2014. The first autochthonous transmissions in the American continent were reported in Brazil in May 2015. Epidemiological observations and phylogenetic analyses have led to the hypothesis that the 2015-2016 ZIKV epidemic in the Americas was the result of a founder event from Southeast Asia to Brazil, followed by spread into South and Central American countries, as well as the USA. Surprisingly, ZIKV was also isolated from the Caribbean in 2014-2015, despite only being reported two years later. The Caribbean isolates originated from patients living in rural areas of Haiti, west of Port-au-Prince, as early as May of 2014. This timeline overlaps with the one of the French Polynesian outbreak. Since the early estimates, new genomes have been sequenced. In light of this data, suggesting an early circulation of ZIKV in the Caribbean, we re-evaluated the timing and the route of introduction of ZIKV into the Americas using 613 ZIKV full genome sequences, and maximum likelihood and Bayesian phylogeography frameworks. Our results highlight a transmission process resulting from multiple introductions, unlike what was previously thought. While confirming the expected role of Brazil as a dissemination hub, we show the near simultaneous and independent emergence of different viral lineages in Brazil and Haiti as early as three years prior the Americas epidemic. Taken together, our findings illustrate the power of timely monitoring of sub-epidemic strains that may represent early indicators of the emergence, or re-emergence, of arboviruses such ZIKV both at the regional and global level.

### A NOVEL INSECT-SPECIFIC FLAVIVIRUS OFFERS A PROMISING PLATFORM FOR FLAVIVIRUS VACCINES THAT EMPHASIZE HIGH DEGREES OF SAFETY WITHOUT SACRIFICING IMMUNOGENICITY

Danielle L. Porier<sup>1</sup>, Sarah N. Wilson<sup>1</sup>, Dawn I. Auguste<sup>1</sup>, Andrew Leber<sup>2</sup>, James D. Weger-Lucarelli<sup>1</sup>, Scott C. Weaver<sup>3</sup>, Albert J. Auguste<sup>1</sup>

<sup>1</sup>Virginia Tech, Blacksburg, VA, United States, <sup>2</sup>Landos Biopharma Inc., Blacksburg, VA, United States, <sup>3</sup>University of Texas Medical Branch, Galveston, TX, United States

Vaccination remains critical for viral disease outbreak prevention and control, but conventional vaccine development typically involves trade-offs between safety and immunogenicity. To overcome this, we used a novel insect-specific flavivirus (named Aripo virus, ARPV) as a vector to create highly safe, single-dose flavivirus vaccine candidates. ARPV was originally isolated from *Ps. albipes* mosquitoes in Trinidad and, unlike the classical insect-specific flaviviruses, phylogenetically clusters with vertebrate pathogenic flaviviruses. ARPV is also uniquely capable of vertebrate cell entry and induction of an immune response, even in the absence of viral replication. To evaluate this platform, we created a pseudo-inactivated chimeric Zika virus (ZIKV) vaccine candidate, designated ARPV/ZIKV, which expresses genes for the key antigenic ZIKV precursor membrane and envelope (prM-E) proteins. Immunization with ARPV/ZIKV showed exceptional safety due to retention of the ARPV backbone's natural host-restriction in vertebrate cells, as demonstrated by its inability to replicate its genome or translate viral proteins in vertebrate cells *in vitro*. ARPV/ZIKV showed a lack of pathogenicity in multiple murine models, including intracranial inoculation of suckling mice. ARPV/ZIKV was also shown to be highly immunogenic. A single dose of ARPV/ZIKV vaccine offered complete protection against ZIKV-induced morbidity and mortality in various murine models, and against *in utero* transmission of ZIKV after infection of gravid IFNAR<sup>-/-</sup> mice. T-cell depletion studies in IFNAR<sup>-/-</sup> mice, and vaccine efficacy studies in Rag1<sup>-/-</sup>, Tcr<sup>-/-</sup>, and muMt<sup>-/-</sup> mice, showed that neutralizing antibodies are the main contributor to ARPV/ZIKV-induced protection. Murine macrophages exposed to ARPV/ZIKV indicated robust PRR, B-cell receptor, Th1 and Th2 polarization, and antigen presentation signaling. Altogether, success with ARPV/ZIKV shows that chimeric insect-specific flaviviruses are a promising new platform to restrict flavivirus emergence via vaccine development.

### CORRELATION BETWEEN FLAVIVIRUS ANTIBODIES IN SERUM AND ZIKA RNA SHEDDING IN BLOOD, SALIVA, URINE, VAGINAL FLUID AND SEMEN OVER TIME

Edwing Daniel Centeno<sup>1</sup>, Omar Zepeda<sup>1</sup>, Yaoska Reyes<sup>1</sup>, Natalie M. Bowman<sup>2</sup>, Sylvia Becker-Dreps<sup>3</sup>, Matthew H. Collins<sup>4</sup>, Filemon Bucardo<sup>1</sup>

<sup>1</sup>Universidad Nacional Autonoma de Nicaragua, UNAN-Leon, León, Nicaragua, <sup>2</sup>Division of Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, <sup>3</sup>Department of Family Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, USA, <sup>4</sup>Hope Clinic of the Emory Vaccine Center, Division of Infectious Diseases, Department of Medicine, School of Medicine, Emory University, Decatur, Georgia, USA, Decatur, GA, United States

During acute infection, Zika virus (ZIKV) can be found in several body fluids, and persist for weeks to months, raising questions about whether early ZIKV-specific antibodies are effective in viral clearance. This study explores the correlation between long term shedding of ZIKV RNA in different body fluids and presence of ZIKV and dengue (DENV) IgG in acute and convalescent serum. Furthermore, IgG specific to ZIKV EDIII (Z-EDIII) were examined by ELISA at 7, 14, 21, 28, 60, 90 and 180 days post symptom onset (PSO). Serological analysis was available from 113 of 290 suspected Zika cases from the ZIKA-TS study performed from January

2016 to February 2018 in León, Nicaragua. Of these, 39 participants with confirmed acute ZIKV infection by triplicate RT-qPCR provided blood, saliva and urine samples following the sampling protocol described above; patients were considered negative if RT-qPCR was negative in all fluids at enrollment. Of the 39 patients, long term shedding ( $\geq 14$  days PSO) was observed in 26% (n=10) in blood, 46% (n=18) in saliva and 67% (n=26) in urine, also in 4 of 6 women that provided vaginal fluid and in 2 of 2 men that provided semen. On acute serum ( $\leq 4$  days PSO), the mean OD of ZIKV IgG was higher in Zika-Negative than in Zika-Positive (0.920 vs 1.200,  $p=0.037$ , n = 50 vs 63) patients. Long term shedders in blood had lower OD of ZIKV IgG than those clearing the virus earlier (0.220 vs 0.650,  $p=0.047$ ); in contrast, these subjects had higher OD of DENV IgG on acute serum than those clearing the virus earlier (1.830 vs 0.810,  $p=0.01$ ); this trend was not observed for RNA shedding in other fluids. In long term shedders, the highest OD (2.259) of Z-EDIII IgG was observed at 14 days PSO, decreased to 1.281 at 30 days PSO, remained between 0.529 and 0.548 at 60 and 90 days PSO and reached 0.772 at 180 DPSO. This study provides novel observations on Z-EDIII antibody response for 6 months after natural infection. Given that long term ZIKA shedders exhibited higher DENV IgG OD in acute serum, further investigation is warranted to determine whether pre-existing cross-reactive immunity due to DENV infection promotes persistent ZIKV infection or RNA shedding.

### A MULTI-MODAL INTERVENTION TO IMPROVE HAND HYGIENE DURING THE PERINATAL PERIOD: A FEASIBILITY STUDY IN KAMPONG CHHNANG, CAMBODIA

Yolisa Nalule<sup>1</sup>, Por Ir<sup>2</sup>, Supheap Leang<sup>2</sup>, Alison Macintyre<sup>3</sup>, Ponnary Pors<sup>4</sup>, Channa Samol<sup>4</sup>, Robert Dreibelbis<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>National Institute of Public Health, Phnom Penh, Cambodia, <sup>3</sup>WaterAid Australia, Melbourne, Australia, <sup>4</sup>WaterAid Cambodia, Phnom Penh, Cambodia

Globally, infections acquired during birth and the first critical days of postnatal care account for an estimated 15% and 10% of all neonatal and maternal deaths. Risk factors for these infections are predominantly poor hygiene practices in health care facilities and the home environment. Behavioural-science informed interventions targeting a wide range of caregivers and environments are lacking. We assessed the feasibility and limited efficacy of a novel multimodal behaviour change intervention delivered at the facility-level to improve the hand hygiene practices among midwives and caregivers during childbirth through the return to the home environment. The intervention engaged midwives in redesigning the delivery room and incorporating visual cues, leveraged the social environment to promote new norms, and delivered interactive training. For caregivers, the intervention visually demarcated "clean hand zones" in the facility, improved access to hand hygiene infrastructure, and incorporated nurture-related cues to guide, remind and reinforce practice. The hand hygiene practices of all caregivers present during childbirth and the postnatal care period of 99 women and newborns were directly observed across 8 health care facilities - half of which received the 6-month intervention. Multilevel logistic regression models, adjusted for baseline measures, assessed differences in hand hygiene practices between intervention and control facilities. The intervention was associated with increased odds of improved practice prior to labour, delivery or immediate childbirth in the delivery room (Adjusted odds ratio [AOR] = 4.7; 95% confidence interval [CI] = 2.7, 7.7), and prior to newborn care in the post-natal care facility ward (AOR = 9.2; CI = 1.3, 66.2); however, the absolute magnitude of improvements was limited. The intervention was not associated with differences in hygiene practices prior to newborn care in the home environment. Our results suggest the potential of a multimodal behaviour change intervention to improve hand hygiene practices that are critical to maternal and neonatal infection in the facility.

### IMPACT OF A DRINKING WATER, SANITATION, HANDWASHING (WASH) IN SCHOOL PROGRAM ON MENSTRUAL HYGIENE KNOWLEDGE, PRACTICES AND MENSTRUAL RELATED ABSENTEEISM AMONG SECONDARY SCHOOL STUDENTS IN BANGLADESH

Debashish Biswas<sup>1</sup>, Abul Kashem Shoab<sup>1</sup>, Mahbub-Ul Alam<sup>1</sup>, Mahbubur Rahman<sup>1</sup>, Mirza Manbira Sultana<sup>2</sup>, Mahfuj-ur Rahman<sup>2</sup>, Leanne Unicomb<sup>1</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>WaterAid Bangladesh, Dhaka, Bangladesh

We evaluated a menstrual hygiene management (MHM) and behavior change intervention implemented between 2017 and 2019 by WaterAid Bangladesh among 300 schools in three geographic locations in Bangladesh. The intervention provided washing and drying facilities for menstrual cloth, disposal facilities for used pads, MHM corners providing pads inside girls' toilets plus behavior change messages. MHM was promoted by female teachers who educate school girls about MHM. This study aimed to examine whether school interventions influenced menstrual hygiene knowledge and practices among school girls. No baseline data were collected so we enrolled pupils from intervention schools and propensity score matched nonintervention (control) schools. Matching scores were derived using school enrollment, geographical locations, and school infrastructure. From randomly selected intervention schools (n=26) and 26 matched controls a total of 1,040 school girls were enrolled between January and March 2020. Data were collected during student interview on reported knowledge, menstrual hygiene practice and absenteeism attributed to menstruation. Odds ratios (OR) and 95% confidence intervals (95% CIs) were determined using generalized linear models, controlling for cluster level effects and adjusting for individual and school level factors. Students who received the intervention attained significantly higher menstruation knowledge scores. The odds that girls managed menstrual hygiene as recommended in the intervention were significantly higher in the intervention schools than in the control schools (Adjusted OR= 1.32, 95% CI: 1.02, 1.70). Girls from intervention schools missed an average of 1.5 days per menstrual cycle compared to 2.5 days for control schools (adjusted OR: 0.92, 95% CI: 0.87, 0.98). Using a control-matched post intervention study design, courtesy bias among intervention school students and selection bias when recruiting control schools cannot be ruled out. Nevertheless, the evaluation suggests that the intervention was successful in improving menstrual hygiene practices and reduced absenteeism during menstruation.

<sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>University of Maryland, Baltimore, MD, United States,

<sup>4</sup>University of California, San Francisco, San Francisco, CA, United States, <sup>5</sup>University of California, Davis, Davis, CA, United States, <sup>6</sup>Stanford University, Stanford, CA, United States, <sup>7</sup>University of Miami, Miami, FL, United States

We hypothesized that a combined drinking water, sanitation, handwashing, and nutritional intervention (N+WSH) would reduce

systemic inflammation. Within a trial in rural Bangladesh, we cluster-randomized pregnant women into control and N+WSH arms (ClinicalTrials.gov NCT01590095). Among the birth cohort, we quantified IL-1 $\beta$ , IL-6, TNF- $\alpha$ , IL-2, IL-12p70, IFN- $\gamma$ , IL-4, IL-5, IL-13, IL-17A, IL-21, IL-10, and GM-CSF at ages 14 and 28 months. Cytokine ratios were included as prespecified outcomes to examine the net inflammatory environment. Analysis was intention-to-treat. We assessed 704 children. After 1 year, TNF- $\alpha$ /IL-10, IL-12/IL-10, IFN- $\gamma$ /IL-10, and IL-17A/IL-10 ratios were lower in the intervention group compared to the control group (mean difference: -0.11 to -0.19, p<0.05), due to a non-significant elevation of IL-10 in the intervention group, indicating the intervention promoted IL-10 driven immuno-regulation. Similar reductions in ratios of pro-inflammatory cytokines to IL-10 were sustained in the intervention group after 2 years. After 1 year, IL-12/IL-4, IL-12/IL-5, IFN- $\gamma$ /IL-5, and IL-12/IL-13 ratios were lower in the intervention group (mean difference: -0.18 to -0.27, p<0.05), suggesting a shift towards a Th2 cytokine response. Subsequently, children in the intervention group experienced a greater decrease in their Th2 response between years 1 and 2. By year 2, there was no difference in Th1 or Th2 response between the groups. These findings indicate that during the first year of life, the N+WSH intervention enhanced IL-10 driven immuno-regulation which continued through year 2. Th2 cytokine driven immune responses, which are important for elimination of extracellular pathogens were also enhanced in year 1, but not in year 2, perhaps because successful reduction of extracellular pathogens could facilitate a rebalancing of the Th1 and Th2 cytokine systems. Our results suggest that the N+WSH intervention enhanced the immuno-protective and immuno-regulatory responses, and suppressed/counteracted the inflammatory/immuno-pathological response, of the immune triad.

<sup>3</sup>University of California, Berkeley, Berkeley, CA, United States, <sup>4</sup>Stanford

University, Stanford, CA, United States, <sup>5</sup>University of California, San

Francisco, San Francisco, CA, United States

Household latrine access generally is not associated with reduced fecal contamination in the environment, but its long-term effectiveness has not been measured. We conducted an environmental assessment nested within the WASH Benefits Bangladesh randomized controlled trial (NCT01590095) to measure the effectiveness of a sanitation intervention on environmental fecal contamination over time. The intervention included latrines, child feces management tools, and behavioral promotion, and intervention uptake was high. We quantified *E. coli* and fecal coliforms in samples of stored drinking water, child hands, mother hands, soil, and food among a random sample of households (n = 720) from the sanitation and control arms of the trial. A total of 16,732 samples were collected during eight quarterly visits approximately 1–3.5 years after intervention initiation. *E. coli* was detected in 81% of stored water samples, 74% of child hand rinses, 75% of mother hand rinses, 95% of soil samples, and 68% of stored food samples. Overall, there were no substantial differences in environmental fecal contamination between the sanitation and control arms. Statistically significant reductions in mean log<sub>10</sub> counts of *E. coli* were found in stored water ( $\Delta$ log<sub>10</sub> = -0.08, 95% CI -0.15, 0.00) and child hands ( $\Delta$ log<sub>10</sub> = -0.08, 95% CI -0.15, 0.00) after pooling across sampling rounds, but the effects were small and not consistent across rounds. In addition, we assessed potential effect modification by follow-up time, season, wealth, community-level latrine density and coverage, population density, and domestic animal ownership. While the intervention

led to statistically significant reductions in *E. coli* counts within some subgroups, there were no consistent patterns of effect modification. Our findings support a growing consensus that on-site latrines are insufficient to prevent fecal contamination in the rural household environment.

0898

### PROMOTING IMPROVED BACKYARD POULTRY-RAISING PRACTICES TO REDUCE YOUNG CHILDREN'S EXPOSURE TO POULTRY FECES: A PILOT STUDY IN RURAL BANGLADESH

Tarique Mohammad Huda<sup>1</sup>, Jesmin Sultana<sup>1</sup>, Elizabeth D. Thomas<sup>2</sup>, Mohammad Rofi Uddin<sup>1</sup>, Shifat Khan<sup>1</sup>, Md. Aminul Islam<sup>1</sup>, Ireen Sultana Shanta<sup>1</sup>, Fosiul Alam Nizame<sup>1</sup>, Mahbubur Rahman<sup>1</sup>, Peter Winch<sup>2</sup>, Laura H. Kwong<sup>3</sup>

<sup>1</sup>icddr, Dhaka, Bangladesh, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Stanford University, Stanford, CA, United States

Backyard poultry-raising is common in rural households in Bangladesh. Raising poultry contributes to fecal contamination of the domestic environment, increasing children's exposure to enteric pathogens, including *Campylobacter* spp. The objective of this study was to investigate the effectiveness of a behavior change communication and counseling intervention to encourage backyard poultry-raising households to confine poultry outside of the household dwelling in and shed at night and improve poultry feces management. We conducted a two-arm pilot study where household members in both arms participated in a behavior change communication and counseling intervention called Neighborhood-based Environmental Assessment and Planning for four months, and households in one arm received a 23 USD subsidy for the construction of poultry shed for nighttime housing. We administered a household survey and spot-check before and after intervention implementation among 37 subsidy and 42 non-subsidy households. At endline, 58% of all households build a poultry shed (87% of subsidy households and 33% of non-subsidy households). The proportion of households confining all poultry outside the household dwelling the previous night was significantly higher at follow-up (33%) compared to baseline (2.5%) (prevalence difference: 30%, 95% CI: 19 to 41). At follow-up, more households had no visible poultry feces piles inside the dwelling compared to baseline (prevalence difference: 26%, 95% CI: 12 to 41), but there were no significant differences in the number of poultry feces piles in the courtyard or veranda at follow-up compared to baseline. Our intervention effectively encouraged households to confine poultry outside of household dwelling at night and to manage poultry feces better. Households receiving a subsidy may be more likely to build a poultry shed within the study period, but some households may be able to build a shed without monetary support. Future studies should assess if housing all poultry outside the household dwelling reduces children's exposure to poultry feces and related health risks.

### \$20 SENSOR MEASURED USE CONSISTENCY IN HOUSEHOLD WATER TREATMENT DEVICES IN LIMPOPO, SOUTH AFRICA

David D. Meyer<sup>1</sup>, Courtney Hill<sup>2</sup>, Kelly McCain<sup>2</sup>, James A. Smith<sup>2</sup>, Pascal O. Bessong<sup>3</sup>, Elizabeth T. Rogawski McQuade<sup>2</sup>, Natasha C. Wright<sup>4</sup>

<sup>1</sup>University of Toronto, Toronto, ON, Canada, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>University of Venda, Limpopo Province, South Africa, <sup>4</sup>University of Minnesota, Minneapolis, MN, United States

The health benefits from household water treatment and safe storage devices depend on correct and consistent use. Occasional lapses in use can cause dramatically non-linear declines in intervention efficacy. Current measures of intervention use fail to capture this non-linearity, even when sensors are used. We invented and validated a novel sensor embedded in the handle of a water treatment or safe storage device that measures how consistently the device is used. We define consistent use nonlinearly as the proportion of days on which a device was used each day for at

least 7 previous days. 232 sensors measured >60,000 water withdrawals on three different types of water treatment or safe storage devices in Limpopo, South Africa. We used our (non-linear) consistent use metric and sensor data to: (1) Demonstrate how households with high, but imperfect use prevalence, are critical targets for behavior change efforts (e.g. increasing use from 89 to 99% of days improves consistent use by 49 percentage points); (2) Emphasize that surveys dramatically overestimate consistent use (by 53 percentage points in our study); and (3) Derive and demonstrate a probabilistic model showing how use prevalence (q) affects contact times in water treatment devices. Mean contact time scales with  $1/q$  and the Nth percentile contact times scales with  $\log(1-N/100)/\log(1-q)$ . Only 5% of field-measured contact times exceed our predicted 95th percentile. Relating contact time and use prevalence has implications for household-level disinfection devices reliant on contact times; e.g., those using chlorine, iodine, bromine, silver, and/or solar radiation. Sensors provided useful and objective data on the prevalence of consistent use. The dramatically reduced cost of sensors (10x less than published alternatives) increases how many water treatment sensors can be deployed by an order of magnitude, enabling widespread sensor use for (and potentially beyond) research.

### SELECTION AND USE OF A SARS-COV-2 SURROGATE IN SURFACE DISINFECTION EFFICACY STUDIES WITH CHLORINE AND ANTIMICROBIAL SURFACES

Gabrielle String<sup>1</sup>, Mitchell White<sup>2</sup>, David Gute<sup>1</sup>, Elke Mühlberger<sup>2</sup>, Daniele Lantagne<sup>3</sup>

<sup>1</sup>Tufts University, Medford, MA, United States, <sup>2</sup>Boston University, Boston, MA, United States, <sup>3</sup>Lancon Environmental LLC, Cambridge, MA, United States

Initial recommendations for surface disinfection to prevent SARS-CoV-2 transmission were developed using previous evidence from potential surrogates. To our knowledge, no appropriate surrogate for SARS-CoV-2 has been identified/confirmed for chlorine and antimicrobial surface disinfection. Furthermore, efficacy of chlorine disinfection against SARS-CoV-2 on surfaces relevant to low-resource contexts is unknown. We completed a study to evaluate the efficacy of two hypothesized antimicrobial surfaces, and four chlorine solutions on non-porous and porous surfaces, against SARS-CoV-2 and three potential SARS-CoV-2 surrogates (coronavirus mouse hepatitis virus (MHV) and bacteriophages Phi6 and MS2), to identify a BSL-1/BSL-2 virus to use in future studies. Additionally, in a follow-on study we used the identified surrogate to test the efficacy of chlorinated disinfection on soiled surfaces in a range of environmental conditions. To mimic soiling conditions, we utilized a combination of BSA, TSA, and bovine mucine as recommended by ASTM test guidelines. Surfaces were maintained in a controlled environmental chamber for one hour, exposed to varying relative humidities (23%, 55%, 85%) and temperatures (4°C, 25°C, and 40°C). We found SARS-CoV-2 can be reduced >4 log<sub>10</sub> on porous and non-porous surfaces within 30 seconds exposure to 0.5% NaOCl. Results indicate coronavirus MHV-GFP is inactivated faster than SARS-CoV-2 (0.05% NaOCl k-value 32.59 min<sup>-1</sup> vs. 3.07 min<sup>-1</sup>) and MS2 is inactivated more slowly (across multiple k-value timepoints). Phi6 is inactivated similarly to SARS-CoV-2 (0.5% NaOCl k-value 21.44 min<sup>-1</sup> vs. 24.44 min<sup>-1</sup>) and we propose Phi6 as a slightly conservative surrogate for SARS-CoV-2 chlorine disinfection. Additionally, disinfection of bacteriophages on wood was challenging, and exposure to antimicrobial surfaces had no disinfection efficacy as tested. We recommend using 0.5% chlorine on surfaces to disinfect SARS-CoV-2, and recommend additional research on Phi6 disinfection with other disinfectants relevant to the field, such as simulated sunlight or soapy water.

0901

### DIAGNOSTIC YIELD OF ADDING THE BIOFIRE® FILMARRAY® MENINGITIS/ENCEPHALITIS PANEL TO ROUTINELY AVAILABLE DIAGNOSTICS FOR CENTRAL NERVOUS SYSTEM INFECTIONS IN BOTSWANA

Christopher G. Williams<sup>1</sup>, Kwana Lechiile<sup>1</sup>, Leah Owen<sup>2</sup>, Hannah Barton<sup>2</sup>, Ezekiel Gwakuba<sup>2</sup>, Thandi Milton<sup>2</sup>, Ponego Ponatshego<sup>1</sup>, Kaelo Seatla<sup>1</sup>, Tshupo Leeme<sup>1</sup>, Ikanyeng Rulaganyang<sup>2</sup>, Tichaona Machiya<sup>3</sup>, William Hurt<sup>2</sup>, Mark Tenforde<sup>4</sup>, Margaret Mokomane<sup>5</sup>, Madisa Mine<sup>5</sup>, David M. Goldfarb<sup>6</sup>, Joseph N. Jarvis<sup>7</sup>

<sup>1</sup>Botswana Harvard AIDS Institute Partnership, Gaborone, Botswana, <sup>2</sup>Botswana U-Penn Partnership, Gaborone, Botswana, <sup>3</sup>Ministry of Health and Wellness, Gaborone, Botswana, <sup>4</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>5</sup>National Health Laboratory, Gaborone, Botswana, <sup>6</sup>BC Children's Hospital Research Institute, Vancouver, BC, Canada, <sup>7</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Despite the availability of routine diagnostics for central nervous system (CNS) infections in Botswana many patients do not receive a microbiological diagnosis. Molecular diagnostics may help address this issue. We aimed to determine the additional yield of a multiplex PCR platform used alongside routine diagnostics in a high HIV-prevalence setting. We prospectively evaluated the FilmArray® Meningitis/Encephalitis (ME) panel which detects 14 common pathogens associated with CNS infection. We tested all CSF samples collected at Princess Marina Hospital in Gaborone. Samples also underwent routine testing including microscopy, Gram stain, cell count, culture, India Ink and cryptococcal antigen (CrAg). We calculated the additional diagnostic yield for all patients and, given the widespread availability of highly sensitive diagnostics, excluding those diagnosed with cryptococcal meningitis (CM) on routine testing. Between May 2017 and November 2018, 690 patients underwent ME panel testing. 319 (46.2%) female, 419 (60.7%) adults >15 years, 45 (6.5%) children 2-14 years, 143 (20.7%) infants 1-23 months and 82 (11.9%) neonates <28 days. 317/419 (75.7%) adults were HIV positive. The ME panel increased the number of patients with a microbiological diagnosis from 101 to 146 (relative increase 44.6%; 12.8 tests required per additional diagnosis). The ME panel detected an additional 15 bacterial infections (9 *S. pneumoniae*, 2 *S. agalactiae*, 2 *H. influenzae*, 2 *E. coli*) and 39 viral infections (15 CMV, 13 HHV-6, 5 VZV, 4 enterovirus, 1 HSV-1 and 1 HSV-2). Excluding neonates, among 533 patients without CM, the ME panel increased the number of patients with a microbiological diagnosis from 26 to 71 (relative increase 173.1%; 10.9 tests required per additional diagnosis). 460/690 (66.7%) had normocellular CSF and 82/690 (11.9%) had CSF pleocytosis without a microbiological diagnosis. The ME panel increased the proportion of patients with a microbiological diagnosis. Scale up of enhanced diagnostics, including those for TB which were not widely used during this study, may help to further characterise the epidemiology of CNS infections in Botswana.

### DEVELOPMENT AND PERFORMANCE EVALUATION OF A LOW-COST, HIGH THROUGHPUT, MULTIPLEX IMMUNOASSAY OF THIRTEEN FEVER SEVERITY AND ETIOLOGY MARKERS

Tegwen Marlais<sup>1</sup>, Becca L. Handley<sup>1</sup>, Elizabeth A. Ashley<sup>2</sup>, Chris Drakeley<sup>1</sup>, Manophab Luangraj<sup>2</sup>, Yoel Lubell<sup>3</sup>, David Mabey<sup>1</sup>, Mayfong Mayxay<sup>2</sup>, Paul N. Newton<sup>2</sup>, Heidi Hopkins<sup>1</sup>, Chrissy H. Roberts<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Lao-Oxford-Mahosot Hospital-Wellcome Trust Research Unit (LOMWRU), Vientiane, Lao People's Democratic Republic, <sup>3</sup>Mahidol-Oxford Tropical Medicine Research Unit (MORU), Bangkok, Thailand

Fever is among the most commonly reported symptoms globally. Commercial kits are available that facilitate multiplexed screening of blood markers of diseases, but these may not be tailored to the purpose of

investigating fever and/or may be time consuming and costly to perform at scale. We developed a bead-based multiplex immunoassay that estimates the levels of 13 fever-relevant immune response markers in dried blood spot (DBS) specimens. The markers, together or in various combinations, were selected for their known utility, both in the identification of bacterial infection, as well as being prognosticators. The markers were angiopoietins 1 & 2, azurocidin, C-reactive protein, chitinase 3-like 1, interleukins 6, 8 & 10, interferon  $\gamma$ -induced protein 10 kDa, myxovirus resistance protein A, soluble triggering receptor expressed on myeloid cells 1, soluble tumor necrosis factor receptor 1 and tumor necrosis factor-related apoptosis-inducing ligand. All reagents were sourced commercially. Cross-reactivity assessments revealed minimal non-specific interaction between either the antibody pairs, or antibodies and recombinant proteins. The 13 assays worked over a wide range of concentrations including those expected in health and febrile disease of different etiologies. The average within-plate and between-plate coefficients of variation (CVs) were 5.3% and 3.9%, respectively. The fully optimised 13-plex assay cost is around £3.30/\$4.60 per sample. The full protocol will be published as an open resource. We tested 720 DBS samples from adult and paediatric inpatient and outpatient fever cases and community controls collected during a prospective study of febrile illness in Lao PDR. Several markers in the panel could differentiate between fever cases and healthy controls, with 4 in particular contributing to this. This assay facilitates large-scale screening of DBS samples from population-based studies to investigate relationships between levels of immune response markers, data from infectious diseases diagnostics and severity of illness in different clinical contexts.

Identifying patients with the highest risk of mortality from easily measurable variables can improve prioritization and thus resource allocation of potentially life-saving interventions. The modified early warning score (MEWS), the quick Sequential (Sepsis-Related) Organ Failure Assessment (qSOFA), and the Universal Vital Assessment (UVA) score were developed as risk-stratification tools but need external validation in new patient groups and settings. We included in the analysis in- and outpatients aged  $\geq 16$  years presenting with fever at four sites in Laos, Malawi, Mozambique, and Zimbabwe as part of a prospective study of infectious causes of fever (Febrile Illness Evaluation in a Broad Range of Endemicities - FIEBRE). We determined mortality at a follow-up visit after

at least 26 days. We evaluated predictive capacity based on the area under the receiver operating curve (AUC), as well as sensitivity at a cut-off which gives 90% specificity. We enrolled 4,023 patients; 1,715 (43%) inpatients, 2,336 (58%) female, median (IQR) age 33 (24 - 45) years, and 782 (19%) HIV-infected. Of the total, 1,182 (29%) were in Laos, 807 (20%) in Malawi, 998 (25%) in Mozambique, and 1036 (26%) in Zimbabwe. Complete outcome information was available for 3,432 (85%); 210 (6.1%) died, including 187 (13.2%) inpatients and 23 (1.1%) outpatients. The UVA had an AUC of 0.77 (95% CI 0.74 - 0.81), outperforming both MEWS with AUC 0.65 (95% CI 0.61 - 0.69) and qSOFA with AUC 0.68 (95% CI 0.65 - 0.72). The relative performance of the scores remained the same on sensitivity analysis assuming patients with missing outcome data either all lived, or all died. The observed AUC of UVA was higher than MEWS and qSOFA in each site, varying from 0.88 (95% CI 0.79 - 0.99) in Malawi to 0.75 (95% CI 0.69 - 0.81) in Laos. At a set specificity of 90%, UVA sensitivity (95% CI) was 46.5% (39.9% - 53.0%) compared to 18.6% (10.9% - 27.5%) for qSOFA, and 22.9% (17.5% - 28.8%) for MEWS. Our findings suggest that of the scores assessed, UVA best predicts mortality in febrile adults across a range of health care settings in Africa and south-east Asia, and may be well-suited for clinical use in similar contexts.

## 0904

### DECREASED MUSCLE OXYGENATION AND PH ARE EARLY AND SENSITIVE INDICATORS FOR DENGUE SEVERITY

**Anon Srikiatkhachorn**<sup>1</sup>, Darunee Buddhari<sup>2</sup>, Alden L. Weg<sup>3</sup>, Kamchai Rungsimanphaiboon<sup>4</sup>, Angkhana Ouppapong<sup>4</sup>, Surachai Kaewhira<sup>5</sup>, Janya Chaisirirat<sup>4</sup>, Alan L. Rothman<sup>1</sup>, Stefan Fernandez<sup>2</sup>, Babs Soller<sup>6</sup>, Sharone Green<sup>7</sup>

<sup>1</sup>University of Rhode Island, Providence, RI, United States, <sup>2</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>3</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>4</sup>Kamphaeng Phet Provincial Hospital, Kamphaeng Phet, Thailand, <sup>5</sup>Pichit Provincial Hospital, Pichit, Thailand, <sup>6</sup>Tradewinds Science Inc., Carlsbad, CA, United States, <sup>7</sup>University of Massachusetts Medical School, Worcester, MA, United States

Management of dengue is challenging due to the lack of an early indicator for disease severity. We have shown that muscle oxygenation (SmO<sub>2</sub>) levels determined twice daily correlated with severity in a small number of pediatric dengue cases. In this study, we evaluated the utility of continuous measurement of SmO<sub>2</sub> and pH as a monitoring tool for dengue severity in a prospective study of patients hospitalized with suspected dengue. Dengue cases were confirmed by RT-PCR of plasma samples and by paired serology. Dengue cases were classified into dengue fever (DF) and dengue hemorrhagic fever (DHF), and into dengue, dengue with warning signs, and severe dengue. Continuous measurement of SmO<sub>2</sub> and pH was carried out with a wearable infrared spectrophotometric device. Forty-four subjects (19 children, 25 adults) completed the study. There were 8 DF, 6 DHF cases in children, and 3 DF and 12 DHF cases in adults. Children with dengue were classified into 7 cases of dengue and 7 cases of dengue with warning signs. There were 8, 5, and 2 cases of dengue, dengue with warning signs, and severe dengue in adults. Different patterns of SmO<sub>2</sub> and pH were observed between DF and DHF with declines in SmO<sub>2</sub> and pH around the time of fever resolution in DHF. A similar trend was found in severe dengue but not in dengue with warning signs. Differences in SmO<sub>2</sub> levels between DF and DHF cases were detected starting 12 hours before fever resolution and persisted for 48 hours. SmO<sub>2</sub> levels were lower in adults with DHF compared to children six hours before defervescence (75.4 (3)% (mean (SD)) in children and 60.3 (7)% in adults). The nadir of muscle oxygenation levels correlated with minimum systolic and diastolic blood pressures, minimum pulse pressures, and muscle pH. The study demonstrated that tissue hypoxia occurred in dengue hemorrhagic fever as early as twelve hours before defervescence, even in the absence of clinical signs of circulatory compromise. Adults with DHF appeared to be more severely affected than children. Monitoring of muscle oxygenation and pH is a promising tool in clinical management of dengue.

## 0905

### TREATMENT OF COVID-19 WITH REMDESIVIR AND CONVALESCENT PLASMA: A PROSPECTIVE, OBSERVATIONAL STUDY

**Pradip Gyanwali**<sup>1</sup>, Meghnath Dhimal<sup>1</sup>, Saroj Bhattarai<sup>1</sup>, Bipin Nepal<sup>2</sup>, Rekha Manandhar<sup>3</sup>, Runa Jha<sup>3</sup>, Prabhat Adhikari<sup>2</sup>, Chhabi Lal Panthi<sup>1</sup>, Bihungum Bista<sup>1</sup>, Suman Pant<sup>1</sup>, Shristi Karki<sup>1</sup>, Janak Koirala<sup>1</sup>, Nepal COVID-19 Clinical Study Collaborators<sup>1</sup>

<sup>1</sup>Nepal Health Research Council, Kathmandu, Nepal, <sup>2</sup>Grande International Hospital, Kathmandu, Nepal, <sup>3</sup>National Public Health Laboratory, Kathmandu, Nepal

Remdesivir and convalescent plasma therapy (CPT) were approved as investigational therapies to treat COVID-19 in Nepal. We conducted a prospective, multicentered, observational study to evaluate the safety and outcomes of remdesivir and CPT to treat COVID-19 in hospitalized patients. Patients over 18 years age, who were admitted to hospitals with a diagnosis of COVID-19 and a positive PCR, and received remdesivir, CPT, or both, were eligible for study enrollment. Other antiviral agents were excluded but immunomodulators including steroids were allowed. Clinical findings, lab results, adverse events, and outcomes were collected in a central electronic database. We enrolled 1315 patients from 31 hospitals across Nepal. Patients were classified as having moderate (24.2%), severe (64%) or life-threatening (11.7%) COVID-19. Of 1083 patients with reported outcomes, 78.4% were discharged (74% in good condition, 4.4% with disability) and 21.6% died. Discharge rate was 84% for remdesivir recipients (N=910), 39% for CPT recipients (N=59), and 54.4% for CPT+REM (N=114) recipients. Most of CPT recipients (98.3%) or CPT+REM recipients (92.1%) had severe to life-threatening infections, and they were admitted to the ICU (CPT 91.8%; CPT+REM 94.6%) compared to REM alone recipients (severe to life threatening 73.3% and ICU admission 57.5%). In a logistic model comparing death vs discharge and adjusted for age, gender, steroid use, and severity, the predicted margin for discharge was higher for remdesivir alone recipients (0.82; 95%CI 0.79-0.84) compared to CPT (0.58; 95%CI 0.47-0.70) or CPT+REM (0.67; 95%CI 0.60-0.74) recipients. Adverse events of Remdesivir and CPT were reported in less than 5% of the patients. In conclusion, most patients who received CPT alone or CPT with remdesivir had severe to life threatening COVID-19 infection and a higher mortality compared to remdesivir alone recipients. Both CPT and remdesivir were tolerated well by the patients in Nepal.

## 0906

### LIMITED CLINICAL DISEASE DESPITE RAPIDLY INCREASING SARS-COV-2 SEROPREVALENCE IN MALI, WEST AFRICA

**John Woodford**<sup>1</sup>, Jennifer Kwan<sup>2</sup>, Abdoulaye Katile<sup>3</sup>, Bourama Kamate<sup>3</sup>, Mamady Kone<sup>3</sup>, Mahamadoun Hamady Assadou<sup>3</sup>, Oumar Attaher<sup>3</sup>, Emily Higbee<sup>1</sup>, Jacquelyn Lane<sup>1</sup>, David Cook<sup>1</sup>, Sara Healy<sup>1</sup>, M'Bouye Doucoure<sup>3</sup>, Amatigue Zeguime<sup>3</sup>, Irfan Zaidi<sup>1</sup>, Justin Doritchamou<sup>1</sup>, Alassane Dicko<sup>3</sup>, Patrick Duffy<sup>1</sup>, Issaka Sagara<sup>3</sup>

<sup>1</sup>Laboratory of Malaria Immunology and Vaccinology, NIAID, MD, United States, <sup>2</sup>Laboratory of Clinical Immunology and Microbiology, NIAID, MD, United States, <sup>3</sup>Malaria Research and Training Center, Mali-NIAID ICER, Bamako, Mali

The burden of SARS-CoV-2 in West Africa is not well understood. We have previously reported that over half of the population around Bamako may have been exposed. To understand the clinical burden associated with SARS-CoV-2 seroconversion we analyzed clinical information collected during a two visit serosurvey at Sotuba (urban), Bancoumana (rural) and Doneguebougou (rural). In a subset of participants co-enrolled in clinical trials at study sites, adverse events (AEs) occurring between serosurvey visits were also assessed. Study visit 1 was completed just before the malaria season (July/October) and visit 2 was completed just after the malaria season (December 2020/January 2021). The two visit completion rate was 94.8% (2533/2672). At visit 1 symptoms were reported

infrequently. Compared to seronegative cases, several systemic symptoms were more common in seropositive cases including fever (8.5% vs 4.0%), chills (1.7% vs 0.4%), myalgia (3.5% vs 0.7%), and headache (11% vs 3.7%). At visit 2, recent symptoms were reported more frequently in all participants. Only chills (3.7% vs 2.1%) and fatigue (4.3% vs 2.5%) were more common among seropositive cases. At each visit, systemic symptoms (any) approached independent association with serostatus following multiple logistic regression (OR 1.72, 95% CI: 0.96-2.98 and OR 1.22, 95% CI: 0.97-1.52). Respiratory and gastrointestinal symptoms did not clearly differ based on serostatus at either visit. In a subset (n=146) at Bancoumana, AEs possibly related to COVID-19 did not differ based on serostatus. In a subset (n=1037) at Doneguebougou, rhinitis (33.3% vs 25.1%) and headache (18.3% vs 9.4%) were more common among seropositive cases. The rate of malaria infection did not differ with serostatus and was approximately 35%. Six hospitalizations were reported in the study period (3 seropositive and 3 seronegative cases), below the rate predicted using age-stratified US COVID-19 data. COVID-19 attributable symptoms and severe complications are uncommon in the community in Mali despite high seroconversion rates and may fall within background illness rates during the malaria transmission season.

Metagenomic investigation of pathogens causing undifferentiated fevers can identify an underappreciated diversity of pathogens, particularly in resource-scarce settings where extensive diagnostics are not available. In peri-urban Cambodia, we enrolled 489 febrile participants from March 2019 to October 2020 via: 1) a cross-sectional hospital-based study of patients 2 to 65 years of age; 2) a community-based longitudinal cohort aged 2-9 years old. Demographics, symptoms, behavioral and risk factor data was collected and stored in a REDCAP® database. Locational data of village locations were referenced using Google Earth. Environmental indices (EI) for surface water and vegetation were extracted from Moderate Resolution Imaging Spectroradiometer products. We isolated RNA from sera and prepared sequencing libraries that were

run on an iSeq100 (Illumina) in Phnom Penh, Cambodia. Next, we performed bioinformatic analysis using IDseq, an open-source cloud-based platform, to identify pathogens. We used a multivariate analysis to identify determinants of vector-borne disease. Ultimately, we identified dengue virus (124/487), chikungunya (10/487), *Plasmodium vivax* (6/487), rickettsial-like pathogens (13/487), and rotavirus A (6/487) in addition to a variety of other pathogens of low abundance. Participants 5 to 18 years of age were more likely to contract vector-borne diseases (for 5 to 10 years of age; OR 2.35, 95% CI (1.11–5.06); OR 2.68 for 10 to 18 years of age; 1.4–5.29) compared to those older than 18 years of age. Likelihood of infection with a vector-borne disease was also increased by household car ownership (OR 1.95, 95% CI 1.19–3.21) and proximity to surface flooding (OR 2.04, 95% CI 1.24–3.49). The pathogen landscape defined by metagenomic sequencing is diverse, but predominantly vector-borne owing to arboviral epidemics during the study.

0908

### KINETICS AND FUNCTIONALITY OF NATURALLY ACQUIRED ANTIBODY RESPONSES TO PLASMODIUM FALCIPARUM GAMETOCYTE ANTIGENS IN AN AREA OF INTENSE MALARIA TRANSMISSION IN UGANDA

Patience Nayebare<sup>1</sup>, Jonathan Mandel<sup>2</sup>, Gerine Nijman<sup>2</sup>, John Rek<sup>1</sup>, Emmanuel Arinaitwe<sup>1</sup>, Ivo Hansen<sup>2</sup>, Matthijs Jore<sup>2</sup>, Moses Kanya<sup>1</sup>, Grant Dorsey<sup>3</sup>, Sarah Staedke<sup>4</sup>, Chris Drakeley<sup>4</sup>, William Stone<sup>4</sup>, Teun Bousema<sup>2</sup>

<sup>1</sup>IDRC, Kampala, Uganda, <sup>2</sup>Radboudumc, Nijmegen, Netherlands, <sup>3</sup>UC-SF, San Francisco, CA, United States, <sup>4</sup>LSHTM, London, United Kingdom

Naturally acquired antibody responses to gametocyte antigens can reduce the transmission of *P. falciparum* gametocytes to mosquitoes. Plasma samples were taken every 3 months between 2011 and 2017 from 433 cohort participants who resided in Tororo, Uganda, during which transmission declined due to highly effective malaria control. Parasite carriage was determined by microscopy and a molecular assay. Overall, 2484 plasma samples (4 time-points over 5 years) were analysed by ELISA for reactivity against total gametocyte (NF54) lysate or recombinant full-length Pfs48/45 and Pfs230-CMB, and for surface recognition in a novel gamete binding assay. Functional transmission blocking immunity was assessed by standard membrane feeding assay (SMFA) with NF54 gametocytes. Analyses are ongoing; preliminary results indicate prevalence of antibodies against Pfs230 of 39.5% (163/413) in children under 5, 65.3% (571/875) in children 5-11 years and 84.9% (372/438) in adults (>18 years). For Pfs48/45, antibody prevalences were 13.4% (37/277), 44.6% (263/590) and 76.0% (231/304), respectively. Compared to parasite-free individuals, anti-Pfs48/45 antibody prevalence was higher in those with submicroscopic infections (OR 2.02, 95%CI 1.28-3.17), microscopically-detected infections (OR 1.80, 95%CI 1.11-2.91) or microscopically-detected gametocytes (OR 3.96, 95%CI 1.35-11.7). Among the first 263 samples tested, we identified 11 samples (individuals aged 6.0 – 65 years) that fully blocked transmission in the SMFA. Ongoing work will examine the kinetics of (functional) immunity, with up to 16 time-points of individuals classified as transmission-blockers and selected non-blockers in relation to malaria exposure. In the largest longitudinal study of its kind, we detected high recognition of recombinant gametocyte antigens. Our study addresses a knowledge gap in our understanding of the relevance of anti-gametocyte immunity in relation to (changes in) parasite exposure and may inform the development and deployment of transmission-blocking vaccines.

### SEX-BASED IMMUNOLOGICAL DIFFERENCES AMONG MALARIA-EXPOSED UGANDANS INCLUDES ABERRANT HEMATOPOIESIS

Jason Nideffer<sup>1</sup>, Maureen Ty<sup>1</sup>, Patience Nayebare<sup>2</sup>, Felistas Nankya<sup>2</sup>, Kenneth Musinguzi<sup>2</sup>, Jessica Briggs<sup>3</sup>, Bryan Greenhouse<sup>3</sup>, Rek John<sup>2</sup>, Moses Kanya<sup>4</sup>, Grant Dorsey<sup>3</sup>, Isaac Ssewanyana<sup>2</sup>, Prasanna Jagannathan<sup>1</sup>

<sup>1</sup>Stanford University, Stanford, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>Makerere University, Kampala, Uganda

Multiple studies have demonstrated a sex-bias in *Plasmodium falciparum* prevalence in malaria-endemic settings, with greater prevalence in males compared to females. A recent study from our collaboration found that this bias was not explained by sex-based differences in behavior, malaria incidence, or force of infection, but was instead attributed to a slower rate of infection clearance among males, suggesting an immunological basis. We therefore compared immune profiles between 49 males and females living in malaria-endemic Tororo, Uganda. Innate and adaptive cellular phenotypes as well as responses to toll-like receptor and malaria antigenic stimulation were compared in males and females by flow cytometry. Malaria-specific antibodies were compared by a high throughput, Luminex-based magnetic bead-based assay. Our analysis yielded sex-based differences in immune cell population frequencies, with men displaying more plasmacytoid dendritic cells and CD14<sup>+</sup> CD16<sup>+</sup> classical monocytes but fewer B cells and T follicular CD4<sup>+</sup> T cells. Additionally, conventional dendritic cells of women more frequently produced TNF $\alpha$  in response to TLR1/2 stimulation. Curiously, our flow cytometric analyses also identified a heterogeneous population of CD19<sup>+</sup>, CD3<sup>+</sup>, HLA-DR<sup>+</sup>, CD11c<sup>+</sup> myeloid cells expressing CD123, which is not typically expressed at high levels on mature myeloid cells in the peripheral blood of healthy individuals. This CD123<sup>+</sup> population was more pronounced among men and appeared to be highly inflammatory, expressing TNF $\alpha$  and IL-6 following TLR1/2 stimulation at approximately twice the frequency of CD123<sup>-</sup> myeloid cells. To further characterize this CD123<sup>+</sup> population, we are performing a single-cell transcriptomic and epitope analysis (CITE-seq) on peripheral blood mononuclear cells of four age-matched men and women who displayed prominent populations of CD123<sup>+</sup> myeloid cells; results will be presented at the conference. We hypothesize that CD123<sup>+</sup> myeloid cells present in the peripheral blood of Ugandan patients constitute an immature population of precursor cells that may arise as a consequence of recurrent malaria infection.

### DYSREGULATION OF THE IMMUNE RESPONSE IL-5 SIGNALING VIA JAK/STAT PATHWAY IN KENYAN CHILDREN WITH SEVERE MALARIAL ANEMIA

Clinton Onyango<sup>1</sup>, Elly O. Munde<sup>2</sup>, Samuel B. Anyona<sup>3</sup>, Evans Raballah<sup>4</sup>, Ivy Hurwitz<sup>5</sup>, Qiying Cheng<sup>5</sup>, Kristan A. Schneider<sup>6</sup>, Christophe G. Lambert<sup>5</sup>, Collins Ouma<sup>7</sup>, Douglas J. Perkins<sup>5</sup>

<sup>1</sup>University of New Mexico-Kenya Global Health Programs, Kisumu and Siaya, Kenya, <sup>2</sup>Department of Clinical Medicine, School of Health Science, Kirinyaga University, Kerugoya, Kenya, <sup>3</sup>Department of Medical Biochemistry, School of Medicine, Maseno University, Maseno, Kenya, <sup>4</sup>Department of Medical Laboratory Sciences, School of Public Health Biomedical Sciences and Technology, Masinde Muliro University of Science and Technology, Kakamega, Kenya, <sup>5</sup>Center for Global Health, University of New Mexico, Albuquerque, NM, United States, <sup>6</sup>Department Applied Computer and Bio-Sciences, University of Applied Sciences Mittweida, Mittweida, Germany, <sup>7</sup>Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Maseno, Kenya

Despite the global decline in malaria over the past two decades, malaria-related morbidity and mortality remains a significant health burden in

sub-Saharan Africa. In holoendemic *Plasmodium falciparum* regions, such as western Kenya, severe malaria in children under five years primarily manifests as severe malaria anemia (SMA, Hb<5.0g/dL and any parasite density). Since previous studies including ours have shown that dysregulation in innate immunity influences the development of SMA, transcriptomic analysis (mRNA-seq) was performed by Next-Generation Sequencing of samples from Kenyan children (3-36 months) with non-SMA (Hb>5.0 g/dL, n=41) and SMA (n=29). Enrichment analyses were performed using MetaCore™ with only false discovery rate (FDR)-adjusted ( $P<0.05$ ) differentially expressed genes ( $\log_2$ ) in the models (total=6,862 genes/network objects). IL-5 signaling via JAK/STAT emerged as a top-ranked pathway (FDR- $3.87\times 10^{-10}$ ). Upon binding of IL-5 to the IL-5 receptor  $\alpha$  (IL5RA) and  $\beta$  (CSF2RB) subunits, several signaling pathways are activated, including the JAK/STAT pathway. Although IL-5 is important for cell differentiation, proliferation, survival, B cell maturation, and induction of pro-inflammatory mediators, its role in the pathogenesis of SMA remains undefined. Transcriptomics analyses revealed that IL5RA gene (*IL5RA*) was upregulated (+1.01), while *CSF2RB* was downregulated (-0.99). Moreover, genes for kinase JAK2 and for a group of proteins phosphorylated by JAK2 were downregulated: *JAK2* (-0.45), *STAT1* (-0.33), *STAT3* (-0.56), *STAT5A* (-0.32), and *STAT5B* (-0.41). Downregulation also occurred for *cyclin D3* (-0.48), *BLIMP1* (-0.59), and *CISH* (-0.57). Results presented here illustrate that SMA is characterized by dysregulation of genes in the IL-5 JAK/STAT signaling pathway that can result in decreased class switch recombination upon antigen encounter, perturbations in B cell differentiation, and reduced cell proliferation.

### A SYSTEMS SEROLOGY APPROACH TO IDENTIFY DOMAIN TARGETS AND FC FUNCTIONS OF ANTIBODIES AGAINST PFEMP1 THAT ARE ASSOCIATED WITH PROTECTION FROM CEREBRAL PLASMODIUM FALCIPARUM MALARIA

Isobel Walker<sup>1</sup>, Wina Hasang<sup>1</sup>, Saber Dini<sup>2</sup>, Agersew Mengist<sup>1</sup>, Janavi Rambhatla<sup>1</sup>, Terrie Taylor<sup>3</sup>, Karl Seydel<sup>3</sup>, Elizabeth Aitken<sup>1</sup>, Anja Jensen<sup>4</sup>, Michael Duffy<sup>5</sup>, Amy Chung<sup>1</sup>, Stephen Rogerson<sup>1</sup>

<sup>1</sup>Peter Doherty Institute, University of Melbourne, Melbourne, Australia, <sup>2</sup>Melbourne School of Population and Global Health, University of Melbourne, Melbourne, Australia, <sup>3</sup>Michigan State University, Blantyre Malaria Project, East Lansing, MI, United States, <sup>4</sup>University of Copenhagen, Copenhagen, Denmark, <sup>5</sup>Bio21 Institute, University of Melbourne, Melbourne, Australia

*Plasmodium falciparum* erythrocyte membrane protein 1 (PfEMP1), a key malaria virulence factor, mediates sequestration of infected erythrocytes in the vasculature. Antibody responses to several semi-conserved domains of PfEMP1 have been associated with protection from severe malaria (SM), and it is hypothesized that antibodies to a key subset of PfEMP1 domains may confer protection. Previous studies measured IgG antibodies to PfEMP1 but did not consider the quality of the antibody response. Several properties of antibody Fc region influence interactions with the innate immune system to induce functions such as phagocytosis, cell cytotoxicity or complement activation. We used a systems serology approach to profile the PfEMP1 targets and functional Fc features of antibodies that correlate with protection from cerebral malaria (CM). Plasma from Malawian children collected at presentation to hospital with CM (n=46) or uncomplicated malaria (UM; n=46). Antibody responses were measured by bead-based multiplex array for 33 recombinant *P. falciparum* domains that have been associated with SM or UM. We profiled antibody isotypes and subclasses (IgG, IgM, IgG1-4), Fc receptor binding (Fc $\gamma$ R1a, IIb, IIIa, IIIb) and complement fixation (C1q) for each antigen. Univariate comparison and multivariate machine learning were used to select 17 out of 418 antibody features that distinguish between UM and CM, with 87% accuracy (ROC). The target antigens associated with a protective response were predominantly PfEMP1 domains that bind to endothelial cell receptors ICAM1 or EPCR, which are thought to mediate cerebral sequestration and cause CM. Total levels of IgG antibody could not distinguish between CM and UM, but the functional Fc properties of the antigen specific antibodies could. Specifically, antibody engagement with Fc $\gamma$ R IIa, IIIb and

c1q were associated with protection, suggesting activation of monocytes, neutrophils and complement may be important protective responses. Characterizing the functional properties of antibodies that relate to protection from SM may advance the development of novel vaccines and therapeutics for malaria.

### DETERMINATION OF MALARIA EXPOSURE IN ETHIOPIAN COMMUNITIES AND ITS RELATIONSHIP TO PLASMODIUM VIVAX MALARIAL BURDEN IN DUFFY-NEGATIVE INDIVIDUALS

Lauren Bradley<sup>1</sup>, Guiyun Yan<sup>1</sup>, Jamez Kazura<sup>2</sup>, Arlene Dent<sup>2</sup>, Delenasaw Yewhalaw<sup>3</sup>

<sup>1</sup>University of California - Irvine, Irvine, CA, United States, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>3</sup>Jimma University, Jimma, Ethiopia

*Plasmodium vivax* is the most common malarial species worldwide, yet it remains rare in Sub-Saharan Africa. During merozoite invasion *P. vivax* must bind to the Duffy antigen receptor expressed on erythrocytes and it has long been understood that Duffy negativity, or the lack of Duffy expression, confers resistance to infection. Duffy negativity is very common in most of Sub-Saharan Africa and generally credited for the lack of *P. vivax* infection on the continent. This antigen system is well studied, yet there has been little exploration on antigenic reactivity of individuals with differing Duffy phenotype. This study seeks to examine how multiple *P. vivax* and *P. falciparum* antigens, as well as mosquito salivary gland antigens, relate to differences in Duffy phenotypes; and to explore if the supposed resistance of Duffy negative individuals to *P. vivax* still yields naturally acquired immunity despite the parasites inability to establish blood stage infection. This is being examined through whole blood and dried blood spots collected during cross sectional survey in southwestern Ethiopia, an area with endemic *P. vivax* transmission and with significant variation in Duffy phenotypes in the human population. Preliminary results indicate that the Duffy phenotype distribution is 54.1% positive, and 48.8% negative. To assess overall seroprevalence patterns antigenic markers were combined and mean fluorescent intensity (MFI) was standardized. Seroprevalence was not significantly different between Duffy negative and Duffy positive peoples for *P. falciparum* antigens ( $P > 0.05$ ), yet it exhibited highly significant variation for *P. vivax* antigens ( $P < 0.0001$ ). Additionally, preliminary PCA analyses of MFI for all antigens show distinct trends between malarial species; while *P. falciparum* antigens exhibit no apparent clustering related to Duffy expression, *P. vivax* antigens show a clear clustering affect between Duffy positive and Duffy negative phenotypes. Further detailed analyses will likely yield more insight into these trends yet our data are the first to show *P. vivax* antigenic variation across Duffy phenotypes.

0913

### IMPACT OF ENDOGENOUS STEROIDS ON HOST IMMUNE RESPONSE DURING BLOOD STAGE PLASMODIUM FALCIPARUM MALARIA

Wael Abdrabou<sup>1</sup>, Massar Dieng<sup>1</sup>, Aïssatou Diawara<sup>1</sup>, Samuel Sermé<sup>2</sup>, Salif Sombié<sup>2</sup>, Vinu Manikadan<sup>1</sup>, Issiaka Soulama<sup>2</sup>, Youssef Idaghdour<sup>1</sup>

<sup>1</sup>New York University, Abu Dhabi, United Arab Emirates, <sup>2</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso

Host responses in *Plasmodium falciparum* malaria vary between individuals and ethnic groups through poorly understood mechanisms. During blood-stage malaria, host and *P. falciparum* metabolomes become heavily intertwined, highlighting the need to understand how peripheral blood metabolites impact immune response and parasite proliferation. Here we use a longitudinal matched *in vivo* metabolomic and transcriptomic profiling of children of the Gouin and Fulani ethnic groups in Burkina Faso before and during infection to investigate the metabolomic perturbations

that impact host immune response. We identify distinct perturbations in steroid biosynthesis as hallmark of *P. falciparum* infection and demonstrate their major role in the host response to infection implicating critical metabolic and immune response pathways. Integrative multi-omic analysis reveals steroid-driven immunosuppression of T-lymphocytes signaling pathways. Analysis of the less malaria-susceptible Fulani ethnic group demonstrates opposing steroid responses during infection supporting the immunosuppressive role of endogenous steroids during blood stage *P. falciparum* malaria.

### PROTECTION-ASSOCIATED IMMUNE RESPONSES FOLLOWING VACCINATION WITH RADIATION-ATTENUATED PLASMODIUM FALCIPARUM SPOROZOITES

Nina Hertoghs<sup>1</sup>, Ying Du<sup>1</sup>, Fergal Duffy<sup>1</sup>, Katharine V. Schwedhelm<sup>2</sup>, Suzanne M. McDermott<sup>1</sup>, M. Juliana McElrath<sup>2</sup>, Stephen C. De Rosa<sup>2</sup>, Kenneth D. Stuart<sup>1</sup>

<sup>1</sup>Seattle Children's Research Institute, Seattle, WA, United States, <sup>2</sup>Fred Hutchinson Cancer Research Center, Seattle, WA, United States

Immunization with radiation-attenuated sporozoites (RAS) can confer sterilizing protection, although the mechanism behind this protection is incompletely understood. *In vivo* animal studies have provided some mechanistic insight into how anti-malarial immunity is achieved, although some of these mechanisms are challenging to study in humans. This project aims to understand protective anti-malarial immunity in humans and in this way, aid the development of a malaria vaccine. To this end, we performed immunological analyses of samples from clinical trials in which malaria naïve volunteers were vaccinated with *Plasmodium falciparum* RAS and whose protection from malaria infection was assayed by controlled human malaria infection (CHMI). Blood samples collected at multiple timepoints during the immunization schedule and after CHMI were analyzed to compare immune responses between protected and non-protected volunteers leveraging integrative analysis of whole blood RNAseq, single cell CITEseq and high parameter flow cytometry on PBMCs. These combined datasets revealed differences in early innate immune responses that indicate divergent paths that either lead to protective immunity or the lack thereof. Non-classical monocytes, early type I interferon responses and T-helper 2 T cells correlate with impaired immunity whereas mature CD1c expressing dendritic cells correlate with T-helper 1 skewed responses in protected subjects. In addition, proliferating V $\delta$ 2  $\gamma\delta$ -T cells after each immunization were associated with protective immunity. Furthermore, preexisting differences in certain cell subsets correlate with protection, suggesting that these baseline immune states can affect immune responses to RAS immunization. Our data indicates that elevated levels of circulating innate lymphoid cells type 2 (ILC2) at baseline are associated with impaired immunity. These findings give insight into the immune responses that confer protection against malaria and may guide further malaria vaccine development.

### EXPANDING INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY (IPTP) THROUGH COMMUNITY DISTRIBUTION ALSO INCREASED IPTP UPTAKE THROUGH ANTENATAL CARE VISITS IN THREE DISTRICTS OF MADAGASCAR

Elmard Rabotovao Solo<sup>1</sup>, Faniry Nomena Andriantsitohaina<sup>1</sup>, Felana Nafindra Andriarinarina<sup>1</sup>, Tsiriariavelo Julie Solondrainy<sup>1</sup>, Gregory Andriamanoarisoa<sup>1</sup>, Hery Harimanitra Andriamanjato<sup>1</sup>, Jean Pierre Rakotovao<sup>1</sup>, Andritahina Razafarijaona<sup>1</sup>, Eliane Razafimandimby Ramiandrison<sup>1</sup>, Christina Maly<sup>2</sup>

<sup>1</sup>Jhpiego, Antananarivo, Madagascar, <sup>2</sup>Jhpiego, Baltimore, MD, United States

In Madagascar, only 10% of eligible women receive the WHO-recommended 3 doses of intermittent preventive treatment in pregnancy (IPTp) with quality-assured sulfadoxine-pyrimethamine (SP), well below the

National Malaria Strategy Plan target of 80%. To improve IPTp coverage, while promoting antenatal care (ANC) attendance, community-delivery of IPTp (C-IPTp) was introduced in three districts. In August 2018, C-IPTp launched in Mananjary district and expanded to Vohipeno and Toliara-2 districts in November 2019. Community health workers (CHW) were trained to identify pregnant women, refer them to ANC, and administer IPTp. The first dose of SP must be administered during ANC while subsequent doses are administered either by CHWs or during ANC. Data were analyzed from the national health management information system and supplementary reporting by CHWs. In Mananjary IPTp3 increased from 33% in December 2018 to 78% in December 2020. Similarly, between December 2019 and December 2020, IPTp3 increased from 44% to 69% in Vohipeno and 52% to 66% in Toliara-2. Initially these increases were driven by C-IPTp with 70% of doses being distributed by CHWs and 30% during ANC. In 2020, the intervention increased ANC awareness through social behavior change and communications (SBCC), community engagement, strengthened collaboration between CHWs and facilities, and an implemented system to harmonize scheduling of ANC4 visits with timing of IPTp3. Alongside increases in overall IPTp3 coverage across all three districts, there was also a meaningful shift in IPTp3 uptake during ANC – moving from 18.6% in December 2018 to 68% in December 2020. In addition, the percentage of pregnant women attending 4 ANC visits increased from 16% in December 2018 to 55% in December 2020. Introduction of C-IPTp with SBCC and improved scheduling practices has boosted both the number of pregnant women protected against malaria and utilization of ANC services. Through concerted project efforts, improvements in IPTp3 coverage originally gained from community-based distribution are gradually being shifted to facility-based distribution.

## 0916

#### CHANGES IN ANTENATAL CARE (ANC) ATTENDANCE AND UPTAKE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY (IPTP) AFTER INTRODUCTION OF COMMUNITY-BASED DISTRIBUTION OF IPTP IN THREE LOCAL GOVERNMENT AREAS (LGA) IN NIGERIA

**Herbert Enyeribe Onuoha<sup>1</sup>**, Bartholomew Odio<sup>1</sup>, Christina Maly<sup>2</sup>, Lawrence Nwankwo<sup>3</sup>, Folayan Waheed Adewale<sup>4</sup>, Elizabeth Njoku<sup>1</sup>, Oniyire Adetiloye<sup>1</sup>, Orji Bright<sup>1</sup>, Emmanuel Dipo Otolorin<sup>1</sup>, Elaine Roman<sup>2</sup>

<sup>1</sup>Jhpiego, Abakaliki, Nigeria, <sup>2</sup>Jhpiego, Baltimore, MD, United States, <sup>3</sup>Ebonyi State Ministry of Health, Abakaliki, Nigeria, <sup>4</sup>Ondo State Ministry of Health, Alagbaka, Akure, Nigeria

In Nigeria, community health workers (CHWs) from three LGAs were engaged to introduce community delivery of IPTp (C-IPTp) with quality-assured sulfadoxine-pyrimethamine to prevent malaria. This approach, which complements IPTp delivery during ANC visits, was carried out in Ohaukwu, Akure South, and Bosso LGAs. C-IPTp was introduced in September 2018 in Ohaukwu and in December 2019 in Akure South and Bosso. A total of 1,062 CHWs were trained on early identification of pregnant women, referral to ANC, IPTp administration, and use of mobile phones to capture and report data. CHWs conduct household visits, provide malaria health education, refer and encourage pregnant women to attend ANC, and provide IPTp. Routine facility data from 2017 before introduction of C-IPTp were compared with 2020 facility and CHW data to understand the effect of C-IPTp across the LGAs. Before C-IPTp, 43% of the estimated number of pregnant women in these areas attended at least one ANC visit as compared to 57% in 2020 ( $p < .05$ ). Attending at least four ANC (ANC4) visits increased in Ohaukwu by ten percentage points to 29% in 2020 ( $p < .05$ ). In Akure South, ANC4 remained steady. Bosso pre-C-IPTp data on ANC4 visits were of too poor quality to conduct a meaningful analysis. Though this project focused on C-IPTp, it also resulted in statistically significant increases in IPTp distribution during ANC visits. From 2017 to 2020, coverage of IPTp doses 1, 2, and 3 all saw increases across the three sites: IPTp1 increased from 54% to 57%; IPTp2 from 36% to 42%; and IPTp3 increased 20 percentage points from 5% to 25%. Of pregnant women receiving all doses of IPTp, 39% did so through ANC

with 61% receiving IPTp from CHWs. These data suggest that in addition to contributing to overall increases in IPTp coverage, C-IPTp may also contribute to increases IPTp delivery in ANC and ANC attendance.

## 0917

#### MAPPING OUT OF YAWS ENDEMICITY IN GHANA, LESSONS TO STRENGTHEN THE PLANNING AND IMPLEMENTATION OF YAWS ERADICATION

**Laud Anthony Wihibeturo Basing**, Deborah Malug

*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*

Yaws caused by *Treponema pallidum* subsp *pertenue* is a disease of poverty and affects communities where basic socio-economic amenities are lacking. With results showing that single-dose azithromycin is effective in the treatment of yaws, the World Health Organisation introduced the Morges strategy with the intent to eradicate yaws by 2030. Ghana is one of the countries with the most yaws cases globally, and the National Yaws Eradication Program in Ghana intends to conduct Mass Drug Administration (MDA) of endemic communities in line with the Total Community Treatment plan of the Morges strategy. It is therefore important to map out endemic communities to ensure that MDA is both effective and financially efficient. Children with suspected yaws lesions were actively selected from schools and communities. A full medical history, study site information including GPS coordinates, demographic data including communities of residence and clinical assessment were taken. Each of the clinically diagnosed children were screened using the DPP@ Syphilis Screen and Confirm Assay (DPP). Samples for PCR were collected by swabbing ulcerative lesions of participants and tested for *Treponema pallidum* subsp *pertenue* and *Haemophilus ducreyi* DNA. In all, 625 children with a median age of 10 years were recruited into the study. While 401 (64.2%) were DPP positive, only 141 (22.6%) of them had *Treponema pallidum* subsp *pertenue* DNA (TPE\_DNA). Based on the DPP results, yaws was endemic in all 4 study sites with participants from 88 communities in 13 districts in 4 regions in Ghana. There was no statistically significant difference between the various districts in terms of DPP results ( $\chi^2=0.9364$ ,  $p=0.817$ ) and 154 (24.6%) of those clinically diagnosed as yaws were positive for *Haemophilus ducreyi* DNA. Our study shows that communities endemic for yaws are also endemic for *Haemophilus ducreyi*. Most yaws endemic communities were found at the border of other districts and regions. It is recommended that MDA should not only target endemic communities, but it should also target entire endemic districts as well as neighbouring districts in order to be effective.

## 0918

#### BASELINE PREVALENCE OF TRACHOMA IN REFUGEE SETTLEMENTS IN UGANDA: RESULTS OF ELEVEN POPULATION-BASED SURVEYS

**Gilbert Baayenda<sup>1</sup>**, Francis Mugume<sup>1</sup>, Alfred Mubangizi<sup>1</sup>, Sarah Byakika<sup>1</sup>, John K. Binta<sup>2</sup>, Darlson Kusasira<sup>3</sup>, Ben Binagwa<sup>4</sup>, Stella Agunyo<sup>4</sup>, Kathryn Crowley<sup>5</sup>, Wangeci Thuo<sup>5</sup>, Mike , French<sup>5</sup>, Elizabeth Plunkett<sup>5</sup>, Jeremiah M. Ngondi<sup>5</sup>

<sup>1</sup>Ministry of Health, Kampala, Uganda, <sup>2</sup>Kampala International University Medical School, Kampala, Uganda, <sup>3</sup>Refugees Department, Office of the Prime Minister, Kampala, Uganda, <sup>4</sup>RTI International, Kampala, Uganda, <sup>5</sup>RTI International, Washington DC, MD, United States

The health risks and needs of refugee populations are often distinct from the surrounding permanent inhabitants of the areas in which they live. There are several settlements in the Northern and Western Regions of Uganda serving refugees from South Sudan and Democratic Republic of Congo (DRC), respectively. Trachoma prevalence surveys were conducted in a number of those settlements with the aim of determining whether interventions for trachoma are required. For the purposes of these surveys, an evaluation unit (EU) was defined as all refugee settlements in one district. Internationally standardized population-based trachoma prevalence survey methods were deployed in 11 EUs to assess prevalence of trachomatous inflammation-follicular (TF) in 1-9-year-olds and

trachomatous trichiasis (TT) unknown to the health system in  $\geq 15$ -year-olds. Household-level water, sanitation and hygiene coverage was also assessed in study populations. A total of 40,892 people were examined across 11 EUs. The prevalence of TF in 1-9-year-olds was  $< 5\%$  in all EUs surveyed. The prevalence of trachomatous trichiasis (TT) unknown to the health system in  $\geq 15$ -year-olds was  $< 0.2\%$  in 5 out of 11 EUs surveyed. Implementation of the antibiotic, facial cleanliness and environmental improvement components of the SAFE strategy are not needed for the purposes of trachoma's elimination as a public health problem in these refugee settlements; however, intervention with TT surgery is needed in 6 EUs. Since instability continues to drive displacement of people from South Sudan and DRC into Uganda, there is likely to be a high rate of new arrivals to the settlements over the coming years. These populations may therefore have trachoma surveillance needs that are distinct from the surrounding non-refugee communities. These methods and approaches to surveys in refugee settlement are applicable to similar settings or in areas where there are internally displaced populations.

### IDENTIFICATION OF SNAILS AND SCHISTOSOMA OF MEDICAL IMPORTANCE VIA CONVOLUTIONAL NEURAL NETWORKS

**Krti Tallam**<sup>1</sup>, Zac Yung-Chun Liu Y. Liu<sup>1</sup>, Andrew J. Chamberlin<sup>1</sup>, Isabel J. Jones<sup>1</sup>, Pretom Shome<sup>1</sup>, Gilles Riveau<sup>2</sup>, Raphael A. Ndione<sup>3</sup>, Lydie Bandagny<sup>2</sup>, Nicolas Jouanard<sup>2</sup>, Paul V. Eck<sup>4</sup>, Ton Ngo<sup>4</sup>, Susanne H. Sokolow<sup>1</sup>, Giulio A. De Leo<sup>1</sup>

<sup>1</sup>Stanford University, Stanford, CA, United States, <sup>2</sup>Centre de Recherche Biomédicale Espoir pour la Santé, Saint-Louis, Senegal, <sup>3</sup>Centre de Recherche Biomédicale Espoir pour la Santé, Saint-Louis, Senegal, <sup>4</sup>IBM Silicon Valley Lab, San Jose, CA, United States

In recent decades, computer vision has proven remarkably effective in addressing diverse issues in public health. We investigate the effectiveness of convolutional neural networks (CNNs) in classifying the environmental stages of parasites and respective invertebrate hosts of medical importance, with schistosomiasis as a reference model. Schistosomiasis is a debilitating parasitic disease, affecting more than 200 million people in tropical and subtropical regions, and transmitted to humans via snail intermediate hosts. We trained our CNN, a feed-forward neural network, on a limited dataset of 5,500 images of snails and 5,100 images of cercariae obtained from schistosomiasis transmission sites in the Senegal River Basin, a region in western Africa that is hyper-endemic for the disease. The image set included both images of two snail genera that are relevant to schistosomiasis transmission—that is, *Bulinus* spp. and *Biomphalaria pfeifferi*—as well as snail images that are non-component hosts for human schistosomiasis. Cercariae shed from *Bi. pfeifferi* and *Bulinus* spp. snails were classified into 11 categories, of which only two, *S. haematobium* and *S. mansoni*, are major etiological agents of human schistosomiasis. The algorithms, trained on 80% of the snail and parasite dataset, achieved 99% and 91% accuracy for snail and parasite classification respectively, when used on the hold-out validation dataset—a performance comparable to that of experienced parasitologists. The promising results of this proof-of-concept study suggests that this CNN model, and potentially similar replicable models, have the potential to support the classification of snails and parasite of medical importance. In remote field settings where machine learning algorithms can be deployed on cost-effective and widely used mobile devices, such as smartphones, these models can be a valuable complement to laboratory identification by trained technicians. Future efforts must be dedicated to increasing dataset sizes for model training and validation, and testing these algorithms in diverse transmission settings and geographies.

0920

### USING IMAGE-RECOGNITION SOFTWARE TO STRENGTHEN THE CAPACITY OF COMMUNITY HEALTH WORKERS

**Emily W. Gower**<sup>1</sup>, Juan Prieto<sup>1</sup>, Hina Shah<sup>1</sup>, Kasey Jones<sup>2</sup>, Hashiya Kana<sup>1</sup>, Jerusha Weaver<sup>1</sup>, Scott McPherson<sup>2</sup>, Robert Chew<sup>2</sup>, Rebecca Flueckiger<sup>2</sup>

<sup>1</sup>UNC Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>RTI International, RTP, NC, United States

Disease identification is a key component for reducing the burden of neglected tropical diseases. Many diseases require screening throughout the community, which necessitates training community members how to identify the disease in question. This process can be costly, and often does not yield optimal outcomes. Evaluation of trachomatous trichiasis (TT) case finders shows that the accuracy of appropriate case detection can be as low as 15-30%. Thus, in this project, we aimed to develop and evaluate two integrated apps focused on better TT case identification, one for automated detection of TT using photographic images and another for taking TT images in community settings and deploying the algorithm. We utilized 3,000 pre-operative photos from an ongoing clinical trial to train the algorithm. Algorithm development included segmentation, extraction and classification steps. We trained different neural networks to evaluate the classification task. The current accuracy of the algorithm is 87%, with a sensitivity of 88% and a specificity of 82%, and we are continuing to refine it. We have successfully integrated the algorithm app onto smartphones, with current processing time of 13 seconds to return a TT screening result following image capture. The associated image-capture app provides a user-friendly interface. We have also demonstrated that lay community members can easily be trained to take photos using smartphones, with over 98% gradable images. We will also report results of field testing in Mozambique and Ethiopia. This approach could be expanded to additional tropical diseases and other ocular conditions and has the potential to improve efficiency and effectiveness in screening communities for these diseases.

### INCORPORATION OF SARS-COV-2 ANTIGENS INTO AN EXISTING MULTIPLEX BEAD ASSAY FOR INTEGRATED SEROLOGICAL SURVEILLANCE OF NEGLECTED TROPICAL AND OTHER DISEASES

**Sarah Gwyn**<sup>1</sup>, Ado Abubakar<sup>2</sup>, Oluwaseun Akinmulero<sup>2</sup>, Eric Bergeron<sup>1</sup>, Jasmine Chaitram<sup>1</sup>, Ayuba Dawurung<sup>2</sup>, Felicia Nwatu Dickson<sup>2</sup>, Mudiaga Esiekpe<sup>2</sup>, Erasogie Evbuomwan<sup>3</sup>, Stacie Greby<sup>4</sup>, Nnaemeka Iriemenam<sup>4</sup>, Thomas Andrew Naanpoen<sup>2</sup>, Loveth Napoloen<sup>2</sup>, McPaul Okoye<sup>4</sup>, Temitope Olaleye<sup>2</sup>, Amy J. Schuh<sup>1</sup>, S. Michele Owen<sup>1</sup>, Awala Samuel<sup>2</sup>, Diana Martin<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Institute of Human Virology, Abuja, Nigeria, <sup>3</sup>Nigeria Centre for Disease Control, Abuja, Nigeria, <sup>4</sup>Centers for Disease Control and Prevention, Abuja, Nigeria

SARS-CoV-2 emerged in December 2019, with confirmed cases reported from most countries. Antibodies to SARS-CoV-2 can estimate the proportion of a population with evidence of previous infection. We validated 4 SARS-CoV-2 antigens (1 spike protein, 2 receptor binding domain proteins and 1 nucleocapsid protein) on an existing multiplex bead assay (MBA) for integrated serosurveillance of vaccine-preventable diseases, malaria, neglected tropical diseases, and waterborne diseases. Receiver operating characteristic curves were created using 87 specimens from confirmed cases positive for SARS-CoV-2 by reverse transcription polymerase chain reaction (RT-PCR) and 118 pre-pandemic (presumed negative) and RT-PCR negative specimens. These were used to determine sensitivity and specificity for each antigen. Positive percent agreement (PPA) was determined using a panel of RT-PCR positive specimens, collected less than ( $n = 54$ ) or more than ( $n = 48$ ) 3 weeks post-symptom onset. Negative percent agreement (NPA) was determined using 97 pre-pandemic specimens. A subset of 119 samples (108 RT-PCR positives,

11 pre-pandemic negatives) were tested at both the Centers for Disease Control and Prevention (CDC) laboratory in Atlanta, GA, USA, and the National Reference Laboratory (NRL) in Gaduwa, Nigeria. Inter-laboratory comparisons were done using linear regression analysis of antibody levels. All assays had a sensitivity >94.3% (95% CI: 87.1-98.7%) and specificity >97.4% (95% CI: 92.7-99.5%). PPA for samples collected >3 weeks post-symptom onset ranged from 93.8% to 97.9% for all antigens, which was significantly higher than PPA for samples collected <3 weeks of symptom onset (55.6-81.5%). NPA for all antigens was 99-100%. The MBA signal was significantly higher in samples collected >3 weeks post-symptom onset than <3 weeks of symptom onset. The correlation coefficient between samples run at the CDC laboratory and the NRL was >0.98 for all antigens. The ability to simultaneously test for antibodies to SARS-CoV-2 antigens and other diseases of public health interest will potentially add value to SARS-CoV-2 or other disease-specific serosurveys.

### COMPLETE GENETIC ATTENUATION OF PLASMODIUM BERGHEI THROUGH A LIVER STAGE-SPECIFIC CRISPR-RGR GENE DELETION STRATEGY

Lucia Pazzagli<sup>1</sup>, Antonella Turco<sup>1</sup>, Gloria Iacomelli<sup>1</sup>, Michela Anna Gucciardino<sup>1</sup>, Giulia Monacchia<sup>1</sup>, Max Lombardi<sup>1</sup>, Matthew Peirce<sup>1</sup>, Scott E. Lindner<sup>2</sup>, **Roberta Spaccapelo<sup>1</sup>**

<sup>1</sup>University of Perugia, Perugia, Italy, <sup>2</sup>Pennsylvania State University, Pennsylvania, PA, United States

The aim of eliminating malaria will, in all likelihood, require an effective vaccine; a goal that currently remains unrealized. Live-attenuated sporozoite vaccine candidates represent the most promising tool for malaria elimination because they can achieve sterile protection. Genetic engineering offers a versatile platform to create Genetically Attenuated Parasites (GAPs). The identification and functional characterization of suitable genes also depends on a flexible and efficient tool for parasite manipulation during liver stage development. To address these twin aims in the rodent *Plasmodium berghei* malaria model for the first time, we adapted a ribozyme-mediated CRISPR gene editing system (CRISPR-RGR) previously established in *P. yoelii* for liver stage-specific gene editing. We generated a single CRISPR-RGR plasmid to express *Streptococcus pyogenes* SpCas9 and a dual ribozyme-guide-ribozyme (RGR) single guide RNA (sgRNA) under the control of liver-stage specific promoters 1 and 2 respectively. Moreover, the construct was designed for site-specific integration at the Silent Intergenic Locus 6 (SIL6). To functionally test this system, we targeted the gene encoding the Schizont Egress Antigen-1 (PbSEA1, PBANKA\_0506000), recently described in *P. falciparum* as a gene involved in erythrocytic schizogony, with two sgRNAs targeting the 5' and 3' ends of its coding sequence. Our preliminary results reveal that the CRISPR-RGR plasmid achieves complete *Pbsea1* gene deletion during parasite liver stage development. Extensive cell growth and DNA replication was observed for *pbea1* liver stage parasites *in vitro* in human hepatoma cells (Huh7), and yet these parasites failed to establish an asexual blood stage infection in mice. Therefore, the use of liver stage-specific gene editing by CRISPR-RGR to delete blood stage-essential genes such as *sea1* represents a novel strategy to create genetically attenuated parasites for the production of malaria vaccine candidates.

## 0923

### A NOVEL K13 MUTATION MEDIATES PLASMODIUM FALCIPARUM RESISTANCE TO OZ439

**Sachel Mok<sup>1</sup>**, Barbara H. Stokes<sup>1</sup>, Anna Y. Burkhard<sup>1</sup>, Tomas Yeo<sup>1</sup>, Jennifer Small-Saunders<sup>1</sup>, John Okombo<sup>1</sup>, Manuel Llinás<sup>2</sup>, David A. Fidock<sup>1</sup>

<sup>1</sup>Columbia University Medical Center, New York, NY, United States, <sup>2</sup>The Pennsylvania State University, University Park, PA, United States

The synthetic ozonide OZ439 is a preclinical antimalarial candidate to replace first-line artemisinin derivatives relied on to treat *Plasmodium falciparum* malaria, including artemisinin-resistant parasites in Southeast

Asia. OZ439 shares the same bioactive endoperoxide moiety with artemisinins but benefits from a longer *in vivo* half-life. Here, we performed *in vitro* resistance selections with OZ439 in the isogenic parasite lines Cam3.II and Cam3.II\_rev that express, respectively, the R539T mutant or wild-type alleles of the artemisinin resistance determinant *k13* gene. Using a ramping approach wherein step-wise increases in drug concentrations were applied over 34 cycles spanning 18 months, we obtained parasites that could survive and recover from a 96h exposure to 1  $\mu$ M OZ439 (227x the IC<sub>50</sub> and the pharmacological C<sub>max</sub> for a 250mg dose). These OZ439-selected parasites recovered within 7-10 days and 18-22 days for Cam3.II and Cam3.II\_rev parasites, respectively. Whole-genome sequencing revealed a novel K13 A212T mutation in the OZ439-selected Cam3.II clones. We used CRISPR/Cas9 editing to introduce A212T into Cam3.II and Cam3.II\_rev parasites and to remove this mutation from a OZ439-selected clone. Phenotypic characterization revealed that A212T combined with the R539T mutation confers an accelerated rate of recovery following a 48h exposure to OZ439 at concentrations ranging from 8 nM to 250 nM. These parasites also maintain high levels of early ring-stage survival to 700 nM dihydroartemisinin, with survival rates of 18-24% after a 4h exposure. However, the A212T mutation alone does not alter the rate of parasite recovery after exposure to OZ439 or the levels of ring-stage survival following a 4h exposure to dihydroartemisinin. Further investigations into the mechanism of resistance in A212T mutant Cam3.II lines using global peptidomic profiling and K13 protein expression studies will be presented. Our results raise important implications for the use of OZ439 to treat artemisinin-resistant malaria.

## 0924

### MITOCHONDRIA AND APICOPLAST INHERITANCE PATTERNS IN PLASMODIUM FALCIPARUM GENETIC CROSSES SUGGEST INCOMPATIBILITIES ACROSS THE LIFE CYCLE

**Sudhir Kumar<sup>1</sup>**, Xue Li<sup>2</sup>, Meseret T. Haile<sup>1</sup>, Biley A. Abatiyow<sup>1</sup>, Ann Reyes<sup>2</sup>, Marina McDew-White<sup>2</sup>, Spencer Y. Kennedy<sup>1</sup>, Nelly M. Camargo<sup>1</sup>, Lisa A. Checkley<sup>3</sup>, Katelyn M. Vendrely<sup>3</sup>, Katrina A. Button-Simons<sup>3</sup>, Ian H. Cheeseman<sup>2</sup>, Stefan H. Kappe<sup>1</sup>, François Nosten<sup>4</sup>, Michael T. Ferdig<sup>3</sup>, Tim J. Anderson<sup>2</sup>, Ashley M. Vaughan<sup>1</sup>

<sup>1</sup>Seattle Children's Research Institute, Seattle, WA, United States,

<sup>2</sup>Texas Biomedical Research Institute, San Antonio, TX, United States,

<sup>3</sup>Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, United States, <sup>4</sup>Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Mae Sot, Thailand

Genetic crosses provide power for linkage analysis when (i) progeny numbers are high, (ii) parental alleles segregate evenly and (iii) numbers of inbred progeny are minimized. Due to meiosis and chromosome crossover events, recombinant parasites inherit nuclear DNA from both parents but inherit their cytoplasmic DNA genomes from only the female gamete. *Plasmodium falciparum* has two cytoplasmic organelles: the mitochondria, with a 6 kb genome, and an organelle of plastid origin, the apicoplast, with a 35 kb genome. To study cytoplasmic genome inheritance and possible incompatibilities, we carried out three unique *P. falciparum* genetic crosses: (1) an allopatric cross between NF54, of African origin with NHP4026, of Southeast Asian origin (2) a sympatric cross between Southeast Asian parasites, MKK2035 and NHP1337 and (3) an allopatric cross between a Cambodian parasite KH004 and a Malawian parasite, Mal31. To date we have recovered 193 recombinant progeny for NF54×NHP4026, 60 recombinant progeny for MK22835 × NHP1337, and 280 recombinant progeny for KH004×Mal31. In the sympatric MK22835×NHP1337 cross, even inheritance of cytoplasmic organellar genomes was observed but in the allopatric crosses (NF54×NHP4026 and KH004×Mal31) 92% and 74% recombinant progeny inherited mitochondria and apicoplast genomes from NHP4026 and KH004 respectively. Since these strains successfully infect mosquitoes, incompetence of male or female gametes is unlikely to explain this inheritance pattern. However, we cannot completely exclude asymmetry in gamete fusion - i.e. an excess of female gametes from NHP4026 and KH004 parents - as an explanation. Using bulk segregant analysis (BSA)

of the progeny from the NF54×NHP4026 cross, we show that there is a significant decrease in NF54 cytoplasmic genome inheritance between the sporozoite and liver stages suggesting a cytoplasmic genome incompatibility during this life cycle transition. Thus, BSA allows us to probe selection across the entire life cycle and suggests incompatibility in cytoplasmic genome inheritance in allopatric genetic crosses.

### FINE-SCALE RELATEDNESS ANALYSIS REVEALS THE RECENT EPIDEMIOLOGICAL HISTORY OF PLASMODIUM FALCIPARUM POPULATIONS IN THE PACIFIC COAST REGION OF SOUTH AMERICA

Angela M. Early<sup>1</sup>, Manuela Carrasquilla<sup>2</sup>, Aimee R. Taylor<sup>2</sup>, Angelica Knudson<sup>3</sup>, Diego F. Echeverry<sup>4</sup>, Timothy J. Anderson<sup>5</sup>, Sania Gonzalves<sup>6</sup>, Dominic P. Kwiatkowski<sup>6</sup>, Caroline O. Buckee<sup>2</sup>, Julian C. Rayner<sup>7</sup>, Fabian E. Saenz<sup>8</sup>, Daniel E. Neafsey<sup>2</sup>, Vladimir Corredor<sup>3</sup>

<sup>1</sup>Broad Institute, Cambridge, MA, United States, <sup>2</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>3</sup>Universidad Nacional de Colombia, Bogota, Colombia, <sup>4</sup>Universidad del Valle, Cali, Colombia, <sup>5</sup>Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>6</sup>Wellcome Sanger Institute, Hinxton, United Kingdom, <sup>7</sup>University of Cambridge, Cambridge, United Kingdom, <sup>8</sup>Pontificia Universidad Catolica del Ecuador, Quito, Ecuador

While global malaria rates have stayed relatively flat in recent years, there is significant geographical heterogeneity within this overall picture. Markedly, there has been a 36% increase in cases reported in the Americas since 2017. In Colombia and Ecuador, 60% and 10% of malaria cases occur in the Pacific coast region, respectively, and are mainly caused by *Plasmodium falciparum*. This region represents a pre-elimination scenario of low transmission that generally permits few outcrossing events. In recent years, however, the frequency of local outbreaks has risen. By increasing the opportunities for recombination, these outbreaks may generate new combinations of drug resistance haplotypes, thus posing a risk for elimination efforts. Here, we analyze 164 whole genome sequences from monoclonal infections sampled in Colombia (126) and Ecuador (38) between 2013 and 2016, to assess whether increased recombination during outbreaks generates genomic novelty. We use identity-by-descent (IBD) to estimate relatedness between parasites and find both high background relatedness and 14 multi-member clonal lineages that account for 98% of samples. Six of these clusters have persisted for at least 10 years, but the population as a whole is not static. By analyzing shared chromosomal segments between pairs of samples, we identify five complete crosses, including a two-generation pedigree. Two of these crosses generated novel combinations of drug-resistance haplotypes. By integrating this with epidemiological data we show that the timing of these crosses likely coincided with periods of heightened transmission when the parental genotypes were at high frequency. Combining our data set with 17 pre-2005 Colombian genomes, we use patterns of intra-chromosomal IBD to identify two hard selective sweeps driven by chloroquine and soft sweeps imposed by sulfadoxine and pyrimethamine (SP). These results show that parasites in low-transmission, low-diversity settings continue to evolve in response to selection pressures via both recombination and *de novo* mutation, making continued surveillance warranted under such conditions anywhere in the world.

Genetics can serve as a fingerprint for unobserved transmission dynamics to complement routine malaria surveillance data. Features derived from malaria parasite genetic data, such as complexity of infection (COI) and sample relatedness, have been shown to be correlated with measures of transmission intensity. However, the standard algorithms for computing a highly resolved estimates of COI and relatedness have been tested on simulated datasets that represent cross-sectional diversity, largely divorced from the temporal epidemiology that shapes the genetic structure of a population. Here, we leverage a layered mathematical modeling approach where we combine EMOD, an epidemiological model of malaria transmission which accounts for transmission history, GENEPI, a malaria parasite genetic model that simulates genomic evolution on a transmission network accounting for co-transmission and superinfection, and an observational component to recreate sampling and sequencing uncertainty. The observational component simulates sequencing uncertainty by collapsing strains from an infection into a single, representative genome with heterozygous positions. This flexible model enables pressure testing of common algorithms with simulated genomes derived from different transmission intensities, genomic scope by number of variants, and infection diversity by variant heterozygosity. We then compared modeled data estimates to empirical data estimates from a country-wide Senegal population genetic dataset with over 1,000 sequenced samples from geo-located health facilities for a population-specific sensitivity analysis. Our findings suggest that the model can be used to understand variant panel properties and algorithm uncertainty estimates for different transmission scenarios that affect population genetics. Broadly, the comparisons between modeled and empirical data might help define best sample collection and sequencing technology strategies to support programmatic decisions guided by transmission-informative genetic features.

### THRIVING STUDENTS, THRIVING COMMUNITIES: THE IMPACT AND COST-EFFECTIVENESS OF SCHOOL-BASED MALARIA CHEMOPROPHYLAXIS

Joshua G. Suresh<sup>1</sup>, Marita Zimmermann<sup>1</sup>, Lauren M. Cohee<sup>2</sup>, Miriam K. Laufer<sup>2</sup>, Sarah Staedke<sup>3</sup>, Chris Drakely<sup>3</sup>, Catherine Maiteki-Sebuguzi<sup>4</sup>, Don Mathanga<sup>5</sup>, Caitlin Bever<sup>1</sup>

<sup>1</sup>Institute for Disease Modeling at Bill & Melinda Gates Foundation, Seattle, WA, United States, <sup>2</sup>University of Maryland School of Medicine, College Park, MD, United States, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Ministry of Health Uganda, Kampala, Uganda, <sup>5</sup>University of Malawi, Blantyre, Malawi

Across sub-Saharan Africa, the prevalence of *P. falciparum* infection often peaks in school-age children, who suffer from adverse consequences on

health and education. However, children over 5 years old are not included in seasonal chemoprevention (SMC) and are generally less likely to use bednets or receive effective case management, leaving a gap in current malaria control efforts. Using mathematical models of transmission in diverse endemic sub-Saharan settings that differ with regards to transmission intensity, seasonality, and school calendars, we investigate the impact of using primary schools to deliver intermittent preventive treatment to school-aged children (IPTsc). An IPTsc strategy of presumptive treatment of all students with dihydroartemisinin-piperazine (DP) once per school term reduces burden in school-age children by about 50%, and reduces the overall clinical burden in the community by about 30%, with greatest community benefit found at lowest transmission intensity. IPTsc outperforms increasing ITN coverage from 70% to 90%, which only reduces overall clinical burden by about 10%. IPTsc also outperforms chemoprophylactic strategies which target children under 5, such as SMC, in terms of overall clinical burden reduction. However, in moderate to high transmission intensity settings where the burden of severe disease is highest in children under 5 years old, chemoprevention for under-5s reduces severe disease burden more than IPTsc. IPTsc combined with traditional under-5 SMC is superior in terms of both impact and cost to expanding SMC to older ages. For the health system perspective, the cost to avert a case with IPTsc is typically much less than the cost of treating a case in a health facility, which means that the cost to perform IPTsc is outweighed by the savings generated from having to treat fewer clinical cases overall. In sum, IPTsc is a promising strategy to reduce the burden of malaria both in school-age children and in the overall community. Operational research will be necessary to optimize IPTsc to specific settings based on transmission intensity, seasonality, and local malaria control interventions.

0928

### USING MATHEMATICAL MODELING TO EXPLORE THE POTENTIAL EFFECT SIZE OF A SEASONAL MALARIA CHEMOPREVENTION TRIAL IN KARAMOJA SUB-REGION, UGANDA

**Branwen Nia Owen**<sup>1</sup>, Munir Winkel<sup>1</sup>, Laura Skrip<sup>1</sup>, Craig Bonnington<sup>2</sup>, Jane Achan<sup>3</sup>, Jimmy Opigo<sup>4</sup>, James Tibenderana<sup>3</sup>, Emilie Pothin<sup>5</sup>

<sup>1</sup>Swiss TPH, Basel, Switzerland, <sup>2</sup>Malaria Consortium, London, United Kingdom, <sup>3</sup>Malaria Consortium, Kampala, Uganda, <sup>4</sup>National Malaria Control Programme, Kampala, Uganda, <sup>5</sup>Swiss TPH / Clinton Health Access Initiative, Basel, Switzerland

As a platform for exploring complex infectious disease dynamics, mathematical modeling can powerfully aid trial planning. We aim to assess the likely effect size of a forthcoming trial of seasonal malaria chemoprevention (SMC) when deployed as planned, and if deviations from the plan occur. Using the microsimulation platform, OpenMalaria, we simulated the trial: treating children <5 years with 5 rounds of SMC, from May to September, at a coverage of 80%. Bednet usage of 28% (derived from MIS 2018) and a 25 day efficacy of the SMC drug (SPAQ) were assumed. Alternative scenarios explored how i. doubling net usage, ii. deploying with a month delay, iii. deploying 4 rounds only, iv. halving drug efficacy duration, and v. decreasing coverage by 10% with each round, would likely influence effect size. Scenarios were run under baseline malaria incidence levels ranging 1,200-3,000 annual episodes/1,000 population, to reflect the heterogeneity of study sites. We defined effect size as the percentage incidence reduction compared to the scenario of no SMC deployment. Baseline incidence assumptions shaped all findings. When deployed as planned, the projected effect size of SMC was greatest when baseline incidence was lowest; the incidence in 2022 decreased by 42% at the lowest incidence level and by 25% at the highest. Effect sizes under the alternative scenarios varied less at higher baseline incidence levels, for instance, when net usage was doubled, the effect size increased 1.5 times at the lowest baseline incidence level, but was no different at the highest incidence level. Shorter drug efficacy duration and decreased coverage lowered the effect size most substantially, followed by deploying 4 rounds instead of 5, while delaying deployment had little effect. The

effect sizes estimated can be used for calculating the necessary sample size for the trial. However, it is vital to first understand the baseline incidence of each site, bednet usage, drug efficacy, and any likely impediments to maintaining target coverage. This analysis demonstrates how mathematical modelling can be instrumental in disentangling complex considerations in trial planning.

0929

### BLOOD FEEDING ON HUMANS VACCINATED WITH AGS-V PLUS, A MOSQUITO SALIVARY PEPTIDE VACCINE, IMPAIRS THE REPRODUCTIVE CAPACITY OF FEMALE Aedes ALBOPICTUS MOSQUITOES

Memoli<sup>7</sup>, Matthew B. Laurens<sup>2</sup>, Jesus G. Valenzuela<sup>1</sup>

<sup>1</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, <sup>2</sup>Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Department of Surgery, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>4</sup>Clinical Monitoring Research Program Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD, United States, <sup>5</sup>Biostatistics Research Branch, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, <sup>6</sup>Imutex Limited, London, United Kingdom, <sup>7</sup>LID Clinical Studies Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Vaccinating humans against mosquito salivary proteins has emerged as a novel approach to protect against mosquito-borne pathogens. While this strategy has focused on blocking infection of the host, it is unclear how the mosquito may be impacted by blood feeding on individuals vaccinated against salivary proteins. As part of a phase 1 clinical trial of AGS-v PLUS, a novel mosquito salivary peptide vaccine (NCT04009824), we tested the hypothesis that blood feeding on individuals vaccinated with AGS-v PLUS would impair mosquito survival and reproduction. Participants were randomized into one of five study arms: placebo, two-dose AGS-v PLUS without adjuvant, single-dose AGS-v PLUS with ISA-51, two-dose AGS-v PLUS with ISA-51, or two-dose AGS-v PLUS with Alhydrogel. Three weeks after the last injection, participants were exposed to feeding by uninfected female *Aedes aegypti* and *Aedes albopictus* mosquitoes, which were then monitored for survival, egg laying capacity, and development from egg to adult. For analysis, each intervention arm was compared individually to the placebo arm at a pre-specified significance threshold of  $p < 0.10$ . Thirty-three participants completed both study drug injections and the mosquito feeding. For *A. albopictus*, feeding on participants vaccinated with two doses of AGS-v PLUS/ISA-51 resulted in decreased numbers of eggs laid (average, 5.1 vs. 13.1 eggs per mosquito;  $p = 0.083$ ) and fewer adult offspring per mosquito (average, 1.6 vs 8.4;  $p = 0.012$ ), with the other three AGS-v PLUS regimens showing similar trends towards lower numbers of both eggs laid and adult offspring. In contrast, none of the vaccine regimens affected oviposition by *A. aegypti*. For both *A. aegypti* and *A. albopictus*, none of the vaccination regimens affected the number of blood fed mosquitoes or mosquito survival. This clinical study provides the first proof-of-principle demonstration that vaccinating humans with mosquito salivary peptides can impair reproduction in female mosquitoes that blood feed on vaccinated individuals. Current work is focused on identifying human immune correlates for these inhibitory effects on mosquito reproduction.

0930

## AEDES ALBOPICTUS BLOOD FEEDING BEHAVIOR: FROM LAB TO FIELD

Kara Fikrig, Laura Harrington

Cornell University, Ithaca, NY, United States

*Aedes albopictus* is a competent vector of numerous pathogens, representing diverse transmission cycles involving unique hosts. Previous blood meal analyses demonstrate a wide range of feeding patterns, from primarily anthropophilic to zoophilic - yet little is known about the drivers of these differences. We assessed *Ae. albopictus* feeding behavior in the field and lab, including feeding patterns, potential fitness implications of host species, and preference. We examined the feeding patterns in Long Island, New York, and contextualized blood meal sources with host availability measured by household interviews and camera traps. We identified 90 blood meals, including 29 human, 22 cat, 16 horse, 12 opossum, 5 dog, 2 goat, and 1 rabbit, rat, squirrel and raccoon. Our study is the first to quantitatively assess *Ae. albopictus* feeding patterns in the context of host availability of wild animals in addition to humans and domestic animals. Host feeding indices showed that cats and dogs were over-utilized compared to humans. Forage ratios suggested a tendency to over-utilize cats and opossums and under-utilize raccoons, squirrels, and birds. This feeding pattern was different from a published study from Baltimore, Maryland, where *Ae. albopictus* fed more often on rats than humans. To understand if these differences were due to host availability or mosquito population variation, we compared the fitness of Long Island and Baltimore *Ae. albopictus* after feeding on rat and human blood. In addition, we examined fitness within the Long Island population after feeding on human, rat, cat, horse, and opossum blood. Our results do not show major mosquito fitness differences by blood hosts, suggesting that fitness benefits do not drive Northeastern *Ae. albopictus* feeding patterns. We then assessed the host preference of *Ae. albopictus* populations across a spectrum of feeding patterns from primarily zoophilic to anthropophilic. Together, these findings provide novel insight into a critical behavior of an important vector of human disease.

## BLOOD MEAL SOURCES AND NONRANDOM HUMAN SELECTION BY ANOPHELES VECTORS OF HUMAN MALARIA IN MALAWI: IMPLICATIONS FOR MALARIA TRANSMISSION

Rex B. Mbewe<sup>1</sup>, John B. Keven<sup>2</sup>, Charles Mangani<sup>3</sup>, Mark L. Wilson<sup>4</sup>, Themba Mzilahowa<sup>3</sup>, Don Mathanga<sup>3</sup>, Clarissa Valim<sup>5</sup>, Miriam K. Laufer<sup>6</sup>, Lauren M. Cohee<sup>6</sup>, Edward D. Walker<sup>1</sup>

<sup>1</sup>Department of Entomology, Michigan State University, East Lansing, MI, United States, <sup>2</sup>Department of Microbiology and Molecular Genetics, Michigan State University, East Lansing, MI, United States, <sup>3</sup>Malaria Alert Center, College of Medicine, University of Malawi, Blantyre, Malawi, <sup>4</sup>Department of Epidemiology School of Public Health, University of Michigan, Ann Arbor, MI, United States, <sup>5</sup>Department of Global Health, Boston University School of Public Health, Boston, MA, United States, <sup>6</sup>Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Despite widespread availability of long-lasting insecticide treated bednet (LLINs), malaria transmission with high human infection incidence continues in Malawi. We hypothesize that biases in mosquito human feeding could be driving infection transmission. The study was conducted to quantify the extent and diversity of human blood feeding by vector mosquitoes in areas with extensive use of LLINs including Balaka district with standard permethrin and Machinga district with piperonyl butoxide synergist LLINs (PBO). Mosquitoes were sampled indoors during 2019-2020 by pyrethrum spray catch and light traps. Human demographic data and blood spots on filter paper by finger prick were collected from consented participants. Mosquitoes were identified by morphological and molecular methods. Mosquito blood meal source and *Plasmodium falciparum* infection in abdomen or head-thorax of mosquitoes was determined by qPCR methods, using host-specific oligonucleotide probes

and parasite-specific probes, respectively. Human blood meals and human blood spots were analyzed by genotyping 24 human microsatellite loci, to generate genetic profiles that were matched using an algorithm executed in R package. Of 635 blood-fed *Anopheles* spp, 44.1% were *An. arabiensis*, 16.2% *An. gambiae* s.s, 33.5% *An. funestus*, 0.3% *An. parensis*, and 5.8% were unidentified *Anopheles* spp. Blood meals were predominantly from humans (80.5%), but also goats (5.2%), dogs (2.0%), human/goat mixed (11.1%), human/dog (0.9%), and dog/goat (0.2%). Samples from Balaka with standard LLIN had a higher human blood index (81.2%) than Machinga (75.3%) with PBO nets, but it was not significantly different ( $p = 0.59$ ). Sporozoite infection in the head-thorax was 16% (99/633) overall, for an estimated annual EIR of 26 infectious bites/person. Genotyping analysis revealed a highly non-random pattern of human host selection with a bias toward feeding upon males aged 6-15 years. These results show a high proportion of human blood meals, regardless of LLIN type, and suggest that the school age males may be important contributors to transmission.

## IMPACT OF RANDOMIZED WMEI WOLBACHIA DEPLOYMENTS ON NOTIFIED DENGUE CASES AND INSECTICIDE FOGGING FOR VECTOR CONTROL IN YOGYAKARTA CITY

Citra Indriani<sup>1</sup>, Stephanie K. Tanamas<sup>2</sup>, Katherine L. Anders<sup>2</sup>, Suzanne M. Dufault<sup>3</sup>, Rubangi Rubangi<sup>4</sup>, Iris A. Ahmad<sup>1</sup>, Adi Utarini<sup>1</sup>, Cameron P. Simmons<sup>2</sup>

<sup>1</sup>Centre of Tropical Medicine, Faculty of Medicine, Public Health and Nursing, Universitas Gadjah Mada, Sleman, Indonesia, <sup>2</sup>World Mosquito Program, Institute of Vector-borne Disease, Monash University, Clayton, Australia, <sup>3</sup>Division of Biostatistics, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, <sup>4</sup>Disease Control Department, Yogyakarta City Health Office, Yogyakarta City, Indonesia

We conducted a cluster randomised trial of deployments of wMel-infected *Ae. aegypti* for dengue control in Yogyakarta City, Indonesia (Applying *Wolbachia* to Eliminate Dengue (AWED) trial). A predefined secondary endpoint was to determine the impact of wMel deployment on dengue cases notified to the surveillance system, which requires hospitals to report cases diagnosed clinically as Dengue Hemorrhagic Fever (DHF). Mixed-effect negative binomial regression was used to model monthly DHF case count (Jan 2006 - Apr 2020) comparing wMel-treated kelurahans (urban villages) with both the pre-intervention period and untreated kelurahans. The boundaries of the 35 kelurahans in the trial site do not all align with those of the 24 AWED clusters and rules were defined to apply a binary wMel intervention status to each kelurahan. Nineteen kelurahans were classified as 'treated' (wMel frequency >50% AND >50% trap positivity for 2 monthly monitoring events in a 6-month rolling window), 10 as 'untreated', and six were excluded from the analysis using binary wMel exposure classification due to highly variable %wMel. A secondary model used quintiles of monthly kelurahan-level wMel prevalence as the predictor of dengue incidence. DHF incidence was 54% lower in wMel-treated vs untreated kelurahans (IRR 0.46 [95% CI 0.34, 0.62]), and 61% lower in kelurahan-months with 80-100% wMel prevalence compared to kelurahan-months with 0-20% wMel (0.39 [0.25, 0.60]). An effect was also seen with 60-80% (0.61 [0.37, 1.00]) and 40-60% wMel (0.56 [0.38, 0.82]). The impact of wMel deployment on insecticide fogging activities, undertaken by vector control teams around the homes of notified DHF cases, was also analysed using negative binomial regression. Pre-intervention, fogging occurred at similar frequencies in areas later randomised to wMel-treated and untreated arms of the trial. After wMel deployment, fogging occurred significantly less frequently in treated areas (0.13 [0.07, 0.27]). These findings show that wMel deployments reduced the application of perifocal insecticide spraying by 87%, consistent with lower dengue case notifications in wMel-treated areas.

### NATURAL WOLBACHIA DETECTED IN WILD ANOPHELES STEPHENSI IN EASTERN ETHIOPIA

Elizabeth Waymire<sup>1</sup>, Sowmya Duddu<sup>1</sup>, Solomon Yared<sup>2</sup>, Dejene Getachew<sup>3</sup>, Dereje Dengala<sup>4</sup>, Meshesha Balkew<sup>5</sup>, Sarah Zohdy<sup>6</sup>, Seth Irish<sup>6</sup>, Tamar Carter<sup>1</sup>

<sup>1</sup>Baylor University, Waco, TX, United States, <sup>2</sup>Jijiga University, Jijiga, Ethiopia, <sup>3</sup>Dire Dawa University, Dire Dawa, Ethiopia, <sup>4</sup>PMI VectorLink Ethiopia Project, Abt Associates, Addis Ababa, Ethiopia, <sup>5</sup>PMI VectorLink Ethiopia Project, Abt Associates, Addis, Ethiopia, <sup>6</sup>U.S. President's Malaria Initiative and Entomology Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States

About 66 percent of Ethiopians are at risk of malaria, a disease caused by the parasite *Plasmodium falciparum* and *P. vivax*. *Anopheles stephensi*, a vector typically found in South Asia and the Middle East, was recently found to be distributed across eastern Ethiopia and is capable of transmitting both *P. falciparum* and *P. vivax*. Between the detection of this vector in the Horn of Africa and increasing insecticide resistance, new methods of vector control need to be investigated in order to control the spread of malaria. *Wolbachia*, a naturally occurring endosymbiotic bacterium of mosquitoes, has been identified as a tool for control of malaria transmission. *Wolbachia* could be used to control the mosquito population through replacement and decrease malaria transmission through suppression, however the presence of *Wolbachia* in wild *An. stephensi* in eastern Ethiopia is unknown. This study aimed to identify the presence and diversity of *Wolbachia* in *An. stephensi* across east Ethiopia. DNA was extracted from *An. stephensi* collected from eastern Ethiopia in 2018 and screened for *Wolbachia* using a 16S targeted PCR assay. Haplotype and phylogenetic analysis of the sequenced 16S amplicons were conducted to compare with *Wolbachia* from other regions. Thus far, 22 mosquitoes were positive for *Wolbachia* out of 193 mosquitoes screened. Multiple haplotypes were detected in the Ethiopian sequences. In addition, phylogenetic analysis revealed that the eastern Ethiopian sequences cluster with other *Wolbachia* sequences in Anopheline mosquitoes in Africa and SE Asia. These findings provide the first evidence of natural *Wolbachia* populations in wild *An. stephensi* in the Horn of Africa and identify the need to do further research to confirm the extent that *Wolbachia* infects *An. stephensi* and investigate its utility in malaria control in the Horn of Africa.

### SUCCESSFUL CRYOPRESERVATION OF MOSQUITO (ANOPHELES STEPHENSI) EGGS

Eric R. James<sup>1</sup>, James Overby<sup>1</sup>, Yingda Wen<sup>2</sup>, Kristen Pluchino<sup>3</sup>, Shane McTighe<sup>4</sup>, Abraham Eappen<sup>1</sup>, Stephen L. Hoffman<sup>1</sup>, Peter F. Billingsley<sup>1</sup>

<sup>1</sup>Sanaria Inc, Rockville, MD, United States, <sup>2</sup>Trancenta Holding, Princeton, NJ, United States, <sup>3</sup>FDA, Silver Spring, MD, United States, <sup>4</sup>WRNMMC, Rockville, MD, United States

Research on mosquitoes, and in particular on *Anopheles* spp., is constrained by the lack of a method for the long-term preservation of stocks of the large number of laboratory-bred strains, and genetically modified (GM) lines. Cryopreservation would provide a powerful tool for mosquito research, negating the need for continuous maintenance and supporting the implementation of mass release programs of GM mosquitoes for disease control. Several insect species have been successfully cryopreserved including some dipteran species, but to date, despite considerable effort, no method has been developed for mosquitoes - until now. We present a method for the cryopreservation of *Anopheles stephensi* eggs that reproducibly yields a hatch rate of ~25%. The cryopreserved eggs are stable in liquid nitrogen vapor phase below -150 °C for more than 5 years. Hatched larvae develop normally through to adults and the females blood feed, mate, and produce viable second-generation eggs that also develop normally. Vector competency of adult mosquitoes obtained from cryopreserved eggs was demonstrated

by infection with the malaria parasite, *Plasmodium falciparum*, and the development of salivary gland sporozoites in numbers similar to those produced in controls. Critical components of the cryopreservation technique are the time of egg harvest after oviposition, the cryoprotectant additive (CPA), the temperature and duration of exposure to the CPA, cooling and thawing rates, and post-thawing dilution. The technique can easily cryopreserve small or large (100,000+) batches of eggs, adequate for banking species and strains, and to date has been used to bank several batches of *A. stephensi* SDA500, the mosquito used to manufacture Sanaria® PfSPZ Vaccine, PfSPZ Challenge, and PfSPZ-GA1, several genetically altered lines of *A. stephensi*, and *A. gambiae*.

### MICROBES INCREASE THERMAL SENSITIVITY IN THE MOSQUITO, AEDES AEGYPTI, WITH THE POTENTIAL TO CHANGE DISEASE DISTRIBUTIONS

Fhallon Ware-Gilmore<sup>1</sup>, Carla Sgrò<sup>2</sup>, Zhiyong Xi<sup>3</sup>, Heverton Dutra<sup>1</sup>, Matthew Jones<sup>1</sup>, Katriona Shea<sup>1</sup>, Matthew Hall<sup>4</sup>, Matthew Thomas<sup>5</sup>, Elizabeth McGraw<sup>1</sup>

<sup>1</sup>Pennsylvania State University, State College, PA, United States, <sup>2</sup>Monash University, Melbourne, Australia, <sup>3</sup>Michigan State University, East Lansing, MI, United States, <sup>4</sup>Monash, Melbourne, Australia, <sup>5</sup>York Environmental Sustainability Institute, York, United Kingdom

Changes in global climate, that include higher temperatures and more frequent extreme thermal events, are expected to cause dramatic shifts in the distributions of infectious diseases. The mosquito *Aedes aegypti* is the primary vector of many disease-causing viruses, worldwide including dengue (DENV), and the geographic range of the mosquito is increasing, partly, due to changing climate. One emerging solution for vector-borne disease control is the release of the insect endosymbiont, *Wolbachia*, whose infection in mosquitoes reduces virus transmission to humans. When temperatures fluctuate, mosquito vectors will be increasingly exposed to temperatures beyond their upper thermal limits, but how they respond may be dependent on genotypic variation in thermotolerance within, and between populations. Here we examine how DENV and *Wolbachia* infection alter *Ae. aegypti* thermotolerance and have investigated whether thermal tolerance is heritable, using a high throughput physiological 'knockdown' assay modeled on studies in *Drosophila*. Such laboratory measures of thermal tolerance have previously been shown to accurately predict insect distributions in the field. We show that DENV and *Wolbachia* infection similarly increase mosquito thermal sensitivity. Surprisingly, in the coinfecting state, *Wolbachia* did not provide protection against DENV associated effects on thermal tolerance, nor were the effects of the two infections additive. The latter suggests that the microbes may act by similar means, potentially through activation of shared immune pathways or energetic tradeoffs. Further, by studying thermal tolerance in the framework of a family breeding design, we found heritability of the trait to be low. In total our work demonstrates that future global projections of DENV transmission risk, and of *Wolbachia*'s potential efficacy may need to take into account the impact of these microbes on vector survival. Additional studies are needed to further explore the role of history of adaptation and genetic variation in a mosquito's thermotolerance.

### COMPARISON OF STATISTICAL METHODS FOR ANALYSIS OF RECURRENT ADVERSE EVENTS IN THE PRESENCE OF NON-PROPORTIONAL HAZARDS AND UNOBSERVED HETEROGENEITY: A SIMULATION STUDY

Noel Patson<sup>1</sup>, Marinus Eijkemans<sup>2</sup>, Mavuto Mukaka<sup>3</sup>, Don Mathanga<sup>4</sup>, Mirium K. Laufer<sup>5</sup>, Lawrence Kazembe<sup>6</sup>, Tobias Chirwa<sup>1</sup>

<sup>1</sup>School of Public Health, University of the Witwatersrand, Johannesburg, South Africa, <sup>2</sup>Julius Center for Health Sciences and Primary Care, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands,

<sup>3</sup>Centre for Tropical Medicine, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom, <sup>4</sup>School of Public Health and Family Medicine, College of Medicine, University of Malawi, Blantyre, Malawi, <sup>5</sup>Center for Vaccine Development and Global Health, University of Maryland, School of Medicine, Baltimore, MD, United States, <sup>6</sup>Department of Biostatistics, University of Namibia, Windhoek, Namibia

In preventive drug trials such as intermittent presumptive treatment for malaria prevention during pregnancy where treatment is repeatedly administered, recurrence of adverse events (AEs) is common. Analysis of the recurrent AEs is challenging due to time-to-AE variations and within-patient correlations, rendering the conventional methods (e.g. Fisher's exact) prone to bias. The correlation comes from individual patient unobserved heterogeneity (i.e. frailty) and the dependence between AEs. Potential AE-dependence can be modelled via time-dependent treatment effects, event-specific baseline and event-specific random effect, while heterogeneity can be modelled via subject-specific random effect. However, the presence of time-dependent effects can lead to biased estimation of the unobserved heterogeneity. Using both simulation study and *Chloroquine for Malaria prevention in Pregnancy* trial data, we investigated whether the lognormal shared frailty models with restricted cubic splines and non-proportional hazards (LSF-NPH) assumption can improve frailty variance estimates compared to the conventional inverse Gaussian shared frailty with proportional hazard (ISF-PH) model, in the presence of time-dependent treatment effects and unobserved patient heterogeneity. We assessed the bias, precision gain and coverage probability of 95% confidence interval of the frailty variance estimates for the models under varying known unobserved heterogeneity and sample sizes in the presence of non-proportional hazards for the drug effects. The ISF-PH model consistently provided better coverage probability and less bias of the frailty variance estimates. The LSF-NPH models yielded better log hazard ratio estimates, precision and model standard errors for frailty variance estimates. The coverage probability of frailty variance estimates for the LSF-NPH improved as the number of restricted cubic splines increased. This study demonstrates the need for improved safety data analysis and preferring LSF-NPH models when there are recurrent AEs and time-dependent treatment effects in malaria chemoprevention in pregnancy trials.

### MODELLING THE EFFECT OF PHARMACEUTICAL AND NON-PHARMACEUTICAL INTERVENTIONS IN THE DYNAMICS OF COVID-19 - A COMPARISON BETWEEN SWEDEN AND THE CZECH REPUBLIC

Patience Bwanu Iliya<sup>1</sup>, Kristan Alexander Schneider<sup>2</sup>

<sup>1</sup>African Institute for Mathematical Sciences, Limbe, Cameroon,

<sup>2</sup>Hochschule Mittweida, University of Applied Sciences, Mittweida, Germany

A year after the onset of the epidemic and multiple epidemic waves later, the Covid19 pandemic remains a global health emergency. The overwhelming pandemic, which increased with the emergence of new variants of the virus, remains somewhat unclear and has raised awareness for an efficient strategy to mitigate the continuous spread of the disease. Herd immunity as a global response to the pandemic could be achieved either by natural infections or through vaccination campaigns. Initially, non-pharmaceutical interventions, e.g., home isolation, social distancing, were the foremost approach by most countries, while other countries like Sweden did not comply with such measures. As shown by the subsequent dynamic of the pandemic, it was erroneously assumed that herd immunity would be achieved faster in Sweden. However, the success of the first implementation of the non-pharmaceutical interventions in the Czech Republic yielded the world's highest death toll during the next wave - "paradox of success". As vaccines have become available, it is crucial to examine the impact of these pharmaceutical interventions, as well as when and how it best fits for the non-pharmaceutical interventions to be relaxed for herd immunity to be reached. Here, we introduce a predictive model

to forecast the effect of different non-pharmaceutical (contact reduction measures, social distancing, and isolation) and pharmaceutical (different vaccines efficacy) interventions on the control of the COVID-19 pandemic.

### SPATIAL VIDEO, GEONARRATIVES AND MACHINE LEARNING CONTEXTUALIZATION DISEASE LANDSCAPES

Andrew Curtis<sup>1</sup>, Jayakrishnan Ajayakumar<sup>1</sup>, Sandra Bempah<sup>2</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Kent State University, Kent, OH, United States

An ongoing data deficiency in many challenging environments is how to acquire granular contextualized spatial data to support on-the-ground epidemiological investigations. When investigating which microenvironments might be predictive of cholera outbreaks, or how risk of malaria varies with micro seasonality, it is important to acquire locations of associated environmental features, such as water points, or drainage channels. Next, we need to include *context*. For example, how do water points vary in type, contamination risk, local use and what is the local perception about them? Do these features change in risk / role / importance across the seasons? And does the surrounding environment have a direct or indirect influence? In this presentation we will focus on Ghana, Haiti, and Kenya to show how a geospatial field technique and an associated software has been used to capture and map the required data for these questions. We will show how spatial video, which is a small robust video camera with an inbuilt global positioning system, has been used to map local mosquito habitats, or where standing water poses a threat to contaminating drinking water (for example). Using bespoke software, we will show spatial video visualization, data improvements such as correcting coordinate paths, and how to map (through digitizing) risk factors. We will then contextualize these environments with geonarratives, which are the addition of informed commentaries collected from local health workers or residents to explain these environments. Using bespoke software these narratives will create an additional map layer of *context*. Finally, we will show how machine learning can be used to automatically extract and map frames from the video to provide a near real time solution to generate and update these types of local area maps. This presentation will provide a detailed explanation of how these techniques work, with results showing granular spatial and temporal variations for each of the three countries for three commonly accepted multi-disease risk environmental variables: trash, standing water and drainage channels.

### USING TECHNOLOGY FOR INSECTICIDE-TREATED NET (ITN) DISTRIBUTIONS - IS IT WORTH IT AND WHY?

Kathryn Clifton<sup>1</sup>, Zainab Ali<sup>2</sup>, Elijah Egwu<sup>2</sup>, Anusha Eregowda<sup>3</sup>, Apoorv Pal<sup>1</sup>, Suzanne Van Hulle<sup>1</sup>, Paul S. Wiedmaier<sup>1</sup>, Diwe Ekweremadu<sup>2</sup>, Sonachi Ezeiru<sup>2</sup>

<sup>1</sup>Catholic Relief Services, Baltimore, MD, United States, <sup>2</sup>Catholic Relief Services, Abuja, Nigeria, <sup>3</sup>George Mason University, Fairfax, VA, United States

In 2018, CRS supported the government of Nigeria with distributing 12 million nets to 22.5 million people. Integrating technology has been key to operating successfully on such a large scale. The project spent just over \$2.4 million on technology as a way to improve geographic coverage, efficiency, transparency, and accountability. An internal study was conducted that involved the use of machine learning to understand whether using technology for ITN distributions was worth the cost. To determine the impact of technology, the study compared the cost of paper-based implementations in the two states of Edo and Osun and the cost of digital implementation in Katsina state. The results showed that while the cost of digital implementation was higher, using technology increased the rate of net pick-up, or redemption, significantly - by up to 10.2%. Machine learning algorithms identified the greatest factors to predict redemption. The Random Forest algorithm had the highest predictive accuracy of 77.9%. Using technology to reduce walking and

wait times, sending reminders, tracking household follow-ups, and identifying missed areas enabled the digital implementation to have a higher impact since more people got a net. Other factors that influenced redemption rates were the amount of time the monitor spent at the household, family size, and day of the week the distribution occurred. Redemption rates in the paper states were 88% for Edo and 89.37% for Osun State, but increased to 98.8% in Katsina state with digital implementation. Technology starts to pay for itself when considering the household health costs of contracting malaria. To understand the value of increasing redemption rates, it is important to understand a myriad of factors: the household cost of contracting malaria, the effectiveness of using an ITN, the malaria prevalence rate in the state, and the likelihood of people using the nets. Assuming that treating a malaria case costs about \$21.20 and that ITNs reduce the risk of contracting malaria by 56%, we estimate that the %improvement of net redemption in Katsina state led to an estimated \$22.5 million in prevented malaria cases.

0940

### ESTIMATING THE IMPACT OF COVID-19 ON HOSPITAL ATTENDANCE IN NIGERIA USING ROUTINE NATIONAL HEALTH MANAGEMENT INFORMATION SYSTEM DATA

**Justus Uzim<sup>1</sup>**, Emeka Okechukwu<sup>1</sup>, Gertrude Odezugo<sup>1</sup>, Emma Mtiro<sup>1</sup>, David Onime<sup>1</sup>, Paul McDermott<sup>1</sup>, Ngozi Azodoh<sup>2</sup>

<sup>1</sup>USAID Nigeria, Abuja, Nigeria, <sup>2</sup>Federal Ministry of Health, Department of Health Planning Research and Statistics, Abuja, Nigeria

After the first COVID-19 case in Nigeria was reported in February 2020, there has been widespread fear with negative impact on society. We assessed the impact of COVID-19 pandemic on health service utilization through a three-year trend analysis of Health Facility (HF) monthly OPD attendance reported through the National Health Management Information System (NHMIS). The HFs assessed were selected through a two-stage random sampling process where six states and sixty high-volume HFs were selected. Level of health care (primary, secondary, tertiary) and ownership (government, private) were also recorded against each HF. Monthly OPD attendance were routinely collected by health workers using standardized registers and entered into the web based NHMIS by local government staff from where data for the analyses were downloaded. Of the 2,160 expected reports, 288 (10%) were missing. Missing data were rebuilt through interpolation using seasonal forecast. Weighted trend series model accounting for yearly seasonality was used to predict OPD attendance trend during the COVID-19 period and this was compared with actual monthly trend. Chi-square test at 95% significance level was also used to compare whether differences 9 month pre-COVID and during COVID-19 periods were significant across ownership, level of healthcare and state. There was a 45% decline between reported and predicted average monthly OPD attendance during COVID-19 period. The decline in government HFs was 51%, compared to 24% in privately owned HFs ( $p < 0.0001$ ). Primary level HFs recorded a 40% decline compared to 43% in secondary and 42% in tertiary HFs ( $p = 0.107$ ). By State, the decline was Bauchi 56%, Imo 52%, Lagos 47%, Taraba 32%, Kaduna 20% and Cross River 12% ( $p < 0.001$ ). The COVID-19 pandemic negatively impacted health service utilization in Nigeria. This could potentially worsen health outcomes. The significant differences based on ownership of HFs may reflect the general perception of better infection prevention strategies and availability of higher quality services in privately owned HFs. This needs to be studied further.

0941

### DEVELOPING A SPATIAL GRID-BASED TECHNIQUE FOR REPRESENTATIVE SAMPLING IN POPULATION-BASED SURVEYS USING MACHINE LEARNING AND GEOGRAPHIC INFORMATION SYSTEM

**Abu Yousuf Md Abdullah<sup>1</sup>**, Kyu Han Lee<sup>2</sup>, Asrafal Alam<sup>1</sup>, Sanwarul Bari<sup>1</sup>, Emily S. Gurley<sup>2</sup>, Solveig Argeseanu Cunningham<sup>3</sup>, Shams El Arifeen<sup>1</sup>, Atique Iqbal Chowdhury<sup>1</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Hubert Department of Global Health, Rollins School of Public Health, Emory University, Atlanta, GA, United States

Population-based surveys are essential to generate denominators for health statistics. Conventional sampling techniques used in population-based representative surveys pose considerable challenges, including the need to pre-enumerate households and the availability of an up-to-date census with administrative boundaries. Similarly, the sampling frame in a conventional grid-based technique considers grid cells where households might be absent such as in agricultural lands, which may introduce operational redundancies. Therefore, to overcome the challenges of conventional sampling, we developed a hybrid method by integrating conventional grid-based sampling with a satellite-based grid cell elimination process. The study aims to compare this hybrid approach with the conventional grid-based method using data from a health and demographic surveillance system (HDSS), which tracks every individual in the Baliakandi sub-district of Bangladesh and aims to capture every stillbirth and under-five death in the area. We developed a spatial grid with a cell size of 500 x 500 meters and a land cover model using Sentinel-2 satellite images and the random forest machine learning classifier. HDSS census helped determine a sampling size of 12000 households ( $n=58869$ ). The sampling frame of the grid-based approach considered all grid cells, but for the hybrid method, the land cover model was used to eliminate cells with no households; the sampling frame was then developed from remaining cells ( $n=605$ ). Results suggest 42% of uninformative cells could be removed using the hybrid approach and save the time and logistics required to deploy survey teams to any of these cells. In 1000 replicated runs, only the hybrid sampling approach could capture the targeted number of households and substantially reduce under- and over-estimations of stillbirths and under-five death rates. The hybrid approach could detect households with a sensitivity and specificity of 86% and 93%, respectively. In conclusion, the hybrid approach offers fast and targeted representative surveys and reduces under-and over-estimations of vital health statistics.

### MACHINE LEARNING APPROACHES FOR COVID-19 MISINFORMATION AND VACCINE ACCEPTANCE IN AFRICA

**Melody Swen**, Rhys O'Neill

Novetta, McLean, VA, United States

In order to understand possible barriers to COVID-19 vaccine acceptance in Africa, Novetta's Rapid Narrative Analysis (RNA) process combined human observation, machine learning, and natural language processing techniques to gain insight into levels of trust on vaccine and vaccine trials from African Twitter users from April 2020 - January 2021. The methodology and foundation for this process was based on the Africa Centres for Disease Control and Prevention Rumor Tracking System (est. April 2020), the purpose of which was to monitor rumors and misinformation around COVID-19 in Africa, and to understand public discussion about the pandemic and obtain background information for public health messaging and programming at the continent level. After five months of operation, an initial analysis was conducted of how social media networking on Twitter impacted COVID-19 vaccine acceptance in Africa. Within the scope of analysis, "trust" or "distrust" in vaccines was defined as positive/negative language, sentiment, or disapproval of a

COVID-19 vaccine. Quantified changes in trust or distrust were measured through the volume of tweets with the respective model-predicted sentiment. A follow-up analysis was conducted retrospectively in January, and covered the time frame from August 2020 - January 2021 to monitor any change in narrative from the first monitored period. RNA's machine learning modeling detected more distrust than trust across all tracked African countries in the first 5 months of data monitoring. Nearly 64% of unique users expressed distrust in vaccines, with only 33% of unique users expressing trust in vaccines. Further analysis through time showed an overall decrease in trusting/distrusting sentiment, and a rise in neutral sentiment, due to increased media exposure of other COVID-19 vaccine trials and increased inoculation.

0943

### EVERY CHILD COUNTS: REACHING ZERO-DOSE CHILDREN USING GEOSPATIAL DATA & TECHNOLOGY

**Kyle Hutchinson**<sup>1</sup>, Jade Yangyuepei Yang<sup>2</sup>, Gloria Musukwa<sup>3</sup>, Julie Dohert<sup>1</sup>, Philimon Ndubani<sup>3</sup>, Francis D. Mwansa<sup>4</sup>, Simon Mutembo<sup>2</sup>

<sup>1</sup>Akros, Lusaka, Zambia, <sup>2</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>3</sup>Macha Research Trust, Macha, Zambia, <sup>4</sup>Ministry of Health, Lusaka, Zambia

Mass vaccination campaigns introduce new vaccines; provide doses to those who may have missed routine doses; and give a second opportunity to those who may not have developed immunity. These campaigns, however, have been known to miss zero-dose children, leaving communities vulnerable to vaccine preventable disease. To address this issue, we utilized a spatial intelligence approach to identify zero-dose children for follow-up after a nation-wide mass vaccination campaign in Zambia for measles and rubella, held during the Covid-19 pandemic in November 2020. To strategically reach zero-dose children, we applied enumeration methods to satellite imagery to establish structure counts for 10 health facility catchment areas in Choma district. We then used Reveal, an open-source platform, which enabled community health workers (CHWs) to navigate and register children at the household-level. An analysis of these data showed this approach allowed zero-dose children to be identified, mapped and vaccinated, using Reveal to navigate and collect data at the household-level during a mop-up activity that followed the campaign. A total of 43,113 structures were enumerated using satellite imagery. Of these structures, 36,964 were found (86%). Only 12,014 structures were eligible for registration, of which 10,928 (91%) were registered. 13,497 children were found and registered within these households. Of these, 11,498 (85%) were fully vaccinated; 1208 (9%) were partially vaccinated; and 791 (6%) were zero-dose. Following the mass vaccination campaign, nurses and CHWs were tasked with visiting the households of these zero-dose children to verify if they were vaccinated during the campaign. If not, a vaccine was provided by the nurse. We found 565 of the 791 zero-dose children. Of these, 363 (64%) were vaccinated during the campaign, while a further 191 (33%) were vaccinated during this targeted mop-up activity. We demonstrate how linking CHWs with a geospatial solution such as Reveal can enable the identification of zero-dose children, as well as the targeted delivery of vaccines, leading to improved coverage rates and community protection.

0944

### ADOPTION OF LOCAL GOVERNMENT AREA PEER MENTORING IMPROVES DATA QUALITY MANAGEMENT ACROSS LOCAL GOVERNMENT AREAS IN CROSS RIVER STATE, NIGERIA

**Linda-Kaka Enyia**<sup>1</sup>, Victor Basse<sup>1</sup>, Augustine Firima<sup>1</sup>, Isu Eleme Edu<sup>2</sup>, Edet Basse<sup>2</sup>, Abba Umar<sup>3</sup>, Abimbola Olayemi<sup>3</sup>, Paul Waibale<sup>4</sup>, Uchenna Nwokenna<sup>3</sup>, Kazeem Ayankola<sup>3</sup>, Thomas Hall<sup>5</sup>, Ratha Loganathan<sup>5</sup>

<sup>1</sup>Management Sciences for Health, Calabar, Nigeria, <sup>2</sup>State Malaria Elimination Programme, Cross River State, Calabar, Nigeria, <sup>3</sup>Management

Sciences for Health, Abuja, Nigeria, <sup>4</sup>Management Sciences for Health, Kampala, Uganda, <sup>5</sup>Management Sciences for Health, Arlington, VA, United States

Available evidence suggests that a functional health system needs quality data to make informed decisions. This cannot be achieved if the personnel generating, reporting, and managing data have gaps in their knowledge and skills. The data generated from all the health facilities are uploaded to the National Health Management Information System (NHMIS) by the local government area (LGA) Monitoring & Evaluation (M&E) officers. Thus, the capacity of the LGA M&E officers can determine the quality of data reported for the district. The problem is further heightened by poor oversight due to inadequate human resource. The President's Malaria Initiative for States (PMI-S) Project conducted a baseline analysis of health facilities in Cross River State in 2019. The report highlighted data quality problems with 398 of 1300 health facilities (31%) reporting inconsistent data in the NHMIS. The LGAs contributing most of the inconsistent data were Akpabuyo and Abi who together contributed 12% of the inconsistent data. PMI-S introduced a peer-to-peer mentoring intervention with a high-performing LGA M&E officer paired with low performing LGA staff across 80 health facilities in the identified LGAs. The main responsibility was to support and improve the capacity of M&E officers in these two neighboring LGAs over a four-month period by helping each other to learn, facilitate skills transfers, and improve performance; and in doing so, encourage learning in themselves, inspire exchange, and learn among other LGAs. After four months of implementation, the proportion of health facilities reporting data quality issues (errors) reduced, for Abi LGA 57.6% (29/51) in 2019 to 0% (0/51) in 2020, and from Akpabuyo LGA 49.8% (19/39) in 2019 to 1% (1/39) in 2020. These findings indicate that health care workers at the LGA level may contribute to better results if they are equipped with the right skills. Peer to peer learning removes hierarchy during learning and encourages networking amongst peers to improve performance. The approach is a cost effective and sustainable approach for the state.

0945

### THE ROLE OF GEOSPATIAL DATA IN GLOBAL HEALTH

**Jaymia Ecker**, Annie Werner, Emily Boytinck

Columbia University, Palisades, NY, United States

Health systems in the global north rely on a wealth of geospatial data to deliver routine healthcare, perform disease surveillance, and respond to disease outbreaks. For example, the United States employs recent population data for its distribution and administration of the COVID-19 vaccine, while most American patients in turn can readily access online information about vaccine availability (often using navigation systems for directions to the nearest vaccination site). These systems rely on precise geo-enabled data that is often lacking in low- and middle-income countries (LMICs). To help address this shortfall, GRID3 (Geo-Referenced Infrastructure and Demographic Data for Development) is working with countries in sub-Saharan Africa to generate, validate, and support the use of geospatial data on population, settlements, infrastructure, and boundaries. GRID3 responds to support requests from government and non-government organizations with tailored technical assistance and skill-building, often working closely with national statistical offices and national health ministries. High-resolution geospatial data on population distributions and characteristics, health infrastructure locations, health catchment areas boundaries, and other operational boundaries can be integrated into local and national systems (such as DHIS2) in order to strengthen the effectiveness and equity of health interventions. This presentation will focus on three use cases of geospatial data in the health sector: 1) malaria prevention; 2) immunization (routine and non-routine); and 3) COVID-19 response.

### DATA QUALITY IMPROVEMENT IN MALARIA PROGRAM USING SOCIAL MEDIA MESSAGING AS A SUPERVISION TOOL IN CROSS RIVER STATE, NIGERIA

**Victor Bassey<sup>1</sup>**, Linda-Kaka Enyia<sup>1</sup>, Kenechukwu Ugbene<sup>1</sup>, Oluwatobiloba Akerlele<sup>1</sup>, Paul Waibale<sup>2</sup>, Abba Umar<sup>3</sup>, Uchenna Nwokenna<sup>3</sup>, Kazeem Ayankola<sup>3</sup>, Abimbola Olayemi<sup>3</sup>, Thomas Hall<sup>4</sup>, Ratha Loganathan<sup>4</sup>, Janet Ekpenyong<sup>5</sup>, Iwara Iwara<sup>5</sup>

<sup>1</sup>Management Sciences for Health, Calabar, Nigeria, <sup>2</sup>Management Sciences for Health, Kampala, Uganda, <sup>3</sup>Management Sciences for Health, Abuja, Nigeria, <sup>4</sup>Management Sciences for Health, Arlington, VA, United States, <sup>5</sup>State Malaria Elimination Programme, Cross River State, Calabar, Nigeria

The COVID-19 pandemic led to restrictions of movement in Cross River State. This affected routine data management activities such as timely data collection and validation, health facility heads of unit meetings, quarterly data quality assurance and supportive supervisory visits to health facilities. There was an increase in positivity rate, higher clinical diagnosis, indiscriminate use of Artemisinin Combination Therapy (ACTs), low uptake of intermittent preventive treatment during pregnancy (IPTp) 1&2 and a decline in National Health Management Information System (NHMIS) reporting rate. We worked with Cross River health officials to leverage WhatsApp technology to improve data collection, processing and supervision. Through the support of the President's Malaria Initiative for States (PMI-S), the WhatsApp group created in May 2020 established an interactive and mentoring platform for malaria stakeholders at the state and local government area (LGA). Data is uploaded by LGA Monitoring and Evaluation (M&E) officers after completion of data validation for the month. Data quality checks were done to see which LGAs did not report or which data was illogical. Facilities with illogical reporting were filtered and displayed on the WhatsApp platform and emails were sent to LGA M&E officers that reported the data with advice for correction. The group facilitated communication among members with reference to topics that were linked to addressing poor management of malaria as seen in the NHMIS as well as in analyzing and presenting data. Adherence to national guidelines on IPTp and case management were consistently discussed on the WhatsApp group. IPTp1 increased from 66% in 2019 to 73% in 2020, and IPTp2 increased from 47% in 2019 to 51% in 2020. The NHMIS reporting rate improved from 81% in 2019 to 83% in 2020 and health facilities reporting no data quality issues with malaria indicators improved from 61% in 2019 to 95% 2020. We will continue to monitor these data indicators for sustained and improved performance while working with senior officials of governments in state and LGA levels to improve sustainability, functionality, and use of the platform.

### ASSESSING THE IMPACT OF COVID-19 ON THE UTILIZATION OF PUBLIC HEALTH SERVICES IN 2020 ON BIKO ISLAND, EQUATORIAL GUINEA

**Jeremias Nzamio Eyono<sup>1</sup>**, Norberto Bosepa Cuba Cuba<sup>1</sup>, Wonder P. Phiri<sup>1</sup>, Godwin Fuseini<sup>1</sup>, Carlos A. Guerra<sup>2</sup>, Jordan M. Smith<sup>2</sup>, Guillermo A. García<sup>2</sup>

<sup>1</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>2</sup>Medical Care Development International, Silver Spring, MD, United States

The impact of the COVID-19 pandemic on health-seeking behavior and its impact on the utilization of health services on Bioko Island were investigated. Using data from the National Health Information System, the monthly average of outpatient consultations and hospitalizations between 2018 and 2019 were calculated and compared to the monthly number of consultations and hospitalizations of the same months in 2020 and 2021. The mean outpatient consultations per month in 2018 and 2019 was 9801. Mean outpatient consultations in 2020 amounted 7409, representing a 24.4% decrease. Regarding hospitalizations per month, the average between 2018 and 2019 was 1062. In 2020, there were 936 hospitalizations, representing a 12% decrease. When disaggregating

these results by year, hospitalizations in 2020 decreased 21% and 0.3% compared to 2019 and 2018, respectively. Preliminary analyses show that the difference between the average of outpatient consultations of 2018 and 2019 compared to 2020 was lower but this was not necessarily the case with hospitalizations. The purpose of this study is to investigate the statistically significant impacts of health services utilization across different diseases and to quantify these differences at temporal scales. These analyses would allow a better understanding of how the pandemic could have affected the burden of disease on Bioko Island outside of COVID-19.

### SARS-COV-2 MUTATIONS AND COVID-19 JABS - PREDICTING THE EFFECTS OF VACCINATION CAMPAIGNS

**Nessma Adil Mahmoud Yousif<sup>1</sup>**, Henri Christian Junior Tsoungui Obama<sup>2</sup>, Pierre Marie Ngougoue Ngougoue<sup>1</sup>, Kristan Alexander Schneider<sup>2</sup>

<sup>1</sup>African Institute for Mathematical Sciences - Cameroon (AIMS Cameroon), Limbe, Cameroon, <sup>2</sup>Hochschule Mittweida, Mittweida, Germany

The world is in the midst of vaccination campaigns as a measure to limit the spread of COVID-19. Several vaccine products have been developed and authorized to put an end to the ongoing COVID-19 pandemic that has put the globe in a state of a global health emergency for more than a year, causing a severe global economic crisis. However, the global COVID-19 response is hindered by the emergence and spread of new virus variants and vaccine distribution inequity among countries. We introduce a generalization of the model underlying the pandemic-preparedness-tool CovidSim 2.1 (<http://covidsim.eu/>) to optimize vaccination strategies, accounting for different age strata, spatial structure, different viral strains, and vaccination strategies assuming different vaccine products. Vaccines are assumed not to immunize perfectly. Some individuals fail to immunize, and others only reach partial immunity. Most importantly, vaccines are assumed to change susceptibility to specific SARS-CoV-2 variants - reflecting that not every vaccine might protect against every SARS-CoV-2 variant. Additionally, the model accounts for unvaccinable individuals (anti-vaxxers, contraindications) and prioritization of specific age groups during vaccination campaigns. Individuals who recover from an infection with a specific strain of the virus are considered to remain susceptible to other variants with mild disease episodes upon infection. The model is exemplified with parameters reflecting the situation in the Federal Republic of Germany to predict disease incidence (and prevalence), assuming general contact reduction interventions (e.g., curfews, social distancing, prohibition of gatherings) and case isolation (in quarantine wards, and home). The predictive model can serve as an advanced decision support tool for COVID-19 management.

### MEASURING GROWTH TRAJECTORIES OF CHILDREN UNDER FIVE YEARS OF AGE: A NOVEL METHOD FOR EXTRACTING ANTHROPOMETRIC DATA FROM HEALTH CARDS

**Solveig A. Cunningham<sup>1</sup>**, Ariel Nhacolo<sup>2</sup>, Abu Mohd Naser<sup>1</sup>, Serei Vatana Nath<sup>1</sup>, Jonathan A. Muir<sup>1</sup>, Parminder S. Suchdev<sup>1</sup>, Inacio Mandomando<sup>2</sup>, Quique Bassat<sup>3</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, <sup>3</sup>Universitat de Barcelona, Barcelona, Spain

A child's growth trajectory is a reflection of overall health and nutrition. Growth monitoring therefore provides an opportunity for preventive and curative healthcare to reduce childhood malnutrition and mortality. We present a novel method for collecting data on children's growth trajectories using data from standard *Road to Health* (RTH) cards, which are issued to children at birth in many countries. Many Health and Demographic Surveillance Systems (HDSS), which collect population-based data at regular intervals across Sub-Saharan Africa and Asia, take photographs of these cards. For preliminary analysis, we selected 60 cards photographed during the 2019 data collection at an HDSS in Manhiça district,

Mozambique. We explored methods for extracting data on height/length and weight; a nurse enters these data on the RTH card both numerically and in graph form by at each clinic visit. We found that digitizing the data was easiest using the free Graph Grabber graphical digitizing software to extract anthropometric data. For best results, it is important for field staff to be trained to ensure the quality of the photographs taken. Photographs that were crooked or blurry could not be used, with only about half of records yielding data at the first attempt. From these records, we were able to create a database with children's age-and sex-specific height/length and weight. From analyses of these data, we identify patterns of growth faltering and link these to children's risk of death before the age of 5y. We estimate the validity and reliability of extraction method, of digitizing graph and handwritten data, and exporting the extracted data into a dataset. This work demonstrates that information on children's growth patterns can be extracted from RTH cards, which are issued at birth and are carefully maintained even by parents living in very difficult conditions. These methods can be used to characterize growth patterns efficiently, not requiring new longitudinal data collection but relying on anthropometric measures already being taken through children's standard clinic visits.

### ASSESSING THE IMPACT OF COVID-19 PANDEMIC IN RURAL BANGLADESH: FINDINGS FROM A CROSS-SECTIONAL SURVEY IN CHAMPS-BANGLADESH STUDY SITE

**Atique Iqbal Chowdhury<sup>1</sup>**, Asrafal Alam<sup>1</sup>, Abu Yousuf Md Abdullah<sup>1</sup>, Md. Mamunur Rashid<sup>1</sup>, Sadeq-ur Rahman Qazi<sup>1</sup>, Shema Mhajabin<sup>1</sup>, Ahmed Ehsanur Rahman<sup>1</sup>, Shams El Arifeen<sup>1</sup>, Solveig Argeseanu Cunningham<sup>2</sup>, Emily S. Gurley<sup>3</sup>

<sup>1</sup>International Centre for diarrhoeal disease research, Bangladesh (icddr,b), Dhaka, Bangladesh, <sup>2</sup>Department of Global Health, Rollins School of Public Health, Emory University, USA, Address: 1599 Clifton Rd NE, Atlanta, GA 30322, GA, United States, <sup>3</sup>John Hopkins Bloomberg School of Public Health, Baltimore (ZIP code- MD 21218), MD, United States

Despite significant public health concerns worldwide, the impact of the COVID-19 pandemic in rural areas is poorly understood. Therefore, this study aims to understand how the pandemic and its associated lockdown from 27 March to 30 May, 2020, have impacted the livelihood, food availability, and uptake of pregnancy and healthcare for children under five in the rural Baliakandi sub-district of Bangladesh. A cross-sectional survey was conducted from 7 November to 13 December 2020, and 1302 women were selected using simple (n=299) and stratified (n=1003) random sampling. A structured questionnaire was used to understand household conditions during the pre-COVID-19 (before mid-March, 2020) and peri-COVID-19 (after mid-March, 2020) period. Results suggested that among the respondents who participated in the survey (n=1176), 16% (n=191) reported that they could not obtain sufficient food and among the respondents who could avail sufficient food (n=985), 44% (n=433) could not obtain the food of their choice after mid-March, 2020. While 73% (n=208) of non-farm business owners (n=286) reported business closures, 44% (n=128) of jobholders (n=288) reported job loss and 34% (n=227) of farmers (n=676) reported disruption in farming since the start of the pandemic. For the women who were pregnant (n=284), only 6 women reported they wanted but could not attend antenatal care due to lockdown-related issues. Similarly, for the households with at least one under five child (n=922), only 6 respondents reported they wanted but could not seek care due to lockdown-related issues. This study revealed that the effect of the pandemic on the healthcare uptake in rural Bangladesh was low within the study period. The worst impact could be found on people's livelihood, particularly in non-agricultural sectors. In fact, people with agricultural livelihood were relatively better at coping with the pandemic-related shocks than the laborers. As the pandemic continues, rural households in Bangladesh could experience food insecurities and malnutrition due to reduced food intake.

### REASONS FOR HOME BIRTHS IN THE BIRHAN HEALTH AND DEMOGRAPHIC SURVEILLANCE SYSTEM

**Bezawit Mesfin Hunegnaw<sup>1</sup>**, Delayehu Bekele<sup>2</sup>, Frederick G. B. Goddard<sup>3</sup>, Yahya Mohammed<sup>4</sup>, Kimiko Van Wickle<sup>3</sup>, Mesfin Zeleke<sup>4</sup>, Chalachew Bekele<sup>4</sup>, Grace J. Chan<sup>5</sup>

<sup>1</sup>Department of Pediatrics and Child Health, St Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, <sup>2</sup>Department of Obstetrics and Gynecology, St Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, <sup>3</sup>Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>4</sup>BIRHAN HDSS, St Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, <sup>5</sup>Division of Medicine Critical Care, Boston Children's Hospital, Harvard Medical School; Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States

Ethiopia is making significant advances to reducing maternal and newborn morbidity and mortality. However, many women still give birth at home without any skilled delivery care which increases the risk for adverse maternal and neonatal health outcomes. In the BIRHAN Health and Demographic Surveillance System based in North Shewa Zone, Ethiopia, we examined the reasons why women give birth at home in order to understand the challenges and better inform the design of solutions. The study design follows an open cohort of pregnant women who were enrolled upon confirmation of pregnancy. For all cohort births, data on location of delivery, reasons for home delivery and other factors were collected. A total of 2039 pregnancies were followed through birth from December 2018 to April 2020, of which 507 (25%) occurred at home or on the way to a facility. Only 19 (4%) of the home births received skilled delivery care at birth. A subset of 414 women who delivered at home were asked where they initially planned to deliver and their reasons for home delivery. Of those interviewed, 287 (70%) reported that they had initially desired to give birth at a health facility. When asked for specific reasons why they delivered at home, 302 women (73%) mentioned that the health facilities were too far away or that no transportation was available. In addition to this, 80 women (20%) mentioned that they chose to deliver at home based on prior evidence of successful home deliveries and 24 respondents (6%) reported that they had no one to accompany them and hence could not go to a health facility. Four women mentioned that they had a previous bad experience at health facilities and decided not to deliver at a health facility. Many women prefer to deliver in health facilities but end up giving unattended births at home. Long distance to health facilities and lack of transportation are important barriers for women to deliver in a health facility. Efforts to improve birth outcomes and skilled delivery attendance need to consider these barriers and explore community-based interventions aimed at improving maternal and neonatal birth outcomes.

### SEX WORK, ANTIBIOTIC USE AND THE MANAGEMENT OF SEXUALLY TRANSMITTED INFECTIONS IN HARARE, ZIMBABWE: AN ETHNOGRAPHIC STUDY

**Salome Manyau<sup>1</sup>**, Justin Dixon<sup>2</sup>, Norest Mutukwa<sup>1</sup>, Faith R. Kandiye<sup>1</sup>, Clare Chandler<sup>2</sup>

<sup>1</sup>Biomedical Research and Training Institute, Harare, Zimbabwe, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

A key global health challenge of our time is the dramatic increase in infections resistant to available antibiotics, including sexually transmitted infections (STIs) such as gonorrhoea and syphilis. Antimicrobial resistance (AMR) is driven by overuse of antibiotics both within and beyond formal healthcare settings, yet little is known about how and why people rely on these substances, particularly in low and middle-income countries (LMICs). An especially under-researched group is sex workers, who are at heightened risk of contracting and spreading STIs, often have poor access to healthcare and have been shown in previous studies to use antibiotics regularly. This paper presents ethnographic research (participant-

observation and in-depth interviews) conducted with 20 sex workers in Harare, Zimbabwe between 2018-2020, which aimed to understand patterns of antibiotic use among sex workers and reasons for this use. We present three key findings: (1) Sex workers were familiar with and regularly used antibiotics like metronidazole, doxycycline, ceftriaxone, and ciprofloxacin, which enabled them to continue working despite regular occupational exposure to STIs. (2) These antibiotics were largely prescribed by a northern-funded NGO clinic devoted to sex workers, towards which they felt considerable belonging in contrast to stigmatising experiences at public clinics. (3) Many women who were not sex workers and thus not eligible to attend the NGO were unable to access antibiotics for STIs (often contracted via partners paying for sex) because of prohibitive costs and stigmatising treatment. We conclude from these findings that attention to individual behaviour risks overlooking the limitations of the ways in which STIs have been managed through vertical programmes for STIs as a way of circumventing integration challenges in health systems. Our research draws attention to issues both within and beyond these programmes that emerge from the perspective of those affected by STIs. In addressing AMR, further effort is needed to reconsider integrated services, recognising the legacies that shape the challenges of integration.

### ASSESSING THE IMPACT OF COVID-19 ON MALARIA TRANSMISSION IN NIGERIA AND ZIMBABWE

**Olufunke A. Alaba**, Akim Tafadzwa Lukwa  
*University of Cape Town, Cape Town, South Africa*

As the COVID-19 pandemic struck several countries globally, low-middle-income countries increasingly shifted their focus on identifying and treating COVID-19; however, the emerging question to date is about the impact of the shift to already on ongoing efforts that had realised public health gains in the control of infectious diseases, such as malaria. Several low-middle-income countries reported a spike in malaria cases during the COVID-19 pandemic. For instance, Zimbabwe's Matabeleland South province reported a significant spike in the number of malaria cases during the COVID-19 crisis. However, the literature reviewed has not clarified whether the increase in the number of malaria-infected patients during the COVID-19 pandemic is linked to misdiagnosis or to other factors such as the insufficient resources needed for malaria control. Malaria control has been argued to largely depend on the mass distribution of long-lasting insecticide-treated nets (LLINs), seasonal malaria chemoprevention (SMC) and indoor residual spraying of insecticide (IRS) across communities and households. There is no doubt that understanding the effect of the concentrated campaigns against malaria is vital to inform future control planning during the COVID-19 crisis. Hence, the WHO has stressed that all routine malaria prevention and control activities should not be hampered and be continued to the extent possible as they tackle the COVID-19 pandemic. However, implementing these preventive activities house-to-house has been more arduous during the COVID-19 pandemic crisis. A modelling analysis by the WHO predicted a greater than 20% rise in malaria morbidity and a greater 50% mortality in sub-Saharan Africa during the COVID-19 pandemic due to a 75% reduction in routine malaria control measures, including ITN distribution and shortage of anti-malarial drugs. In Nigeria alone, interrupting malaria control management, such as delaying LLIN campaigns for six months, could result in 81,000 additional deaths. This study seeks to understand the effect of the COVID-19 pandemic on malaria control in Zimbabwe and Nigeria.

0954

### GLOBAL HEALTH TRAINING DURING A PANDEMIC: LESSONS AND IMPACT ON THE FUTURE

**Daniel Tisch**, Peter Zimmerman  
*Case Western Reserve University, Cleveland, OH, United States*

The Master of Public Health (MPH) Program at Case Western Reserve University maintains a focus on Global Health training and collaborations. The training program has grown from a historical global health framework

of shared training resources across five schools and nine departments. This CWRU Framework for Global Health continues to provide the administrative and training environment for integrated curricula, workshops, a certificate program, and mentored field experiences that link with MPH students, faculty, MPH-dual degree programs and partnerships into the inter- and trans-disciplinary structure. This serves as a core for MPH Global Health Concentration students and also provides opportunities to students across all five MPH concentrations and 11 dual degrees to foster diverse skills, perspectives, and public health impact. The MPH program recently completed a self-study and strategic planning process that incorporated surveys and feedback from students, faculty, internal partners, external partners, and external reviewers. Through this, our Global Health competencies were updated and aligned with curricula, training experiences, outcomes, and partnerships to prepare our students to be effective leaders and partners in global health. The program has designed approaches to overcome the complexities of global health training including program partner and international mentoring, language barriers, cost, time, and safety. COVID-19 travel and course delivery restrictions have fostered further innovations to global health training. Many students took advantage of new online training and local in-person global health experiences during social distancing and travel restrictions associated with the pandemic. Our courses also shifted learning methodologies, objectives, and examples, during a time of remote and dual delivery education. This presentation highlights our approach to establishing and supporting international training partnerships that meet the needs of our students, partners, and communities.

### ADDRESSING GENDER EQUITY AND SOCIAL INCLUSION BARRIERS TO IMPROVE ACCESS AND UPTAKE OF SCHOOL MASS DRUG ADMINISTRATION AMONG SCHOOL-AGED CHILDREN IN TANZANIA

**Isaac Njau**<sup>1</sup>, Taroub Faramand<sup>2</sup>, Amanda Ottosson<sup>2</sup>, Sara Pappa<sup>2</sup>, Stella Kasindi Mwitwa<sup>3</sup>, Wemaeli Anderson Mweteni<sup>4</sup>

<sup>1</sup>Ministry of Health, Community Development, Gender, Elderly and Children (MOHCDGEC), Dodoma, United Republic of Tanzania, <sup>2</sup>WI-HER, LLC, Vienna, VA, United States, <sup>3</sup>WI-HER, LLC, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>IMA World Health, Dar es Salaam, United Republic of Tanzania

The Neglected Tropical Disease Control Program (NTDCP) in Tanzania, in partnership with USAID's Act to End Neglected Tropical Diseases (NTDs) | East project (Act | East), implemented a pilot intervention in Pangani District Council, applying WI-HER's iDARE (Identify, Design, Assess, Record, Expand) methodology to identify and address gender equity and social inclusion (GESI)-related barriers and solutions around school-aged children who have missed or refused annual school mass drug administration (SMDA) to treat soil-transmitted helminths (STH) and schistosomiasis (SCH). District MDA records (2018-2020) revealed fluctuating coverage, with none reaching the 100% threshold, as the most recent round reached 91.9% of school-aged children. The pilot focused on a select number of zones and schools with especially low coverage, as low as 68.2% in the previous SMDA. The pilot followed co-creation of a GESI-integrated MDA training curriculum, and application through a national, regional, and district-level training cascade, which included training for the Pangani NTD team implementing the pilot. The Tanga Region NTD Officer led the pilot team, which included Pangani NTD Officers for Health and Education and the Council Social Welfare Officer, four zonal coordinators, front-line health workers (FLHWs), and teachers. Using iDARE, the team identified GESI issues affecting treatment uptake among school-aged children, to include parents not allowing children to take, fears of sterility or impotency, fear of side effects and mistrust of medicines. Community influencers were identified to help implement solutions to tackle these barriers and improve uptake. After the start of testing solutions, 97.7% of children and parents in the two zones who had not previously taken SMDA reported that they intended to take medication during the next SMDA. SMDA (March 2021) results showed an average of 99.1% of children across four schools that had previously low coverage, within the

two zones, took the medication. Identifying and addressing GESI barriers can better reach school-aged children and change behaviors to increase SMDA coverage.

0956

### MULTI-SECTORAL COLLABORATION TO IMPROVE ACCESS TO MEDICINE FOR SICKLE CELL DISEASE IN SUB-SAHARAN AFRICA

**Roland Hammond-Addo**<sup>1</sup>, Anthony Nsiah-Asare<sup>2</sup>, Christine Quao<sup>3</sup>, Charles Kiyaga<sup>4</sup>, Jonathan M. Spector<sup>5</sup>, Kwaku Ohene-Frempong<sup>6</sup>

<sup>1</sup>Novartis Global Health and Corporate Affairs, Accra, Ghana, <sup>2</sup>Office of the President of Ghana, Accra, Ghana, <sup>3</sup>Novartis Global Health and Corporate Affairs, East Hanover, NJ, United States, <sup>4</sup>Uganda Ministry of Health, Kampala, Uganda, <sup>5</sup>Novartis Institute for Tropical Diseases, Cambridge, MA, United States, <sup>6</sup>Sickle Cell Foundation of Ghana, Accra, Ghana

Acknowledging the potential role of public-private partnerships (PPPs) cited in the Sustainable Development Goals to help address global health challenges, we report outcomes from a novel, fit-for-purpose multi-sectoral collaboration designed to improve access-to-medicines for individuals with sickle cell disease (SCD) in sub-Saharan Africa. Novartis, a global medicines company, worked with stakeholders in Africa for three years to understand how it could constructively contribute to improved health outcomes for people with SCD. Access to hydroxyurea (HU), a generic medicine shown to improve outcomes for patients with SCD, emerged as a priority activity. A Memorandum of Understanding for the establishment a PPP was signed among the Ministry of Health (MOH), Ghana Health Service, Sickle Cell Foundation of Ghana (SCFG), and Novartis with the aim of bolstering healthcare system architecture to address SCD. The company increased its manufacturing capacity for HU and registered the medicine for the indication of SCD in Ghana (constituting the first time that Novartis registered HU for SCD and the first time that HU was registered specifically for SCD in Ghana). To help launch the program, the company provided the Ghana MOH with approximately 6 million capsules of HU as bridging stock according to WHO guidelines. This stock seeded the development of a large, organized HU-for-SCD treatment program involving all major SCD Treatment Centres in Ghana and managed by the SCFG. As subsequent steps, and in response to requests from local partners, the company worked with local partners to identify an optimal pricing scheme for HU in Ghana, initiated drug development for a child-friendly dispersible formulation of HU, and registered HU in six additional countries (Uganda, Tanzania, Kenya, Nigeria, DRC and Congo Brazzaville). We will present details of the collaborations and report lessons learned that include following the lead of local stakeholders and leveraging the core competencies of all partners in pursuit of maximizing opportunities for sustainable health solutions.

### DEVELOPING GOOD LABORATORY PRACTICE IN INSECTICIDE TRIAL FACILITIES IN AFRICA: THE VITAL ROLE OF LABORATORY TECHNICIANS AND LABORATORY SUPERVISORS

**Sara Begg**<sup>1</sup>, Graham Small<sup>2</sup>, Kirsten Duda<sup>1</sup>, Alexandra Wright<sup>3</sup>, Imelda Bates<sup>1</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Innovative Vector Control Consortium, Liverpool, United Kingdom, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

New vector control products are urgently needed to maintain the enormous gains we have recently seen in the battle against malaria, moving towards eradication. Vital in this is the network of trials facilities in Africa who evaluate these products by conducting studies against local mosquito populations. However, until recently, lack of quality management systems (QMSs) at these trials facilities made it impossible to assess if studies had been conducted correctly, without significant deviations from study protocols. To address this, the Innovative Vector Control Consortium

(IVCC) initiated a project in 2016 to support a network of 7 African trials facilities towards Good Laboratory Practice (GLP) certification. With GLP compliant QMSs, trials facilities can generate data that are reliable, repeatable and auditable. The Liverpool School of Tropical Medicine's Centre for Capacity Research conducted semi-structured interviews with 74 staff at these facilities, to investigate project challenges, enablers, and outcomes. The study found that laboratory technicians and supervisors were vital in developing a GLP compliant QMS and, in turn, many experienced career progression. An important challenge for laboratory staff was developing new habits, particularly working to Standard Operating Procedures (SOPs). Enabling activities were early sensitisation to the purpose and benefits - both individual and institutional - of GLP, a collaborative and iterative SOP development process that considered infrastructural limitations, and regular training to consolidate SOP compliance. As a result of the project, several laboratory staff were promoted, including into Quality Assurance and project management roles, or transitioned into academic roles via IVCC funded PhDs. The project also resulted in inter-facility and interdisciplinary learning, with laboratory staff providing peer-to-peer learning to both IVCC supported trial facilities and to African One Health laboratories. This study emphasises that RCS projects should include technical staff, who form the backbone of data generation and who can in turn support regional RCS efforts.

0958

### THE DISPARATE BURDEN OF STRESS AND CONCERN ASSOCIATED WITH THE COVID-19 PANDEMIC: FINDINGS FROM AN ONGOING COMMUNITY-BASED CLUSTER STUDY IN CENTRAL NEW YORK

**Anjee Panjwani**, Harry Taylor, Michael Conroy, Natalia DeMaria, Andrea Shaw, Julia Cramer, Megan Harris, Daniel Lichtenstein, Stephen Thomas, Frank Middleton, Kathryn B. Anderson  
*SUNY Upstate Medical University, Syracuse, NY, United States*

The COVID-19 pandemic has wrought profound disparities in infection rates across communities. We hypothesized that the psychological toll, both directly associated with personal risk and indirectly associated with COVID-19-related stressors, would similarly display heterogeneity across populations. We examined factors associated with stress and solicited concerns across diverse domains of physical, mental, and financial health. Starting in June 2020, we identified individuals recently infected with SARS-CoV-2 and enrolled these patients and their households. Surveys were conducted on enrollment and associated infections were identified by RT-PCR, IgM, and IgG testing. Mixed effects logistic regression models, with random effects for clustering by household, were used. A total of 70 households (183 participants) were enrolled as of March 2021. Median age was 34 years (range 1–78 years). 55.1% identified as female and 88.1% as white, non-LatinX. 64.0% of household members were found to have infection on enrollment. 28.2% were unemployed, 39.4% were working from home, and 43.9% were essential workers. Those who reported significant stress were not more likely to have COVID but were more likely to be female (OR=3.74), working from home (OR=9.31), to be essential workers (OR=5.43), and to have been enrolled in 2021 versus 2020 (OR=3.34, p=0.07). Among those reporting significant stress, predominant concerns were mental health (OR=7.53 for somewhat concerned or higher), personal health (OR=13.75), and financial stability (OR=2.82). Levels of concern for community public and economic health were statistically improved in 2021 versus 2020. These findings underscore an unfolding mental health crisis in the context of the COVID-19 pandemic, independent of infection status. Optimism about community health is improving, possibly due to the increasing availability of vaccines. However, accumulating stress and indirect burdens of the pandemic are particularly evident among essential workers, those working from home, and women. These findings should prompt focused efforts for mental health and other supportive interventions.

0959

## MEASURING DIVERSITY OF SARS-COV-2 VARIANTS

**Arlinda Sadiku**, Kristan A. Schneider, Henri Christian Junior Tsoungui Obama

*Hochschule Mittweida, Mittweida, Germany*

A year after the onset of the COVID-19 pandemic, different vaccines have been produced and distributed to countries to help control the global pandemic. However, as vaccination campaign strategies are deployed around the globe, major attention goes to the emerging strains of the virus as the effectiveness of the different vaccine products on those variants is unknown. As the effectiveness of the vaccines might differ for each variant, it is crucial for an effective deployment of the vaccination campaigns to understand and study the diversity of these variants in a spatial and temporal context. Here, we use a definition of diversity measures based on a solid theoretical foundation, which gives us a framework that allows studying patterns of diversity among sub-populations. The term sub-populations can be interpreted at different levels of granularity, hence maximizing the potential applications of the method. Our approach allows studying diversity patterns through a straightforward graphical analysis. We apply the method to study: (i) the diversity of SARS-CoV-2 variants between the seven most modernized countries in the world (G7) and sub-Saharan African countries; (ii) the diversity of variants over a time period in some targeted countries, e.g., UK, USA, South Africa; and (iii) the diversity of the variants between sub-Saharan African countries, South Asian countries, and South American countries. The results show a difference in the diversity of SARS-CoV-2 variants between the G7 and the sub-Saharan African countries, but this shows more in low-frequency variants. Over the studied time period, an increase in diversity is observed in some countries, which shows a change in which strain is dominating. We discuss differences in diversity that is observed between countries in sub-Saharan Africa, South Asia, and South America.

## A CROSS-SECTIONAL STUDY TO CHARACTERIZE CHILDHOOD ANEMIA AND INFORM CONTROL STRATEGIES IN RURAL NORTHERN, PERU

**Lauralee J. Fernandez**<sup>1</sup>, Ricardo Gamboa<sup>2</sup>, Percy Vilchez<sup>2</sup>, William E. Lambert<sup>1</sup>, Caren Weinhouse<sup>3</sup>, Sarah E. Rothenberg<sup>4</sup>, Molly L. Kile<sup>4</sup>, Seth E. O'Neal<sup>1</sup>

<sup>1</sup>Oregon Health & Science University – Portland State University, School of Public Health, Portland, OR, United States, <sup>2</sup>Universidad Peruana Cayetano Heredia, Centro de Salud Global, Tumbes, Peru, <sup>3</sup>Oregon Institute of Occupational Health Science, Oregon Health & Science University, Portland, OR, United States, <sup>4</sup>School of Biological and Population Health Sciences, Oregon State University, Corvallis, OR, United States

A third of children globally have anemia, with children under 6 years in low to middle-income countries (LMICs) bearing the greatest burden. Children with mild anemia often present few acute symptoms; however there is evidence of long-term effects such as delayed neurodevelopment. Standard treatment in LMICs is iron supplementation, which is ineffective in the presence of other microdeficiencies, chronic disease, parasitosis, and heavy metal exposure. Iron supplementation in Peru significantly increased since 2010; however, changes in anemia prevalence were minimal. We aim to characterize plausible causes of anemia in Tumbes, Peru, and evaluate if chronic methylmercury and arsenic exposure are associated with childhood anemia. We conducted a cross-sectional study in a rural district near a river with heavy metal exposure from decades of upstream gold mining runoff, and a rural district over 50 km away from the river. We surveyed parents for anemia risk factors, and measured children's blood count (CBC). We are currently measuring ferritin, vitamin B12, folate, and C-reactive protein in blood and testing stool for parasitosis. We will process hair and toenail samples for mercury and other metals by fall. We recruited 264 children aged 6-69 months participated and 16.7% (44/264) had anemia (<11 g/dL by WHO guidelines). In communities near river, anemia prevalence was

17.3% (26/150) and significantly higher among males. In communities far from the river, prevalence was 15.8% (18/114) and significantly higher among children without latrines or toilets. We have completed micronutrient analysis for 17 children with anemia and 8 were ferritin deficient (>30g/L by WHO guidelines). Iron deficiency anemia is typically more prevalent among girls and in households with lower socioeconomic status. Therefore, significant association with being male and lack of association with latrine suggest other types of anemia are prevalent near the river. Evaluating environmental exposure in addition to other causes may help inform and improve development of childhood anemia prevention strategies in this region.

0961

## THE PANIC PHASE OF THE PANDEMIC: IMPACT OF THE EARLY PHASE OF COVID-19 ON REPRODUCTIVE, MATERNAL, NEWBORN AND CHILD HEALTH SERVICE UTILIZATION AT A TERTIARY HOSPITAL AND CATCHMENT HEALTH CENTERS IN ADDIS ABABA: A MIXED-METHOD STUDY

**Delayehu Bekele**<sup>1</sup>, Ewenat Gebrehanna<sup>1</sup>, Ferid Abas<sup>1</sup>, Mekitie Wondafrash<sup>2</sup>

<sup>1</sup>Saint Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia,

<sup>2</sup>Saint Paul's Institute for Reproductive Health, Addis Ababa, Ethiopia

The emergence of the COVID-19 pandemic has presented a unique challenge to the already strained health system in developing countries. The fear of exposure to COVID-19 in health facilities and the shift of attention and resources from essential services was expected to decrease the reproductive, maternal, newborn, and child health (RMNCH) services utilization. A mixed quantitative and qualitative study was conducted at Saint Paul's Hospital and 16 catchment health centers to assess the impact of the early phase of the COVID-19 pandemic on RMNCH services utilization. Data on the service uptake covering a period of 25 months (April 2018-April 2020) was collected. The service uptake after the COVID-19 first case was detected in-country (March 13, 2020) was compared with the preceding months and the same time frame in the previous years. All most RMNCH service uptake has decreased significantly. The highest impacted services have seen a decrement of 42.8% and 29.4% for family planning, 38.1% and 24.8% for safe abortion, and 28.1% and 31.2% for antenatal care uptake in the two months after the first report of COVID-19 compared to the preceding two months and same time frame in the previous year respectively. Deliveries were the least affected with a decrement of 7.4% compared to the preceding two months. The stillbirth rate has increased from 22.0 to 27.2 per thousand births after COVID-19 compared preceding two months. In the qualitative study, participants have corroborated that there was a significant decline in client flow. The reasons attributed to the decline were the restriction of public transport, change in working hours, and fear of exposure to COVID-19 at health facilities. These findings indicate that such essential health services are highly vulnerable at times of disasters like the current pandemic. Emergency preparedness and resilience measures should be put in place to avoid similar failures in the future. Close monitoring of the RMNCH service uptake should be done and continued till we come out of the COVID-19 pandemic.

0962

## COVID-19 IPC OUTCOME ASSESSMENT IN USAID MTAPS-SUPPORTED HEALTH FACILITIES

**Afeke Kambui**, Fozo Alombah, Andre Zagorski, Kim O. Hoppenworth, Chris Weller

*Management Sciences for Health, Arlington, VA, United States*

As part of the global COVID-19 pandemic response, USAID tasked its Medicines, Technologies and Pharmaceutical Services (MTaPS) Program with providing technical support to countries in infection prevention and control (IPC). IPC areas of critical importance to health care workers and patient safety included: application of COVID-19 precautions, triage for (severe) acute respiratory infections, and waste management. During

the program's initial COVID-19 response (March to October, 2020) in Cameroon, Côte d'Ivoire, and Mali, MTaPS supported IPC implementation and trained 2390 health workers in 128 health facilities in COVID-19-related IPC topics. To improve facility-level compliance to IPC standards, MTaPS adapted WHO AFRO IPC Scorecards to rapidly identify priority gaps prior to conducting training. The program then reassessed facilities to monitor compliance with local and global guidelines over the course of IPC implementation. Beyond training, our interventions included: remote and face-to-face mentoring and coaching; monitoring visits to health facilities at frequencies prescribed by the Scorecard; provision of needed tools and job aids, and advocacy towards facility managers. Data from 44 facilities across the three countries shows that 91% of supported facilities increased their IPC compliance scores with 41% of facilities improving by at least 25% over the course of the interventions. The percentage of facilities with high IPC compliance (scoring 80-100%) increased from 16% to 55%. The use of the scorecard provided an opportunity to engage facility management - eager to improve their score - to develop strategies to strengthen adherence to IPC guidelines as part of a continuous quality improvement process. This session will present lessons emerging from the experience on how best to rapidly improve IPC readiness for COVID-19 in health facilities. We will also discuss the impact of the program's efforts on countries' COVID-19 response. MTaPS will continue the work to institutionalize these interventions in supported countries to ensure sustainable results.

0963

#### UTILIZATION OF FACILITY-BASED ESSENTIAL MATERNAL AND CHILD HEALTH SERVICES DURING COVID-19 PANDEMIC IN NORTH SHEWA ZONE, ETHIOPIA

**Chalachew Bekele Shiferaw**<sup>1</sup>, Delayehu Bekele Mammo<sup>2</sup>, Bezawit Mesfin Hunegnaw<sup>3</sup>, Kimiko Wickle<sup>4</sup>, Christine Tedijanto<sup>5</sup>, Michelle Korte<sup>6</sup>, Lisanu Tadesse<sup>7</sup>, Fanos Ashenafi<sup>1</sup>, Grace J. Chan<sup>8</sup>

<sup>1</sup>Birhan HDSS, St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, <sup>2</sup>Department of Obstetrics and Gynecology, St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, <sup>3</sup>Department of Pediatrics and Child Health, St. Paul's Hospital Millennium Medical College, Addis Ababa, Ethiopia, <sup>4</sup>Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>5</sup>Francis I. Proctor Foundation, University of California San Francisco, San Francisco, CA, United States, <sup>6</sup>Department of Global Health and Population, Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>7</sup>HaSET Director, Addis Ababa, Ethiopia, <sup>8</sup>Division of Medicine Critical Care, Boston Children's Hospital, Harvard Medical School; Department of Epidemiology, Harvard T.H. Chan School of Public Health, Boston, MA, United States

Ethiopia reported the first case of COVID-19 on March 13, 2020, and various measures have been taken since then to prevent the spread and transmission of the virus. As a result of the ongoing preventive measures and fear of risk of exposure by the community, it was anticipated that utilization of maternal, newborn and child health (MNCH) services at health facilities would decrease. The aim of the study was to assess the trend of MNCH service utilization during the first six months of the COVID-19 pandemic. The study was conducted at eight health facilities in Ethiopia as part of the BIRHAN Health and Demographic Surveillance System. A mixed quantitative and qualitative study design was used. The trend of service utilization during the first six months of COVID-19 (March to August 2020) was compared to corresponding time and data points of the preceding year (March to August 2019). The utilization of antenatal, postnatal, family planning, facility delivery and child immunization services at health facilities did not change during the initial six months of the pandemic. However, facility attendance for sick visits for children under 5 years old decreased by 42% as compared to the preceding year. This could be due to reduction in the prevalence of childhood illnesses as a result of COVID-19 prevention measures like hand hygiene and mask wearing. Provision and utilization of essential MNCH services are crucial to ascertain favorable maternal and child health outcomes. In the setting of developing countries like Ethiopia, health systems are too fragile to withstand the shock due to effects of the pandemic. Our study presents early findings

on the utilization of MNCH services that remained preserved as well as some that were negatively affected. Government leaders, policy makers, and clinicians who want to improve the resilience of their health system will need to continuously monitor service utilization, while engaging with clients to understand and address their evolving concerns about MNCH service uptake, during the pandemic to prevent increases in maternal and child morbidity and mortality.

0964

#### DYNAMICS IN THE OPINION OF CAMEROONIAN POPULATION REGARDING ACCEPTABILITY OF COVID-19 VACCINES: A NATIONWIDE ONE-YEAR LONGITUDINAL SURVEY FOR POLICY MAKING

**Laurentine Sumo**<sup>1</sup>, Valerie Makoge<sup>2</sup>, Gabriella Ondoua Nganjou<sup>3</sup>, Hugues Nana Djeunga<sup>3</sup>

<sup>1</sup>University of Bamenda, Bamenda, Cameroon, <sup>2</sup>Medical Research Centre, Institute of Medical Research and Medicinal Plants Studies (IMPM), Yaoundé, Cameroon, <sup>3</sup>Centre for Research on Filariasis and Other Tropical Diseases (CRFi/MT), Yaoundé, Cameroon

The severe acute respiratory syndrome coronavirus-2 (SARS-CoV-2) disease, commonly called COVID-19, is an infectious disease that has imposed an important burden on all life aspects of populations worldwide. A race against time has made possible the development of vaccines with proven efficacy in an extremely short timeframe. However, the success of immunization campaigns and therefore the attainment of herd immunity - a prerequisite to return to normal life - rely on the acceptance of vaccines by populations. In fact, vaccine hesitancy has been reported among several populations worldwide, mostly because of the celerity with which these vaccines have been developed, the potential adverse events arising with the early immunization campaigns, as well as all the fake news surrounding this pandemic. In Cameroon, the decision is yet to be made on the choice of the vaccine that will be used as well as when and in which conditions immunization campaigns will be launched. In this context, it appears urgent to investigate the willingness of the populations to get vaccinated, as well as the dynamics and reasons for changes in their opinions over a year. To this end, we will carry out an online nationwide longitudinal survey with quarterly follow-up among Cameroonians to investigate their willingness to get vaccinated, as well as the dynamics and reasons of changes in their opinions over one year. We will use the health belief model (HBM) to understand the participants' compliance with vaccines and the reason why their initial opinion can change. This study will be soon launched, and the findings generated will be translated as a policy brief and shared with the Ministry of Public Health and stakeholders engaged in the fight against COVID-19 to guide decision making and policy change or adaptation. This will be helpful to design adapted communication messages to convince as many as possible people to get vaccinated and therefore rapidly reach herd immunity.

0965

#### GLOBAL SURVEY OF HEALTH WORKER PERCEPTIONS OF LOCAL INFECTION PREVENTION AND CONTROL FOR COVID-19: IMPACTS AND REFLECTIONS

**Jeni A. Stollow**<sup>1</sup>, Nina Gobat<sup>2</sup>, Caitlin Pilbeam<sup>3</sup>, Dayo Spencer-Walters<sup>2</sup>

<sup>1</sup>Temple University, Philadelphia, PA, United States, <sup>2</sup>WHO - World Health Emergencies Program, Geneva, Switzerland, <sup>3</sup>University of Oxford, Oxford, United Kingdom

Health workers face stigma, occupational hazards, and increased risk of exposure to severe acute respiratory syndrome-2 virus (SARS CoV-2) in their role providing treatment and care to patients in health facilities. Protection of health worker physical and mental health was a research priority identified in the 2020 World Health Organization (WHO) COVID-19 Research Roadmap. To aid rapid deployment of research, the Social Science Working Group, the Infection Prevention and Control (IPC) Working Group, and the Global Outbreak Alert and Response Network

(GOARN-Research) developed research guidance - *Global Survey of Healthcare Worker Perceptions of Local Infection Prevention and Control for COVID-19*. The guidance protocol aimed to generate rapid evidence for optimizing COVID-19 IPC by understanding health workers' views of local IPC procedures. A free, pre-packaged, customizable research guidance protocol was rapidly developed and published on the WHO website. This presentation will describe findings from our process evaluation which assessed how the protocol was developed, utilized, and modified to meet the dynamic needs of the COVID-19 pandemic. Data from the process evaluation were collected via observations of fortnightly meetings with the research teams implementing the protocol; surveys across 16 study sites assessing researchers' use of the protocol and impact of their findings; and follow-up key informant interviews with the primary investigators across study sites. We will present our findings of protocol use from 52 countries, that included over 10,000 health workers. Furthermore, key findings from each study site will be discussed. Findings from the process evaluation demonstrate that universal protocols are essential in an outbreak, epidemic, or pandemic setting as resources, time, money, tools, protocols, and personnel are often limited to execute research. In such emergency settings, it is critical that research be rolled out quickly, effectively, and with rigor to aid on the ground response.

0966

### IMPLEMENTATION OF ACUTE ILLNESS SURVEILLANCE THROUGH TEXT MESSAGING AMONG A COMMUNITY-BASED COHORT IN PONCE, PUERTO RICO

**Nicole M. Perez-Rodriguez<sup>1</sup>**, Liliana Sanchez-Gonzalez<sup>1</sup>, Chelsea G. Major<sup>1</sup>, Olga D. Lorenzi<sup>1</sup>, Dania Rodrauez<sup>1</sup>, Laura E. Adams<sup>1</sup>, Mariely Linares<sup>2</sup>, Gladys Gonzalez-Zeno<sup>2</sup>, Jorge Munoz-Jordan<sup>1</sup>, Vanessa Rivera-Amill<sup>2</sup>, Gabriela Paz-Bailey<sup>1</sup>

<sup>1</sup>Division of Vector Borne Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States, <sup>2</sup>Ponce Health Sciences University/ Ponce Research Institute and Centro Medico Episcopal San Lucas, Ponce, PR, United States

Dengue virus (DENV) is a common cause of acute illness in endemic areas, but reported cases represent a small proportion of symptomatic infections. We implemented a community-based cohort study in 2018 in Ponce, Puerto Rico to measure the incidence of DENV and other arboviral infections through annual interviews and serum specimen collection. In May 2020, an acute illness surveillance component was initiated in which participants are sent weekly texts asking if they had fever, cough, or other symptoms. Those reporting fever can provide serum samples for DENV molecular testing. As part of expanded activities for COVID-19 investigation, participants reporting COVID-like symptoms can provide nasal swabs for SARS-CoV-2 and seven other respiratory viruses for molecular testing. During May 2020-March 2021, an average of 2,311 participants (57% of the cohort) received weekly texts; average response rate was 37% (n=854). A total of 687 respondents reported symptoms (2% of all responses received); of these, 28 (4%) provided serum and nasal swabs and 60 (9%) provided nasal swabs only. As of December 2020, of the 88 participants that provided nasal swabs, five (6%) participants tested positive for SARS-CoV-2. To identify strategies to increase the response rate, 102 nonrespondents were surveyed about reasons for not replying to the text messages for 2 consecutive weeks. The most frequently reported reasons were being too busy (23%), confusion about the objective of the text messages (20%), not liking to receive or send text messages (16%), and not having symptoms (13%). To address this, informational videos and flyers were shared with participants via email and social media platforms and text message content underwent additional cognitive testing and revision. Our surveillance findings were consistent with COVID-19 surveillance data trends from Ponce. Text messaging surveillance can be a useful tool to monitor for illness at the community-level to help inform public health response. Activities to increase awareness and highlight the importance of community-based disease surveillance will continue among participants to improve their involvement.

0967

### EFFICACY OF MOSQUITO BLOODMEAL- BASED SURVEILLANCE IN RURAL GUATEMALA

**Rebekah J. McMinn<sup>1</sup>**, Andrea Chacon<sup>2</sup>, Delaney Worthington<sup>1</sup>, Emma Harris<sup>1</sup>, Brian Foy<sup>1</sup>, Molly Lamb<sup>3</sup>, Andrea Scorza<sup>1</sup>, Daniel Olson<sup>3</sup>, Greg Ebel<sup>1</sup>

<sup>1</sup>Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Fundacion Guatemalteca para la Salud y la Educacion, Ratalhue, Guatemala, <sup>3</sup>University of Colorado, Aurora, CO, United States

There is an increasing need for surveillance methods that allow for rapid detection of circulating pathogens in low-resource areas. Mosquito blood meals are a convenient sample source that can sensitively detect blood-borne pathogens present in humans (xenosurveillance) and may represent an attractive alternative to traditional surveillance methods. In the present study, we evaluated the feasibility and effectiveness of xenosurveillance in rural Guatemala. Twenty households from two communities were enrolled and followed from August to December 2019. When febrile illness was reported in a household, blood-fed indoor mosquitos as well as blood samples from each member of the household were collected and preserved on FTA cards and sent to Colorado State University for further processing. Shotgun sequencing on a subset of pooled samples was first used to identify relevant circulating viruses. Quantitative PCR (qPCR) was then used for sensitive and targeted detection of identified viruses in all samples. The host source of each mosquito bloodmeal sample was also identified using a tagged cytochrome-oxidase PCR and subsequent consensus-level sequencing (bloodmeal ID). A total of 507 mosquito blood-meals and 175 human blood samples were collected during the course of this study. The majority of blood-fed mosquito species collected were identified as *Aedes aegypti* (43.7%). We have detected human gamma herpesvirus in both mosquito blood-meal and human blood samples and have verified these results using qPCR. Though there was a dengue virus 2/3 outbreak in the area during our study, we did not detect dengue virus (DENV) in any of our samples. This was expected given the prevalence of DENV in the community and limited sample set. Results from bloodmeal ID reveal human bloodmeal sources across all mosquito species, though this rate is highest among *Aedes albopictus* (75%) and *Anopheles* sp. (72.7%). Our results indicate that xenosurveillance can be used to detect non-mosquito borne pathogens circulating in humans and mosquito host-feeding patterns can be used to hone future mosquito collection.

0968

### GLOBALLY PROMOTING COVID 19 VACCINES FOR INTERNATIONAL OIL AND GAS COMPANY

**Malick Diara**, Susan Ngunjiri, Candace McAlester, Muhammad W. Fazail

*ExxonMobil, Spring, TX, United States*

To globally protect the health and safety of our workforces, in addition to our business operations from the unprecedented impact of COVID-19 pandemic, we implemented preventive and mitigation safeguards, including a global workplace communication approach promoting COVID-19 vaccine awareness, access and use. In order to accomplish the intended results of our global COVID-19 vaccine initiative, we initiated a needs assessment review across our operations to anticipate the vaccine prioritization by local health authorities, their planned distribution by the public and / or private sector and the potential ability to locally obtain vaccines for our workers and dependents. In addition, we regularly reviewed the growing scientific evidence published on the different vaccine types, including their safety and effectiveness while monitoring their approvals by countries with stringent drug regulatory authorities and pre-qualification by the World Health Organization. As vaccines became available across the globe, we continued our scientific surveillance and its coordinated internal sharing with our global Company workforces, clinicians, and senior executives for effective awareness, vaccine use and supportive environment. Main enablers of such initiative relied

on our structured system integrating safety and health with executive Company interfaces built during SARS, MERS, and Ebola with insights from global renowned experts. Key challenges were related to the progressive information availability on the disease, the vaccines safety, effectiveness and ability to prevent transmission, combined with their restricted commercial availability for global access to our workers. As a result, a global workplace framework for COVID 19 vaccine was rolled out with vaccine demand, supply and policy components. It helped affiliates recommend vaccines for our workers, considering individual and community benefits, promote vaccine confidence, and encourage early vaccination through community or workplace sites.

0969

### EXPANDING XENOSURVEILLANCE CAPABILITIES USING LONGITUDINAL DATA COLLECTED FROM HOUSEHOLDS IN RURAL GUATEMALA

Emma Harris<sup>1</sup>, Andrea Chacon<sup>2</sup>, Delaney Worthington<sup>1</sup>, Rebekah McMinn<sup>1</sup>, Brian Foy<sup>1</sup>, Molly Lamb<sup>3</sup>, Andrea Scorza<sup>1</sup>, Daniel Olson<sup>3</sup>, Gregory Ebel<sup>1</sup>

<sup>1</sup>Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Fundacion Guatemalteca para Salud y la Educacion, Ratalhue, Guatemala, <sup>3</sup>University of Colorado, Aurora, CO, United States

Rapid detection of established and emergent human pathogens is necessary for efficient implementation of public health response. This is often inhibited by acquisition of high-quality samples and infrastructure for sample testing and analysis in resource-limited communities. Previously we demonstrated our ability to use blood-fed mosquitoes as tools for human pathogen surveillance (xenosurveillance) in resource limited regions of West Africa. Furthermore, a recent pilot study in Guatemala compared household-matched mosquito and human blood samples to reveal circulating pathogens, including Epstein-Barr virus. Leveraging an expanded cohort in the same rural Guatemalan community, we hypothesize that mosquitoes can be used as a non-invasive, self-supported sampling sources for xenosurveillance. We have enrolled 107 individuals across 40 households in two communities of southwestern Guatemala who will be followed prospectively for one year of weekly syndromic surveillance. Households with individuals reporting symptoms of fever, arthralgia, and/or rash will be activated for a four-week period in which blood will be acquired from enrolled subjects, domestic animals, and replete mosquitoes. Blood samples will be preserved on FTA cards, which will be used for targeted PCR screening of human pathogens, as well as next-generation sequencing. To date, 21 individuals across seven households have reported syndromic illness of fever ( $n = 9$ ) and arthralgia ( $n = 6$ ). Replete mosquitoes ( $n = 520$ ) collected were represented by the genera *Culex* and *Aedes*. Molecular analysis of these samples is ongoing. Data collected throughout this study will allow for comparison between samples (i.e. mosquito versus domestic animal versus mosquito), demonstrating the untapped potential for mosquitoes to be used in pathogen surveillance. This work will also create sustainable infrastructure for disease monitoring in rural and resource-limited communities that are particularly vulnerable to the burden of disease.

0970

### ANTIMICROBIAL CONSUMPTION SURVEILLANCE IN A RESOURCE LIMITED SETTING: FINDINGS FROM THIRTEEN HOSPITALS IN UGANDA

Reuben Kiggundu, John Paul Waswa, Moses Sembatya, Marion Murungi, Hassan Kassuja

Management Sciences for Health, Kampala, Uganda

Surveillance of consumption and use of antibiotics is a key strategy to inform antimicrobial stewardship (AMS). This study analyzed public health surveillance data on the use of antibiotics to inform the implementation of AMS programs in 13 hospitals in Uganda. We conducted a cross-sectional study for patients admitted to 13 hospitals in Uganda between September 2019 and September 2020. One hundred patient files from

each of the 13 hospitals were collected through interval sampling, for a total of 1,300 files, using an Excel tool to measure and analyze antibiotic use. Most patients, 74.4% (967/1300), had at least one antibiotic prescribed with an average of 2.27 (SD = 0.6) antibiotics prescribed per encounter. Of the administered antibiotics, 86% were injectable. The mean daily defined dose (DDD) per 100 bed days was  $0.847 \pm 0.86$ . In total, 18,333.9 DDDs/100 bed days were used across all health facilities. Of these, cephalosporins were the most frequently used class, accounting for 28.6%, followed by penicillins, nitroimidazoles, fluoroquinolones and macrolides at 27%, 26%, 6% and 5% respectively. Based on WHO's antibiotic classification, 1104.2 DDDs/100 bed days were consumed from the "Access" class with 729.8 DDDs/100 bed days from the "Watch" class,  $p=0.2238$ . Most (62%) prescriptions were from the "Access" class, with the "Watch" class accounting for 38% of prescriptions. Less than 1% of prescriptions were from the "Reserve" class. Extensive use of antibiotics, a high proportion of which are injectable, should be a focus of AMS interventions. The findings necessitate implementation of periodic antimicrobial use and consumption surveillance in health facilities in order to strengthen AMR control activities.

0971

### THE REMOTE EMERGING DISEASE INTELLIGENCE NETWORK (REDI-NET): AN INTRODUCTORY OVERVIEW

Nicole L. Achee<sup>1</sup>, Le Jiang<sup>2</sup>, Yvonne-Marie Linton<sup>3</sup>, John P. Grieco<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Viral and Rickettsial Diseases Department, Infectious Diseases Directorate, Naval Medical Research Center, Silver Spring, MD, United States, <sup>3</sup>Walter Reed Biosystematics Unit (WRBU), Smithsonian Institution Museum Support Center, Suitland, MD, United States

Epidemics of novel emerging infectious diseases are becoming more frequent worldwide and outbreaks will inevitably continue into the foreseeable future. Proactive surveillance efforts are often challenged by a lack of expertise and/or capacity, causing serious delays in sample processing and/or timely data analysis and release. To overcome these obstacles and effectively detect, predict and contain potentially emergent zoonotic diseases of relevance, we need to change our current approach, streamline and improve the accuracy and timeliness of the 'data-to-decision' process, and provide health authorities with timely, comprehensive, actionable data for decision-making on protection and mitigation strategies. The Remote Emerging Disease Intelligence Network (REDI-NET) will develop a flexible, scalable and expandable computing substrate—'a system of systems'—upon which a myriad range of global health platforms can be developed and customized to support specific disease modeling, prediction and policy-decisions in support of public health. The REDI-NET consortium will leverage pre-existing and real-time surveillance data to provide a one-stop shop for health decision makers. REDI NET will operate through four specific aims: Aim 1: Establish robust SOPs for rigorous data capture and matched capabilities across field and reference laboratories; Aim 2: Active NGS surveillance across varied ecologies for broad spectrum pathogen detection; Aim 3: Enable remote, in-situ verified, near real-time data acquisition for actionable reporting and Aim 4: Institute a data management pipeline for actionable reporting and threat forecasting. Expected outcomes include more effective surveillance tools and methodologies; an open-access data repository of regional pathogen and infected sample distribution, abundance, ecology; greater numbers of trained laboratory and field personnel with a foundational background in detecting and responding to emerging disease outbreaks; and expert guidance for local jurisdictions and public health agencies on the most appropriate surveillance methods, sample processing and data usage.

## COMPREHENSIVE PROFILING OF SOCIAL MIXING PATTERNS IN RESOURCE POOR COUNTRIES

**Moses C. Kiti**<sup>1</sup>, Obianuju Aguolu<sup>2</sup>, Alessia Melegaro<sup>3</sup>, Steven Riley<sup>4</sup>, Herberth Maldonado<sup>5</sup>, Samuel Prassana<sup>6</sup>, Charfudin Sacoor<sup>7</sup>, Azucena Bajardi<sup>8</sup>, Momin Kazi<sup>9</sup>, Fauzia Malik<sup>2</sup>, Ben Lopman<sup>1</sup>, Saad B. Omer<sup>2</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Yale University, New Haven, CT, United States, <sup>3</sup>Bocconi University, Milan, Italy, <sup>4</sup>Imperial College London, London, United Kingdom, <sup>5</sup>Universidad del Valle de Guatemala, Guatemala, Guatemala, <sup>6</sup>CMC Vellore, Tamil Nadu, India, <sup>7</sup>Centro de Investigação de Saúde de Manhiça, Manhiça, Mozambique, <sup>8</sup>Barcelona Institute of Global Health, Barcelona, Spain, <sup>9</sup>The Aga Khan University, Karachi, Pakistan

Social contact patterns are key determinants of the transmission of pathogens that spread directly from person to person. These data are increasingly important in mathematical models investigating the impact of interventions against disease transmission such as physical distancing and targeted vaccination. Unfortunately, there are little data on contact patterns from low-and-middle-income-countries (LMICs) where morbidity and mortality from infectious diseases is high. In this proposed research, we present a framework that aims to characterize epidemiologically relevant household and community social contact patterns in urban and rural sites in Mozambique, Guatemala, India and Pakistan. Through formative work, we will develop standardized social contact diaries sensitive to the social and cultural contexts in each setting. For instance, we will explore the usability of self-report diaries within each setting, as well as the use of "shadows" or third party individuals to record contacts on behalf of children and individuals who cannot read and write. Participants will report sociodemographic characteristics (age, sex, occupation, household structure) and contact attributes defined by the number, frequency, duration and location of contacts over two continuous days. In addition, we will use wearable proximity sensors to automatically detect and record interactions between household members focusing on infants, who experience the highest infectious disease burden. Participants will wear the sensors over 7 days while also keeping a contact and location diary over two days. Primary outcomes will be social mixing matrices stratified by age, gender, urbanity among other key variables of interest. Leveraging the multiple data collection approaches, we will cross-validate the diaries and sensors as tools for measuring age-specific interactions between individuals. Social contact data from these studies will be made freely accessible to the scientific community. These data may be used to parameterize mathematical models of infectious disease spread and control in LMICs.

## AN INTEGRATED QUALITATIVE APPROACH TO SURVEILLANCE, MONITORING, AND EVALUATION FOR NATIONAL MALARIA CONTROL PROGRAMS

**Lwendo Moonzwe Davis**

*ICF, Rockville, MD, United States*

Surveillance, Monitoring and Evaluation (SME) is critical for the continued success of National Malaria Control Programs (NMCP) since it provides the information necessary for effective program planning and management. Interventions aimed at improving NMCPs focus on both the target population and the program provider. Qualitative approaches are often used to understand the target population and barriers to intervention success. While there is growing emphasis on qualitative approaches in provider focused SME, metrics of success tend to focus on quantitative measures. The integration of qualitative approaches is one way to identify barriers that impede sustaining the gains made from provider focused capacity building efforts. We analyzed SME tools commonly used by NMCPs including the Performance of Routine Information System Management (PRISM) Tools, and Routine Data Quality and Supervision Tools for current and potential integration of qualitative data collection

elements. Data collection tools were imported into NVivo for coding and analysis. Preestablished and emergent codes were applied to assess the extent to which qualitative data was collected and integrated. Findings indicate that qualitative approaches focus on understanding the program implementation and interventions, but the systematic integration of qualitative data is limited. There are greater attempts to integrate qualitative data into planning and supervision. Although several tools examine the capacity of service providers and system performance, there is limited understanding of the barriers that continue to hinder performance. Qualitative data collection efforts can be tailored to facilitate the systematic analysis, interpretation and integration of findings into quantitative metrics or outputs. We propose an approach to systematically collect, analyze and utilize qualitative data to improve SME and highlight how such data is useful for understanding and addressing the barriers that hinder optimal uptake of capacity building efforts and subsequent improvement to NMCPs.

## CLINICAL AND LABORATORY CHARACTERISTICS, AND OUTCOMES OF PATIENTS HOSPITALIZED WITH CORONAVIRUS DISEASE 2019: A RETROSPECTIVE ANALYSIS FROM BANGLADESH

**Monira Sarmin**, Mustafa Mahfuz, Lubaba Shahrin, Tahmeed Ahmed, Mohammad Jobayer Chisti

*icddr/b, Dhaka, Bangladesh*

Started on 31 st Dec 2019, from Wuhan city, China, Coronavirus disease 2019 caused a global pandemic by March 11, 2020, and resulted in a total of 3,046,271 (20<sup>th</sup> April 2021) global deaths. After one year of its origin, still, different variants are emerging and continuing their havoc worldwide. Bangladesh detected its first case on 8<sup>th</sup> March 2020, only 66 days later the first cases detected in China. Now also facing its second wave with increasing detection and case fatality rate (out of 732,060 confirmed cases, 10,683 deaths by 20<sup>th</sup> April 2021). In this retrospective chart analysis, we aimed to describe the epidemiology, clinical features, laboratory and radiological characteristics, treatment, and outcomes of Bangladeshi COVID-19 patients by comparing hypoxemic and non-hypoxemic patients treated in a makeshift COVID-19 unit of icddr/b. Statistical analyses were done using the SPSS software, version 20. By March 2021, among the identified 439 cases, 232 took outpatient care, stayed in home isolation and 207 remained in-patient. 293 (66%), 51 (12%), 95 (22%) were mild, moderate, and severe/critical cases respectively. Nineteen patients (4.3%) died while 10 (2.2%) were referred to different facilities for appropriate care. Out of 207 in-patients, 88 patients required oxygen therapy, which was given by nasal cannula, face mask, non-rebreather mask, HFNC, or mechanical ventilator as appropriate. All hypoxemic patients received steroids, antibiotics, and anticoagulants following standard hospital guidelines on the management of COVID 19 patients. Multivariable logistic regression identified age [1.07 (1.02-1.13)], dyspnea [3.56 (1.06-11.96)], high CRP [(1.13 (1.03-1.25))], and lymphopenia [(6.18 (1.81-21.10))] as the independent predictor for hypoxemia in patients hospitalized for COVID 19 (for all p<0.05). These simple clinical and laboratory parameters may help clinicians to identify COVID-19 cases who are at risk of developing fatal hypoxemia and thereby strengthen their follow-up and monitoring to abate mortality and morbidity, especially in resource-limited settings.

## MODULATING FACTORS OF HOUSEHOLD TRANSMISSION OF SARS-COV-2 IN A COMMUNITY-BASED STUDY

Jenny Ji<sup>1</sup>, Alexander Winnett<sup>1</sup>, Natasha Shelby<sup>1</sup>, Jessica A. Reyes<sup>1</sup>, Reid Akana<sup>1</sup>, Noah W. Schlenker<sup>1</sup>, Emily S. Savelle<sup>1</sup>, Anna Romano<sup>1</sup>, Michael K. Porter<sup>1</sup>, Alyssa M. Carter<sup>1</sup>, Matthew M. Cooper<sup>1</sup>, Jacob T. Barlow<sup>1</sup>, Colten Tognazzini<sup>2</sup>, Matthew Feaster<sup>2</sup>, Ying-Ying Goh<sup>2</sup>, Rustem F. Ismagilov<sup>1</sup>

<sup>1</sup>California Institute of Technology, Pasadena, CA, United States, <sup>2</sup>Pasadena Public Health Department, Pasadena, CA, United States

Limitations in vaccine availability and uptake in middle and low income countries support an ongoing need to reduce community and household transmission of SARS-CoV-2. To identify factors modulating household transmission, we collected demographic, household composition, infection-control practice, and COVID-19 risk perception data from individuals in the Los Angeles region of Southern California who either recently tested positive or were at risk of infection from a household contact. We monitored respondents daily for new infection using high sensitivity RT-qPCR testing. We compared the combined responses of households where transmission was observed to those without transmission, and we compared the individual responses of participants who became infected during enrollment to those who remained negative. As of mid-April, 141 participants from 41 households (average size of 3.4 persons;  $\pm 1.2$  S.D.) have participated, with a broad age distribution (25.5% < 18, 45.4% 18-40, 24.8% 41-65, and 4.3% > 65 years old), 56.0% female, 64.5% reporting Hispanic/Latinx ethnicity, and 53.9% of participants identifying as white, 10.6% African American, and 8.5% Asian by race. Annual household incomes range from less than \$5,000 to more than \$500,000. After grouping by households with observed transmission ( $n=17$ ) and those without ( $n=24$ ), we calculated odds ratios to evaluate if factors like ventilation (e.g. windows, fans, and HEPA filters) or infection control practices (e.g. disinfecting surfaces, isolating sick household members in their own room, and maintaining social distance between all household members) are associated with transmission risk. The efficacy of these factors will be further investigated by analysis of responses from individuals who were initially infected in the household ( $n=41$ ), became infected ( $n=35$ ), or did not ( $n=65$ ), to examine the role of individual behaviors. Study enrollment and data collection is ongoing, and formal results will identify specific interventions (e.g. infrastructure, resources for at-risk households, infection control messaging) to reduce household transmission of SARS-CoV-2 globally.

0976

## ASSESSMENT OF KNOWLEDGE AND PERCEPTIONS RELATED TO THE COVID-19 PANDEMIC AMONG HEALTHCARE WORKERS IN NON-GOVERNMENTAL HEALTH FACILITIES IN CAMEROON

Sylvie Kwedi Nolna<sup>1</sup>, Chanceline Bilounga Ndongo<sup>2</sup>, Bernard Fortune Melingui<sup>3</sup>, Akindeh Nji<sup>4</sup>, Georges Nguéfack Tsague<sup>1</sup>, Sandra Bitchoka<sup>1</sup>, Lucrece Eteki<sup>5</sup>, Mark Marchant<sup>6</sup>, Palmer Masumbe Netongo<sup>7</sup>, Palmer Masumbe Netongo<sup>4</sup>

<sup>1</sup>Faculty of Medicine, University of Yaounde I, Yaounde, Cameroon, <sup>2</sup>Ministry of Public Health, Yaounde, Cameroon, <sup>3</sup>Institute de Recherche pour le Developement (IRD), Yaounde, Cameroon, <sup>4</sup>Department of Biochemistry, University of Yaounde I, Yaounde, Cameroon, <sup>5</sup>World Health Organisation, Cameroon, Yaounde, Cameroon, <sup>6</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>7</sup>Navajo Technical University, Crownpoint, NM, United States

Healthcare workers (HCWs) currently face unprecedented demand and pressure due to the COVID-19 pandemic. In Cameroon, most actions for the pandemic response by the Ministry of Public health (MOPH) is mainly focused on governmental health facilities. However, a recent WHO report showed that the majority of populations in Sub-Saharan African countries prefer to seek care at private clinics/hospitals, Faith-based health centers, and 17.8% sought care from traditional healer. We aimed to assess the

knowledge and perceptions of HCWs about COVID-19 in Yaounde and Douala. We did a quantitative descriptive cross-sectional study in Non-Governmental health facilities in Yaounde and Douala from September to November 2020. A snowball sampling method was then used to include HCWs within selected health facilities. A pre-tested structured questionnaire was administered to HCWs and responses were entered into REDCap database. HCWs from Douala were slightly more knowledgeable on COVID-19 symptoms with 88.3% correct answers compared to 86.6% in Yaounde. Knowledge on immunity acquisition after recovery did not significantly differ between male and female (70.7% for men and 70.5% for women). In general, 2.9% of survey participants previously had experienced a confirmed COVID-19 infection, medical doctors were the most infected health profession (6.6%). About one third of healthcare workers did not easily get access to personal protective equipment (PPE) in their workplace. More HCWs in public health facilities (62.9%) felt confident in their institution's ability to manage COVID-19 infected individuals followed by HCWs in non-lucrative health facilities (44%), and denominational ones (35.9%). While 57.9% of respondents found their training on COVID-19 to be insufficient, 90% were concerned about the risk of getting contaminated by COVID-19 with similar proportions (89.3%) amongst both men and women ( $p=0.013$ ). This study highlights an adequate knowledge on the symptoms and aspects of immunity of COVID-19 by healthcare workers in non-governmental facilities in Cameroon.

0977

## COMMUNITY SARS-COV-2 DYNAMICS AND CYCLE THRESHOLD USE FOR ENHANCED PUBLIC HEALTH SURVEILLANCE IN THE DOMINICAN REPUBLIC

Amy Paulino, Miguel Delgadillo, Leandro Tapia, Claudia Suero, Leeany Maletta, Stephanie Trochez, Jason A. Castillo, Paula M. Duque-Canaan, Alejandro Vallejo-Degaudenzi, Daniela Hidalgo, Diego del Orbe-Matos, Jhansmel Cabrera, Jose M. Campana, Estefani Sanchez, Roberto Paulino-Ramirez

Instituto de Medicina Tropical & Salud Global, Santo Domingo, Dominican Republic

Asymptomatic COVID positive hotspots may be going undetected by public health surveillance systems. This study aimed to understand viral load dynamics of SARS-CoV-2 in the Dominican Republic using the Cycle threshold (Ct) value of RdRP gene amplification as a marker for the public health surveillance of undetected transmission pockets. 3,309 saliva samples were analyzed across 24 hospitals in the Dominican Republic and processed by automatic nucleic acid purification. Levels of viral RNA were determined by RT-qPCR. Results were considered "Detected" when Ct of the RdRP gene amplification was <37 and considered "Undetected" when the Ct was >37 or if no amplification curve was detected. Positivity rates were compared with RT-qPCR Ct values and were used as a proxy for viral load as it is inversely proportional to the sample's viral load. The samples yielded a positivity rate of 18.01%. Mean Ct was 29.3 ( $r = -0.034$ ,  $p=0.04$ ) and correlated significantly with community positivity rates. Mean age for positive samples was 39.8 years old (yo) [SD=15] with a distribution from 35-54 yo. There was no significant correlation identified between age groups [ $F(19, 30)=0.65$ ,  $p=0.5$ ] or between mean Ct by age groups and community positivity. No difference in viral load was found when comparing symptomatic and asymptomatic COVID-positive patients ( $t(140)=0.52$ ,  $p=0.6$ ). Mean Ct in the asymptomatic population was significantly and inversely correlated with the community positivity rate ( $r=-0.43$ ,  $R^2=0.181$ ,  $p=0.0002$ ). Significant differences were found in Ct when comparing time elapsed from the date of onset of symptoms to the date of RT-qPCR test [ $F(3, 319)=6.6$ ,  $p=0.0002$ ]. Our findings indicate that viral loads are comparable between age groups and between symptomatic and asymptomatic presentations, thus widespread surveillance strategies should be implemented to detect younger and asymptomatic populations that could serve as community transmission pockets. The use of RT-qPCR Ct values to understand community viral load should be considered as a tool for public health surveillance especially in resource-limited countries such as the Dominican Republic.

### IMPLEMENTATION OF VACCINATION CAMPAIGNS TO RESPOND TO COVID-19 AND OTHER EPIDEMIC THREATS IN LOW- AND MIDDLE-INCOME COUNTRIES: LEARNING FROM KEY INFORMANTS' EXPERIENCES WITH MENINGITIS A, YELLOW FEVER, AND EBOLA VIRUS DISEASE

Julie Collins<sup>1</sup>, David S. Kennedy<sup>1</sup>, Rosie Westerveld<sup>2</sup>, Kate A. Nelson<sup>2</sup>, Hana Rohan<sup>1</sup>, Hilary Bower<sup>1</sup>, Daniel G. Bausch<sup>1</sup>

<sup>1</sup>UK Public Health Rapid Support Team, London School of Hygiene & Tropical Medicine/Public Health England, London, United Kingdom,

<sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Recent vaccination campaigns to control outbreaks of meningitis A (MenAfriVac), yellow fever (YF-17D), and Ebola virus disease (rVSV-ZEBOV) have faced similar challenges to those expected for the implementation of COVID-19 vaccines in low- and middle-income countries (LMICs). We explored how these three vaccines were implemented to extract transferable lessons for COVID-19 vaccination and inform country preparedness for future epidemics. We conducted 24 semi-structured interviews with purposively selected key informants who had been involved in vaccination campaigns for these three diseases in Africa and the Americas. Participants were asked to reflect on barriers, enablers and lessons across a range of thematic areas relating to vaccine implementation. A number of lessons were developed from key informants' experiences. These include: ensuring the availability of operational funds to support pre-campaign community engagement and social mobilisation activities; recruiting additional health workers from within communities, rather than bringing in external staff; supporting vaccination teams to have open, frank discussions with communities about the disease and response measures; working with communities to 'map' social groups and tailor vaccine delivery strategies; investigating opportunities to integrate vaccine campaigns; investing in active rumour monitoring; strengthening surveillance for case detection and pathogen differentiation; and strengthening national ownership of, access to, and capacity to analyse vaccination campaign data. As COVID-19 vaccines continue to be distributed worldwide, these experiences and perspectives can assist countries in designing implementation strategies that utilise and build on learnings from past campaigns.

0979

### CHALLENGES OF OBTAINING NASOPHARYNGEAL AND MINIMALLY INVASIVE TISSUE SAMPLES (MITS) FOR ASSOCIATED RSV MORTALITY AMONG DECEASED INFANTS IN LMIC COMMUNITY SETTING

Waliyah Mughis<sup>1</sup>, Saima Jamal<sup>1</sup>, Nazia Ahsan<sup>1</sup>, Christina Arif<sup>1</sup>, Syeda Quratulain Zaidi<sup>1</sup>, Farah N. Qamar<sup>1</sup>, Fauzia A. Malik<sup>2</sup>, Saad B. Omer<sup>2</sup>, Norman Goco<sup>3</sup>, Lindsay Parlborg<sup>3</sup>, Christina Paganelli<sup>3</sup>, Abdul Momin Kazi<sup>1</sup>

<sup>1</sup>Aga Khan University, Karachi, Pakistan, <sup>2</sup>Yale University, New Haven, CT, United States, <sup>3</sup>RTI International, Durham, NC, United States

The burden of respiratory syncytial virus (RSV) in Pakistan has been established in a community-based surveillance study, where it was found that neonate/infant mortality rate attributed to RSV infection is 2.7% (as high as 4.9% in high season). The process of obtaining 588 nasopharyngeal specimens and 14 lung/thorax tissue specimens using minimally invasive tissue sampling (MITS) from recently deceased infants in low-income communities is currently ongoing and has several challenges. IDIs and FGDs were conducted in the formative phase with community stakeholders before nasopharyngeal/MITS collection regarding community understanding of post-mortem examination methods, perceptions and barriers for household specimen collection and the acceptability of a purpose-built van parked at the household for the MITS procedure. Logistical challenges included design and protocol development of a purpose-built van for MITS procedure outside bereaved family's household. Contextual challenges included working with a religiously conservative population's preconceptions of biopsy and post-mortem examination,

particularly among community fears of COVID-19 surveillance. We obtained official rulings from religious scholars and leaders of Islamic, Christian, and Hindu faiths regarding the acceptability and usefulness of MITS as a health tool for ascertaining cause of death or disease in infants. During the sampling phase, regular meetings were conducted with general population and community stakeholders for MITS advocacy and myth surveillance. Staff were trained in counseling, advocacy, communication skills. Receiving timely death alerts and obtaining consent from grieving parents in a critical window of <1 hour before the infant's shrouding, ritual bath & burial was possible through support of key community partners and the presence of study staff: community health workers/mobilizers from the same neighborhood as the parents. In conclusion, advocacy with key community partners including religious scholars and local stakeholders helped in timely death alerts and support for parental consent for MITS in the community.

### THE GEOGRAPHICAL AND TEMPORAL SEROPREVALENCE OF BORRELIA BURGdorFERI AND B. MIYAMOTOI IN NEW ENGLAND FROM 2018-2019

Demerise Johnston<sup>1</sup>, Michel Ledizet<sup>2</sup>, Jill R. Kelly<sup>3</sup>, Robert Smith<sup>4</sup>, Tom Warcup<sup>5</sup>, John Stratidis<sup>6</sup>, Jonathan Schwab<sup>7</sup>, Sukanya Narasimhan<sup>8</sup>, Joppe W. Hovius<sup>9</sup>, Victoria Majam<sup>1</sup>, Hong Zheng<sup>1</sup>, Bonkougou Sougrnooma<sup>1</sup>, Yanhong Deng<sup>10</sup>, Kaitlin R. Maciejewski<sup>10</sup>, Sanjai Kumar<sup>1</sup>, Peter J. Krause<sup>11</sup>

<sup>1</sup>Food and Drug Administration, Silver Spring, MD, United States, <sup>2</sup>L2 Diagnostic, New Haven, CT, United States, <sup>3</sup>Yale School of Public Health, New Haven, CT, United States, <sup>4</sup>Maine Medical Center, Portland, ME, United States, <sup>5</sup>Block Island Medical Center, Block Island, RI, United States, <sup>6</sup>Danbury Hospital, Danbury, CT, United States, <sup>7</sup>Northampton Area Pediatrics, Northampton, MA, United States, <sup>8</sup>Yale School of Medicine, New Haven, CT, United States, <sup>9</sup>University of Amsterdam, Amsterdam, Netherlands, <sup>10</sup>Yale Center for Analytical Sciences, New Haven, CT, United States, <sup>11</sup>Yale School of Public Health/Yale School of Medicine, New Haven, CT, United States

*Ixodes* ticks are formidable vectors that transmit various bacterial, parasitic, and viral pathogens, including two *Borrelia* species, *Borrelia burgdorferi*, the causative agent of Lyme disease, and *B. miyamotoi*, the causative agent of tick-borne relapsing fever. Although the relative risk of exposure to these agents has been studied at a few New England sites, no prevalence studies have been carried out for both pathogens over a large geographic region over time. It may be that significant variability in the relative frequency of these pathogens exists over space and time in New England. Accordingly, we collected deidentified residual human sera from 11 clinical laboratories in five New England states (Maine, New Hampshire, Rhode Island, Massachusetts, and Connecticut) between the months of May and August from 2018-2019 to test for exposure to the two pathogens. Antibody detection assays included an FDA cleared ZEUS ELISA (*Borrelia* VlsE1/pepC10 IgG/IgM) for *B. burgdorferi* and a multiplex Luminex assay for *B. miyamotoi*. Residential zip codes were collected at the time of sera acquisition to determine spatial distribution between counties and clinic sites. Of 2778 serum samples, 266 (9.6%) were *B. burgdorferi* seroreactive and 66 (2.4%) were *B. miyamotoi* seroreactive. No significant differences were found for seropositivity to either pathogen in 2018-2019 by performing a two-way ANOVA ( $p$ -adj= 0.199). A chi-square test for relative risk pooling seropositivity across all sites found a greater risk of exposure to *B. burgdorferi* compared to *B. miyamotoi* ( $X^2=126.9$ ,  $p<0.016$ ). A total of 12/2778 sera (0.4%) were seropositive for both pathogens. Sufficient sera were available to also test for *Babesia microti* antibody by IFA in 2018. Of 1481 serum samples, 160 (10.8%) were seroreactive to *B. burgdorferi*, 146 (9.9%) to *B. microti*, and 37 (2.5%) to *B. miyamotoi*. Seroprevalence for *B. burgdorferi* and for *B. miyamotoi* were stable across time and space with evidence of variation between geographic locations. The views and opinions expressed here are those of the authors and do not represent the official position of FDA

0981

### SOLUBLE FACTORS SECRETED BY BABESIA MICROTI-INFECTED RED BLOOD CELLS INDUCE CYTOKINE PRODUCTION IN MACROPHAGES

Biniyam Hagos<sup>1</sup>, Ioana Brasov<sup>1</sup>, Alessandra Luchini<sup>2</sup>, Lance Liotta<sup>2</sup>, Fatah Kashanchi<sup>2</sup>, **Robert Molestina<sup>1</sup>**

<sup>1</sup>ATCC, Manassas, VA, United States, <sup>2</sup>George Mason University, Manassas, VA, United States

*Babesia microti* is the primary cause of human babesiosis in North America. Despite recent increases in the disease, the pathogenesis and immune response to *B. microti* infection remain poorly understood. Studies in laboratory mice have shown a critical role for macrophages in eliminating parasites and parasitized red blood cells (RBCs). Notably, the effector parasite molecules that activate macrophages are still unknown. Recent evidence identified a novel protein export mechanism in *B. microti* that features a network of tubes of vesicles that extend from the parasite plasma membrane to the RBC cytoplasm. Vesicles harboring *Babesia* proteins are released from the infected RBC (iRBC) to the extracellular environment. We postulate that these parasite-derived extracellular vesicles (EVs) participate in intercellular communication between iRBCs and neighboring cells. When macrophages function as recipients, changes in the production of cytokines with key roles in the host innate immune response occur. To test this hypothesis, we examined cytokine responses in macrophages exposed to *B. microti*-iRBCs using an *in vitro* co-culture model. Pro-inflammatory cytokines such as IP-10, G-CSF, IL-6, TNF- $\alpha$ , MIP-1 $\alpha$ , MIP-2, IL-1 $\alpha$ , and RANTES were markedly increased in the supernatants of macrophages co-incubated with iRBCs, as compared to uninfected RBCs, using antibody arrays. These effects were dependent on parasite growth, as treatment with the antiparasitic drug clindamycin resulted in significant decreases in cytokine secretion by macrophages exposed to iRBCs. These results support the hypothesis that soluble factors released by *B. microti*-iRBCs cause phenotypic changes in macrophages. Identification of secreted parasite antigens found in EVs isolated from iRBC will provide insights into the mechanisms of intercellular communication between *B. microti* and macrophages which contribute to the induction of the innate immune response in the mammalian host.

0982

### VARIATION IN COMPOSITIONAL PROFILES OF AMBLYOMMA AMERICANUM MICROBIOTA DRIVEN BY SEX AND RANGE

Luis Eduardo Martinez<sup>1</sup>, Paula Lado<sup>2</sup>, Hans Klompen<sup>1</sup>, Risa Pesapane<sup>1</sup>, Sarah Short<sup>1</sup>

<sup>1</sup>Ohio State University, Columbus, OH, United States, <sup>2</sup>Colorado State University, Fort Collins, CO, United States

*Amblyomma americanum* ticks have undergone recent range expansion. We examined the microbiota of 187 *A. americanum* ticks from 4 regions spanning their historical and current geographic range. Using massively parallel sequencing targeting the 16S rRNA V4 region, we analyzed the bacterial community composition of each individual tick. Consistently, the most prominent members of the community for each sample were either *Coxiella*, *Rickettsia* or *Rickettsiella*. Alpha diversity was significantly different between males and females at all regions tested; male ticks possess richer but uneven communities. Random forest analysis revealed that sex is a significant predictor of microbiome diversity, and indicator species analysis pinpointed taxa that are most or least commonly associated with each sex (224 for males, 1 for females). Regarding beta diversity, both ordination and PERMANOVA analyses revealed significant differences driven by sex and geographical origin. In addition, a mantel correlogram showed that the dissimilarities were structured by the distance between collection sites. Null model and phylogenetic analyses showed that for females and males, respectively, drift (88.11%; 85.90%), dispersal limitation (11.23%; 12.96%), homogeneous selection (0.61%; 0.10%), and homogeneous dispersal (0.00%; 1.03) were ecological drivers of microbial community dynamics. Our results suggest the microbiome may offer an additional layer of genomic information to study the range

expansion of this relevant vector. Diagnosis of pathogenic *Rickettsia* and other pathogens is underway. We aim to identify indicator taxa whose signature profiles allow us to build a model to predict their presence.

0983

### INITIAL EVALUATION OF THE INBIOS LYME DETECT™ IGM IGG ELISA FOR DETECTION OF LYME DISEASE

Dindo Reyes, Gregory Ireton, James Needham, Syamal Raychaudhuri, **Aarthy C. Vallur**

InBios International Inc, Seattle, WA, United States

Tick-borne diseases continue to pose a substantial and growing public health problem in the United States. The most common tickborne disease in the United States is Lyme disease, caused by the spirochete *Borrelia burgdorferi sensu strictu*. With an estimated incidence of 240,000-440,000 new infections annually, Lyme disease is an important and expensive emerging illness in the US. Symptoms of early Lyme disease include fever, fatigue, headaches and weakness. Late Lyme disease symptoms such as arthritis, fatigue, carditis, memory loss and loss of sight are more prevalent than previously estimated. The Johns Hopkins Bloomberg School of Public Health has estimated that Lyme disease costs the US health care system an average of \$712m to \$1.3b annually. Early detection is important to minimize the debilitating manifestations of late Lyme disease. Diagnosis of Lyme disease currently involves a laborious 2-tier testing algorithm. Due to the complex immune response in Lyme disease, many antigens are needed to achieve necessary sensitivity. InBios developed the Lyme Detect™ IgM/IgG ELISA using a recombinant, multi-epitope fusion peptide antigen, VOVO, made by the National Institutes of Health. In initial evaluation, the ELISA had a sensitivity of 100% (14/14) and specificity of 95% (2/40) on commercially obtained Lyme disease and healthy control samples respectively. When the ELISA was tested on the well characterized panel of samples established by the CDC defined by the stage of Lyme disease, good correlation with the 2-tier algorithm was seen. High sensitivity of 100% was observed for Stage 1 convalescent, Stage 2 neurologic Lyme and Stage 3 arthritic Lyme samples. For Stage 1 acute samples which fall within the early "window period" of detection prior to sero-conversion, 1/5 samples were IgM positive, better than the 2-tier algorithm which did not detect any of the 5 samples. High specificity was observed on the control samples (92%) in the panel. The InBios Lyme Detect™ IgM/IgG ELISA is promising in initial evaluation and upon further development and FDA clearance can be a sensitive, specific, easy to use and interpret 1-tier test for Lyme disease.

0984

### IDENTIFICATION OF CODING REGIONS FOR THE INNOVATION OF THE CONFIRMATORY DIAGNOSIS OF CARRION'S DISEASE

Giovanna Mendoza-Mujica, Victor Jimenez-Vasquez, Karen Calvay-Sánchez, Yanina Zárate-Sulca

Instituto Nacional de Salud-Perú, Lima, Peru

The current gold-standard method for the diagnostic of Carrion's disease is the bacteriological culture which is accurate but time-consuming. Other methods like blood smear inspection are fast but low sensitive, the serological methods are based on the interaction between patient antibodies and all the expressed proteins which limits specificity, molecular methods are based on classical gene regions like *glTA*, *RibC* and *ialB* among other genes that are not unique for *Bartonella bacilliformis* and therefore subject to cross reactivity. In addition, there are currently two proposed subspecies for *Bartonella bacilliformis* and no available methods for their identification and distinction. This study aims to find unique and specific coding regions of *Bartonella bacilliformis* at species and subspecies levels for the development of an accurate and sensitive method for the molecular diagnosis of Carrion's disease. Search was based on sequence similarity for all coding regions identified in *Bartonella bacilliformis* strain KC584 with 4 databases as follows: against complete genomes of febrile-illness-associated bacterial species from *Leptospira*, *Rickettsia*, *Anaplasma*, *Orientia*, *Neorickettsia*, *Borrelia* and *Brucella* genera, against

complete available genomes of Bartonella genera species, against 16 B. bacilliformis complete and partial genomes corresponding to both identified subspecies and against Human genome GRCh38.p13. Sequence similarity was assessed with BLASTplus and resulted regions were processed in primer-BLAST for the identification of primers and probes, we finally used Oligoanalyzer for primers quality analysis by measuring GC content, melting temperature, secondary structure and dimer formation. We identified four coding regions, Flagellar hook-length control protein FliK, TOPRIM-domain-containing protein, YdaU family protein and POR-domain-containing protein and one hypothetical protein for the detection of B. bacilliformis and both proposed subspecies. All regions represent good candidates for the implementation of an accurate and fast molecular method by conventional and multiplex real-time PCR.

0985

### DERMACENTOR VARIABILIS AND ITS ASSOCIATED RICKETTSIAE IN SOUTHEASTERN VIRGINIA; THE POTENTIAL ROLE OF PATHOGEN SPILLOVER FROM LOCAL SYMPATRIC TICK SPECIES

Alexandra Nicole Cumbie<sup>1</sup>, Holly Gaff<sup>2</sup>, Wayne Hynes<sup>2</sup>

<sup>1</sup>Virginia Tech, Blacksburg, VA, United States, <sup>2</sup>Old Dominion University, Norfolk, VA, United States

Hard-bodied ticks are the most medically important group of arthropods in the United States. *Dermacentor variabilis*, the American dog tick, is a common vector in the United States with its geographic range extending across the eastern portion of the country and parts of the west. This tick is historically the vector of *Rickettsia rickettsii*, the causative agent of Rocky Mountain Spotted Fever; it has also been observed to harbor other spotted fever group rickettsiae. In Virginia, the number of spotted fever group rickettsiosis cases range between 300-400 cases per year, but often the rickettsial agent is not identified to species level. There are a variety of rickettsial species reported in Virginia including *R. rickettsii*, *R. amblyommatis*, *R. montanensis*, and *R. parkeri*. *Rickettsia* can be detected in multiple tick species, but are typically transmitted by a single vector; all of which are sympatric with *D. variabilis*. The purpose of this study was to assess current *D. variabilis* populations in Virginia for their associated rickettsiae. From 2012 to 2018 as part of a long-term active surveillance project, adult *D. variabilis* were collected using standard flagging methods while immatures were collected using small mammal trapping. Rickettsiae were detected using real-time PCR and confirmed using Sanger sequencing. *Dermacentor variabilis* in Virginia were observed to harbor *R. montanensis*, *R. parkeri*, and *R. amblyommatis*, with the most common rickettsial species being *R. montanensis*. No samples had detectable *R. rickettsii* infection. The occurrence of pathogen spillover among sympatric tick species appears to be common in *D. variabilis* when other tick species are dominant in the same area.

0986

### DETECTION OF AN EXOTIC RICKETTSIA IN AN INVASIVE TICK COLLECTED FROM AN INVASIVE AMPHIBIAN

Carrie De Jesus, Madison Harman, Christina Romagosa, Samantha Wisely

University of Florida, Gainesville, FL, United States

Invasive species can transport their associated parasites and pathogens from their native to non-native ranges. In Florida, invasive reptile and amphibian species have established populations with ticks from their native ecosystem. For example, *Amblyomma rotundatum* is a reptile and amphibian feeding tick from South America that can vector tick-borne pathogens. We conducted pathogen surveillance on *A. rotundatum* collected from cane toads (*Rhinella marina*) in Florida to determine if exotic pathogens were detected. We examined 99 cane toads from a population in Homestead, Florida collected from June to October 2019. Individual toads were examined for ticks and collected if present. DNA was extracted from individual ticks. Using PCR, we surveyed for *Rickettsia*, *Anaplasma*, *Ehrlichia* and *Borrelia* bacteria. Positive PCR results were Sanger sequenced

to identify pathogen species. Out of the toads examined 18/99 (18.2%) were infested with ticks. We collected 88 ticks and on average toads were infested with 4.89 ticks. PCR results were negative for *Anaplasma*, *Ehrlichia* and *Borrelia*. Of the toads infested with ticks 11/18 were positive for *R. bellii*. *Rickettsia bellii* is a mildly pathogenic Spotted Fever *Rickettsia*. Phylogenetic analysis indicated that the *R. bellii* strain from the toads in Florida matched closely to *R. bellii* sequences collected in Central and South America and deposited in Genbank. Our study suggests that exotic ticks can bring their pathogens with them and remain established in the system for 70 years. Understanding the pathogens invasive ticks carry can provide valuable insight on the risk of establishment of tick-borne pathogens to native and invasive wildlife. Ongoing research is being conducted to screen ticks for additional parasites and examine more cane toad populations in Florida.

### CAUSES OF ACUTE FEBRILE ILLNESS IN SELECTED HOSPITALS OF BANGLADESH

Pritimoy Das<sup>1</sup>, M Ziaur Rahman<sup>1</sup>, Sayera Banu<sup>1</sup>, Mahmudur Rahman<sup>1</sup>, Daniel W. Martin<sup>2</sup>, Mahabub Ul Anwar<sup>2</sup>, Cecilia Y. Kato<sup>2</sup>, Adam L. Cohen<sup>2</sup>, Michael Friedman<sup>2</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh (icddr), Dhaka, Bangladesh, <sup>2</sup>Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States

Understanding region-specific distribution of pathogens causing acute febrile illness (AFI) is important for clinical management in resource-poor settings. We aimed to explore the proportion of AFI caused by specific pathogens in Bangladesh. During May 2019-March 2020, study physicians screened patients aged >2 years presenting to outpatient departments of 4 public hospitals in different regions. We randomly enrolled patients who had measured fever ( $\geq 100.4^\circ\text{F}$ ) during assessment with onset within the past 14 days but did not take any antibiotics in the past 24 hours. Their blood and urine were tested at icddr, b [rapid diagnostic tests, bacterial culture, polymerase chain reaction (PCR)]. Acute and convalescent samples were sent to Centers for Disease Control and Prevention (USA) for *Rickettsia* and *Orientia* (R/O) and *Leptospira* tests. Among 690 AFI patients, 67 (9.7%) had typhoid (*Salmonella* Typhi) detected, 51 (7.4%) *Escherichia coli*, 28 (4.1%) dengue, and 1 hepatitis (HEV). Of the 441 patients tested for R/O, 27 (6.1%) had rickettsioses. We found 5 (2%) *Leptospira* cases among the 250 AFI patients tested for it. Eight AFI patients (1%) were hospitalized, but no deaths were reported. Typhoid was more prevalent in Rajshahi (15%, 35/231). Dhaka had most dengue cases (68%, 19/28) with the highest prevalence here than other locations (8%, 19/233). R/O affected young adults (IQR 7-23 years) and was more prevalent in the 21-25 years age-group (11%, 8/70). The highest prevalence of rickettsioses was in Rajshahi (10%, 18/182). Though there was no significant difference in gender or urban/rural residency, R/O was more likely to be found in patients who had a history of recent animal entry inside their house than not (OR 2.5, 95% CI 1.1-5.5), and in Rajshahi region than in Sylhet (OR 4.7, 1.1-20). Most (67%) R/O were from Rajshahi. *S. Typhi* and *E. coli* were the most common bacterial causes of AFI in Bangladeshi hospitals. Dengue was the most common viral infection, predominant in Dhaka. R/O was also common based on PCR alone and may be much higher once acute/convalescent antibody results are available. These results can help guide empiric outpatient AFI management.

0988

### EVALUATION OF THE ECONOMIC BURDEN OF SCABIES IN FIJI

Rabindra Baskota

Ministry of Health and Population, Kathmandu, Nepal

We analysed data of the Big Skin Health Intervention: Fiji Trial (BigSHIFT) in order to evaluate the economic burden of scabies in Fiji. The trial included 3643 outpatient and 58 hospital admitted cases of scabies from the Northern Division of Fiji between July 2018 and June 2019. We applied cost of illness approach to estimate the total cost of scabies from the

government perspective. We used micro-costing method to identify items related to direct cost of treating scabies. The cost items were valued by using bottom-up approach. Information on cost was derived from the reports of Fiji Ministry of Health. We also did one way sensitivity analysis to examine the variation in the cost estimates between the report of Fijian Ministry of Health and World Health organisation (WHO). Our study evaluated the direct medical costs associated with scabies in the whole population of Northern Division of Fiji which is highly endemic of scabies and has poor socioeconomic condition. Total economic burden was estimated separately for hospital admitted and outpatient cases. The data indicated that scabies poses a significant burden to public health, health resource utilisation and health budget. The notable contributors for direct medical costs were costs of clinic visits and cost of medicines for outpatient cases. For hospital admitted cases, cost for hospital bed, diagnostic tests and medicines were the main contributors. This study will provide information to make informed decisions about allocation of the limited resources in low-and-middle-income countries like Fiji. The findings will strengthen scabies control program by prioritising scabies alongside other neglected tropical diseases. Because we have evaluated the economic cost from government perspective, the findings of this study will help policy makers and governments to design programs and strategies for scabies control. It will help to identify target groups for scabies control interventions like mass drug administration and provide evidence to inform future cost effectiveness analysis of those interventions.

0989

#### ALPHA-GAL: AN EMERGING TICK-BORNE DISEASE OF CONCERN IN THE CAROLINAS

Kyndall C. Dye-Braumuller<sup>1</sup>, Madlyn Wils<sup>1</sup>, Chris Evans<sup>2</sup>, Melissa Nolan<sup>1</sup>

<sup>1</sup>University of South Carolina, Columbia, SC, United States, <sup>2</sup>South Carolina Department of Health and Environmental Control, Columbia, SC, United States

Tick-borne disease (TBD) incidence is increasing globally. The southeastern US, home to multiple ticks which pose public health threats, has been identified as a hotspot of concern regarding TBD. According to the South Carolina Department of Health and Environmental Control, approximately 74% of all reported vector-borne disease cases from the past 5 years have been tick-borne. According to the North Carolina Department of Public Health, approximately 91% of vector-borne disease from the same time frame are tick-borne. One emerging TBD in the southern US and internationally is alpha-gal syndrome, a novel food allergy to the mammalian oligosaccharide galactose-alpha-1,3-galactose (alpha-gal), associated with the bite of a hard tick. The Lone Star tick, *Amblyomma americanum*, is most associated with cases in the US. This disease is not nationally nor state reportable in either of the Carolinas; however recent case reports of alpha-gal have raised concern. Much is still unknown regarding this disease, including definitive clinical manifestations and the induction mechanism for pathogenesis. In response to these recent cases of alpha-gal, environmental sampling began in March 2020 in South Carolina to determine the distribution of the tick vector and understand potential areas of high risk. Ticks were collected through dragging and CO<sub>2</sub>-baited traps at state parks and from dogs at local animal shelters. All ticks were identified and processed for pathogen testing. *Am. americanum* was the most collected tick in the state and was found in all regions where alpha-gal human cases have been reported. Testing results for this species revealed multiple pathogens of public health importance. In addition to our tick surveillance data, recent clinical cases of alpha-gal in South Carolina will be described along with their relation to surveillance results. The findings of our two-part state-wide active tick surveillance and passive human surveillance will provide the audience with important information to aid in public health officials' preparedness regarding this emerging TBD threat in the US, South Africa, South America, Europe, Australia and Asia.

0990

#### FIRST REPORT OF DABIESHAN AND LIHAN TICK VIRUS (BUNYAVIRALES: PHENUIVIRIDAE) IN TICKS IN LAO P.D.R.

Khamsing Vongphayloth<sup>1</sup>, Sarah Temmam<sup>2</sup>, Jodi Fiorenzano<sup>3</sup>, Somphavanh Somlor<sup>1</sup>, Marc Eloit<sup>4</sup>, Paul Brey<sup>1</sup>

<sup>1</sup>Institut Pasteur du Laos, Vientiane, Lao People's Democratic Republic,

<sup>2</sup>Institut Pasteur, Paris, France, <sup>3</sup>Naval Medical Research Unit No. 2,

Sembawang, Singapore, <sup>4</sup>Institut Pasteur and Paris-Est University, Paris and Maisons-Alfort, France

In Laos, definitive diagnosis for vector-borne illnesses is often not available thus causing these infectious diseases to be limitedly defined. In order to identify common and emerging tick-borne pathogens in Laos, NAMRU-2 Singapore (SG) and Institut Pasteur du Laos studied the distribution vector potential of ticks to act as vectors of new or neglected arboviruses. Between 2019-2020, 376 ticks were collected from Xienkhouang Province and screened for tick-borne virus through conducting RT-PCR and Next Generation Sequencing (NGS). The ticks were pooled into 12 large pools with the nucleotide sequences of the L and S segments obtained by NGS. NGS identified 2 viral species, Dabieshan tick virus and Lihan uukuvirus, of the genus *Uukuvirus* (former classified as *Phlebovirus*). Dabieshan tick virus was detected in 2 pools of *Haemaphysalis* ticks collected by dragging, with a 72-88% (L segment) and 53% (S Segment) nucleotide identity with the prototype strain previously identified in Chinese *Haemaphysalis longicornis* ticks. Lihan uukuvirus was detected in 2 pools of *Rhipicephalus microplus* collected from cows, with a 99.6-99.8% (L segment) and 85.3-97.5% (S Segment) nucleotide identity with the prototype strains previously identified in *Rhipicephalus microplus* ticks from various locations. The 4 large positive pools were broken into 18 min pools for RT-PCR pathogen screening. From mini pools, the prevalence rate among these samples was 22% (4 positives out of 18 mini pools (36 ticks)). The results from this study are the first to record Dabieshan and Lihan tick viruses in Lao P.D.R. Future research studies are needed to determine the pathogenicity of these viruses to livestock and humans in Laos.

0991

#### IDENTIFICATION OF TICK-BORNE RICKETTSIAIN COMMUNAL LANDS, RANCHES, AND PROTECTED AREAS OF ESWATINI

Kimberly J. Ledger, Samantha M. Wisely

University of Florida, Gainesville, FL, United States

African tick-bite fever, caused by the bacteria *Rickettsia africae*, is the most commonly reported travel-related tick-borne disease. Furthermore, tick-borne rickettsioses are increasingly implicated in acute febrile illness in rural, pastoral and mixed farming communities across the continent. Living in close association with animals and participating in outdoor activities are key drivers of rickettsial infections. The goal of this study was to identify tick-borne spotted fever group *Rickettsia* from host-seeking ticks in a landscape of wildlife, livestock, and humans, and explore distributional patterns in the ticks and rickettsial species. We collected questing ticks from the vegetation at 26 sites between 2018 and 2019 across conservation areas, ranches, and communal rangelands in Eswatini. We identified ticks using morphology and molecular methods and then tested them for rickettsial DNA using real-time PCR assays, conventional PCR assays, and direct sequencing of multiple loci. We detected rickettsial DNA in three out of seven tick species collected (*Amblyomma hebraeum*, *Haemaphysalis elliptica*, and *Rhipicephalus simus*). Using sequences from three genes, rickettsial samples grouped into four distinct clades: *Ri. africae*, *Ri. conorii*, *Rickettsia massiliae*, and *Rickettsia barbariae*. We found an average prevalence of 55% for *Ri. africae* in *A. hebraeum*, 4.2% for *Ri. conorii* in *H. elliptica*, and 4.4% for *Ri. massiliae* in *Rh. simus*. *Rickettsia africae* was detected in multiple conservation areas, ranches, and communal rangelands, while detection of *Ri. conorii* was limited to a single communal rangeland and single ranch and detection of *Ri. massiliae* was limited to a single conservation area and single ranch. These results illustrate the widespread presence *Ri. africae* (agent of African tick-bite fever) and the occurrence of *Ri. conorii* (agent of Mediterranean spotted

fever) in Eswatini. This study expands our understanding of the challenges faced by travelers visiting conservation areas and rural communities living close to wildlife and livestock.

## SPOTLIGHT REPORT: TICKS AND TICK-BORNE DISEASES OF UGANDA

**John Tarpey**

*Loyola University New Orleans, New Orleans, LA, United States*

John Tarpey<sup>1</sup>, Alexander Potter<sup>2,3,4</sup>, David B. Pecor<sup>2,3,4</sup>, Michael von Fricken<sup>5,6</sup>, Dawn Zimmerman<sup>6</sup>, Yvonne-Marie Linton<sup>2,3,4</sup>

<sup>1</sup>Loyola University of New Orleans, New Orleans, LA, USA<sup>2</sup>Walter Reed Biosystematics Unit (WRBU), Smithsonian Institution Museum Support Center, Suitland, MD, USA<sup>3</sup>Department of Entomology, Walter Reed Army Institute of Research, Silver Spring, MD, USA, <sup>4</sup>Smithsonian Institution–National Museum of Natural History, Washington, DC, USA<sup>5</sup>George Mason University, College of Health and Human Services, Fairfax, VA, USA<sup>6</sup>Global Health Program, Smithsonian's National Zoological Park and Conservation Biology Institute, Washington, DC, USA

The risk posed by tick vectors of tick-borne diseases (TBDs) affecting humans, livestock and wildlife is not well defined in Uganda. Country-wide surveillance data for ticks and tick-borne pathogens is severely lacking. To address this critical knowledge gap, a systematic literature review of peer-reviewed studies of ticks and TBDs in East Africa was performed, augmenting our own surveillance data that is available in VectorMap. Inclusion and exclusion criteria were defined *a priori* and targeted publications reporting tick or tick-borne pathogen distribution data in Uganda, from the year 1901 to 2020. This work is part of a larger effort to examine and compile historical data from several East African countries. Publications were obtained through PubMed, CABI, SCOPUS, and WOS. A total of 1057 publications were screened by title and abstract, of which 33 met our criteria were mined for tick and TBD surveillance data, including but not limited to; tick species, pathogen presence, collection location, collection method and date. Locality descriptions were georeferenced and spatial uncertainty was calculated for each record. These preliminary results identified 33 unique tick species, including several medically important species in Uganda. This data provides a baseline for future studies to further analyze TBD risk in Uganda, and throughout the East African region.

## EFFECTIVENESS OF ONE VERSUS TWO DOSE MASS DRUG ADMINISTRATION REGIMENS FOR THE CONTROL OF SCABIES

**Susanna J. Lake**<sup>1</sup>, Daniel Engelman<sup>1</sup>, Oliver Sokana<sup>2</sup>, Dickson Boara<sup>2</sup>, Titus Nasi<sup>2</sup>, Julie Zinihite<sup>3</sup>, Christina Gorae<sup>2</sup>, Sophie L. Phelan<sup>4</sup>, Millicent H. Osti<sup>1</sup>, Tibor Schuster<sup>1</sup>, Anneke C. Grobler<sup>1</sup>, Ross Andrews<sup>5</sup>, Margot J. Whitfeld<sup>6</sup>, Michael Marks<sup>7</sup>, Lucia Romani<sup>4</sup>, Andrew C. Steer<sup>1</sup>, John M. Kaldor<sup>1</sup>

<sup>1</sup>Murdoch Children's Research Institute, Melbourne, Australia, <sup>2</sup>Ministry of Health and Medical Services, Honiara, Solomon Islands, <sup>3</sup>Solomon Islands National University, Honiara, Solomon Islands, <sup>4</sup>The Kirby Institute, Sydney, Australia, <sup>5</sup>Australian National University, Canberra, Australia, <sup>6</sup>St Vincents Hospital, Sydney, Australia, <sup>7</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Mass drug administration (MDA) is an effective control strategy for scabies in populations where there is a high prevalence. Two-dose ivermectin based MDA has been shown to reduce population prevalence of scabies by around 90%. Current two-dose regimens present barriers to widespread implementation including challenges of cost, logistics in isolate communities, and integration with control of other neglected tropical disease. The Regimens of Ivermectin for Scabies Elimination (RISE) study investigated whether one-dose MDA is as effective as two-dose MDA to control scabies in a high prevalence setting. The study was based

in 20 villages in Western Province in Solomon Islands. All residents of the village on the day of the study were eligible to participate. Villages were randomised in a 1:1 ratio to receive either one or two doses of ivermectin based MDA. Topical permethrin was offered to participants who met exclusion criteria for ivermectin. Scabies and impetigo prevalence in each village was assessed at baseline and 21 months after the intervention. We enrolled 5239 participants at baseline and found an overall population prevalence of scabies of 15.0% (95% CI 11.8-19.1) and impetigo prevalence of 5.6% (95% CI 4.2-7.3). Results for the 21-month timepoint will be available in May 2021. We will compare the relative reduction in scabies and impetigo prevalence in each arm. If there is less than a 5% difference in reduction we will consider one dose non-inferior to two doses. The results of this study will guide policy for the dosing regimens of ivermectin for scabies MDA in high prevalence settings.

## A COMPARATIVE STUDY OF TWO SAMPLING METHODS ON PYRETHROID RESISTANT MALARIA PARASITE VECTORS IN WESTERN KENYA.

**Noriko Tamari**<sup>1</sup>, Noboru Minakawa<sup>2</sup>, Kyoko Futami<sup>2</sup>, Peter A. Lutiali<sup>3</sup>, George O. Sonye<sup>4</sup>, Beatrice Awuor<sup>4</sup>, Stephen Munga<sup>5</sup>, Kacey C. Ernst<sup>1</sup>, Melanie L. Bell<sup>1</sup>

<sup>1</sup>Department of Epidemiology and Biostatistics, Mel and Enid Zuckerman College of Public Health, University of Arizona, Tucson, AZ, United States, <sup>2</sup>Institute of Tropical Medicine (NEKKEN), Nagasaki University, Nagasaki, Japan, <sup>3</sup>Centre for Research in Tropical Medicine and Community Development, Nairobi, Kenya, <sup>4</sup>Ability To Solve By Knowledge Project, Mbita, Homa Bay, Kenya, <sup>5</sup>Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya

While long-lasting insecticide-treated nets (LLINs) are widely accepted for controlling malaria, pyrethroid resistance has become widespread among malaria vector populations in Africa. In western Kenya, *Anopheles gambiae sensu stricto* (s.s.) has developed a point mutation in the voltage-gated sodium channel (L1014S) related to knockdown resistance. Resistant *Anopheles arabiensis* and *Anopheles funestus* s.s. enhance the enzymes that metabolize pyrethroid insecticides. Thus, pyrethrum spray catch method (PSC) may underestimate the number of anopheline mosquitoes present during indoor collections. We investigated whether PSC remains effective for monitoring pyrethroid resistant anopheline populations. Specifically, we compared the numbers of female anophelines collected, the species composition and the proportion of blood-fed mosquitoes between PSC and light trap (LT). Cross-sectional data were collected from 10 traditional houses from each of 15 communities between December 2013 and January 2014 in western Kenya. One hundred fifty households sampled once for LT (Day 1) and once for PSC (Day 2). The number of *An. gambiae* s.s. collected was too few to compare the methods. Negative binomial mixed models showed that compared with LT, PSC collected a fewer number of *An. funestus* s.s. [adjusted Risk Ratio (aRR): 0.24, 95% confidence interval (CI): 0.17, 0.35] and *Anopheles rivulorum* (aRR: 0.18, 95%CI: 0.06, 0.53), but the numbers of *An. arabiensis* were not significantly different between the two methods (aRR: 0.94, 95%CI: 0.65, 1.38). Generalized linear mixed models for binomial proportions showed that PSC collected higher proportions of blood-fed *An. arabiensis* (aRR: 53.50, 95%CI: 25.10, 114.07) and *An. funestus* s.s. (aRR: 487.28, 95%CI: 224.40, 1059.07) than LT. All *An. rivulorum* had fed blood in PSC. The results suggest that PSC is still effective for monitoring blood-fed pyrethroid resistant anopheline populations, and LT should be used to monitor the number of *An. funestus sensu lato* in particular. Further studies are needed to compare both methods based on the proportion of resistant individuals in the population.

0995

### ESTABLISHING A PRACTICAL INSECTICIDE RESISTANCE MONITORING METHODOLOGY FOR ORALLY INGESTED DINOTEFURAN

George Parsons<sup>1</sup>, Rosemary Susan Lees<sup>1</sup>, John Vontas<sup>2</sup>, Mathias Mondy<sup>3</sup>, Julian Entwistle<sup>3</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom,

<sup>2</sup>Foundation for Research and Technology - Hellas, Heraklion, Greece,

<sup>3</sup>IVCC, Liverpool, United Kingdom

Attractive Targeted Sugar Baits (ATSB®) are being evaluated as part of an Integrated Vector Management (IVM) approach. They are likely to be particularly effective against outdoor biting mosquitoes, as well as mosquitoes that are resistant to pyrethroids. An ATSB based on the neonicotinoid dinotefuran has been developed by Westham Co. and is under evaluation in conjunction with IVCC. As with any insecticide-based intervention it will be important to monitor for the possible emergence of vector resistance. While methods for detecting resistance to neurotoxic insecticides via tarsal contact are recommended by the World Health Organization (WHO), these are not applicable for the also neurotoxic but orally ingested dinotefuran, due to its negative log P which hampers tarsal uptake. Sophisticated oral application assays have been developed, able to determine dose response curves among several *Anopheles* strains, including some highly resistant to pyrethroids, by using uranine markers and in a tightly controlled laboratory setting. However, the applicability of those feeding assays in the field is limited. Instead, the WHO method for topical application (TA) bioassays was adapted; applying dinotefuran to the thorax of adult *Anopheles* mosquitoes with organic carrier bypasses lipid cuticle barriers and is more analogous to ingestion than tarsal exposure. The TA dose response is being compared and correlated with the respective response of the oral toxicity bioassays, across several *Anopheles* strains. Should this correlation be fully established, a TA diagnostic dose (DD) can be determined based on WHO guidelines, to be used as a reliable proxy for monitoring the development of resistance in field populations. This DD will be further validated against field populations in three African countries where pilot trials of the bait stations are underway, and used to routinely monitor for the emergence of resistance after deployment of the bait stations. The suitability of the approach and correlation between oral ingestion and topical application across populations with different responses, needs to be evaluated case by case, for other oral toxins.

0996

### POST MARKET SURVEILLANCE OF PYRETHROID-PBO NETS: LEARNINGS FROM PERMANET® 3.0

Duncan K. Athinya<sup>1</sup>, Melinda P. Hadi<sup>2</sup>

<sup>1</sup>Vestergaard Frandsen (EA) Limited, Nairobi, Kenya, <sup>2</sup>Vestergaard Sàrl, Lausanne, Switzerland

With widespread pyrethroid resistance, pyrethroid-PBO nets are increasingly becoming a standard, core vector control intervention. Randomized control trials in Uganda and Tanzania indicated pyrethroid-PBO nets were more effective than pyrethroid-only LLINs in preventing malaria even with high level pyrethroid resistance. Knowledge gaps exist in understanding the long term effectiveness of pyrethroid-PBO nets due to differences in design and concentrations of the pyrethroid and PBO. Vestergaard conducts post market surveillance of PermaNet® 3.0 based on adapted methodology from WHO guidelines for evaluation of LLINs. PermaNet® 3.0 were targeted for collection from households 2 to 3 years post distribution and evaluated for bioefficacy, chemical content, and physical integrity. Samples collected from Nigeria, Equatorial Guinea, Sudan, Ethiopia, and Uganda ranged in period of use from 2.5-3.3 years. All samples passed the WHO optimal effectiveness criteria (≥95% knockdown or ≥80% mortality, pyrethroid susceptible *An. gambiae* s.s. Kisumu strain). Deltamethrin content ranged from 1.8-3.5 g/kg; PBO content ranged from 3.5-8.6 g/kg. Further testing was conducted on samples from Uganda using a characterized pyrethroid resistant lab strain with documented target site and metabolic mechanisms including P450

monooxygenase. A new, unused PermaNet® 3.0 and PermaNet® 2.0 were used as the positive controls. After 3.3 years of use in Uganda, PermaNet® 3.0 killed 4.5 times more resistant mosquitoes than PermaNet® 2.0 but reported reduced mortality in bioassay compared to a new PermaNet® 3.0 indicating loss of efficacy, but still significantly more efficacious than a pyrethroid-only net. Post market surveillance of pyrethroid-PBO nets is essential for long term monitoring and addressing data gaps in understanding the insecticidal and PBO availability throughout the lifetime of a pyrethroid-PBO net. There is need to expand the current WHO guidelines to include testing with well characterized pyrethroid resistant strains, in addition to guidance on the post market surveillance of the new types of nets.

0997

### COUNTRYWIDE INSECTICIDE RESISTANCE MONITORING IN NIGER: SUPPORT FOR ITN DISTRIBUTION DECISIONS MAKING

Hadiza Soumaila<sup>1</sup>, Boube Hamani<sup>2</sup>, Abdoulaye Daouda<sup>2</sup>, Iro Souleymane<sup>2</sup>, Samira Gouro<sup>2</sup>, Mamane Sani Zaman Allah<sup>2</sup>, Fatouma Abdoulaye Daouda<sup>2</sup>, Ibrahim Issa Arzika<sup>3</sup>, Soumana Amadou<sup>3</sup>, Izamne Mahamadou<sup>3</sup>, Saadou Kadri<sup>3</sup>, Noura M Sale<sup>3</sup>, Wilfried Hounkanrin Zoukifouly<sup>3</sup>, Boubacar Mahamadou<sup>3</sup>, Rabiou Labbo<sup>3</sup>, Hadiza Jackou<sup>2</sup>, Sabiti Idrissa<sup>2</sup>, Eric Coulibaly<sup>4</sup>, Els Mathieu<sup>4</sup>, Zila Tohon<sup>4</sup>, Jenny Carlson<sup>5</sup>, Ellen Dotson<sup>6</sup>, Awolola Taiwo Samson<sup>6</sup>, Cecilia Flatley<sup>7</sup>, Dereje Dengela<sup>7</sup>, Dereje Dengela<sup>7</sup>, Joseph Chabi<sup>8</sup>

<sup>1</sup>PMI VectorLink Project, Niamey, Niger, <sup>2</sup>National Malaria Control Program, Niamey, Niger, <sup>3</sup>Centre de Recherche Médicale et Sanitaire, Niamey, Niger, <sup>4</sup>U.S. President's Malaria, Niamey, Niger, <sup>5</sup>U.S. President's Malaria, Washington DC, MD, United States, <sup>6</sup>Entomology Branch, 6U.S. Centers for Disease Control and Prevention, Atlanta, GA, USA, Atlanta, GA, United States, <sup>7</sup>PMI VectorLink Project, Washington DC, MD, United States, <sup>8</sup>PMI VectorLink Project, Abidjan, Côte D'Ivoire

The PMI VectorLink project conducted insecticide resistance monitoring in seventeen sites selected across Niger by the National Malaria Control Programme (NMCP). Since 2018, vector susceptibility to pyrethroids, organophosphate, carbamate, neonicotinoid, and pyrrole were tested every year. The susceptibility status, resistance intensity and synergist assay against the main malaria vector, *An. gambiae* s.l. was determined for alpha-cypermethrin, deltamethrin, permethrin, pirimiphos-methyl, chlorfenapyr and clothianidin. Two-five-day old adult mosquitoes emerged from collected larvae were tested using WHO susceptibility test kits and CDC bottles assay. Insecticide resistance allele frequencies were further characterized using polymerase chain reaction methods. From 2018 to 2020, resistance to all pyrethroids was observed at all sites. Insecticide susceptibility to all three pyrethroids in all sites was below 60% and in some cases as low as 0%. Pre-exposure to piperonyl butoxide (PBO) substantially increased susceptibility to pyrethroids to varying degrees. Mortality against deltamethrin averaged increased in mortality from 30 to 70%, for permethrin, 0 to 60%, and for alpha-cypermethrin, 5 to 70%. Susceptibility to clothianidin 2% and chlorfenapyr 100ug/ bottle was recorded in all sites, except for chlorfenapyr in Tessaoua and Magaria where possible resistance was noted. Vectors were susceptible to pirimiphos-methyl in only five sites (Madarounfa, Magaria, Matamey, Say, and Tillabery), moderately resistant in six sites (Agadez, Balleyara, Boboye, Gaya, Madaoua, and Niamey V), and highly resistant in four sites (Guidimouni, Keita, Tchintabaraden, and Tessaoua). Both *kdr-w* and *Ace-1* mutations were recorded at frequencies between 0.22 - 0.38 and between 0.05 - 0.09, respectively, across the sites. The data collected in Niger supported the NMCP on making decision to purchase Interceptor G2 mosquito nets in fifteen District and PBO LLINs in eight Districts for the 2022 ITN mass campaign

0998

### EVIDENCE SUPPORTING DEPLOYMENT OF NEXT GENERATION INSECTICIDE TREATED NETS IN BURKINA FASO BIOASSAYS WITH EITHER CHLORFENAPYR OR PIPERONYL BUTOXIDE INCREASE MORTALITY OF PYRETHROID-RESISTANT ANOPHELES GAMBIAE S.L.

**Aristide Hien**<sup>1</sup>, Diloma Dieudonné SOMA<sup>1</sup>, Dramane Coulibaly<sup>1</sup>, Abdoulaye Diabaté<sup>1</sup>, Allison Belemvire<sup>2</sup>, Mame B Diouf<sup>3</sup>, Djenam Jacob<sup>4</sup>, Adama Koné<sup>5</sup>, Ellen Dotson<sup>6</sup>, Taiwo S. Awolola<sup>6</sup>, Richard M. Oxborough<sup>4</sup>, Roch K. Dabiré<sup>1</sup>

<sup>1</sup>Institut de Recherche en Sciences de la Santé (IRSS), Bobo-Dioulasso, Burkina Faso, <sup>2</sup>U.S. President's Malaria Initiative, U.S. Agency for International Development, Washington DC, MD, United States, <sup>3</sup>U.S. President's Malaria Initiative, US Embassy Ouagadougou, Burkina Faso, Ouagadougou, Burkina Faso, <sup>4</sup>PMI VectorLink Project, Abt Associates Inc., Rockville, MD, United States, <sup>5</sup>PMI VectorLink Burkina Faso, Abt Associates Inc., Ouagadougou, Burkina Faso, Ouagadougou, Burkina Faso, <sup>6</sup>Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States

Pyrethroid resistance poses a major threat to the efficacy of insecticide treated nets (ITNs) in Burkina Faso and throughout sub-Saharan Africa. There are ITNs available treated with alternative insecticides, including piperonyl butoxide (PBO)-based ITNs and Interceptor® G2 (treated with chlorfenapyr and alpha-cypermethrin). Before deploying alternative ITNs on a large scale it is critical to characterize resistance profiles of primary malaria vector species. Larvae from the predominant vector, *Anopheles gambiae* s.l., were collected in 2019 from 15 sites located throughout Burkina Faso and reared to adults for bioassays to assess insecticide resistance status. WHO tube tests were used to determine the intensity of resistance to pyrethroids commonly used on ITNs at 1x, 5x and 10x times the diagnostic dose and to conduct PBO synergist bioassays with deltamethrin and permethrin. Bottle bioassays were conducted to determine susceptibility to chlorfenapyr. Results showed high intensity resistance to deltamethrin and alpha-cypermethrin at all sites. Resistance intensity to permethrin was either moderate or high in 13 sites. PBO pre-exposure followed by deltamethrin exposure partially restored susceptibility in all but one of the remaining sites (often reaching mortality greater than 80%). PBO pre-exposure followed by permethrin exposure partially restored susceptibility in 12 sites but there was no significant increase in three sites. Susceptibility to chlorfenapyr was confirmed at 14 sites. High pyrethroid resistance intensity in *An. gambiae* s.l. is widespread across Burkina Faso and may be a predictor of reduced pyrethroid-only ITN effectiveness. PBO + deltamethrin ITNs would likely provide greater control than pyrethroid-only nets. However, since susceptibility in bioassays was not fully restored in most sites following pre-exposure to PBO, Interceptor G2 may be a better long-term solution, as susceptibility to chlorfenapyr was observed in nearly all sites. This study provides evidence supporting the introduction of Interceptor G2 nets and PBO nets, which were distributed in Burkina Faso in 2019 as part of a mass campaign.

### ACCOUNTING FOR HETEROGENEITY IN WILD ADULT SAMPLES TO MEASURE INSECTICIDE RESISTANCE IN ANOPHELES MALARIA VECTORS

**Inga Holmdahl**<sup>1</sup>, Caroline Buckee<sup>1</sup>, Lauren Childs<sup>2</sup>

<sup>1</sup>Harvard TH Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Virginia Tech, Blacksburg, VA, United States

Systematic, long-term, and spatially representative monitoring of insecticide resistance in *Anopheles* malaria vectors is needed to quantify the impact of insecticide resistance on malaria transmission, and to combat failing interventions when resistance emerges. Resistance assays on wild-caught adult mosquitoes offer an alternative to the current protocols, and can be done cheaply, in a shorter time frame, and in the absence of an insectary. We developed a discrete-time deterministic mosquito lifecycle model to simulate different types of insecticide assays and to evaluate

the bias in insecticide resistance bioassays using either adult-captured or larval-captured samples. We incorporated non-lethal effects of insecticide exposure that were demonstrated in laboratory experiments. Using output from this model, we simulated assays from either larval-captured or adult-captured samples. We found that the bias in adult-captured assays depended on the level of insecticide resistance in the population, rather than spatial structure of the population or insecticide coverage. Using the model, we compared the results of these assays to true resistance as measured by the presence of the resistance allele, and constructed a correction model that can be used to reduce bias in adult-sampled assays. In a sample of 100 test mosquitoes, simulated 1000 times, we found that compared to adult-captured assays (MSE = 0.0059), larval-captured assays were a better measure of true resistance (MSE = 0.0018). Using the correction model, we were able to improve the accuracy of the adult-captured assay results (MSE = 0.0038). These results show that adult-captured bioassays—which have logistical advantages over the standard larval-captured assays—can be improved using a simple mathematical approach and used to inform resistance monitoring programs.

### COLLECTING TRASH FOR PROFIT TO REDUCE VECTOR BREEDING SITES IN SOUTH COAST KENYA

**Francis M. Mutuku**<sup>1</sup>, Lydiah Kibe<sup>2</sup>, Amy Krystosik<sup>3</sup>, Mumini Dzoga<sup>1</sup>, Scholastica Ratanya<sup>1</sup>, Gathenji Njoroge<sup>4</sup>, Jenna Forsyth<sup>3</sup>, Jenna Forsyth<sup>3</sup>, A. Desiree LaBeaud<sup>3</sup>

<sup>1</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>2</sup>Kenya Medical Research Institute, Nairobi, Kenya, <sup>3</sup>Stanford University, San Francisco, CA, United States, <sup>4</sup>University of California Berkeley, Berkeley, CA, United States

Dengue virus (DENV), chikungunya virus (CHIKV), and Zika virus (ZIKV) are three important arboviruses that are spread by the same mosquito vector (*Aedes aegypti*). Recent studies suggest strong link between *Aedes spp.* mosquitoes breeding and plastics. Some of the plastics utilized by *Aedes aegypti* for breeding include water storage like buckets, jerrycans, basins and drums and discarded plastic containers or plastic waste. Efficient management of garbage especially plastic waste has been associated with reduced transmission and risk of both dengue and chikungunya. However, the focus for majority of studies on solid waste is on describing performance of waste management systems and household waste generation behavior and rarely on ways of improving efficiency of waste reduction, recovery and recycling. This study described the relationships among the different actors in informal recycling in Ukunda and Likoni with an aim of increasing the efficiency of recovering plastic wastes and thus minimizing potential *Aedes Spp.* breeding habitats. We determined that the efficiency of the solid waste management in Ukunda and Likoni is very low. No formal plastic waste recovery and recycling was observed. However, a thriving informal plastic waste recycling was observed with waste pickers, yard shop operators and middlemen as key players. This informal recycling channel is able to remove a substantial amount of plastic waste from the environment. However, their efficiency is curtailed by setbacks such market price fluctuations, low value on plastic wastes, plastic transportation issues and government levies and taxes among others. Approaches to address the identified setbacks were developed through a business incubator and the resulting improvements in plastic waste recycling are discussed.

### INTEGRATED VECTOR MANAGEMENT IN PUERTO RICO AND THE CARIBBEAN IN THE MIDST OF A PANDEMIC

**Marianyoly Ortiz**, Grayson Brown

Puerto Rico Science, Technology and Research Trust, San Juan, PR, United States

*Aedes aegypti* is the leading vector for dengue, Zika, chikungunya, and yellow fever, and caused over 3 million cases of dengue fever in the Americas in 2019 alone, the highest number in history for this region (PAHO, 2020). In Puerto Rico, this mosquito has caused over 70,000 cases

of arboviral diseases over the last decade, resulting in the island becoming the USA jurisdiction with the highest number of arboviral diseases and an important source of travel-related cases in North America. Despite this, vector control strategies are becoming limited given the development of insecticide resistance in mosquitoes and the increased environmental and public concerns about pesticides. Novel techniques like Wolbachia and genetically modified mosquitoes are undergoing significant field trials to demonstrate effectiveness and feasibility but require significant community and stakeholder engagement to be implemented. The COVID-19 pandemic severely impacted current vector management activities throughout Puerto Rico and limited the adoption of integrated vector management territory-wide. Limitations arose from government-issued executive orders and policy decisions, citizen concerns that affected community mobilization efforts, concerns about the interaction between some vector control techniques and COVID-19, diagnosis of dengue vs COVID-19, among other complications. This presentation will examine the specific situations in more detail so as to understand how simultaneous outbreaks of dissimilar diseases can be better managed in the future.

1002

### INCENTIVIZING MULTIPLE OBJECTIVES IN ACTIVE SURVEILLANCE FOR URBAN DISEASE VECTORS

**Claudia Arevalo-Nieto**

UPCH, Arequipa, Peru

Large-scale vector control campaigns have successfully reduced infectious disease incidence around the world. In addition to preventing new infections, these campaigns produce a wealth of information about the distribution and density of insect vectors, which can be incorporated into risk maps. These maps can effectively communicate risk map data to technicians on the ground, although encouraging them to use the data remains a challenge. We carried out a series of rolling trials in which we evaluated risk map use under different incentive schemes. Participants in the studies were trained field technicians tasked with house-to-house surveillance for insect vectors of Chagas disease in Arequipa, Peru. A novel incentive scheme based on poker best achieved a dual objective: to encourage technicians to preferentially visit higher-risk houses while surveilling evenly across the search zone. The poker incentive structure may be well-suited to improve entomological surveillance activities and other complex multi-objective tasks.

1003

### IMPROVED GERMLINE PROMOTERS FOR CAS9 EXPRESSION AND INCREASED DRIVE EFFICIENCY IN THE YELLOW FEVER MOSQUITO Aedes Aegypti

**Estela Gonzalez**, Michelle A. Anderson, Lewis Shackelford, Katherine Nevard, Sebald A. Verkuil, Joshua X. Ang, Tim Harvey-Samuel, Luke Alphey

The Pirbright Institute, Pirbright, United Kingdom

The mosquito *Aedes aegypti* is one of the most important vectors involved in the transmission of several arboviruses such as dengue, yellow fever, chikungunya, and Zika virus. To decrease the incidence of these vector borne diseases, the control of mosquito populations plays an essential role and is often the only way to prevent disease outbreaks. New mosquito control approaches based on CRISPR/Cas9 technology are under development and could be a complementary strategy to improve the mosquito control campaigns that nowadays rely mainly on insecticides (i.e., extensive spraying and insecticide-treated bed nets). The 'Homing Endonuclease' gene drive has garnered attention as a means of introducing and driving a trait in a population and recent studies in different dipterans such as *Drosophila melanogaster*, *Anopheles gambiae*, *Anopheles stephensi* and *Ae. aegypti* have demonstrated the feasibility of this system. However, inheritance rates in *Ae. aegypti* have not reached those described in *Anopheles* species, in which inheritance bias approaches 100%. In this study we utilised six germline-specific regulatory elements to express Cas9 and assessed their ability to bias the inheritance

of a sgRNA expressing transgene (*kmo*<sup>gRNAs</sup>). A total of 14 Cas9-expressing isolines were generated and assessed by crossing them to the *kmo*<sup>gRNAs</sup> line and the trans-heterozygous F<sub>1</sub> were crossed to a wild type mosquito line (Liverpool strain) to determine the inheritance rate of the *kmo*<sup>gRNAs</sup>. Our results reveal several isolines which have strong (glm;  $p < 0.001$ ) predictors for increased inheritance of *kmo*<sup>gRNAs</sup>. One insertion using the *sds3* regulatory region biased inheritance of the *kmo*<sup>gRNAs</sup> element up to 89.8%. Several isolines using the *shutdown* regulatory region could also bias inheritance up to 90.1%. These data present the greatest inheritance bias reported in a gene drive system in *Ae. aegypti* to date. These results suggest that further improvement can be achieved in the development of a gene drive system in yellow fever mosquitoes.

1004

### ASSOCIATION OF VGSC MUTATIONS V410L, V1016I AND F1534C WITH PYRETHROID RESISTANCE IN Aedes Aegypti POPULATIONS FROM CENTRAL AMERICA

**E. David Castañeda**<sup>1</sup>, Juan C. Lol<sup>1</sup>, Ana H. Gómez<sup>1</sup>, Francisco J. López<sup>1</sup>, Monica Barrientos<sup>2</sup>, Denis Escobar<sup>3</sup>, Emperatriz Lugo<sup>4</sup>, Mario Avila<sup>5</sup>, Cesar Burgos<sup>6</sup>, Rodrigo Marin<sup>7</sup>, Audrey Lenhar<sup>8</sup>, Norma R. Padilla<sup>1</sup>

<sup>1</sup>Centro de Estudios en Salud, Universidad del Valle de Guatemala, Guatemala, Guatemala, <sup>2</sup>Ministerio de Salud Pública y Asistencia Social, Guatemala, Guatemala, <sup>3</sup>Instituto de Investigaciones en Microbiología, Universidad Nacional Autónoma de Honduras, Tegucigalpa, Honduras, <sup>4</sup>Ministerio de Salud de Nicaragua, Managua, Nicaragua, <sup>5</sup>Ministerio de Salud de Panamá, Panama City, Panama, <sup>6</sup>Centro de Control de Enfermedades Tropicales, Ministerio de Salud Pública, República Dominicana, Santo Domingo, Dominican Republic, <sup>7</sup>Ministerio de Salud de Costa Rica, San José, Costa Rica, <sup>8</sup>Center for Disease Control and Prevention (CDC), Atlanta, GA, United States

*Aedes aegypti* is the main vector of dengue Zika, and chikungunya in Latin America. Recent outbreaks of Zika (2016) and dengue (2019) in Central America reflect the need for effective vector control. The main strategy for the control and prevention of these *Aedes*-borne diseases is insecticide-based vector control, with a high reliance on pyrethroid insecticides. However, resistance to pyrethroids has been detected in the region, and there limited knowledge of mechanisms underlying this resistance in Central America. Therefore, we genotyped *Ae. aegypti* populations from several sites in Guatemala, Honduras, Nicaragua, Costa Rica, Panama and Dominican Republic to detect the *vgsc* V410L, V1016I and F1534C mutations and associate their frequencies with phenotypic resistance status. We found co-occurrence of these three mutations in all populations. Frequencies for the V1016I and F1534C mutations ranged from 0.42 to 1.0, and 0.69 to 1.0, respectively. The V410L mutation was present in all sites with frequencies ranging from 0.35 to 0.80, representing a widespread presence and the first report of this mutation in field populations in Central America and the Dominican Republic. We observed an association of the V1016I and V410L mutations with pyrethroid resistance in field populations from Costa Rica, Panama and Honduras. The F1534C mutation was found to be fixed in most of the populations, except in three sites from Honduras, where an association between this mutation and deltamethrin resistance was confirmed. Two distinct haplotypes and evidence of selective sweep were found when analyzing the *kdr* region where the 1016 codon is located. We found that these three VGSC mutations are common and widespread in Central America and Dominican Republic, and can partially explain detected pyrethroid resistance.

## INSECTARY INFORMATION SYSTEM: BUILDING-BLOCKS FOR REPRODUCIBLE SCIENCE IN VECTOR BIOLOGY

**Edgar Manrique**<sup>1</sup>, Manuela Herrera-Varela<sup>2</sup>, James Beuzeville-Jaen<sup>1</sup>, Lutecio Torres-Torres<sup>1</sup>, Jorge Ruiz-Cabrejos<sup>3</sup>, Gabriel Carrasco-Escobar<sup>4</sup>, Dionicia Gamboa<sup>5</sup>, Joseph M. Vinetz<sup>6</sup>, Jan E. Conn<sup>7</sup>

<sup>1</sup>Laboratorio ICEMR-Amazonia - Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Grupo de Investigación en Entomología, Facultad de Medicina, Universidad Nacional de Colombia, Bogotá, Colombia, <sup>3</sup>Health Innovation Laboratory, Institute of Tropical Medicine "Alexander von Humboldt," Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>4</sup>School of Public Health, University of California San Diego, La Jolla, CA, United States, <sup>5</sup>Departamento de Ciencias Celulares y Moleculares, Facultad de Ciencias y Filosofía, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>6</sup>Yale University School of Medicine, New Haven, CT, United States, <sup>7</sup>Department of Biomedical Sciences, School of Public Health, State University of New York, Albany, NY, United States

Data are an extraordinarily valuable resource and there remain gaps in the development of collection methods and analyses to optimize their use for the benefit of public health. For vector-borne diseases, insectaries could benefit from a custom Laboratory Information System (LIS). Although guidelines have been produced to direct and facilitate rearing mosquitoes in insectaries, less effort has been spent on the information that should be systematically collected to implement a successful, long lasting, sustainable, and productive insect colony. The aim of this study is to describe the implementation of an affordable LIS at an insectary housing a colony of the main vector of malaria in Amazonian Peru, *Nyssorhynchus darlingi*, using open-source software to reduce multiple barriers of costs and logistics. This *Ny. darlingi* colony maintains self-contained mosquito generations and was initially established in 2013 at the Amazonia ICEMR laboratory in Iquitos, Loreto, Peru. Implementation of the LIS began at generation 74 and the colony currently stands at generation 90. The LIS included the revision of guidelines for establishing and maintaining insectaries that breed anopheline mosquitoes, mapped the activities in our insectary, identified data inputs, and designed digital forms. The digital forms captured essential mosquito life cycle information and recorded mosquito development and environmental conditions. Two forms were developed, the first to estimate hatch and survival rate of juvenile stages until pupation by following a sample of eggs per each generation, and the second to collect data about the productivity of the colony. In addition, temperature and humidity were recorded in dataloggers at 30 minutes intervals. All the information collected was processed and displayed in a dashboard to visualize key vector biology metrics through interactive figures and tables. Through continuous monitoring of the insectary, this system provided the ability to plan experiments prospectively, and to foresee and prevent adverse scenarios that could affect the colony health.

## ABUNDANCE OF AEDES AEGYPTI FEMALE MOSQUITOES IN SPACES SURROUNDING RESIDENTIAL AND NON-RESIDENTIAL STRUCTURES IN WESTERN AND COASTAL KENYA

**Bryson A. Ndenga**<sup>1</sup>, Francis Mutuku<sup>2</sup>, Gladys Agola<sup>1</sup>, Joel Mbakaya<sup>1</sup>, Samwel Ndire<sup>1</sup>, Said Malumbo<sup>3</sup>, Paul Mutuku<sup>3</sup>, Angelle D. LaBeaud<sup>4</sup>

<sup>1</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>2</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Vector Borne Disease Control Unit, Msambweni, Kenya, <sup>4</sup>Stanford University, Stanford, CA, United States

*Aedes aegypti* is the main vector transmitting human arboviruses like yellow fever, chikungunya, dengue, and Zika. This vector is known not to fly far away from areas it can find both blood-meals and oviposition sites. This study investigated the abundance of *Aedes aegypti* female mosquitoes in spaces surrounding residential and non-residential structures in Kisumu and Ukunda in western and coastal Kenya. Two Biogents

(BG)-traps baited with carbon dioxide (CO<sub>2</sub>) were placed outdoors, one at a residential and the other at a non-residential structure, within eight selected zones both in Kisumu and Ukunda. Trapped mosquitoes were collected daily at about mid-day for four consecutive days. A total of 517 female mosquitoes were collected: 193 (37.3%) in Kisumu and 324 (62.7%) in Ukunda. Mean density of female *Aedes aegypti* mosquitoes varied in spaces surrounding different structures: yard shops (4.0); garages (1.8); gardens (1.6); open spaces (1.4); banana plantations (1.2); residential houses (0.9); unfinished/uninhabited houses (0.9) and churches (0.3). These abundances were significantly lower in unfinished/uninhabited houses (P=0.023 OR 0.210), residential houses (P=0.016 OR 0.224), churches (P<0.001 OR 0.079) and banana plantations (P=0.035 OR 0.292) compared to yard shops. Yard shops are places where trash (glass, metal, plastic) is sorted and informally recycled and often remains uncovered for many months; therefore, providing ample habitat for container breeders like *Aedes aegypti*. In conclusion, the risks of being bitten by female *Aedes aegypti* mosquitoes is higher in areas surrounding yard shops than in the other residential and non-residential structures. Yard shops may be an important place to target vector control in our urban sites in Kenya.

## BEHAVIORAL RESPONSES OF PYRETHROID-RESISTANT ANOPHELES GAMBIAE MOSQUITOES TO INSECTICIDE-TREATED BED NET

**Maxwell G. Machani**<sup>1</sup>, Eric Ochomo<sup>1</sup>, Fred Amimo<sup>2</sup>, Andrew Githeko<sup>1</sup>, Guiyun Yan<sup>3</sup>

<sup>1</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>2</sup>Jaramogi oginga odinga University, Bondo, Kenya, <sup>3</sup>College of Health Sciences, University of California, Irvine, CA 92697, USA, Irvine, CA, United States

Long-lasting insecticidal nets are an effective tool in reducing malaria transmission. However, with increasing insecticide resistance little is known about how physiologically resistant malaria vectors behave around a human-occupied bed net, despite their importance in malaria transmission. This study assessed the host-seeking behavior of the major malaria vector *Anopheles gambiae* s.s. when an intact human-occupied treated bed net is in place, with respect to their insecticide resistance status under semi-field conditions. Pyrethroid resistant and susceptible females of *Anopheles gambiae* s.s. were color-marked with fluorescent powder and released inside a semi-field environment housing a hut which was occupied by a human host. Inside the hut, the occupant slept under an insecticide-treated bed net trap or untreated bed net trap. The window exit trap was installed to catch mosquitoes exiting the hut. A prokopack aspirator was used to collect indoor and outdoor resting mosquitoes in the morning. Clay pots were placed outside the hut to collect mosquitoes resting outdoors. The proportion of resistant females caught in the treated bed net trap was higher compared to the susceptible females (OR=1.445; P<0.00019). Resistant mosquitoes were less likely to exit the house when a treated bed net was present compared to the susceptible mosquitoes. The susceptible females were 2.3 times more likely to stay outdoors away from the treated bed net (OR=2.25; P<0.0001). The resistant mosquitoes showed significantly reduced avoidance behavior compared to the susceptible mosquitoes that were observed to exit the house and remained outdoors when a treated bed net was used. However, further investigations of the behavior of resistant mosquitoes under natural conditions should be undertaken to confirm these observations and improve the current intervention which are threatened by insecticide resistance and altered vector behavior.

### IMPROVING URBAN ENTOMOLOGICAL MONITORING IN MALABO, BOKO ISLAND

Nestor Bela Rivas<sup>1</sup>, Raul Nguema<sup>1</sup>, Godwin Fuseini<sup>1</sup>, Wonder P. Phiri<sup>1</sup>, Olivier Tresor Donfack<sup>1</sup>, Carlos A. Guerra<sup>2</sup>, Guillermo A. García<sup>2</sup>

<sup>1</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>2</sup>Medical Care Development International, Silver Spring, MD, United States

Malaria transmission on Bioko Island, where historical entomological inoculation rates were record breaking, has been successfully curbed over the past 17 years due to intense vector control. In recent years, as local transmission declined, malaria importation linked to frequent travel between the island and mainland Equatorial Guinea has become more evident and has been pointed as a major challenge for malaria control and elimination. In particular, data suggest that much of the malaria prevalence observed in the capital, Malabo, could be explained by importation. However, it remains unclear how much local transmission actually occurs in the city. Historical entomological sentinel sites continually monitor vector populations, but these sites are located mostly in rural and in some peri-urban areas and this has limited the availability of entomological data in urban Malabo. Here, we expand entomological monitoring in Malabo identifying suitable urban sites where to establish light trap collections (LTC). It is known that malaria vectors are not urban-friendly, hence these sites had to be selected carefully in order to maximize the probability of collecting anopheline mosquitoes. We used a comprehensive spatial decision support system to define clusters and identify the most suitable houses at the center of these clusters. Clusters corresponded mostly to 1x1 km areas and their yolks were defined as houses located within the 200x200 m center, though this configuration varied according to housing distribution. Houses with open eaves and no air conditioning were prioritized for LTC as these characteristics were assumed to increase the chances of mosquitoes entering a house. Outdoor traps were also placed in some of these houses and in specific locations within their neighborhoods. Mosquitoes will be collected once a month in eight houses from April to October. In the same areas, anopheline breeding sites will be identified monthly to complement LTC. The augmented urban entomological data will be used to inform the assessment of local transmission in Malabo and to measure the impact of indoor residual spraying on urban mosquito populations.

1009

### SOME LIKE IT HOT: HOW URBAN MICROCLIMATE ACROSS A TROPICAL CITY IMPACTS AEDES MOSQUITOES LIFE HISTORY

Eduardo Hernandez-Acosta<sup>1</sup>, Adam Hendy<sup>2</sup>, Barbara Chaves<sup>3</sup>, Eloane Andrade<sup>3</sup>, Michaela Buenemann<sup>1</sup>, Marcus Lacerda<sup>3</sup>, Nikos Vasilakis<sup>2</sup>, Kathryn A. Hanley<sup>1</sup>

<sup>1</sup>New Mexico State University, Las Cruces, NM, United States, <sup>2</sup>University Of Texas Medical Branch, Galveston, TX, United States, <sup>3</sup>Fundação de Medicina Tropical Doutor Heitor Vieira Dourado, Manaus, Brazil

Urbanization is accelerating and there is considerable concern about its impact on vector-borne diseases. Changes in microclimate associated with urban heat islands may affect the biology of vector mosquitoes. To investigate such impacts, we first quantified microclimate in sites spanning three levels of urbanization, categorized using the normalized different built-up index (NDBI), in Manaus, Brazil, a tropical city that experiences high levels of arbovirus transmission mediated by *Aedes aegypti* and *Ae. albopictus*. High NDBI sites had significantly lower mean, maximum, and daytime-mean humidity than medium or low NDBI sites (DF=2, P<0.02 for all comparisons), and high NDBI sites were 1.2°C hotter than medium or low sites, though this difference was not significant. *Ae. aegypti* were significantly more abundant at high NDBI sites than other sites, whereas *Ae. albopictus* did not show a significant difference in distribution. We experimentally tested the impact of high NDBI microclimate on *Ae. aegypti* life-history by simulating the temperature and humidity of high NDBI or a control (forest-like conditions) in a cycling incubator. We also varied food

availability to assess the interaction between the effects of microclimate and nutrition. *Ae. aegypti* larvae reared with *ad libitum* food pupated faster than the food-restricted larvae, showing an independent effect of food availability (P=0.015, DF=1, F=7.35). When food was restricted, high NDBI microclimate decreased the time to pupation relative to control NDBI (P=0.028, DF=6.11, t=-2.36). Time from pupae to adult eclosion, which was only measured in *Ae. aegypti* with food restriction, was faster in larvae reared at high NDBI conditions (P=0.046, DF=5.17, t=2.064). Adult female mosquitoes reared at high NDBI were smaller (P=0.007, DF=1, F=7.72), and adult females reared with *ad libitum* food were larger (P=0.0001, DF=1, F=17.51). Adult females reared at control settings live significantly longer compared to the high NDBI microclimate (P=0.001, DF=1, X<sup>2</sup>=10.28). These results suggest that urbanization and microclimate may lead to greater vectorial capacity in *Ae. aegypti* mosquitoes.

1010

### HUMAN-MOSQUITO CONTACT: A MISSING LINK IN OUR UNDERSTANDING OF MOSQUITO-BORNE DISEASE TRANSMISSION DYNAMICS

Panpim Thongsripong<sup>1</sup>, James M. Hyman<sup>2</sup>, Durrell D. Kapan<sup>3</sup>, Shannon N. Bennett<sup>1</sup>

<sup>1</sup>Department of Microbiology, Institute of Biodiversity Sciences and Sustainability, California Academy of Sciences, San Francisco, CA, United States, <sup>2</sup>Department of Mathematics, Tulane University, New Orleans, LA, United States, <sup>3</sup>Department of Entomology and Center for Comparative Genomics, Institute of Biodiversity Sciences and Sustainability, California Academy of Sciences, San Francisco, CA, United States

The emergence and intensification of novel and established vector-borne diseases (VBDs) are an increasing threat to global public health. Yet despite the key role that contact between hosts and vectors plays in driving VBD transmission, transmission risk has been primarily studied through the lens of vector density and overlooks host-vector contact dynamics. Thus, we continue to have a limited understanding on how contact dynamics are influenced by various biological and environmental factors that drive mosquito-borne disease transmission, impeding our ability to control them. To fill this gap, we reviewed current knowledge of host-vector contact with an emphasis on mosquito bite rates and risks. We showed that the dynamical contact rate is affected by mosquito and vertebrate factors, as well as other environmental influences, challenging a classic assumption that mosquitoes bite at a fixed rate determined by the duration of their gonotrophic cycle. We also found a lack of standardized description for host-vector contact rates; therefore, we provided a modeling framework based on distinct biological and mathematical definitions of host-mosquito contact rate, blood-feeding rate, and biting rate. We explored alternative ecological assumptions based on the functional response, blood index, forage ratio, and ideal free distribution within a mechanistic host-vector contact model that better reflects our new modeling framework. A renewed focus on contact dynamics between hosts and vectors contributed new insights into the mechanisms behind VBD spread and emergence that are sorely lacking. Our framework identified critical gaps in current knowledge of host-vector contact to guide future research directions that inform VBD prevention and control.

1011

### ECO-BIO-SOCIAL DETERMINANTS OF THE BREEDING AND INSECTICIDE SUSCEPTIBILITY OF AEDES AEGYPTI LARVAE IN ARBOVIRAL FOCI IN ABIDJAN, CÔTE D'IVOIRE

Julien Z. Zahouli<sup>1</sup>, Benjamin Koudou<sup>1</sup>, Pie Müller<sup>2</sup>, Jürg Utzinger<sup>2</sup>

<sup>1</sup>Centre Suisse de Recherches Scientifiques en Côte d'Ivoire, Abidjan, Côte D'Ivoire, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

Our ability to deal with *Aedes* mosquito-borne arboviral outbreaks in Africa, including Côte d'Ivoire, is limited. We explored the ecological, biological and social (eco-bio-social) factors of *Aedes aegypti* breeding, and dengue and yellow fever transmission risk indices in the large city of Abidjan, Côte d'Ivoire. We sampled *Ae. aegypti* immatures (larvae and

pupae) and breeding containers, and household socio-ecological data in six clusters in Abidjan, Côte d'Ivoire from September to October 2020. We calculated *Stegomyia* indices (container index: CI, household index: HI and Breteau index: BI), and pupal counts (pupae/container: PC, pupae/house: PH and pupae/person: PP). Moreover, *Ae. aegypti* larvae were tested against deltamethrin, DDT, bendiocarb, and malathion. We determined insecticide resistance ratio ( $RR_{50}$ ) and lethal concentration ( $CL_{50}$ ). The most productive *Ae. aegypti* breeding sites were outdoor water-holding containers; tires (53.7%), discarded cans (25.3%) and uncovered potable water receptacles (17.6%). CI, HI and BI were estimated at 77.2%, 57.1% and 137.2, and PC, PH and PP were of 2.31, 1.45 and 0.93, respectively. *Ae. aegypti* larval infestation and pupal counts were correlated with complex community behaviors related to water and waste management. Breeding sites' positivity and productivity were associated with unmanaged waste, water supply interruptions and long water storage duration. Domestic areas were more favorable for immature production compared with commercial and public spaces, and then schools and religious facilities. *Ae. aegypti* larvae were susceptible to deltamethrin, malathion, bendiocarb, but resistant to DDT. In Abidjan, Côte d'Ivoire, *Ae. aegypti* breeding and larvae indices were correlated with socio-ecological determinants. Moreover, *Ae. aegypti* larvae were susceptible to insecticides. However, the risks of transmission of dengue and yellow fever viruses were above the World Health Organization (WHO)-established epidemic thresholds. Integrated community-based vector control programs coupled with larviciding are recommended to achieve effective arbovirus vector management.

## 1012

### LONGITUDINAL MONITORING OF MALARIA VECTORS IN GOBU SEYO, ETHIOPIA TO ASSESS TRENDS IN BITING BEHAVIORS OF MALARIA VECTORS FROM 2012-2017

Allie Busbee<sup>1</sup>, Ryan Wiegand<sup>2</sup>, Gabriel Ponce de Leon<sup>2</sup>, Meshesha Balkew<sup>3</sup>, Gedeon Yohannes<sup>3</sup>, Dereje Dengela<sup>3</sup>, Seth Irish<sup>4</sup>, Sarah Zohdy<sup>4</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>President's Malaria Initiative, VectorLink Ethiopia, Addis Ababa, Ethiopia, <sup>4</sup>President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

Entomological surveillance is important to understand bionomics and behavior of malaria vectors. Longitudinal monitoring provides information on seasonality, biting times, and indoor/outdoor biting behaviors. Entomological surveillance was conducted from 2012 and 2017 in Gobu Seyo, located in the Oromia Region of Ethiopia, using human landing collections, pyrethrum spray catches, and CDC light traps for two nights each month during the hours of 6pm-6am. Temperature and humidity were recorded in hourly increments during collections. Analysis of these data addressed longitudinal variations in peak biting times across seasons and between years to inform future timelines for collections and protocol methodologies. Data were analyzed using a negative binomial regression model to assess primary vectors collected, biting times and locations, and seasonality to evaluate inter- and intra-annual variability. Potential covariates were analyzed including: collection location, temperature, and humidity. *Anopheles arabiensis* and *Anopheles pharoensis* were the most collected species both making up 20% of the observations followed by *Anopheles coustani* making up 19% of observations. Other species collected were *An. demeilloni* at 11%, *An. christyi* at 5%, *An. ziemanni* at 7%, and culicine species at 7% of total collections. Initial analysis across years suggested a range of peak biting times across all species occurring between the hours of 8pm-12am, with less biting occurring in the early evening and early hours of the morning. The total number of mosquitoes collected per night decreased over time from 17 in 2012 to 3 in 2017 with large variances. Large variation was likely due to seasonality of the mosquitoes, temperature, and humidity during collections. Smaller variation was noted in species, seasonality, and biting time across years. Total numbers of mosquitoes collected decreased over the years, possibly

related to malaria vector control. These data suggest using trends from longitudinal data sets as a method to assist in decision making about the frequency of entomological collections.

## 1013

### AN EVALUATION OF LONGITUDINAL ANOPHELES STEPHENSI EGG VIABILITY AND RESISTANCE TO DESICCATION

Laura Leite, Rachel Denny, Zachary Kaplan, Seth Irish, Ellen Dotson, Sarah Zohdy

Centers for Disease Control and Prevention, Atlanta, GA, United States

*Anopheles stephensi*, an urban vector of malaria endemic to Asia, was detected in Djibouti in 2012 and has since established as an invasive species in Ethiopia, Sudan, and Somalia. This expansion of *An. stephensi* presents a serious threat to malaria control and elimination efforts in Africa. To control the species and halt further expansion, it is critical to understand the biological characteristics and determinants that may have facilitated invasion. In Ethiopia, *An. stephensi* larvae colonize artificial containers, many of which are shared with *Aedes aegypti*. The success of *Ae. aegypti* as an invasive vector is often attributed to its use of artificial containers and the ability of *Ae. aegypti* eggs to remain viable in the absence of water for months. While *An. stephensi* is found in artificial containers, it is unclear whether the eggs can remain viable in the absence of water for extended periods. In 1927, Chalam found *An. stephensi* to remain viable in soil for up to 12 days, but this work has not been revisited since. Here, we evaluate whether *An. stephensi* eggs can resist desiccation and remain viable under a range of temperature, humidity, and temporal thresholds. Batches of ~200-400 eggs from two laboratory strains of *An. stephensi* (STE2 and SDA500) were placed in five environmental conditions mimicking a range of temperature (15°-35° C) and relative humidity (15-75+%) conditions in the Horn of Africa. Egg batches were hatched at 0, 7, 14, and 21 days and larval survival was measured. Under most conditions, no viable larvae emerged after 7 days in the absence of water. However, for both strains in multiple experimental replicates viable larvae were produced after 2 weeks in the absence of water in only one condition (15°C and >75% RH). This suggests that viable eggs may be transported in the absence of water through trade or commerce routes. Persistence of *An. stephensi* eggs in the absence of water should be considered as programs engage in surveillance and control of *An. stephensi* in Africa.

## 1014

### THE ROLE OF NUTRITION IN RESISTANCE AND TOLERANCE TO BACTERIAL INFECTION IN AEDES AEGYPTI MOSQUITOES

Dominique Magistrado, Sarah M. Short

The Ohio State University, Columbus, OH, United States

Mosquito immunity may be separated into two categories. 1) resistance: the ability to directly limit pathogen levels, and 2) tolerance: the ability to limit the deleterious effects of infection. Immune tolerance is a critical but relatively understudied defense strategy utilized by disease vector mosquitoes during infection. Further, factors that may influence tradeoffs in resistance and tolerance are not well understood. Here, we investigated the potential effect of nutrition on resistance and tolerance to a pathogenic strain of *E. coli* in *Aedes aegypti* mosquitoes. We exposed adult female *Aedes aegypti* mosquitoes to four different nutritional regimens that varied in 1) blood meal (presence or absence), and 2) sucrose (1% or 10%), in order to determine how a mosquito's adult diet may influence investment in resistance and/or tolerance. Using this study design, we can also determine whether blood and/or sugar feeding act independently or interact to influence tolerance and resistance. On days 1, 3, and 5 post-infection, we assessed population survival and accompanying average bacterial load by homogenizing and culturing mosquitoes then counting bacterial colony forming units. We built a generalized linear model using blood, sucrose, bacterial load, and time to predict probability of survival. Significant main effects are indicative of individual factors affecting resistance, while any significant interaction between a factor and bacterial load indicates that the factor

affects tolerance. We have collected data from multiple replicates and are actively performing analysis. Our preliminary data analysis reveals that sucrose concentration significantly impacts resistance. Specifically, we have discovered that exposure to 1% sucrose better equips a mosquito to resist *E. coli* infection. Further analysis to determine whether diet impacts tolerance is ongoing. Final results will reveal a previously unknown relationship (or equally important lack thereof) between a mosquito's diet and the balance between resistance and tolerance.

### EPIDEMIOLOGY OF VECTOR-BORNE AND NEGLECTED TROPICAL DISEASES ALONG THE TEXAS-MEXICO BORDER

Lauren M. Leining<sup>1</sup>, Rojelio Mejia<sup>1</sup>, Kristy O. Murray<sup>1</sup>, Eric L. Brown<sup>2</sup>, Sarah M. Gunter<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>University of Texas Health Science Center at Houston, Houston, TX, United States

Neglected tropical diseases (NTDs) are a group of parasitic and vector-borne infections that disproportionately affect the world's most impoverished populations. Although NTDs and vector-borne diseases have been previously identified in Texas, their prevalence and distribution are not well characterized. Autochthonous cases of Zika, dengue, and parasitic infections have been reported but are rare and often found in the southernmost part of the state near the US-Mexico border. Understanding the burden of vector-borne and parasitic diseases in Texas is critical for prevention, treatment, and control efforts. Our study aimed to determine the epidemiology of vector-borne and NTDs in a cohort of 610 Mexican American adults living in Starr County, Texas along the US-Mexico border. Starr County is the most impoverished county in the state with 32.5% living below the poverty line, putting them at increased risk for NTDs. Each member of the cohort was enrolled and followed for one year between 2018 to 2020, with serial serum samples collected to screen for chikungunya, dengue, West Nile, Zika, and Chagas disease. Stool samples were screened for *Ascariasis lumbricoides*, *Necator americanus*, *Trichuris trichiura*, *Toxocara canis and cati*, *Strongyloides stercoralis*, *Taenia solium*, *Cryptosporidium sp.*, *Entamoeba histolytica*, *Blastocystis spp.*, and *Giardia lamblia*. We tested serum collected at baseline, 3 months, 6 months, and 12 months for IgG reactivity to vector-pathogens. Helminth and protozoan pathogen testing was conducted using DNA extracted from baseline stool samples using multi-parallel qPCR. We found a seroprevalence of 1.0% for Chagas disease, 0.6% for chikungunya, 15.1% for dengue, 12.8% for West Nile, and 0.9% for Zika. We also identified *Blastocystis spp.* in stool samples. This is the first large-scale cohort study of vector-borne and neglected tropical diseases in this high-risk region. Our findings demonstrate these pathogens are endemic in Texas and could help inform public health response in the region.

1016

### GUT MICROBIOTA IN Aedes triseriatus CONTRIBUTES TO DETOXIFICATION OF TANNIC ACID

Shicheng Chen<sup>1</sup>, Ting Yu<sup>2</sup>, Edward Walker<sup>3</sup>

<sup>1</sup>Oakland University, Rochester, MI, United States, <sup>2</sup>Guangdong Academy of Agricultural Sciences, Guang Zhou, China, <sup>3</sup>Michigan State University, East Lansing, MI, United States

Larval *Aedes triseriatus* mosquitoes live in the water-filled containers where they utilize plant detritus as carbon sources. During the microbial decomposition of leaf litter in container aquatic habitats, the chemical alterations and microbial processing of leaf litter releases compounds such as tannins into the water column, which affects the mosquito output and mosquito vectorial capacity. We tested the hypotheses that tannic acid alters bacterial abundance and community structure in mosquito larval habitats and the specific mosquito-associated gut microbiota contribute to the detoxification of tannic acid. Addition of tannic acid at 0.35mg/ml in the microcosms caused up to 50% larval mortality compared to the negative control without tannic acid. Supplement with kanamycin and tannic acid in the microcosms led to 75% larval mortality compared

to the negative control, indicating that microbiota in the rearing system contribute to tannic acid detoxification. The bacteria in water column, on the leaf surfaces, in the larval and adult *A. triseriatus* midguts reared with or without tannic acid addition were studied by sequencing the V4 region of 16S rRNA genes. *Proteobacteria* and *Bacteroidetes* dominated the community [>86.8% of operational taxonomic units (OTUs)]; most taxa were assigned to *Pseudomonas*, unclassified *Enterobacteriaceae*, *Serratia* and *Flavobacterium*. Bacterial communities were significantly different in water column, on the leaf surfaces and in the larval midgut between control and tannic acid addition, indicating that tannic acid altered the microbial structures in mosquito rearing system. However, bacterial communities were similar in adult mosquito midgut fed with sucrose, showing that the microbiome reconstructed in the adult stage. The proportion of *Pseudomonas* unclassified *Enterobacteriaceae* and *Serratia* was significantly higher in water column, on the leaf surfaces and in larval mosquitoes in the tannic acid supplemented microcosms than that in the control without tannic acid addition, indicating that they possibly contributed to the detoxification of the tannic acid.

1017

### MATHEMATICAL MODEL OF THE TRANSMISSION FOR VISCERAL LEISHMANIASIS

Looli Mohamed Alawam Nemer<sup>1</sup>, Kristan Schneider<sup>2</sup>

<sup>1</sup>African Institute for Mathematical Science, Khartoum, Sudan, <sup>2</sup>Mittweida University, Mittweida, Germany

Visceral leishmaniasis (VL) or kala-azar is a protozoan disease caused by parasites of genus *Leishmania* that affects millions of people worldwide, with a fatality rate comparable to that of malaria. In 2015, the World Health Organization (WHO) classified VL as a neglected tropical disease (NTD) due to relatively minimal granted attention from the public, resulting in high mortality rates (more than 20,000 in 2015) and endemic spreading in poverty-stricken regions around the globe. VL is a vector-borne disease transmitted to humans through a bite of sandflies that have previously taken a blood meal from an infected reservoir host or an infected human. Importantly, VL is mainly caused by two kinds of *Leishmania* parasites, *Leishmania donovani*, and *Leishmania infantum*. After or during the treatment of VL, a varying proportion of cases develop a cutaneous form of leishmaniasis, known as post-kala-azar dermal leishmaniasis (PKDL). In this study, we present a predictive model to forecast the spread of VL in a human population, accounting for the effect of different interventions, the animal reservoir of the parasite, and the vector's population dynamics. The human population is subdivided into susceptible, early infectious, asymptomatic, infected-treated, infected untreated, temporarily immune, early infectious stage of post-kala-azar dermal leishmaniasis (PKDL), treated PKDL, untreated PKDL, and fully recovered individuals. The reservoir animal population is subdivided into susceptible, exposed (infected but not yet infectious), asymptomatic, and infected. The vector population is subdivided into susceptible, incubating, and infectious vectors. The model is exemplified using parameters from the literature based on the underlying biological features of the disease. We analytically calculate the effective reproduction number to investigate the parameter relevant to the disease transmission and control. In the simulation, we consider different scenarios of different interventions to examine which scenario eradicates the disease.

1018

### BRUGIA MICROFILARIAE ENHANCE DISSEMINATION OF ZIKA VIRUS INTO THE HEMOCOEL OF Aedes Aegypti MOSQUITOES

Jefferson Vaughan, Tyler Achatz, Kyle O'Donnell, Staci Dreyer, Kelsey Morin, Jakson Martens, Dawn Cleveland, David Bradley  
University of North Dakota, Grand Forks, ND, United States

Concurrent ingestion of microfilariae (MF) and arboviruses by mosquitoes can enhance the transmission of virus compared to when virus is ingested alone. After being ingested, MF penetrate the mosquito midgut and

introduce virus into the hemocoel, creating disseminated viral infections much sooner than normal. This is termed MF enhancement of arboviral transmission. We investigated *Brugia* MF enhancement of Zika viral dissemination within *Aedes aegypti* mosquitoes. Blood containing virus ( $9.5 \times 10^4$  PFU/ml) plus *B. pahangi* MF was membrane-fed to a batch of *A. aegypti*. Blood containing only virus ( $9.2 \times 10^4$  PFU/ml) was fed to another batch of *A. aegypti* mosquitoes. Mosquitoes in the virus + MF group ingested an average of 103 MF. After four days, the viral infection rate was significantly lower in mosquitoes fed virus + MF (38%, 25/65) versus mosquitoes fed virus-only (80%, 64/80). However, viral dissemination within the 25 infected mosquitoes fed virus + MF (28%, 7/25) exceeded that in the 64 infected mosquitoes fed virus-only (3%, 2/64). Earlier studies showed MF enhancement is facilitated by viral adherence to MF, and that MF transport virus across the mosquito midgut. To examine MF affinity to Zika virus, 5 ml of virus ( $5.7 \times 10^5$  PFU/ml) was split into two aliquots. Approximately 40,000 MF was added to one and an equivalent volume of diluent added to the other. After 1 h incubation, samples underwent 9 successive cycles of centrifugation and washing, diluting virus beyond the theoretical limit of detection. Residues were assayed for virus by plaque assay and mosquito injection. Plaque assay of the virus + MF residue detected virus at  $10^7$  dilution, whereas plaque assays of the virus-only residue detected virus at  $10^6$  dilution. Moreover, 4 of 29 mosquitoes (14%) injected with the virus + MF residue became infected with Zika virus, whereas none of 32 injected mosquitoes from the virus-only group became infected. This suggests that Zika virus adheres to *B. pahangi* MF and that during midgut penetration, *B. pahangi* MF carries Zika virus into the mosquito hemocoel. These studies provide another example of MF enhancement of arboviral transmission.

#### ANALYSIS OF DENV2 3'UTR RNA STRUCTURES REVEALS SPECIES-SPECIFIC ROLES IN FLAVIVIRAL BIOLOGY

Rita M. Meganck, Long Ping V. Tse, Ralph S. Baric

UNC Chapel Hill, Chapel Hill, NC, United States

The structured 3' UTR of flaviviral RNAs, which accumulates as the subgenomic flaviviral RNA (sfRNA), is involved in multiple virus-host interactions during infection. In the current study, we focused on the dumbbell (DB) RNA structures present in the 3'UTR/sfRNA. Previous work using the DENV2 3' UTR on a reporter mRNA demonstrated that the DB structures are the necessary and sufficient elements for RNA stability and translation. In the current study, we created DB mutants in the DENV2 infectious clone and successfully recovered infectious viruses. DB mutant viruses are attenuated in a cell-type specific manner, and some viruses are incapable of replication in mammalian cells, demonstrating a critical role in trans-species infection and replication. Interestingly, further passage of a DB-deleted DENV2 led to the appearance of a virus population with dramatically increased growth efficiency. Sequencing identified silent mutations in the coding region of the viral genome suggesting a role for RNA structures and possible long-range RNA interactions between the 3' UTR and coding regions. Because the 3' UTR multi-functional, we performed multiple experiments to tease apart the role of DB mutations in viral replication, genome stability, and viral translation and how these mutations differentially regulate growth in insect and mammalian cells. Overall, our study highlights the importance of the DB RNA structures in the viral genomic RNA independent of the sfRNA.

#### DENGUE KNOWLEDGE, ATTITUDES, AND PRACTICES: BASELINE DATA FROM THE COESA STUDY

Laura Pierce<sup>1</sup>, Monica Zahredine<sup>2</sup>, Kellyanne Abreu<sup>3</sup>, Mayana Azevedo Dantas<sup>3</sup>, Andrea Caprara<sup>3</sup>, Valéry Ridde<sup>4</sup>, Kate Zinszer<sup>2</sup>

<sup>1</sup>McGill University, Montreal, QC, Canada, <sup>2</sup>University of Montreal, Montreal, QC, Canada, <sup>3</sup>State University of Ceará, Fortaleza, Brazil, <sup>4</sup>Centre Population et Développement, Institut de recherche pour le développement, Université de Paris, Paris, France

The cluster randomized controlled trial COESA - Sustainable, healthy cities was designed to examine the impact of a community mobilization intervention compared to typical dengue control practices on the risk of dengue virus infection in young children. The study includes knowledge, attitude, and practice (KAP) surveys, which are commonly used in vector-borne disease research to determine acceptability of vector control interventions and identify potential barriers to care seeking. Despite the frequent use of KAP surveys in dengue studies, methods of analyzing this data are highly variable and often result in the loss of data complexity. Alternative analytic methods such as principal component analysis (PCA) and factor analysis can be used to retain the maximum variability in KAP data while reducing the data for use in further analyses. Baseline COESA survey responses were collected from 389 participating households in Fortaleza, Brazil in 2019-2020; survey topics included demographic characteristics and KAP related to dengue and dengue control. Descriptive statistics were calculated from the responses and analyzed thematically. PCA was used with factor analysis to validate the KAP portion of the questionnaire, and to create a reduced KAP index. Participants' survey responses reflected a broad understanding of dengue transmission, fever as a key symptom of dengue, and vector control practices. Participants were generally aware of the severity of dengue, but ambivalent about the capacity of the community to control dengue on their own. KAP was well represented in an index generated through PCA and factor analysis: 3 factors extracted from the KAP data explained 53.8% of the variance. Further regression-based analyses will include seroprevalence data from children in participating households. Despite limited sample size, the analysis allowed us to explore methodologies and provide feedback to the primary study investigators for guiding future research on KAP, and can help inform future planning, implementation, and evaluation of vector control interventions.

#### GENETICALLY ENGINEERED DENV PRODUCES ANTIGENICALLY DISTINCT MATURE PARTICLES

Longping V. Tse, Rita M. Meganck, Stephanie Dong, Lily E. Adams, Laura J. White, Aravinda M. deSilva, Ralph S. Baric  
University of North Carolina, Chapel Hill, NC, United States

Maturation of Dengue viruses (DENV) alters the structure, immunity and infectivity of the virion and highly mature particles represent the dominant form *in vivo*. The production of highly mature virions principally relies on the structure and function of the viral premature protein (prM) and its cleavage by the host protease furin. We developed a reliable clonal cell line which produces single-round mature DENVs without the need for DENV reverse genetics. More importantly, using protein engineering coupled with natural and directed evolution of the prM cleavage site, we engineered genetically stable mature DENVs without comprising viral yield and independent of cell, host, or passage. Using these complementary strategies to regulate maturation, we demonstrate that the resulting mature DENVs are antigenically distinct from their isogenic immature forms. Given the clinical importance of mature DENVs in immunity, our strategy provides a reliable strategy for the production of stable, high-titer mature candidate DENV live virus vaccines, genetically stabilized viruses for DENV maturation and immunity studies, and models for maturation-regulated experimental evolution in mammalian and invertebrate cells. Our data from directed-evolution across host species reveals distinct

maturation-dependent selective pressures between mammalian and insect cells, which sheds light on the divergent evolutionary relationship of DENVs between its host and vector.

### TRANSCRIPTOMIC PROFILES OF ACUTE DENGUE SPECIFIC CD8 T CELLS

Alba Grifoni<sup>1</sup>, Hannah Voic<sup>1</sup>, Alison Tarke<sup>1</sup>, Sunil Premawansa<sup>2</sup>, Gayani Premawansa<sup>3</sup>, Ananda Wijewickrama<sup>4</sup>, Alessandro Sette<sup>1</sup>, Daniela Weiskopf<sup>1</sup>

<sup>1</sup>La Jolla Institute for Immunology, La Jolla, CA, United States, <sup>2</sup>University of Colombo, Colombo 00300, Sri Lanka, Colombo, Sri Lanka, <sup>3</sup>North Colombo Teaching Hospital, Ragama 11010, Sri Lanka, Colombo, Sri Lanka, <sup>4</sup>National Institute of Infectious Diseases, Colombo, Sri Lanka

Accumulating evidence demonstrates that CD8 T cells contribute to protection from severe DENV disease. However, molecular programs associated with DENV-specific CD8 T cell in the acute phase of disease have not been defined. Here, we studied the transcriptomic profiles of human DENV-specific CD8 T cells isolated after stimulation with DENV epitopes from donors that have been admitted to the hospital with either the mild (dengue fever, DF) or severe form (dengue hemorrhagic fever, DHF) of dengue disease and compared the profiles of DENV-specific CD8 T cells from the same donor in convalescent phase of disease. Analyses of these data suggest that while both antigen stimulation and time from infection are associated with clear transcriptomic changes, disease severity is not. This study provides the first transcriptomic analysis of DENV-specific CD8+T cell responses in acute disease demonstrates that there are no qualitative differences as drivers of disease severity.

1023

### IDENTIFICATION OF DISTINGUISHING CLINICAL FEATURES OF COVID-19, DENGUE, AND INFLUENZA AMONG ADULTS PRESENTING TO EMERGENCY DEPARTMENTS AND URGENT CARE CLINICS — PUERTO RICO, 2012-2021

Joshua M. Wong<sup>1</sup>, Hannah R. Volkman<sup>1</sup>, Laura E. Adams<sup>1</sup>, Carene Oliveras Garcia<sup>2</sup>, Alma Martinez-Quinones<sup>1</sup>, Janice Perez-Padilla<sup>1</sup>, Jorge Bertran-Pasarell<sup>3</sup>, Diego Sainz de la Peña<sup>3</sup>, Vanessa Rivera-Amill<sup>2</sup>, Gabriela Paz-Bailey<sup>1</sup>

<sup>1</sup>Dengue Branch, Division of Vector-Borne Diseases, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States, <sup>2</sup>Ponce Health Sciences University/Ponce Research Institute, Ponce, PR, United States, <sup>3</sup>Auxilio Mutuo Hospital, San Juan, PR, United States

Dengue, influenza, and SARS-CoV-2 are pathogens of global concern and can present with similar signs and symptoms. Healthcare providers in low-resource settings often make a presumptive diagnosis in the absence of virologic testing. In Puerto Rico, an enhanced surveillance system operating from three emergency departments in southern Puerto Rico and San Juan and an urgent care clinic in Ponce has collected information on signs and symptoms, clinical laboratory results, and blood and nasopharyngeal specimens for pathogen identification from enrolled participants with fever since January 2012, and fever or symptoms of acute respiratory infection since March 2020. We analyzed data from 13,431 adults with polymerase chain reaction confirmed dengue (n=276), influenza A/B (n=2,064), or SARS-CoV-2 (n=303) enrolled from May 2012-January 2021 and assessed symptoms, laboratory results, and days post illness onset (DPO) until presentation. We adjusted for age, region, and DPO and calculated adjusted odds ratios (aOR) and 95% confidence intervals (CI) using logistic regression for clinical characteristics of participants with COVID-19 compared to dengue or influenza. Median DPO was shortest for influenza (2 days; interquartile range [IQR] 1-3), and dengue (3 days; IQR 2-4), and longest for COVID-19 (4 days; IQR 2-7), p<0.01. Cough (aOR 8.4; 95% CI 5.2-13.5) and shortness of breath (aOR 5.5; 95% CI 2.3-13.2) were associated with a diagnosis of COVID-19 compared to dengue. Facial flushing (aOR 20.6; 95% CI 9.8-43.5) and thrombocytopenia (aOR 24.4;

95% CI 13.3-45.0) were associated with dengue compared to COVID-19. Runny nose was associated with influenza compared to COVID-19 (aOR 8.3; 95% CI 5.8-12.1). Symptoms and laboratory findings at presentation can assist clinicians in assessing the likelihood of dengue or COVID-19. Although few symptoms clearly distinguish influenza from COVID-19, patient presentation >4 days after symptom onset might suggest COVID-19. These findings may assist healthcare providers in making time-sensitive decisions related to triage, isolation, and management while pursuing pathogen-specific testing.

1024

### SEROPREVALENCE OF DENGUE AND ZIKA VIRUSES IN A COMMUNITY-BASED COHORT STUDY IN SOUTHERN PUERTO RICO

Laura E. Adams<sup>1</sup>, Dania M. Rodriguez<sup>1</sup>, Stephen S. Whitehead<sup>2</sup>, Liliana Sanchez-Gonzalez<sup>1</sup>, Freddy A. Medina<sup>1</sup>, Jorge L. Munoz-Jordan<sup>1</sup>, Vanessa Rivera-Amill<sup>3</sup>, Gabriela Paz-Bailey<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, San Juan, Puerto Rico, <sup>2</sup>National Institutes of Health, Bethesda, MD, United States, <sup>3</sup>Ponce Health Sciences University/Ponce Research Institute, Ponce, Puerto Rico

Limited dengue virus (DENV) and Zika virus (ZIKV) seroprevalence estimates are available for Puerto Rico, which are needed to inform the potential use of DENV vaccines. A DENV vaccine has been approved but not yet implemented for children 9-16 years old living in endemic areas of the United States who had a previous DENV infection. The last DENV outbreak in Puerto Rico occurred in 2013, followed by a chikungunya outbreak in 2014 and a ZIKV outbreak in 2016. Communities Organized to the Prevent Arboviruses (COPA) is a cohort study initiated in 2018 in Ponce, Puerto Rico, to assess arboviral disease risk and provide a platform to evaluate interventions. We recruited participants aged 1-50 years from households in 38 study clusters. Participants are interviewed and provide a blood specimen annually. Specimens from the first year of COPA were tested for the 4 DENV serotypes and ZIKV using a plaque reduction neutralization assay (PRNT). Neutralizing antibody titers (PRNT50) positive at serum dilutions greater than 1:10 against DENV 1-4 or ZIKV were considered indicative of a previous infection. We used preliminary data to assess the seroprevalence of DENV and ZIKV by age. During 2018-2019, 4,090 participants were enrolled and serology results are available for 552 participants aged 1-16 years. Overall, 49% (n=271) were seropositive for DENV; seroprevalence was 21% (29/138) among children 1-8 years old and 58% (242/414) among children 9-16 years old. Overall, 37% (n=203) had neutralizing antibodies against more than one DENV serotype. A total of 36% were seropositive for ZIKV, including 20% among children 0-8 years old and 41% among children 9-16 years old. Less than half (46%) were negative for both flaviviruses. In this sample of children 1-16 years old in Puerto Rico, about half had evidence of a previous DENV infection and more than one-third with previous ZIKV infection, with increasing seroprevalence by age. These preliminary DENV seroprevalence data from southern Puerto Rico suggest moderate transmission intensity as defined by WHO.

1025

### DENGUE VIRUS INFECTION LOWERED THE PERCENTAGE OF ATYPICAL MEMORY B CELLS IN KENYAN CHILDREN

David M. Vu<sup>1</sup>, Sangeeta Kowli<sup>1</sup>, Francis M. Mutuku<sup>2</sup>, Amy R. Krystosik<sup>1</sup>, Jael S. Amugongo<sup>3</sup>, Said L. Malumbo<sup>3</sup>, Phillip K. Chebii<sup>4</sup>, Priscillah W. Maina<sup>3</sup>, Holden T. Maecker<sup>1</sup>, A. Desiree LaBeaud<sup>1</sup>

<sup>1</sup>Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Vector Borne Disease Control Unit, Msambweni, Kenya, <sup>4</sup>Msambweni County Referral Hospital, Msambweni, Kenya

Expansion of the peripheral blood atypical memory B cell (aMBC) population has been reported in residents of areas with high endemic malaria transmission and has been associated with chronic malaria exposure. Much remains unknown regarding the prevalence and clinical

impact of this phenomenon, particularly in children. From April to May 2018, we surveyed the composition of peripheral B cells in a cross-section of children residing in Kwale County, Kenya, a coastal area with high endemic transmission of *P. falciparum* malaria. We recruited 33 subjects (median age 5.4 years, IQR 4.3-9.4) who had enrolled in a previous study during a febrile illness. Malaria testing by light microscopic exam of peripheral blood smears, and dengue virus RNA detection by RT-PCR, were performed at the time of the febrile illness. 6 subjects (18%) had dengue virus detected in blood, 13 subjects (39%) had malaria, and 3 of these subjects were infected with both malaria and dengue virus. Blood samples for the present study (U24 A1118648) were collected at a median of 18 weeks (IQR 14.1-50.3) later, and phenotypically characterized using mass cytometry. Overall, CD27<sup>+</sup>CD21<sup>+</sup> aMBCs comprised 39.5 ±12% (mean ±SD) of peripheral CD19<sup>+</sup> B cells, while CD27<sup>+</sup>CD21<sup>+</sup> classical MBCs made up 5.9 ±2.9%. CD27<sup>+</sup>CD21<sup>+</sup> activated MBCs made up 6.3 ±3.3%, and CD27<sup>+</sup>CD21<sup>+</sup> naïve B cells made up 48.3 ±12%. Correlation matrix did not reveal significant associations ( $p < 0.05$ ) between the magnitude of the aMBC fraction and age, sex, length of the interval between febrile illness and blood collection for phenotyping, or malaria parasitemia at the time of the previous febrile illness. Curiously, dengue viremia, but not coinfection with malaria and dengue, correlated with lower percentage of aMBCs (Pearson's coefficient -0.43,  $p = 0.013$ ). A linear regression model predicted that dengue virus viremia lowered the aMBC population by 13.1% ( $p = 0.014$ ). The unanticipated association between dengue virus infection and lower aMBC frequency highlights the need to consider the potential effects of multiple exposures to endemic or epidemic infections when investigating human immunity.

1026

#### SAMPLE-SPARING MULTIPLEX SEROLOGIC ASSAY TO DETERMINE FLAVIVIRUS INFECTION HISTORY

**Lindsay Carvalho Dahora**, Bruno Segovia-Chumbez, Salman Khan, Aravinda de Silva, Premkumar Lakshmanane

*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Accurate serodiagnosis of past flavivirus infection is exceedingly difficult due to significant cross-reactivity in the antibody response across flaviviruses, especially in urban settings supporting the cocirculations of multiple flaviviruses. Here, we used a structure-based approach and identified flavivirus-specific epitopes on the envelope protein domain 3 (EDIII) to develop a microsphere bead-based multiplex assay for simultaneously measuring antigen-specific antibodies to multiple flaviviruses. We expressed and purified EDIII antigens from Zika virus, the four serotypes of the dengue viruses, and yellow fever virus in mammalian cells. The recombinant antigens were produced as fusion proteins with self-labeling protein (SLP) to attach a single biotin molecule at a distant site from EDIII. Using this strategy, we were able to control the orientation of EDIII antigens binding to the surface of avidin-coated microspheres. Using this approach, we were able to detect flavivirus-specific antibody concentrations as low as 100 pg/mL in our multiplex assay. When the multiplex assay was used to test a panel of convalescent sera from individuals with neutralizing antibody to just one flavivirus (primary immunity to DENV1-4, ZIKV or YFV), the binding signals were strongly correlated with neutralizing antibody profiles. These data suggest that our antigen panel and assay format is able to accurately establish primary infection history with late convalescent human samples with less than 1/50th of a microliter of sample. Studies are currently in progress to define the performance of the assay for defining exposure to two or more different flaviviruses or flavivirus vaccines.

1027

#### EVOLUTION AND GENOMIC EPIDEMIOLOGY OF DENGUE VIRUS IN RURAL AND URBAN COMMUNITIES IN KENYA

**Sindiso Nyathi**<sup>1</sup>, Francis Mutuku<sup>2</sup>, Bryson Ndenga<sup>3</sup>, Katharine Walter<sup>1</sup>, Jason Andrews<sup>1</sup>, Shannon Bennett<sup>4</sup>, A. Desiree LaBeaud<sup>1</sup>

*<sup>1</sup>Stanford University, Stanford, CA, United States, <sup>2</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>4</sup>California Academy of Sciences, San Francisco, CA, United States*

Dengue is a mosquito-transmitted viral infection that poses a significant public health risk, particularly in developing countries. The causative agent, dengue virus (DENV), is an arbovirus whose geographic range covers 128 countries across tropical and subtropical regions of the world, making it the most common human mosquito-transmitted viral disease. Despite the increasing burden of dengue in Kenya, the influences of the virus' evolution, and their interplay with population and global-level factors have not been examined. The objective of this study is to assess the genetic structure of circulating dengue virus and evaluate the extent of gene flow across Kenya as well as migration from outside Kenya. Blood samples from a cohort of acutely ill patients recruited from 4 clinical sites in western and coastal Kenya between 2014 to 2018 were collected and preserved in *Trizol* reagent. Viral RNA was isolated and high sensitivity reverse transcriptase PCR was conducted to test for the presence of dengue virus. Genomic material obtained from DENV positive samples was enriched using a multiplex, tiled-amplicon enrichment protocol with custom primers and complete viral genomes for phylogenetic analysis were obtained via next generation sequencing. 7,563 total patients were recruited into the acutely ill cohort between 2014 and 2018. Of the 2,547 blood samples available for analysis in the study biobank to date, 256 samples were tested for viral presence, and 32 had dengue virus Ct values suitable for sequencing. Preliminary viral sequencing results suggest the circulation of Genotype-II lineage of DENV-2. The evolutionary characteristics of infectious agents like dengue virus drive disease dynamics, and modern advances in genomics and computation allow researchers to model these evolutionary and disease dynamics. Inferences from these models can inform disease preparedness measures in advance of outbreaks, as well as intervention measures during outbreaks, making them invaluable to policy makers.

#### EVALUATING VIRAL GENOMICS AND DISEASE SEVERITY USING NANOPORE SEQUENCING: A PROOF-OF-CONCEPT ANALYSIS

**Beatriz Carvalho Marques**<sup>1</sup>, Darlan Silva Candido<sup>2</sup>, Cassia Fernanda Estofolete<sup>1</sup>, Lívia Sacchetto<sup>1</sup>, Karina Rocha Dutra<sup>1</sup>, Flávia Salles<sup>3</sup>, Fernanda Simões Dourado<sup>1</sup>, Ester Cerdeira Sabino<sup>1</sup>, Nuno Faria<sup>4</sup>, Maurício Lacerda Nogueira<sup>1</sup>

*<sup>1</sup>School of Medicine of Sao Jose do Rio Preto, São José do Rio Preto, Brazil, <sup>2</sup>University of Oxford, Oxford, United Kingdom, <sup>3</sup>Institute of Tropical Medicine - University of São Paulo, São Paulo, Brazil, <sup>4</sup>University of Oxford, Oxford, Brazil*

Dengue virus genetic variability provided the heterogeneity of circulating strains in the population, leading to the circulation of different genotypes and an increase in the number of existing strains that may have differences in the potential to cause epidemics. The high genetic variability and the evolution of the disease to lethal forms represent a severe threat to the population, and accurate identification of the genetic variability of the virus is essential to understand the processes of dispersion and virulence, as well as the identification of a variant gene responsible for an epidemic. In 2019, the Brazilian Southeast region reported 65.7% of all dengue cases identified in Brazil, and São José do Rio Preto, located in the northeast of São Paulo state, confirmed 32,727 cases, among 400,856 in the state. Here, we characterize, using a Nanopore portable genomic approach, the genetic diversity of DENV-2 detected in 22 serum samples obtained from patients with infection classified as dengue without warning signs and dengue with warning signs attended at Hospital

de Base of São José do Rio Preto in 2019, during a dengue outbreak. Demographic, epidemiological, and clinical data (symptoms and radiologic and laboratory observations) were also analyzed. The phylogenetic reconstruction and the clinical data showed that in São José do Rio Preto there are the circulation of two strains belonging to the American/Asian genotype of DENV-2: BR3 and BR4 (BR4A and BR4B), these results indicate that we cannot differentiate dengue samples without warning signs from dengue samples with warning signs, since the analyzed samples were grouped with other samples from different DENV-2 lineages. In addition, through this work, it can be proved that the sequencing platform Nanopore Minlon can be used as a methodology for monitoring viral strains during an epidemic.

### MODELLING THE HETEROGENEITY IN DENGUE TRANSMISSION INTENSITY IN SRI LANKA USING AGE-SPECIFIC CASE SURVEILLANCE DATA

Nayantara Wijayanandana<sup>1</sup>, Christian Bottomley<sup>1</sup>, Hasitha Tissera<sup>1</sup>, Henrik Salje<sup>2</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Cambridge University, Cambridge, United Kingdom

The first dengue cases in Sri Lanka were reported in Colombo, the capital of Sri Lanka in 1962. Since then, it has expanded to, and become established in, other districts following human movement patterns. Colombo has also had the highest incidence of dengue compared to other districts to date. We used dengue case data from the national surveillance system to assess the spatio-temporal heterogeneity of dengue transmission within Sri Lanka by estimating transmission intensity from age-specific incidence profiles in Colombo and other districts where dengue has appeared later; namely Batticaloa district in the east and Kurunegala district in the centre. A catalytic model was fitted to single year age-stratified case incidence data in these three districts for the years 2010-2015, and then separately for 2000-2016 for Colombo. We estimated the force of infection ( $\lambda$ ), the basic reproduction number  $R_0$ , and probabilities of case detection for primary, secondary, and post-secondary infections and compared age specific reporting for above and below 15 years. Many studies have estimated  $\lambda$  using seroprevalence data, but such data is scarce in Sri Lanka to obtain district level estimates and estimate the spatial heterogeneity across the country. This method, using incidence data, will be expanded to obtain estimates for other districts using aggregate data. Understanding the spatial heterogeneity in dengue transmission intensity can help inform which populations and areas to target in a dengue vaccination strategy.

### COMPREHENSIVE MUTAGENESIS OF DENGUE VIRUS ENVELOPE PROTEINS TO MAP ANTIBODY EPITOPES AND IDENTIFY RESIDUES ESSENTIAL FOR FUNCTION

Edgar Davidson, J. Tabb Sullivan, Jen M. Pfaff, Ariadna Grinyo, Mallorie E. Fouch, Benjamin J. Doranz

Integral Molecular, Inc., Philadelphia, PA, United States

To characterize the immune response to dengue virus (DENV) infection, we have epitope mapped over 200 anti-DENV monoclonal antibodies (MAbs), using high-throughput, rapid screens of MAb binding to DENV prM/E comprehensive mutation libraries for all four DENV serotypes, 3,380 mutations in total. Each library of individual mutant expression plasmids was transfected into human cells to achieve native protein expression and folding, and immunoreactivity of MAbs to each individual prM/E variant was quantified by high-throughput flow cytometry. The epitopes obtained were both conformational (including quaternary) and non-conformational, were spread across prM and E domains I-III, and many have been correlated with their abilities to protect against DENV infection. A number of anti-DENV MAbs cross-reacted with ZIKV prM/E, predominantly within the fusion loop but also within Domain II of the E protein, identifying critical immunogenic residues shared by DENV and ZIKV. We have also

produced DENV virions from all four DENV mutation libraries using a previously developed DENV reporter virus particle (RVP) system, allowing us to screen each individual DENV Env variant protein for DENV particle budding and infectivity. For DENV3, we identified residues whose mutation eliminated virus infectivity but did not impact E protein expression, antigenicity, virion assembly, or particle budding. We identified variants that showed increased DENV virion budding, up to 5-fold above wild-type, indicating the ability to engineer highly expressed, non-infectious DENV variants for use in vaccine design. From these experiments, we have identified neutralizing epitopes in DENV prM/E and specific sites that are critical for DENV infectivity, providing new targets and opportunities for vaccine development. To identify uncharacterized DENV cellular receptors we assayed wild-type DENV RVP infectivity in non-permissive cells expressing our membrane proteome array (MPA) of 6,000 unique human membrane proteins. This has identified candidate membrane proteins that enable DENV infectivity.

### DIFFERENTIALLY EXPRESSED PROTEOMICS PROFILING IN DENGUE REVEALS MULTIPLE UPREGULATION OF INFLAMMATORY PATHWAYS

Fadel Muhammad Garishah<sup>1</sup>, Collins K. Boahen<sup>1</sup>, Nadira Vadaq<sup>1</sup>, Silvita F. Riswari<sup>1</sup>, Setyo G. Pramudo<sup>2</sup>, Rahajeng N. Tunjungputri<sup>2</sup>, Bacht Alisjahbana<sup>3</sup>, Muhammad H. Gasem<sup>2</sup>, André J. van der Ven<sup>1</sup>, Quirijn de Mast<sup>1</sup>

<sup>1</sup>Radboud University Medical Center, Nijmegen, Netherlands, <sup>2</sup>Center for Tropical and Infectious Diseases, Faculty of Medicine Diponegoro University, Dr. Kariadi Hospital, Semarang, Indonesia, <sup>3</sup>Clinical Infectious Disease Research Center, Faculty of Medicine Universitas Padjadjaran, Bandung, Indonesia

Severe dengue is characterized by detrimental inflammation with cytokine storm which jeopardizes endothelial lining integrity leading to multiple complications. The pathogenesis of dengue-associated inflammation and plasma leakage remains incompletely understood. Therefore, a deep understanding of inflammatory proteins regulation during dengue virus infection (DENV) is an important step towards a proper development of diagnostic, and therapeutic measures. We analyzed acute dengue samples (N=43), paired convalescent samples (N=35) and adult healthy volunteers (N=10) using a 386 targeted extensive inflammatory panel from Olink Proteomics AB to determine the differentially expressed proteins (DEPs) and the inflammatory pathways. Our results demonstrated that dengue patients exhibited 242 DEPs consisted of 203 upregulated and 39 downregulated proteins from paired acute vs convalescent samples (N=35). We further validated our finding by comparing acute dengue patients (N=43) versus adult healthy controls (N=10) and demonstrated 219 DEPs consisted of 204 upregulated and 15 downregulated proteins. Next, to further understand the biological relevance of these inflammatory proteins, we stratified the functions of these DEPs using STRING database and observed 7 major important pathways including interferon-gamma (IFNG) pathway, endothelial related markers, dendritic cell and macrophage activation, natural killer cell activation, B-cell activation, chemotaxis pathway and tumor-necrosis factor (TNF) pathway. Several differentially expressed proteins that were unreported previously such as TRIM21, ESM1, GPB2, LAMP3, SIGLEC1, MZB1, CRIM1, CDON and TNFSF11 suggesting the activation of both innate and adaptive antiviral responses. Taken together, our findings provided both validation and novel findings in term of inflammatory host-response against DENV infection.

### LONGITUDINAL ASSESSMENT OF DENGUE 1-SPECIFIC HUMORAL IMMUNE MEMORY IN HUMAN COHORTS FOLLOWING DENGUE-1 INFECTION IN BOTH ENDEMIC AND NON-ENDEMIC TRANSMISSION SETTINGS

Zoe L. Lyski<sup>1</sup>, Brian L. Booty<sup>2</sup>, Luisa I. Alvarado<sup>3</sup>, Rachel M. Rodriguez<sup>3</sup>, Vanessa Rivera-Amill<sup>3</sup>, William B. Messer<sup>1</sup>

Dengue virus (DENV) is one of the most important vector-borne viral pathogen effecting humans worldwide. Following DENV infection, naïve host B-cells expand, produce, and secrete DENV-specific antibodies (Abs) that recognize viral antigens, specifically epitopes present on the surface of virions and secreted non-structural protein 1 (NS1). After viral clearance, some of these B-cells become antibody secreting long-lived plasma cells (LLPC), while others become memory B cells (MBCs) that remain in circulation, poised to expand on repeat infection. This MBC "founder" population is expected to play a critical role in broader DENV immunity that is established following second DENV infection. Here we quantify DENV-specific MBCs in humans following DENV-1 infection in a longitudinal manner. Using peripheral blood mononuclear cells (PBMCs) from DENV-1 immune donors from endemic (n=15) and non-endemic (n=24) cohorts with times post infection ranging from <1-43 years, we use two complimentary approaches to quantify the MBC population. PBMCs were stimulated *in vitro* to become antibody-secreting cells and the resulting antibodies assessed for DENV-specificity by ELISA. Additionally, a flow cytometry approach was utilized to quantify human MBCs (CD3-CD14-CD19+CD27+IgD-) that directly bind fluorescently labeled DENV. These DENV-specific MBCs can be single cell sorted, screened for functional properties of interest and cloned for monoclonal antibody (mAb) production or sequenced with full isotype resolution using the 10X genomics platform. Using these approaches, we identified DENV-whole virus and NS1-specific MBCs that remain in circulation decades after infection with varying frequencies in subjects from both endemic and non-endemic transmission settings. These experiments lay the foundation to characterize the DENV-specific MBC repertoire overtime and functionally assess the Abs they are programmed to secrete. The results of this project will provide insight into the MBC founder population following DENV infection in boosting and non-boosting environments.

### DEVELOPMENT OF THE INBIOS NORO DETECT™ A LATERAL FLOW IMMUNOASSAY (LFI) FOR MULTIPLEX DETECTION OF NOROVIRUS GENOGROUPS I, II AND IV

Brianda Santos, Jean Chen, Lihong Li, Scott Delbecq, Syamal Raychaudhuri, Aarthi C. Vallur

InBios International Inc, Seattle, WA, United States

Noroviruses (NoV) are the leading cause of acute viral gastroenteritis. In the US, an annual incidence of 19-21 million infections is reported with 2.3 million seeking medical care. NoV caused 58% of food-borne illnesses in the US at a cost of \$2 billion annually. Children under 5 and the elderly are at high risk for severe symptoms and death. NoV spreads easily in contact clusters and about 2500 outbreaks are reported annually. Prevention and early detection are the only measures to control outbreaks. Though there are ten genogroups of NoV, outbreaks are attributed mostly to GI/ GII and GIV, rarely. The ideal detection tool will be useful in near patient settings and sensitive for early detection of suspected genogroups. The gold standard for the detection of NoV is RT-PCR of fecal samples. Though sensitive and specific, RT-PCR is not applicable in near patient settings or during outbreaks when rapid diagnosis is necessary. The only FDA cleared device is the RIDASCREEN®Norovirus EIA, which detects NoV antigens but it is not intended for diagnostic use. To fill the gap in NoV diagnostics, we developed the InBios Noro Detect™, a LFI cassette for rapid, sensitive, and specific detection of GI, GII and GIV NoVs from fecal

swabs suitable in near patient settings. The LFI incorporates pan- NoV reactive antibodies raised using virus like particles (VLPs). In preliminary studies, the LFI could detect 5 GI, 8 GII and a GIV NoVLPs including known and suspected causes of outbreaks, at the level of  $\leq 10$  ng when spiked in fecal samples. The LFI is amenable for use with direct application of fecal swabs without the need for additional sample processing. This will allow safe handling of infected samples and improve utility for rapid detection. Direct application resulted in a LOD of 6-12 ng/mL on average for GI and GII VLPs compared to 10-15 ng/mL for pre- solubilized sample. Notably, for GII.4 which is associated with most outbreaks, direct sampling yielded a LOD of 3 ng/mL, by far the most sensitive detection of this important NoV. With planned development and FDA clearance, the InBios Noro Detect™ will be the first test to offer rapid, near patient diagnosis of NoV.

### EVIDENCE OF RIFT VALLEY FEVER VIRUS CIRCULATION IN CATTLE PARKS IN SLAUGHTERED OF MAN DISTRICT (CÔTE D'IVOIRE)

Clémence Konan Adjoua Rose Marie Kouassi<sup>1</sup>, Négnorogo Guindo-Coulibaly<sup>2</sup>, Valery E. Adjogoua<sup>3</sup>, Yannick K. Konan<sup>4</sup>, Sylla Yahaya<sup>3</sup>, Yahaya Karamoko<sup>5</sup>, Hortense Kette-Faye<sup>3</sup>

<sup>1</sup>Nangui Abrogoua University/Institut Pasteur Côte d'Ivoire, Abidjan, Côte d'Ivoire, <sup>2</sup>Cocody University, Abidjan, Côte d'Ivoire, <sup>3</sup>Institut Pasteur Côte d'Ivoire, Abidjan, Côte d'Ivoire, <sup>4</sup>Cocody University/Institut Pasteur Côte d'Ivoire, Abidjan, Côte d'Ivoire, <sup>5</sup>Nangui Abrogoua University, Abidjan, Côte d'Ivoire

Rift Valley Fever Virus is a viral zoonosis caused by an arbovirus transmitted by Culicidae. This arbovirus can seriously affect different species of domestic ruminants, causing severe outbreaks, economic losses and humans' mortality. This study was designed to investigate RVFV infection in cattle and mosquito in the slaughterhouse of Man city, western Côte d'Ivoire. Blood samples were collected from two cattle parks during dry seasons. Mosquito were collected during rainy and dry seasons. Mosquitos were trapped using six light traps, installed in general at 6:00 pm and visited the following morning at 6:00 am during four consecutive days. Molecular diagnosis of RVFV was carried out by real-time RT-PCR with specific primers; Forward: 3'-TGAAAATTCCTGAGACACATGG-5', Reverse: 3'-ACTTCCTTGCATCATCTGATG-5' and Probe: FAM -CAATGTAAGGGCCCTGTGGACTTGTG-TAMRA for L segment. Blood samples were analysed for RVF IgM and IgG detection using Enzyme-Linked immunosorbent assay. Forty blood samples from animals and 634 adults mosquitoes belonging to five species: *Anopheles gambiae* (1.7%), *Culex cinereus* (6.6%), *Culex quinquefasciatus* (91%) *Culex nebulosus* (0.5%) and *Mansonia* sp. (0.2%) were collected. No IgG and IgM antibodies against RVFV were found in any of 40 sera. More than 70% of *Culex quinquefasciatus* regardless of site and season was observed. RVFV was successfully detected in 50% of *Culex cinereus*' pools and 6% of *Culex quinquefasciatus*' pools. In conclusion, this study diagnosed for the first time RVFV from mosquito in western country. It was found in *Culex* (*Culex quinquefasciatus* and *Culex cinereus*) which represents the most abundant genera in study site.

### ASSESSING THE EFFECTS OF MEASLES INFECTION ON CHILDHOOD INFECTIOUS DISEASE MORTALITY IN BRAZIL AND THE U.S.

Siyang Xia<sup>1</sup>, Cricket C. Gullickson<sup>2</sup>, C. Jessica E. Metcalf<sup>2</sup>, Bryan T. Grenfell<sup>2</sup>, Michael J. Mina<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Princeton University, Princeton, NJ, United States

Despite an effective vaccine, measles infections remain a public health concern globally, causing hundreds of thousands of deaths each year, predominately in children. A danger of measles infection stems from its facilitation of other infections. By damaging preexisting immunological memory through the infection of immune memory B, T, and plasma

cells, the measles virus causes “immune amnesia” that increases one’s susceptibility to other infections, potentially for years. This effect can lead to a positive association between measles and other infectious diseases in epidemiological records. Examining this hypothesis in distinct settings could help evaluate measles’ contribution to childhood infectious disease burdens. Here, we analyzed the annual mortality of children age 1-9 in Brazil from 1980 to 1995 and children age 1-4 in the U.S. from 1921 to 1937. In Brazil, linear regressions between annual non-measles infectious disease mortality (e.g., respiratory and diarrheal diseases) and measles mortality showed a high correlation ( $R^2=0.944$ ). This correlation could be confounded by a general decrease of all-cause mortality across years that reflects overall improvements in healthcare. To control that, we 1) modeled the time trends using change-point analyses and extracted residuals of mortality (i.e., “detrrending”), and 2) calculated mortality differences between every two consecutive years (i.e., “difference”). With both methods, in Brazil, measles mortality remained significantly positively correlated with non-measles mortality (detrrending  $R^2=0.523$ , difference  $R^2=0.700$ ). Similar results were also observed separately in São Paulo and Rio de Janeiro. In the U.S., although original mortality data showed a low correlation ( $R^2=0.088$ ), removing time trends revealed significant correlations between measles and non-measles mortality (detrrending  $R^2=0.304$ , difference  $R^2=0.459$ ). These results support that measles dynamics partially drove the variations of other infections, and emphasize the disproportionate benefits of measles vaccination in reducing childhood infectious disease mortality.

#### EMERGING ROUTE OF SARS-COV-2 IN BANGLADESH: AN IN-SILICO APPROACH

**Md. Mahmudul Hasan**, Dipok Kumer Shill  
*University of Dhaka, Dhaka, Bangladesh*

Severe acute respiratory syndrome coronavirus-2, the etiological factor behind coronavirus disease 2019 (CoVID-19), has afflicted most countries and territories of the globe - infecting millions followed by the extirpation of hundreds of thousands. Commensurate with what is perceived as the race of sequencing and annotating the coronavirus genome, a number of research institutions hailing from Bangladesh have delved deep into this matter - having sequenced a good few isolate of the virus collected from Bangladesh. Here, we performed comparative analysis of publicly available 1254 ‘Spike Protein’ sequences derived from submitted Bangladeshi sequences. Phylogenetic analysis presumably revealed that the virus gained entrance to Bangladesh from multiple countries. The viruses isolated from Chattogram were closely related to strains from Saudi Arabia whereas those in Sylhet were similar to those from United Kingdom and South Africa. Missense mutations mostly had weak effects on the pathogenesis. Molecular docking analysis to evaluate the effect of the mutations on the interaction between the viral spike proteins and the human ACE2 receptor, though no significant difference was observed. This study provides some preliminary insights into the origin of Bangladeshi SARS-CoV-2 isolates, mutation spectrum and a possible emergence of Bangladeshi strain.

1037

#### DEVELOPMENT AND APPLICATION OF IMMUNO-FOCUS-BASED MICRO ASSAYS TO MEASURE INFECTIOUS BETACORONAVIRUS AND INFLUENZA A VIRUS UNDER BIOSAFETY LEVEL-2 CONDITIONS

**W. W. Shanaka I. Rodrigo**, Natasha Virjee, Christopher Hsiung, Margaret Cotton, Matthew Hardwick  
*ResInnova Laboratories, Silver Spring, MD, United States*

Infections with enveloped, RNA respiratory viruses, such as the current pandemic Betacoronavirus, severe acute respiratory syndrome coronavirus-2 (SARS-CoV2), and seasonal Influenza A viruses are significant global health threats. In the wake of this pandemic, numerous exposure-prevention and therapeutic technologies have been developed, such as metal ion-embedded surface materials, disinfectants, germicidal

Ultraviolet light-emitting devices, antiviral drugs, and vaccines. However, the field is hampered by the lack of rapid, and reliable *in vitro* bioassays that can measure infectious virus particles in a high or semi-high throughput manner within safe biosafety level (BSL)-2 facilities. Such assays are essential for evaluating the efficacy of antiviral and infection prevention technologies. *In vitro* assays with SARS-CoV2 require high-containment BSL-3 facilities, are costly, unsafe, and limited to developed countries. To this end, we adapted simple, efficient, and robust cell line-based assay platforms, based on previously published assays for dengue viruses (Rodrigo, W. W. S. I. et al., *Am. J. Trop. Med. Hyg.* 2009 Jan; 80(1): 61-5. PMID: 19141841), employing a Betacoronavirus (HCoV-OC43) and Influenza A virus [A/PR/8/34 (H1N1)] that may be performed within BSL-2 facilities. These immuno-focus/spot-based quantitative assays were compared to classical plaque assay methodologies. We used human RD cells for HCoV-OC43 and MDCK cells for the Influenza A virus. We further optimized various cell- and virus-based assay parameters including the cell integrity, focus staining, various testing methodologies, signal-to-noise ratio, linearity, detection limits and robustness. Our new methodology is rapid (detection within 16-24 hours), may be miniaturized from 24-wells to 96-wells, and is easily adapted to various test articles, methodologies, cell lines and virus strains. These assays may be adopted for serum neutralization end-point determinations during preclinical or clinical stage vaccine evaluations, antiviral screening, diagnostics, and plasmid-based virus reverse genetics.

1038

#### HEPATITIS B VIRUS INFECTION IN NIGERIA: A SYSTEMATIC REVIEW AND META-ANALYSIS OF DATA PUBLISHED BETWEEN 2010 AND 2019

**Busayo I. Ajuwon**, Isabelle Yujuico, Katrina Roper, Alice Richardson, Meru Sheel, Brett A. Lidbury  
*Australian National University, Acton, Australia*

HepatitisB virus infection results in substantial human morbidity and mortality worldwide. In Nigeria, the burden of this infection is significant, due to increase in complications of cirrhosis and liver cancer attributable to HBV. However, estimates of HBV prevalence vary widely in literature, and the use of routine pathology tests to enhance early detection in vulnerable populations remain largely unknown. We conducted a systematic review and meta-analysis. PubMed, Advanced Google Scholar and African Index Medicus were searched between January 2010 and December 2019. A random-effect model based on proportions was used to estimate the population-based prevalence of HBV and identify pathology assays and/or bio-markers that are used to support diagnosis and clinical management in the Nigerian population. Heterogeneity was analysed and sub-group analyses were performed. The final analyses included 47 studies with 21702 participants. We obtained a pooled prevalence of 9.5% in the Nigerian population. A prevalence estimate above 7% in a population is classified as high. Sub-group analyses revealed the highest HBV prevalence in rural setting (10.7%). The North West region had the highest prevalence (12.1%) among Nigeria’s six geopolitical zones/regions. Among routine pathology assays, Full Blood Counts (FBC) accounted for the highest prevalence estimate of 16.5%. The estimate of total variation between studies indicated substantial heterogeneity. These variations could be explained by setting, geographical region and pathology assay. We provide an up-to-date prevalence of HBV in Nigeria. Understanding true disease prevalence will provide critical data to optimise and assess the impact of current prevention and control strategies in Nigeria, including disease surveillance and diagnoses, vaccination policies and management for those infected.

### HOST GENETIC FACTORS AND ROTAVIRUS INFECTIONS IN A VACCINATED BIRTH COHORT OF NICARAGUA

Yaoska Reyes<sup>1</sup>, Fredman González<sup>1</sup>, Lester Gutierrez<sup>1</sup>, Patricia Blandon<sup>1</sup>, Edwing Centeno<sup>1</sup>, Omar Zepeda<sup>1</sup>, Christian Toval-Ruiz<sup>1</sup>, Nadja Vielot<sup>2</sup>, Lennart Svensson<sup>3</sup>, Sylvia Becker-Dreps<sup>2</sup>, Johan Nordgren<sup>3</sup>, Filemón Bucardo<sup>1</sup>

<sup>1</sup>National Autonomous University of Nicaragua, León (UNAN-León), León, Nicaragua, <sup>2</sup>Department of Family Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>3</sup>Division of Molecular Medicine and Virology, Department of Biomedical and Clinical Sciences, Linköping University, Linköping, Sweden

Nicaragua introduced the rotavirus Rotateq vaccine into the national immunization program in 2006 and Rotarix in 2015. The vaccine coverage has been approximately 90%. Despite that, a proportion of vaccinated children remain susceptible to rotavirus acute gastroenteritis (AGE). Studies have shown that histo blood group antigens (HBGAs) influence Rotarix vaccine take, with non-secretor and/or Lewis "a" children having less seroconversion and less vaccine strain shedding after vaccination. However, whether this has an impact on vaccine effectiveness is unclear as these children are also less susceptible to wild type rotavirus of same genotype. To assess rotavirus AGE and the association with HBGAs in a vaccinated cohort, a total of 444 Nicaraguan children were weekly followed weekly from birth until 3 years to investigate the incidence of rotavirus AGE by RT-qPCR. Of 1,491 episodes of AGE reported from June 2017 until February 2021, 123 were rotavirus-positive (8%). The overall incidence of rotavirus AGE was 11.7/100 child-years, and this was higher in secretor compared to non-secretor children (13.1 vs. 3.3/100 child-years,  $p=0.002$ ). After stratification by Lewis phenotype, the incidences of rotavirus-AGE was 12.9, 11.7 and 3.3/100 child-years for Lewis b, Lewis negative and Lewis a, respectively. No strong association between ABO blood group and rotavirus incidence was observed. Forty-six samples were successfully genotyped. Of these, 16 (35%) were highly homologous with the monovalent rotavirus vaccine strain G1P[8], followed by G8P[8] (11, 24%) and Equine-like G3P[8] (11, 24%). Interestingly, most genotyped wild-type rotavirus occurred after 6 months of age (21/27) as compared to prior to vaccination (4/27). This study suggests that secretor vaccinated children have higher risk of rotavirus P8, and warrants further studies on susceptibility to genotypes variants.

### ANTIBODY RESPONSE TO SARS-COV-2 INFECTION OVER SIX MONTHS AMONG NICARAGUAN OUTPATIENTS

Fredman Gonzalez<sup>1</sup>, Omar Zepeda<sup>1</sup>, Christian T. Ruiz<sup>1</sup>, Armando Matute<sup>1</sup>, Hernan Vanegas<sup>1</sup>, Nancy Munguía<sup>1</sup>, Edwing Centeno<sup>1</sup>, Yaoska Reyes<sup>1</sup>, Lennart Svensson<sup>2</sup>, Johan Nordgren<sup>2</sup>, Aravinda M. de Silva<sup>3</sup>, Sylvia Becker-Dreps<sup>4</sup>, Lakshmanane Premkumar<sup>3</sup>, Filemón Bucardo<sup>1</sup>

<sup>1</sup>National Autonomous University of Nicaragua (UNAN), León., Leon, Nicaragua, <sup>2</sup>Division of Molecular Virology, Department of Clinical and Experimental Medicine, Linköping University., Linköping, Sweden, <sup>3</sup>Department of Microbiology and Immunology, University of North Carolina School of Medicine, Chapel Hill, Chapel Hill, NC, United States, <sup>4</sup>Departments of Family Medicine and Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

New information is emerging about SARS-CoV-2 epidemiology and immunity, but little of this information comes from low- and middle-income countries or from patients receiving care in the 5 outpatient setting. The current study investigated the SARS-CoV-2 infection status and antibody 6 responses in 157 patients seeking care for a respiratory disease suggestive of COVID-19 in 7 private healthcare clinics during the first wave (June–October 2020) of infections in Nicaragua. 8 We examined nasal swabs for the presence of viral RNA via RT-PCR and longitudinally 9 collected sera for the changes in SARS-CoV-2 Spike antibody levels over six months. Among 10 patients with confirmed SARS-CoV-2 infections, we

evaluated if clinical symptoms were 11 associated with age, hematological parameters and co-morbidities. The combination of PCR and 12 paired serology identified 60 (38%) of the 157 outpatients as acute COVID-19. While both PCR 13 and serology identified the majority ( $n = 38$ , 64%) of the acute infections, a notable number of 14 outpatients were identified by RT-qPCR ( $n = 13$ , 22%) or by serology ( $n = 9$ , 14%) only. During 15 the longitudinal study, we identified 6 new infections by serology among the 97 non-COVID-19 16 subjects. In conclusion, this study report that more than one third of the outpatients seeking care 17 for acute respiratory disease during the first epidemic wave of SARS-CoV-2 in Nicaragua had an 18 acute mild COVID-19 infection that correlate with prolonged humoral response. This immune 19 response to the RBD antigen, more likely IgG dependent, significantly increased between the 20 acute to convalescent and decay in the late convalescent but still remained seropositive.

### EVALUATION OF SARS-COV-2 CIRCULATION AND IMMUNOLOGICAL CHARACTERIZATION IN A HOSPITAL COHORT IN SAO JOSE DO RIO PRETO, SAO PAULO, BRAZIL

Guilherme R. Campos<sup>1</sup>, Cintia Bittar<sup>2</sup>, Alice Versiani<sup>1</sup>, Cecilia A. Banho<sup>1</sup>, Marília M. Moraes<sup>1</sup>, Thayza M. dos Santos<sup>1</sup>, João P. Araujo Júnior<sup>3</sup>, Paula Rahal<sup>2</sup>, Maurício L. Nogueira<sup>1</sup>

<sup>1</sup>School of Medicine of São José do Rio Preto - FAMERP, São José do Rio Preto, Brazil, <sup>2</sup>Institute of Bioscience, Language and Exact Sciences - UNESP, São José do Rio Preto, Brazil, <sup>3</sup>Institute of Biotechnology - UNESP, Botucatu, Brazil

In a global context COVID-19 is the biggest health threat in the present days. In just one year, SARS-CoV-2 has infected more than 126 million people around the world, reaching more than 2.7 million deaths. In Brazil, COVID-19 was responsible, until the beginning of April 2021, for almost 12.5 million cases and 300,000 deaths. Since epidemiological studies are used to reveal the extent of viral spread and to direct control measures to contain the disease, this project consists in the study of a hospital cohort in Sao Jose do Rio Preto, located in the northwest region of the state of Sao Paulo, Brazil, to evaluate the circulation of SARS-CoV-2 variants and the impacts in a clinical level during the pandemic period. The monitoring of patients at the *Hospital de Base* of the Faculty of Medicine of Sao Jose do Rio Preto (FAMERP) has been carried out. Nasopharyngeal and blood samples collected from these patients were used in the screening of SARS-CoV-2 variants and evaluation of immunological aspects, respectively. Until now, 183 nasopharyngeal samples, from November 2020 and March 2021, were screened by a Sanger sequencing approach that can detect mutations in the RBD region of SARS-CoV-2 spike protein. This method can effectively track most of the variants of concern (VOC) described until now, like B.1.1.7, B.1.351, P.2 and P.1. Our data shows that, in November of 2020, the distribution was composed by 42% of P.2 variant (derived from B.1.1.28) and 58% of other variants (that cannot be discriminated by this approach), while in December the scenario was similar (35% P.2 and 65% others). However, in January of 2021, P.1 variant was detected (5%) and P.2 was, at that moment, the most frequent in the population (68%). After this point, a clade replacement between P.1 and P.2 was observed, where in March 2021, P.1 was detected in more than 90% of the analyzed samples, while P.2 was present in less than 5%. To confirm these data, a subset of samples were also submitted to complete genome sequencing by NGS methods, and to observe the impact of these variants in a clinical level, we will analyze clinical data, pro-inflammatory cytokines and PBMCs will be analyzed from the subjects.

### HYPOGLYCEMIA IN EBOLAVIRUS DISEASE

Masumbuko Claude Kasereka<sup>1</sup>, Richard Kitenge<sup>2</sup>, Zubia Mumtaz<sup>1</sup>, Bonita Lee<sup>1</sup>, Stan Houston<sup>1</sup>, Michael Hawkes<sup>1</sup>

<sup>1</sup>University of Alberta, Edmonton, AB, Canada, <sup>2</sup>Ministry of Health, Kinshasa, Democratic Republic of the Congo

Ebolavirus disease (EVD) is associated with multisystem organ failure and high mortality. Severe hypoglycemia is common, life-threatening, and correctable in critically ill patients, but glucose monitoring may be limited in Ebola Treatment Units (ETUs) because of infectious risk and/or resource limitations. We conducted a retrospective review of consecutive patients admitted to two ETUs in Butembo and Katwa, Eastern DRC. Glucose measurements were done at the bedside using a handheld glucometer, or using the Piccolo xpress Chemistry Analyzer (Abaxis, Union City, CA). Between 30 March and 1 Oct 2019, 418 patients were admitted, of whom 376 (92%) had at least one glucose measurement, and were included in the analysis. The median age of patients was 30 years (IQR 20 to 45) and 56% were female. 6,360 glucose measurements (median of 11 per patient (IQR 4 to 22) over the hospital admission) were recorded. Severe ( $\leq 2.2$  mmol/L) and moderate (2.3 to 3.9 mmol/L) hypoglycemia were recorded at least once during the ETU admission in 94 (25%) and 127 (34%) patients, respectively. 1,973 infusions of glucose-containing intravenous solutions were administered to 301 patients (78%), including 18 patients (4.7%) who received D5W, 122 (32%) D10W, 59 (15%) D50W boluses, and 254 (66%) Ringer's lactate with 5% dextrose. The total corrective dose of intravenous glucose administered over the admission was median (IQR) 100g (3.6-200), 150g (50-430), and 190g (51-430) in patients with no, moderate, and severe hypoglycemia, respectively ( $p < 0.0001$ ). Patients with hypoglycemia had higher peak viral load ( $p = 0.0079$ ), creatinine ( $p = 0.00051$ ), AST ( $p < 0.0001$ ), and ALT ( $p < 0.0001$ ). The case fatality rate was 48%. Compared to patients without hypoglycemia, severe hypoglycemia was associated with an increased hazard of death (HR 1.5 (95%CI 1.02-2.2),  $p = 0.039$ ) whereas moderate hyperglycemia was not (HR 1.1 (95%CI 0.73-1.6),  $p = 0.71$ ). In summary, hypoglycemia is common in patients with EVD, requires repeated correction with intravenous dextrose solutions, and is associated with organ injury and mortality.

1043

### SARS-COV-2 VIRAL LOAD PEAKS PRIOR TO SYMPTOM ONSET: A SYSTEMATIC REVIEW AND INDIVIDUAL POOLED ANALYSIS OF CORONAVIRUS VIRAL LOAD FROM 66 STUDIES

Amy E. Benfield<sup>1</sup>, Laura A. Skrip<sup>2</sup>, Andrea Clement<sup>1</sup>, Rachel A. Althouse<sup>3</sup>, Stewart Chang<sup>2</sup>, Benjamin M. Althouse<sup>2</sup>

<sup>1</sup>University of Colorado, Boulder, Boulder, CO, United States, <sup>2</sup>Institute for Disease Modeling, Seattle, WA, United States, <sup>3</sup>Legacy High School, Marysville, WA, United States

The kinetics of SARS-CoV-2 viral loads within individuals is important in understanding its transmission dynamics in populations. Viral load likely contributes to the transmission potential of the virus, but current findings around the temporal viral load dynamics and shedding, particularly the peak of transmission potential, remain inconsistent across studies. To characterize the temporal viral load dynamics and the duration of viral shedding of SARS-CoV-2 and other human coronaviruses, we conducted a systematic review and meta-analysis in which we collected and analyzed individual-patient data. We searched PubMed through June 8th, 2020 and collated unique individual-patient data from papers that reported novel data concerning quantitative viral load or the duration of viral shedding of coronaviruses. We analyzed viral load trajectories using a series of generalized additive models that treated paper ID as a random effect, and we analyzed the duration of viral shedding by fitting log-normal survival analytic models which accounted for interval censoring. We obtained individual-patient data from 66 papers, representing 1198 patients across 14 countries. We found that SARS-CoV-2 viral load peaks prior to symptom onset and remains elevated for up to three weeks, while

MERS-CoV and SARS-CoV peak after onset. SARS-CoV-2, MERS-CoV, and SARS-CoV had median viral shedding durations of 4.8, 4.2, and 1.2 days after symptom onset, respectively. Disease severity, age, and specimen type all had an effect on viral load, but sex did not. Using a pooled analysis of the largest collection of individual-patient data on coronavirus viral load to date, we are the first to report that SARS-CoV-2 viral load peaks prior to - not at - symptom onset. Peak viral loads occurring before the onset of symptoms make syndromic surveillance and symptom-based isolation policies challenging. Detailed estimation of the trajectories of viral load and virus shedding can inform modeling of transmission dynamics and clinical interventions for coronavirus infections.

### OROPOUCHE VIRUS IN VITRO REPLICATION IS INHIBITED BY ACRIDONE

Mayara Lucia Webber<sup>1</sup>, Clarita Maria Secco Avilla<sup>2</sup>, Gabrielle Grisolia Assad<sup>1</sup>, Gislaine Celestino da Silva<sup>2</sup>, Maurício Lacerda Nogueira<sup>2</sup>, Leticia Ribeiro de Assis<sup>3</sup>, Luis Octavio Regasini<sup>3</sup>, Carolina Colombelli Pacca<sup>2</sup>

<sup>1</sup>Faceres Medical School, São José do Rio Preto, Brazil, <sup>2</sup>Famerp, São José do Rio Preto, Brazil, <sup>3</sup>Julio de Mesquita Filho - UNESP, São José do Rio Preto, Brazil

Over the decades, arboviruses have been responsible for important public health issues, Oropouche orthobunyavirus (OROV) is an emerging arbovirus associated with a fever illness called Oropouche fever in the Amazon region of South and Central America, is neurotropic in animal models and can cause encephalitis and meningitis in humans. However, the pathogenic determinants associated with neurological involvement is not fully understood and there is still no antiviral therapy specified for the treatment of these infections. In this study, we report the inhibition of virus replication in Vero E6 cells by plaque reduction assay and immunofluorescence. Cells were infected with 25 PFU of OROV for 1h at 37°C, following overlay with MEM+1% carboxymethylcellulose (CMC) with or without four different acridones (FAC16, FAC20, FAC21, FAC22). Treated cells showed efficient inhibition of the viral replication at concentrations that presented minimal toxicity to the cells. The assays showed that the acridone FAC20 and FAC22 completely inhibited viral replication with no plaque formation, whereas FAC21 showed a 90% reduction, while FAC16 reduced approximately 75% plaque formation with no effect on cell viability. The virucidal activity was performed with the compounds to identify a possible mechanism of action. In this assay, FAC20 completely inhibited plaque formation, whereas FAC16 and FAC21 inhibited approximately 85% plaque formation and FAC22 showed a 90% reduction in plaque formation. Our results suggest that these are promising molecules to be studied with potential antiviral activity against the Oropouche virus.

### RAPID SPREAD OF SARS-COV-2 INFECTION IN THE COMMUNITY OF SOTUBA, A PERI-URBAN AREA OF BAMAKO, MALI, FROM JULY TO JANUARY 2021

Mamady Kone<sup>1</sup>, John Woodford<sup>2</sup>, Sibiri Sissoko<sup>1</sup>, Jacquelyn Lane<sup>2</sup>, Intimbeye Tembène<sup>1</sup>, Abdoulaye Katile<sup>1</sup>, Mahamadou Hamady Assadou<sup>1</sup>, Amatigue Zeguime<sup>1</sup>, M'Bouye Doucoure<sup>1</sup>, Sara Healy<sup>2</sup>, Jennifer Kwan<sup>2</sup>, Jennifer Hume<sup>2</sup>, David Cook<sup>2</sup>, Michal Fried<sup>2</sup>, Mahamadou S. Sissoko<sup>1</sup>, Abdoulaye Djimde<sup>1</sup>, Alassane Dicko<sup>1</sup>, Patrick Duffy<sup>2</sup> and Issaka Sagara<sup>1</sup> <sup>1</sup>MRTC, Mali-NIAID ICER, USTTB, Bamako, Mali. <sup>2</sup>LMIV, NIAID, Rockville, Maryland, USA.

The Mali Ministry of Health, the Malaria Research and Training Center and the Laboratory of Malaria Immunology and Vaccinology conducted a longitudinal seroprevalence study in the peri-urban community of Sotuba, Bamako to understand local COVID-19 epidemiology. A total of 587 individuals  $\geq 6$  months of age provided blood samples tested for antibodies against SARS-CoV-2 spike and receptor binding domain proteins using an assay qualified for use in Mali. Samples were collected between July and

October 2020 and December 2020 and January 2021. No participant or a household member reported a previous COVID-19 diagnosis at enrollment. 89.9% (528/597) of participants completed study visits. The seropositivity rate was 13.1% (95% CI: 10.4-15.9) at Survey 1 and increased markedly over the study period to 44.9% (95% CI: 40.7-49.1) at Survey 2. After adjusting for community age-distribution and assay performance, the seroprevalence was 19.0% (95% CI: 14.2-23.8) at Survey 1 and 70.4% (95% CI: 56.8-84.1) at Survey 2. This represents a daily infection rate of almost 1% of the population every two days over the study period. The seropositivity rate increased with age group at both visits. At Survey 2 the adjusted seropositivity rate was 38.8% (95% CI: 28.9-48.7) in participants aged <10 years, 63.7% (95% CI: 49.5-77.9) aged 10-17 years, and 77.2% (95% CI: 61.5-92.9) in adults aged ≥18 years. Seropositivity rates did not differ by sex. These results suggest rapid community spread of SARS-CoV-2 in Bamako. **Keywords:** SARS-CoV-2, COVID-19, Seroprevalence, Peri-urban, Mali, West Africa.

### AGGRESSIVE COMMUNITY AND WORKPLACE SPREAD OF SARS-COV-2 B.1.1.7 AND SEVERE ILLNESS ON A LARGE UNIVERSITY CAMPUS

Loni Taylor<sup>1</sup>, Tykeara Mims<sup>2</sup>, Aishatu Yusuf<sup>2</sup>, Benika Dixon<sup>2</sup>, **Rebecca S. Fischer<sup>2</sup>**

<sup>1</sup>Texas A&M University, College of Veterinary Medicine, College Station, TX, United States, <sup>2</sup>Texas A&M University, School of Public Health, College Station, TX, United States

Active and passive surveillance among employees and students at one of the largest universities in the United States was stood up in August 2020 to closely monitor and mitigate SARS-CoV-2 infections on campus. In February 2021, the COVID-19 Surveillance team was alerted to the first local case of the B.1.1.7 SARS-CoV-2 variant infection, which was in a campus member. An outbreak investigation using existing health surveys and prospective interviews was immediately launched. The investigation revealed a cluster bridging community and campus transmission; 16/34 (45%) students and campus employees (median age 29 yrs (range 23-40); 44% male) tested positive for SARS-CoV-2 over a short, 9-day period. Campus cases initially emerged from community spread, where 6/18 (33%) party attendees (5 of whom were campus members) tested positive, some with unknown test results. Only 1 case underwent viral typing, done at a private laboratory through standard statewide recommended protocols, and 2 domestic animals linked to the cluster were the first to be reported with confirmed B.1.1.7 illness. Viral transmission was estimated to occur up to 18 hours before symptoms manifested in the source cases, with incubation period 3 (2-5) days. All cases exhibited symptoms, mainly (82%) mild, though at least 1 experienced long-term respiratory dysfunction and depleted oxygen saturation levels. Community infections crossed quickly into the campus environment, owed to pre-symptomatic spread, and burned rapidly through a workplace environment on campus during close contact in low airflow environments while single-masked and other rigorous public health measures in place. Since this investigation, a higher rate of B.1.1.7 infections has been observed in the campus setting compared to the community setting. Local health departments and academic institutions should partner for multifaceted surveillance and mitigation. Genomic surveillance, particularly tracking emergence and spread of SARS-CoV-2 mutants of potential concern should inform recommendations and guidelines and can be tailored to phenotypes, such as high transmissibility, of local viral strains.

### CHARACTERIZATION OF THE COVID-19 DISEASE IN CARTAGENA DE INDIAS: AN EFFICIENT PREVENTION AND CONTAINMENT STRATEGY

Fabián Espitia-Almeida<sup>1</sup>, Steev Loyola<sup>2</sup>, Eder Cano-Pérez<sup>1</sup>, Jaison Torres-Pacheco<sup>1</sup>, Ramiro Pereira-Lentino<sup>3</sup>, Dacia Malambo-García<sup>1</sup>, **Doris E. Gomez-Camargo<sup>1</sup>**

<sup>1</sup>UNIMOL Research Group, Faculty of Medicine, University of Cartagena, Cartagena de Indias, Colombia, <sup>2</sup>Doctorate in Tropical Medicine, Faculty of Medicine, University of Cartagena, Cartagena de Indias, Colombia, <sup>3</sup>Departmental Laboratory of Public Health of Bolivar, Cartagena de Indias, Colombia

The Severe acute respiratory syndrome type 2 (SARS-CoV-2) is the causal agent of the coronavirus disease 2019 (COVID-19) which was first described in Wuhan, Hubei province (China). SARS-CoV-2 causes a respiratory disease and is mainly transmitted from person to person through aerosols generated by coughing, breathing and talking. Because short-distance transmission in closed and non-ventilated spaces is the route that describes the majority of currently confirmed cases, therefore it is necessary and priority the characterization the disease epidemiology and identify areas with a high rate of cases. A data-driven response to COVID-19 allow to reduce the transmission through effective public health approaches that mitigate the impact on the population. The retrospective study of the epidemic allows the characterization of the dynamics and groups that were greatly affected by COVID-19. Hence, in the context of COVID-19 surveillance this lack of information translates into a lack of evidence that potentially could be used to improve public health intervention and policies especially in low-income countries with reduced availability of vaccines. UNIMOL was the first laboratory that worked in COVID-19 diagnosis in Cartagena, Colombia. Therefore, we have processed 107,127 samples to date, which corresponds to approximately 90% of the data reported for Cartagena-Colombia. We reconstructed the epidemic curve from April 2020 when the first COVID-19-case was reported to April 2021 using historical laboratory results. Furthermore, epidemic curves were constructed according sex, age groups, occupation and local residence to explore differences across the time. We tracked cases and deaths across the time using heat maps considering correction by population sizes. Finally, we evaluated the correlation between the daily positivity percentage and the epidemic curve in order to validate its use as a metric to measure COVID-19 dynamic. Our study illustrated the occurrence of COVID-19 cases considering demographic characteristics in Cartagena that was one of the Colombian cities with the lowest occurrence of cases and deaths related COVID-19.

CD47 is an anti-phagocytic (don't eat me) signal that inhibits programmed cell removal of self and loss of this molecule by aging erythrocytes is associated with increased susceptibility to clearance by macrophages. We have investigated the role of CD47 in malaria immunity and pathogenesis in murine malaria models. Previously, we demonstrated that absence of CD47 confers resistance to infection with *Plasmodium yoelii* 17XNL, a murine malaria that exhibits an aged-based preference for young erythrocytes. Next, we established that CD47 blockade with an anti-CD47 monoclonal antibody promotes survival and reduces the pathologic features of cerebral malaria during *Plasmodium berghei* ANKA (Pb-A) infection in C57BL/6 mice, a murine model of experimental cerebral malaria (ECM). To delineate the immunological mechanism of CD47

regulation of ECM pathogenesis, we present studies comparing *Pb*-A infection in wildtype (WT) versus CD47 KO C57BL/6 mice. In CD47 KO mice, absence of CD47 resulted in partial but highly significant ( $p < 0.001$ , log-rank) resistance to ECM; following infection with *Pb*-A parasites, 22/23 (95.6%) WT mice developed ECM by day 10 post-infection. In contrast, only 13/23 (56.5%) of CD47 KO mice succumbed to malaria during the cerebral phase of infection. Through flow cytometric analysis of brain sequestered and splenic immune cell subsets and cytokine profiling of serum, we show that absence of CD47 during *Pb*-A malaria is associated with a significant reduction in brain sequestered CD8<sup>+</sup> T cells which are pathogenic during ECM and alteration of a small subset of cytokines. In addition, comparative analysis of WT versus CD47 KO brain tissue by immunohistology demarcates clear differences in pathologic features such as hypertrophied endothelial cells, presence of parasite hemozoin, macrophage infiltration, vascular lesions, and ring hemorrhages. A further understanding of the mechanism of anti-CD47 antibody-mediated protection from ECM may open avenues for novel immunologic-based treatment options against cerebral malaria in African children.

1049

### QUANTIFICATION OF THE SPOROZOITE INOCULUM FROM MOSQUITOES WITH HIGH AND LOW SALIVARY GLAND LOADS

Deborah Stiffler<sup>1</sup>, Maya Aleshnick<sup>2</sup>, Photini Sinnis<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Oregon Health and Science University, Beaverton, OR, United States

*Plasmodium* parasites cycle between their mosquito and mammalian hosts, and both transmission stages are associated with severe bottlenecks in parasite numbers. Thus, the transmission stages have been recognized as an excellent target for interventions that could reduce the likelihood of successfully infecting a new host. We recently found that most infected mosquito bites did not result in a blood stage infection in the rodent malaria model, *Plasmodium yoelii* in Swiss Webster mice. Importantly, the likelihood of success was strongly correlated with the salivary gland sporozoite load of the infecting mosquito, with a steep increase in infection likelihood when mosquitoes had salivary gland loads greater than 10,000 sporozoites. In this study, we set out to determine how sporozoite inoculum size relates to salivary gland sporozoite load. Previous studies on this topic are conflicting, with the majority finding no association between gland load and inoculum size. We hypothesized that the high biological variability inherent in these data, combined with the use of mosquitoes whose sporozoite loads were biased towards either the low or the high end, could account for the lack of consensus on this topic. To test this, we manipulated culture conditions to generate mosquitoes with a range of salivary gland sporozoite loads that include the 4 to 5 log span observed in the field. We then allowed single *P. yoelii*-infected mosquitoes to probe on individual mouse ears and collected that ear tissue for quantification of injected sporozoites using a novel and highly sensitive qPCR assay that amplifies genomic DNA from a region of the mitochondrial genome. This work supports our previous finding that parasite loads in the mosquito impact the likelihood of a blood-stage infection. Further, we provide new information about the quantity of sporozoites transmitted during probing, allowing us to make connections between the salivary gland sporozoite load, the number of sporozoites deposited in the skin, and the potential for a subsequent blood stage infection.

### EXPERIMENTAL INFECTION OF PIGTAILED MACAQUES WITH PLASMODIUM KNOWLESI MALARIA PARASITES

Melanie J. Shears<sup>1</sup>, Rebekah Reynolds<sup>1</sup>, Sumana Chakravarty<sup>2</sup>, B. Kim Lee Sim<sup>2</sup>, Stephen L. Hoffman<sup>2</sup>, Sean C. Murphy<sup>1</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>Sanaria Inc., Rockville, MD, United States

*Plasmodium knowlesi* (Pk) parasites can infect a range of non-human primate host species with varied disease outcomes. Pigtailed macaques (*Macaca nemestrina*) are one of several non-human primate reservoir hosts for Pk in Southeast Asia. As wild pigtailed macaques do not show signs of Pk blood stage carriage, infections in this host species are believed to be benign. Mild infections have also been reported for other related macaque species originating from areas where Pk is endemic. By contrast, experimental infection of non-natural hosts typically results in more severe disease outcomes. The best studied example is the rhesus macaque (*M. mulatta*), where Pk infection frequently causes severe disease that can be fatal if untreated. Severe disease has also been reported for other host species originating from outside the geographic range of Pk parasites. These observations suggest that pigtailed macaques have evolved traits that limit Pk disease severity, and because of this, may offer promise as a new potential model for chronic malaria. However, no previous studies have characterized Pk infection and disease in pigtailed macaques in a well-controlled experimental setting. Here we report results from a pilot Pk infection study in captive pigtailed macaques. Adult male macaques were infected intravenously with 2500 purified, cryopreserved Pk sporozoites (PkSPZ) and blood stage parasitemia was assessed daily beginning 6 days post-infection by Giemsa-stained thin smears and 18S rRNA RT-PCR. Infections were found to be highly reliable, with all animals becoming RT-PCR positive on days 6-7 and patent by Giemsa smear by day 11. Remarkably, blood stage parasite burdens plateaued at day 12-13 and remained just above the limit of detection by Giemsa smear until chloroquine treatment was initiated 2-3 weeks later. Despite this ongoing blood stage infection, animals did not display signs of disease, anemia or any other hematological abnormalities. These findings confirm that pigtailed macaques can be reliably infected with PkSPZ in an experimental setting and sustain low-level blood stage parasite burden for multiple weeks without apparent symptoms.

Howard<sup>1</sup>, Holly Torano<sup>1</sup>, Sachy Orr-Gonzalez<sup>1</sup>, Tarik Ouahes<sup>1</sup>, Almahamoudou Mahamar<sup>2</sup>, Bacary S. Diarra<sup>2</sup>, Alassane Dicko<sup>2</sup>, Lynn E. Lambert<sup>1</sup>, Michal Fried<sup>1</sup>, Patrick E. Duffy<sup>1</sup>

<sup>1</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Malaria Research & Training Center, Faculty of Medicine, Pharmacy & Dentistry, University of Sciences Techniques & Technologies of Bamako, Bamako, Mali

*Plasmodium falciparum* sequesters in the placental intervillous space, causing placental malaria (PM) and leading to poor prognoses for both mother and child. VAR2CSA, the PfEMP1 variant surface protein, facilitates placental sequestration by binding to chondroitin sulfate A (CSA) expressed on syncytiotrophoblasts, causing severe pathologies. Women acquire antibodies against VAR2CSA over subsequent pregnancies, which is correlated with improved outcomes. We have established a novel model of PM in the non-human primate *Aotus nancymae*, which is characterized by sequestration of late-stage *P. falciparum* CS2 parasites in the placenta that express VAR2CSA and bind to CSA. Further, these *Aotus* develop antibodies against VAR2CSA over subsequent pregnancies that inhibit the binding of maternal field isolates to CSA. We have previously reported the use of this model for VAR2CSA-based vaccine studies. Here we provide

extensive data on *P. falciparum* infections in the *Aotus* model from nearly one hundred infections during pregnancy. We have tested five different strains in the model, with varying outcomes. The more virulent strains quickly develop high parasitemias, increasing the risk of miscarriage, while others, including CS2, do not. We present data on the course of infection in these strains, as well as VAR2CSA-specific immune responses. We also assess the effect of gravidity and the length of infection on parasitemia. Finally, we analyze pregnancy outcomes and the birth weight of the neonate in the context of PM. Our advances with the *Aotus nancyrae* PM model demonstrate its value in understanding PM infection and immunity. They also provide a foundation for future vaccine studies, including heterologous challenge in pregnancy malaria.

1052

### IN VITRO GROWTH PHENOTYPES OF SINGLE PARASITE LINEAGES CLONED FROM MULTICLONAL MALARIA ISOLATES

Standwell Nkhoma, Amel O. Ahmed, Sharmeen Zaman, Timothy T. Stedman

ATCC, Manassas, VA, United States

Measurement of malaria parasite proliferation in cultured erythrocytes is critical for elucidating key determinants of phenotypes, including drug susceptibility, virulence, and fitness. Multiple parasite lineages with different proliferation rates or fitness may coexist within a clinical isolate, resulting in complex growth interactions and variations in phenotype. We measured proliferation rates of three *Plasmodium falciparum* isolates, including Cambodia IPC\_3445 (MRA-1236), IPC\_5202 (MRA-1240), IPC\_6403 (MRA-1285), and parasite lineages previously cloned from each of these isolates by limiting dilution. Following synchronization, *in vitro* cultures were maintained over four consecutive asexual parasite life cycles, with parasite sampling at the end of every cycle to estimate parasitemia and growth rate. Cell cycle duration was measured by monitoring the development of 0 to 3 hr post-invasion rings from 36 to 52 hrs. In parallel with isolates and component parasite lineages, growth rates and cell cycle times were measured for parasite lines 3D7 (MRA-102) and DD2 (MRA-150) as controls. We observed significant differences in parasite growth rate (GR), fold-change in parasitemia (FC), and cell cycle duration between parasite isolates and clonal lineages that make up each isolate. For example, while parental isolate IPC\_5202 exhibits similar a proliferation rate to one of its constituent lineages, MRA1240-hap1 (GR: 1.02±0.04 vs. 0.97±0.03; FC: 65±14 vs. 61±2), two other constituent lineages differ markedly, MRA1240-hap2 (GR: 0.95±0.02; FC: 51±3) and MRA-1240-hap3 (0.93±0.03; FC: 46±2). We observed that the most abundant parasite haplotype often dominates the growth phenotype, masking the effect of minority haplotypes akin to recent observations from drug susceptibility testing. Our results also show diminished proliferation of isolate MRA-1236 (GR: 0.90±0.05; FC: 38±7) relative to the component lineages MRA1236-hap1 (GR: 1.14±0.02; FC: 90±20) and MRA1236-hap2 (GR: 1.02±0.01; FC: 82±5) suggestive of competitive suppression. All parasite lines will be available through BEI Resources.

1053

### PRO AND ANTI-INFLAMMATORY CYTOKINE RESPONSES DURING PREGNANCY ASSOCIATED MALARIA IN MANGALURU, INDIA

Rajeshwara N Achur<sup>1</sup>, Valleesha Chandrashekar<sup>1</sup>, Punnath Kishore<sup>1</sup>, Kiran K. Dayanand<sup>1</sup>, Suchetha N. Kumari<sup>2</sup>, Channe D Gowda<sup>3</sup>

<sup>1</sup>Kuvempu University, Shivamogga, India, <sup>2</sup>KSHEMA, Nitte University, Mangaluru, India, <sup>3</sup>Pennsylvania State University, Hershey, PA, United States

Malarial infections during pregnancy results in placental parasite sequestration leading to maternal anemia, low birth weight, intrauterine growth retardation and infant mortality, especially during *Plasmodium falciparum* infections. However, the complications of *P. vivax* have not been well characterized. The Severe Malarial Anemia (SMA) not only results

due to dyserythropoiesis, destruction of infected and non-infected red blood cells, but also due to imbalanced inflammatory cytokines response. In this study, we analyzed the burden of malarial anemia, inflammatory cytokine profiles and the associated complications during uncomplicated and severe malaria in the southwestern coastal city of Mangaluru, India. Among 105 pregnant individuals in the malarial infected group, 39% were non-anemic, 29.5% had mild anemia, whereas 23.8% and 7.6% had moderate and severe anemia, respectively. Among SMA patients, mixed infections were the highest (23.1%), followed by *P. falciparum* (10%) and *P. vivax* (8.3%). The hemoglobin levels decreased significantly in mixed (8.1 g/dL), *P. falciparum* (8.6 g/dL) and *P. vivax* (9.3 g/dL) infections. A highly significant increased pro-inflammatory response and decreased anti-inflammatory cytokine responses were observed with increase in anemic intensity, especially during *P. falciparum* infections ( $P < 0.002$ ). Further, positive correlation was observed between TNF- $\alpha$  and IL-6 levels in patients with *P. vivax* infections during moderate anemia ( $r = 0.594$ ,  $p = 0.025$ ), severe anemia ( $r = 0.005$ ,  $p = 0.0012$ ) and during *P. falciparum* with severe anemia ( $r = 0.005$ ,  $p = 0.0015$ ). The IL-6 and IL-10 levels showed a significant inverse relationship in patients with severe anemia during *P. vivax* ( $r = -0.167$ ,  $p = 0.0014$ ) and *P. falciparum* ( $r = -0.245$ ,  $p = 0.0012$ ) infections. Pregnant women with SMA suffered from complications such as jaundice (12.5%), hematuria (12.5%), acute renal failure (25%), hepatomegaly (25%) and metabolic acidosis (25%). In conclusion, although *P. vivax* is considered to be benign, our data indicates its role in SMA, cytokine imbalance and its associated complications as observed in *P. falciparum* infections.

### VAR GENES TRANSCRIPTION PROFILING OF PLASMODIUM FALCIPARUM FROM AN INDUCED-MALARIA EPISODE IN AOTUS MONKEYS

Ariel H. Magallon Tejada<sup>1</sup>, Kevin Escala<sup>1</sup>, Mihail Perez<sup>1</sup>, Mario Quijada<sup>1</sup>, Joe Smith<sup>2</sup>, Nicanor Obaldia<sup>1</sup>

<sup>1</sup>Gorgas Memorial Research Institute for Health Studies, Panama, Panama, <sup>2</sup>Center for Global Infectious Disease Research - Seattle Children's Research Institute, Seattle, WA, United States

Cytoadherence of *Plasmodium falciparum*-infected erythrocytes (iE) to host cells is a major pathogenic factor mediated by the highly polymorphic *P. falciparum* erythrocyte membrane protein-1 (PfEMP1). The *var* genes encoded PfEMP1s bind diverse receptors, including CD36, intercellular adhesion molecule 1 (ICAM-1), and endothelial protein C receptor (EPCR), as well as mediate rosette formation with uninfected red blood cells. Whereas CD36 binding has been linked to mild malaria, parasite adhesion to ICAM-1, EPCR, and rosetting have been associated with severe malaria. *Aotus* monkeys represents an important *in vivo* model system in the study of *Plasmodium* biology. *Aotus* has been used to study *P. falciparum* sequestration and may provide information useful in understanding the parasite ligands involved in the bone marrow niche or anemia. However, little is known about the parasite-host interactions in the *Aotus* monkey model. In this study, we analyzed the transcriptional pattern of PfEMP1/*var* genes of FVO-strain *P. falciparum* isolated from an induced-malaria episode in *Aotus* monkeys. The animals were assessed daily for 27 days for parasitemia. Parasitized erythrocytes were cryo-conserved and RNA preparations were obtained at days 0, 5, 13, 20 and 22. We observed a reduction in Hb levels by day 22 when parasite density had reached ~6% (Hb: day 0, 20.8g/dL; day 22, 15.1 g/dL) at which point monkeys were treated with 20 mg/kg mefloquine. Optical microscope examinations of blood samples revealed a large proportion of *P. falciparum*-infected erythrocytes bound to uninfected erythrocytes, a cytoadhesive phenotype known as rosetting. Transcriptional profiling of *var* genes identified higher transcript levels of specific *var* genes associated to rosetting, and others unknown. Our study indicates that *Aotus* monkey model can be used to investigate the rosetting virulence trait and has the potential to study other PfEMP1 subsets for their interaction with specific vascular locations.

### FUNCTIONAL CHARACTERIZATION OF A PUTATIVE PHOSPHATIDYLETHANOLAMINE BINDING PROTEIN OF MALARIA PARASITE

Abhisheka Bansal<sup>1</sup>, Manish Sharma, Komal Rani

Jawaharlal Nehru University, New Delhi, India

Raf Kinase Inhibitor Protein (RKIP), a member of the phosphatidylethanolamine binding protein (PEBP) family, is a classical regulator of MAPK signaling pathway in mammalian cells. Malaria parasite, *Plasmodium falciparum* RKIP (PfrKIP) is a putative PEBP that shares limited similarity in protein sequence with HsRKIP, the *Homo sapiens* homolog of PfrKIP. Interestingly, the classical components of MAPK pathway are not expressed in malaria parasite. The physiological function of RKIP in *P. falciparum* lifecycle remains unknown. Here we show that PfrKIP is a *bona fide* PEBP. We have generated a transgenic parasite line wherein the endogenous PfrKIP is tagged with a V5 epitope tag. We show that RKIP is expressed in the asexual stages of *P. falciparum* by probing the PfrKIP-V5 parasite lysate with anti-V5 antibodies in Western blot. The V5 tagged protein in PfrKIP-V5 parasite lysate was further verified by specific antibodies generated against recombinant PfrKIP protein. Mutant PfrKIP recombinant proteins differing from WT protein in amino acid residues in the PEBP binding domain have been generated to elucidate key molecular determinants that facilitate PfrKIP-lipid interaction. Importantly, lipid interaction studies with recombinant PfrKIP and HsRKIP show qualitative differences in lipid interaction profiles. Ongoing studies on complete and conditional knock-out of endogenous *pfrkip* will help in functional characterization of the gene in parasite biology. Moreover, qualitative differences in the lipid interaction profile of PfrKIP and HsRKIP suggests that specific inhibitors of PfrKIP may be designed that may be used as anti-malarial compounds for malaria control.

### HOST INFLAMMATION AND PARASITE VAR EXPRESSION ASSOCIATED WITH CEREBRAL MALARIA IN KENYAN CHILDREN

Elizabeth Hemming-Schroeder<sup>1</sup>, Sidney Ogolla<sup>2</sup>, David Midem<sup>2</sup>, James W. Kazura<sup>1</sup>, Arlene Dent<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Kenya Medical Research Institute, Kisumu, Kenya

Cerebral malaria primarily afflicts children and is the leading cause of malaria deaths. However, the pathogenesis of cerebral malaria is not fully understood. A unique feature of *Plasmodium falciparum* (Pf) is the ability to sequester in vascular tissues through binding of Pf Erythrocyte Membrane Protein 1 (*PfEMP1*) to specific endothelial receptors (e.g. ICAM-1, EPCR). *PfEMP1* is encoded by approximately 60 *var* genes with the extracellular head region of *PfEMP1* composed of cysteine-rich interdomain regions (CIDRs) and Duffy-binding-like (DBL) domains. Endothelial activation and possible damage by cytoadherent Pf contributes to immune mediated pathogenesis in addition to systemic inflammation characteristic of malaria. A better understanding of the molecular pathways involved in cerebral malaria may inform new adjunct therapies to reduce malaria mortality and morbidity. We aim to identify biomarkers of systemic inflammation and *PfEMP1* variants associated with cerebral malaria in Kenyan children. We enrolled 34 children presenting with cerebral malaria and 17 children presenting with uncomplicated malaria. We measured pre-treatment plasma levels of cytokines indicative of systemic inflammation (IFN- $\gamma$ , TNF $\alpha$ , IL-6, IL-10, IL-21, IL-8, and IL-27) and biomarkers of endothelial cell activation (Eotaxin, PAI-1, MPO, neutrophil elastase, VEGF, and angiopoietin-2). Total Pf biomass was estimated by Pf Histidine Rich Protein 2 (HRP2), and *var* expression of specific head variants was assessed by qPCR. Preliminary analysis based on feature selection by random forest cross-validation indicates that 7 (of 45 tested) feature variables distinguish cerebral malaria from uncomplicated malaria with a 9.8% out-of-bag error rate. These 7 features in order of decreasing variable importance are plasminogen activator inhibitor 1, neutrophil elastase, IL-21, DBL $\alpha$ 1.7 of

DC13 (EPCR binding), vascular endothelial growth factor, DBL $\beta$  (ICAM-1 binding), and HRP2. These results suggest that both inflammation and sequestration lead to cerebral malaria.

1057

### ASEXUAL PARASITE AND GAMETOCYTE DYNAMICS FOLLOWING 3-DAY OR 5-DAY ARTEMETHER-LUMEFANTRINE TREATMENT FOR PLASMODIUM FALCIPARUM MALARIA IN UGANDAN CHILDREN

Justin Goodwin<sup>1</sup>, Richard Kajubi<sup>2</sup>, McKenzie Colt<sup>1</sup>, Meghan Whalen<sup>3</sup>, Martina Wade<sup>1</sup>, Francis Orukan<sup>2</sup>, Moses Were<sup>2</sup>, Francesca T. Aweeka<sup>3</sup>, Norah Mwebaza<sup>2</sup>, Sunil Parikh<sup>1</sup>

<sup>1</sup>Yale Schools of Medicine and Public Health, New Haven, CT, United States, <sup>2</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States

Parasite clearance after antimalarial treatment is often used to assess therapeutic response, drug efficacy, and in the context of artemisinin-based combination therapy, artemisinin resistance. Microscopy has been the gold standard for monitoring parasite clearance and recurrent infections. However, the development of ultrasensitive RNA and DNA-based detection can be used to study parasite dynamics at densities below the limit of detection of microscopy or traditional PCR. Recent studies with 14-day follow-up using newer diagnostic approaches have detected persistent submicroscopic parasitemia up to 14 days after artemether-lumefantrine (AL) treatment, though the significance of persistent detection remains unclear. We conducted a randomized PK/PD study of standard 3-day (6-dose) versus 5-day (10-dose) AL for the treatment of uncomplicated malaria in HIV-infected and HIV-uninfected children in Uganda. Ultrasensitive RT-PCR and parasite genotyping using amplicon deep sequencing is underway to determine the dynamics of clonal parasites in 72 HIV-infected and 234 HIV-uninfected children over 42-days of follow-up. We are further assessing gametocyte prevalence and clearance following treatment. Preliminary RT-PCR showed high correlation with microscopically determined parasite densities on day 0 in HIV-uninfected children ( $n = 202$ ,  $R = 0.71$ ,  $p < 2.2e-16$ ), and was able to achieve a limit of detection of 5-50 parasites/mL. While 42% of children had microscopically detectable parasites on day 42, nearly 70% of children had 18S-RNA detectable at every time point throughout 42 days of follow-up. Median parasite density at day 0 was 3,224 parasites/ $\mu$ L, which decreased to a median of 0.1 parasites/ $\mu$ L by day 14 before increasing to 38 parasites/ $\mu$ L by day 42. Our final analysis, which will be presented, will determine whether improved AL exposure more effectively clears parasites after treatment or prevents earlier recurrence. Furthermore, we will use extended follow-up and sequencing data to further explore if persistent parasitemia extending out to day 14 and beyond potentially represents viable asexual parasites.

1058

### CHRONIC AOTUS NANCYMAE MODEL OF PLACENTAL MALARIA

Holly M. Torano, Jennifer Howard, Lynn E. Lambert, Justin Yai Doritchamou, Tarik Ouahes, Steven Nadakal, Alicia Spiegel, Ankur Sharma, Rhea Stevens, Michal Fried, Patrick E. Duffy

NIH/NIAID/LMIV, Bethesda, MD, United States

Placental malaria (PM) infection is characterized by sequestration of *Plasmodium falciparum* parasitized erythrocytes (PE) that bind to chondroitin sulfate A (CSA) in the intervillous spaces of the placenta. This interaction is mediated by VAR2CSA, a large variant antigen expressed on the PE surface. We previously reported a model for acute human PM using *P. falciparum* infection of pregnant *Aotus nancymae* for up to a week, and observed sequestration of CSA-binding parasites within the intervillous spaces of the *Aotus* placenta and the acquisition of broadly neutralizing antibodies following multiple pregnancy malaria episodes, as seen in malaria-exposed pregnant women. However, this model does not replicate the intervillitis (IVS) seen in chronic human PM. Here, we

have optimized this model to allow infections of greater duration and collected placentas to examine parasite sequestration and IVS. Pregnancy was detected and dated by ultrasound and *Aotus* were inoculated with *P. falciparum* strain CS2 blood-stage parasites at ~11 (mid) or ~17 (late) weeks gestation, followed by Cesarean section 7, 12, 13, 14 or 17 days post-inoculation. To assess the impact of chronic infection on the protective antibody (Ab) response, antibodies against VAR2CSA were measured by ELISA and against PE surface antigen by flow cytometry. Functional Abs with the ability to block PE binding to CSA were measured by a binding inhibition assay. We found that animals with infections for 13 or more days developed IVS, while animals with 7 or 12-day infections did not. ELISA titers were also higher after longer infections versus the shorter 7-day infections. These results suggest that the chronic model with a 13+ day infection duration has a pathology similar to that of chronic human PM and may provide a valuable tool for testing future vaccines.

### AN ECOLOGICAL ANALYSIS EXPLORING THE IMPACT OF SEASONAL MALARIA CHEMOPREVENTION IN BURKINA FASO AND NIGERIA USING NATIONAL HOUSEHOLD SURVEYS (2010-2018)

Monica A. de Cola<sup>1</sup>, Benoit Sawadogo<sup>2</sup>, Taiwo Ibinaiye<sup>3</sup>, Sol Richardson<sup>1</sup>, Arantxa Roca-Feltre<sup>1</sup>, Christian Rassi<sup>1</sup>, Patrick Walker<sup>4</sup>, Lucy Okell<sup>4</sup>

<sup>1</sup>Malaria Consortium, London, United Kingdom, <sup>2</sup>Malaria Consortium, Ouagadougou, Burkina Faso, <sup>3</sup>Malaria Consortium, Abuja, Nigeria, <sup>4</sup>Imperial College London, London, United Kingdom

In 2012, the World Health Organization (WHO) issued a policy recommendation for the use of Seasonal malaria chemoprevention (SMC) in the Sahel and sub-Saharan regions of Africa as an effective malaria control strategy for children ages 3-59 months. Malaria Consortium has supported the SMC programme in Burkina Faso and Nigeria since 2014. Clinical trials have shown the intervention to prevent around 75% of clinical malaria episodes. Results of previous analyses to assess impact of the intervention under routine programmatic conditions have varied markedly between countries. This can be due to methods of measurement and/or quality of data. A previous analysis using population based household surveys (Demographic Health Surveys from 2010; Malaria Indicator Surveys from 2014 and 2017) in Burkina Faso showed strong evidence of a decrease in odds of malaria and anemia in districts with SMC. The analysis overlaid the household data with SMC programme data, geographic data from the Burkina Faso Mapping Institute, and rainfall data from the Burkina Faso Meteorological Institute. Adjustments were made to this model to investigate the decaying effect of impact of SMC as well as any effect of treatment seeking behaviour. The analysis was replicated using household survey data from Nigeria in 2010, 2015, and 2018. A mixed effects logistic regression with random intercepts for district was conducted to estimate the level of impact of SMC during the implementation period and up to 5 months after. A cubic spline was fitted to adjust for seasonal factors other than rainfall. Preliminary results indicate there is strong evidence that after controlling for a variety of factors that there is a decrease in odds of malaria confirmed by rapid diagnostic test in districts with SMC in Burkina Faso (OR 0.26, 95% CI: 0.20-0.33,  $P < 0.001$ ) and Nigeria (OR 0.39, 95% CI: 0.29-0.51,  $p < 0.001$ ). Further adjustments are being made to the model and results will be presented. The results from this analysis will be compared to data from routine health information systems in both countries.

### PROFILING TRENDS IN SUSCEPTIBILITY TO FRONTLINE ANTIMALARIALS IN KENYA BETWEEN 2008-2021 THROUGH SUSTAINED REGIONAL SURVEILLANCE

Duncan Musamali Wakoli<sup>1</sup>, Hoseah Akala<sup>1</sup>, Bartholomew Nyangahu Ondigo<sup>2</sup>, Agnes Cheruiyot<sup>3</sup>, Edwin Mwakio<sup>3</sup>, Douglas Ongeri Ochora<sup>4</sup>, Redemptah Yeda<sup>4</sup>, Charles Okudo<sup>4</sup>, Dennis Juma<sup>4</sup>, Ben Andagalu<sup>4</sup>, Amanda Roth<sup>4</sup>

<sup>1</sup>US Army Medical Research Directorate-Kenya, Department of Biochemistry and Molecular Biology Egerton University, Kisumu, Kenya, <sup>2</sup>Department of Biochemistry and Molecular Biology Egerton University, <sup>3</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, NIH, Bethesda, MD, USA, Kisumu, Kenya, <sup>4</sup>US Army Medical Research Directorate-Kenya, Kisumu, Kenya, <sup>4</sup>US Army Medical Research Directorate-Kenya, Kisumu, Kenya

Antimalarial drug resistance has been a hindrance to achieving a malaria free world since the first case of chloroquine resistance was recorded in South Eastern Asia (SEA) in 1950s. Consequently, evaluating the association of the scarce frontline antimalarials sensitivity with molecular markers is a top priority for efficient monitoring of drug failure and guiding treatment policy in the country. A total of 255 clinical *P. falciparum* isolates collected from subjects presenting with uncomplicated malaria at six hospital sites in Kenya between 2008 and 2021 were tested for immediate *ex-vivo* and *in-vitro* susceptibility to selected antimalarials using SYBR Green I fluorescence-based assay. Drugs tested include; piperazine (PPQ), dihydroartemisinin (DHA), lumefantrine (LM), artemether (ART) and chloroquine (CQ). W2 and D6 reference clones were tested in parallel as the assay and test controls. Additionally, each isolate was assessed for drug resistance markers in *Pfcr*, *Pfmdr1*, *Pfdhps*, *Pfdhfr*, *Pfpm2/3*, *Pfexo* and *Pfk13* genes using qPCR and mass ARRAY platform. Lumefantrine median IC<sub>50</sub>s inclined significantly between 2008; 11.0 nM, n=54 (IQR 2.7 nM to 26.9 nM) and 2021; 30.55 nM, n=51 (IQR 3.2 nM to 47.7 nM) ( $p < 0.05$ ). A steady statistically significant decline in median IC<sub>50</sub> for CQ was observed between 2008; 7.9 nM, n=36 (IQR 3.9 nM to 15.8 nM) and 2021; 4.6 nM, n=62 (IQR 3.1 nM to 8.2 nM) ( $p < 0.05$ ). However, the PPQ susceptibility during the study timeline was stable, median IC<sub>50</sub> of 16.8 nM, n=34 (IQR 10.8 nM to 23.1 nM) in 2008 and 14.1 nM, n=42 (IQR 6.4 nM to 21.3 nM) in 2021. There were varying trends in response of naturally acquired infection clinical isolates between 2008 and 2021 as depicted by increasing sensitivity to CQ and impaired response to LM. These findings underscore the paucity of the drug resistance profile trends and warrant continued surveillance in order to support effective treatment.

<sup>1</sup>Department of Immunology and Infectious Diseases, Harvard T.H. Chan School of Public Health, Boston, MA USA, Boston, MA, United States, <sup>2</sup>Metabolomics Platform, The Broad Institute, Cambridge, MA USA, Boston, MA, United States, <sup>3</sup>University of California, San Diego, San Diego, CA, United States, <sup>4</sup>Center for Systems Biology, Massachusetts General Hospital, Boston, MA USA, Boston, MA, United States

Halofuginone (HFG) is a potent antimalarial drug that targets the *Plasmodium falciparum* cytoplasmic prolyl tRNA synthetase (*PfcPRS*). Previously, we had shown that parasites selected for an extended time with increasing concentrations of HFG develop high-level resistance conferred by mutations in the *pfcpr* target (mutant EC<sub>50</sub> = 180nM, Dd2 wildtype (WT) EC<sub>50</sub> = 0.7nM). In contrast, short-term exposure to HFG yielded parasites with moderate resistance yet no mutation in the *pfcpr* locus (EC<sub>50</sub> = 18-24nM). Previous studies showed that exposure to HFG triggers

a novel mechanism of drug tolerance, termed the Adaptive Proline Response (APR), wherein intracellular proline levels increase twenty-fold. Whole genomes sequencing of these parasites identified mutations in the major facilitator superfamily related protein 4 gene (*pfmfr4*, PF3D7\_0914700) resulting in predicted frameshift and nonsense mutations. This led to the hypothesis that APR mediated HFG-resistance was due to a loss of *PfMFR4* function. To test this hypothesis, we used CRISPR/Cas9 to disrupt the locus and generate *MFR4* knockout parasites (Dd2- $\Delta$ MFR4). Interestingly, Dd2- $\Delta$ MFR4 parasites showed a moderate HFG-resistance phenotype similar to that observed in APR parasites (Dd2 WT EC50 = 0.7nM, Dd2- $\Delta$ MFR4 EC50 = 14nM). However, these parasites were not previously exposed to HFG. To further understand the role of *MFR4* in modulating intracellular proline levels, we performed metabolomic studies in the Dd2- $\Delta$ MFR4 parasites. Metabolite profiling of Dd2- $\Delta$ MFR4 parasites showed an over 20-fold increase in intracellular proline levels relative to Dd2 WT parasites. These findings reveal a new drug resistance mechanism in *P. falciparum* that modulates metabolic homeostasis, which has implications for both parasite biology and antimalarial drug development.

### UPDATE ON MULTIDRUG RESISTANT PLASMODIUM FALCIPARUM MALARIA: TREATMENT OPTIONS IN THE CONTEXT OF CHANGING DRUG SUSCEPTIBILITY PROFILE IN CAMBODIA

Mariusz Wojnarski<sup>1</sup>, Somethy Sok<sup>2</sup>, Nonlawat Boonyalai<sup>1</sup>, Pattaraporn Vanachayangkul<sup>1</sup>, Panita Gosi<sup>1</sup>, Nillawan Buathong<sup>1</sup>, Sohei Hom<sup>3</sup>, Darapiseh Sea<sup>1</sup>, Michele Spring<sup>1</sup>, Jessica Lin<sup>4</sup>, Threechada Boonchan<sup>1</sup>, Paphavee Lertsethtakarn<sup>1</sup>, Piyaporn Saingam<sup>1</sup>, Chaipayorn Chaisatit<sup>1</sup>, Sabaithip Sriwichai<sup>1</sup>, Worachet Kuntawunginn<sup>1</sup>, Kittijarankon Phontham<sup>1</sup>, Montri Arsonok<sup>1</sup>, Saowaluk Wongarunkochakorn<sup>1</sup>, Lychhea Hout<sup>3</sup>, Pheaktra Oung<sup>3</sup>, Soklyda Chann<sup>5</sup>, Sovannarith Em<sup>5</sup>, Krisada Jongsakul<sup>1</sup>, Prom Satharath<sup>2</sup>, John Brooks<sup>6</sup>, Philip Smith<sup>1</sup>, Rekol Huy<sup>3</sup>, Brian Vesely<sup>1</sup>, Samantha Demons<sup>1</sup>, Shannon Takala-Harrison<sup>7</sup>, Mark M. Fukuda<sup>1</sup>, Chanthap Lon<sup>1</sup>, Dyosoley Lek<sup>8</sup>, Norman Waters<sup>1</sup>

<sup>1</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>Ministry of National Defense, Department of Health, Phnom Penh, Cambodia, <sup>3</sup>National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia, <sup>4</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>5</sup>Armed Forces Research Institute of Medical Sciences, Phnom Penh, Cambodia, <sup>6</sup>Naval Medical Research Unit 2, Phnom Penh, Cambodia, <sup>7</sup>University of Maryland School of Medicine, Baltimore, MD, United States, <sup>8</sup>National Center for Parasitology, Entomology and Malaria Control, Phnom Penh, Cambodia

Multi-drug resistant (MDR) strains of *Plasmodium falciparum* (*Pf*) continue to pose a significant threat to malaria elimination efforts in the Greater Mekong Subregion (GMS). The introduction of new drug combinations targeting multi-drug resistant strains of *Pf* was proposed for areas where conventional artemisinin-based combination treatments (ACTs) are losing their effectiveness. To guide optimal treatment options, we investigated anti-malarial drug susceptibilities of 638 *Pf* samples collected from 2015 to 2020 including both military and civilian populations. In Northern Cambodia, we observed a rise in IC90 values from 12.3 nM to 64 nM ( $p < 0.001$ ) for mefloquine (a component of first line ACT treatment). During the same period, there was corresponding decrease in piperazine IC90s, from 987 nM to 32.8 nM in Northern Cambodia. A similar decrease in mefloquine drug susceptibility was observed in Eastern Cambodia but without significant changes in PIP susceptibility (IC90s <100 nM). There were no 'triple mutant' isolates with K13 mutations, amplified *pfmdr1* and increased PM2 copy number despite concerns about the emergence of these strains. Samples from Northern Cambodia demonstrated a pattern of drug susceptibility similar to isolates from the neighboring Thai province. Utilizing whole genome sequencing, the relatedness of these parasites is being explored. The samples were also tested against 13 additional antimalarials and found to be highly susceptible to tafenoquine (IC50 138 nM) and pyronaridine (IC50 6.4), the 2 latest antimalarials

approved for treatment. Corresponding treatment outcome data are available for 92 isolates collected as part of multi-center clinical trial (APACT study) in which volunteers received treatment with single-dose primaquine and one of the following: artesunate-pyronaridine, artesunate-pyronaridine plus atovaquone-proguanil, or artesunate-mefloquine plus atovaquone-proguanil. The treatment outcomes for these combinations and the effect of the partner drugs on the metabolism of primaquine will also be presented to help guide optimal drug combinations in the GMS.

1063

### HOST INFLAMMATORY, MATRIX METALLOPROTEINASE AND CELL DEATH RESPONSES TO ACUTE MALARIA TREATED WITH MEFLUQUINE AND THE ROLE OF CURCUMIN SUPPLEMENTATION

Oludele John Olanlokun, Wisdom O. Abiodun, Olufunso O. Olorunsogo

University of Ibadan, Ibadan, Ibadan, Nigeria

Pro-inflammatory signaling cascade, cell death and activation of matrix metalloproteinases are sepsis events in *Plasmodium* infection. It is however, not known if treatment with mefloquine (MF), an antimalarial drug with curcumin (CM) supplementation will modulate this effect. Malaria was induced using chloroquine sensitive (NK 65, study 1), and chloroquine resistant (ANKA, study 2) strains of *Plasmodium berghei* in thirty male Swiss mice (n=5). Following confirmation of parasitemia, animals received 10mL/kg distilled water (infected control), MF (10mg/kg), MF and CM (25mg/kg), MF and CM (50mg/kg), CM (25mg/kg) and CM (50mg/kg). Five mice (not infected) were used as control. After treatment, the animals were terminated via cervical dislocation. Liver mitochondria were isolated via differential centrifugation. Serum Interleukins 1 beta and six (IL-1 $\beta$  and IL-6), Tumour Necrosis Factor alpha (TNF $\alpha$ ), C-reactive protein (CRP), Immunoglobulins G and M (IgG and IgM), caspases 3 and 9 (C3 and C9) were assayed using ELISA techniques, mitochondrial membrane permeability transition (mPT), F<sub>0</sub>F<sub>1</sub> ATPase and lipid peroxidation (mLPO) were determined spectrophotometrically. Matrix metalloproteinases 2 (MMP2) and 9 (MMP9) expressions were determined electrophoretically. CM supplementation (25mg/kg) significantly decreased serum IL-6, TNF $\alpha$  and CRP compared with MF only. In the resistant model, CM prevented mPT pore opening, significantly decreased F<sub>0</sub>F<sub>1</sub> ATPase activity and mLPO. MF activated caspase 3 while supplementation with CM significantly decreased this effect. CM supplementation increased immunoglobulin levels. MMP2 and MMP9 were selectively expressed in the susceptible groups only. Malarial treatment elicits different cell death response mitigated by curcumin supplementation.

1064

### MOLECULAR MARKERS OF ANTIMALARIAL DRUG RESISTANCE IN UGANDAN CHILDREN WITH SEVERE MALARIA AND RISK OF READMISSION OR REPEAT ILLNESS

Adnan Gopinadhan<sup>1</sup>, Dibadyuti Datta<sup>1</sup>, Jenny Legac<sup>2</sup>, Caitlin Bond<sup>1</sup>, Andrea L. Conroy<sup>1</sup>, Robert O. Opoka<sup>3</sup>, Philip J. Rosenthal<sup>2</sup>, Chandy C. John<sup>1</sup>

<sup>1</sup>Indiana University School of Medicine, Indianapolis, IN, United States, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>Makerere University, Kampala, Uganda

We investigated the presence of anti-malarial drug resistance markers in *P. falciparum* samples from a cohort of Ugandan children with severe malaria (cerebral malaria or severe malarial anemia) and asymptomatic community children (CC) enrolled from 2008-2013. 159 children with severe malaria (SM) and 49 CC with asymptomatic parasitemia were tested and followed up for 2 years. Children with SM were treated with parenteral quinine or artemether before 2011, and after 2011 with either of these drugs or artesunate, each followed by oral quinine or artemether-lumefantrine. From enrollment filter paper blood spots, we evaluated polymorphisms in genetic markers of resistance associated with response to chloroquine (*pfcr*); chloroquine, quinine, and lumefantrine (*pfmdr1*); or artemisinin

(*pfkelch13*). In children with SM, prevalence of the mutant *pfcr1* K76T allele was 96%, indicating widespread chloroquine resistance. For *pfmdr1*, prevalence of mutant or mixed alleles for N86Y, Y184F, and D1246Y, were 71%, 50%, and 75%, respectively. Parasite genotypes were similar in asymptomatic CC. After hospital discharge, children with SM infected with the mutant *pfmdr1* 1246Y allele had an increased risk of readmission (age adjusted hazard ratio 2.44 [95% CI, 1.10, 5.41],  $p=0.03$ ) and a higher incidence rate ratio (IRR) of outpatient visits for illness (age adjusted IRR 1.85 [95% CI, 1.00, 3.44],  $p=0.05$ ) than children infected with only the WT D1246 allele. For *pfkelch13*, prevalence of mutations upstream of the propeller domain in children with SM and asymptomatic CC was 56% and 51% respectively. We identified two infections with A578S and one with S522C mutation in the propeller domain of *Pfkelch13*. The study data support the need for continued surveillance of markers associated with resistance to antimalarial drugs, and highlight the possibility of drug resistance leading to an increased risk of repeat infections or readmission for SM.

1065

### EMERGENCE AND EXPANSION OF PLASMODIUM FALCIPARUM WITH PFK13 POLYMORPHISMS POTENTIALLY ASSOCIATED WITH ARTEMISININ RESISTANCE IN UGANDA

**Victor Asua<sup>1</sup>**, Melissa D. Conrad<sup>2</sup>, Jennifer Legac<sup>2</sup>, Deborah Chin<sup>3</sup>, David Giesbrecht<sup>3</sup>, Emmanuel Arnaitwe<sup>1</sup>, Patrick Tumbwebaze<sup>1</sup>, Roland Cooper<sup>4</sup>, Ozkan Aydemir<sup>3</sup>, Yeka Adoke<sup>1</sup>, Moses R. Kanya<sup>1</sup>, Samuel Nsohya<sup>1</sup>, Grant Dorsey<sup>2</sup>, Jeffrey Bailey<sup>3</sup>, Philip J. Rosenthal<sup>2</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>University of California, San Francisco, CA, United States, <sup>3</sup>Brown University, Providence, RI, United States, <sup>4</sup>Dominican University of California, San Rafael, CA, United States

For over a decade, artemisinin-based combination therapies (ACTs) have been the mainstay of treatment of uncomplicated malaria in Africa. Resistance to artemisinins, mediated by several polymorphisms in the propeller domain of the *P. falciparum* Kelch protein (PfK13), is widespread in southeast Asia. Recent reports suggest that previously rare Pfk13 polymorphisms associated with artemisinin resistance are now emerging in parts of Africa. We are continuing surveillance for key resistance associated polymorphisms at 16 health facilities across Uganda, including dideoxy and molecular inversion probe deep sequencing of *pfk13* and analysis of 8 microsatellites flanking the *pfk13* gene. Preliminary results for samples collected in 2020 are reported here. Out of 952 samples with available data from dideoxy sequencing, we observed 22 Pfk13 polymorphisms, 4 with prevalences above 5% at individual sites. Two polymorphisms, 469Y and 675V, which are candidate markers for artemisinin resistance based on results in southeast Asia, had prevalences of 4.2-30.5% and 1.2-12.5%, respectively, with results similar to those seen in samples from 2018-19, but with spread to additional sites. Two other polymorphisms, 469F and 442L, were seen at sites in south-western Uganda at prevalences up to 29.7% and 7.1%, respectively. Considering older samples, analysis of flanking microsatellites in samples from 2018-19 suggested local emergence and clonal expansion of mutant isolates. Next generation deep sequencing of 2020 isolates, a more sensitive assay for minority variants, and assessment of prevalences of other drug resistance-associated polymorphisms, is underway. Our results provide evidence of emergence of *P. falciparum* with genetic polymorphisms that may diminish the efficacy of ACTs in Africa.

### CARDIAC SAFETY MONITORING OF ARTEMISININ-BASED COMBINATION THERAPY IN HIV-INFECTED AND HIV-UNINFECTED UGANDAN CHILDREN

**McKenzie Colt<sup>1</sup>**, Audun J. Lier<sup>2</sup>, Malik Koire<sup>3</sup>, Francis Orukan<sup>4</sup>, Meghan Whalen<sup>5</sup>, Grace Kisitu<sup>3</sup>, Norah Mwebaza<sup>4</sup>, Richard Kajubi<sup>4</sup>, Francesca Aweeka<sup>5</sup>, Sunil Parikh<sup>1</sup>

<sup>1</sup>Department of Epidemiology of Microbial Diseases, Yale School of Public Health, New Haven, CT, United States, <sup>2</sup>Section of Infectious Diseases, Yale School of Medicine, New Haven, CT, United States, <sup>3</sup>Center of Excellence in Health Equity, Training and Research, Baylor College of Medicine, Houston, TX, United States, <sup>4</sup>Infectious Disease Research Collaboration, Makerere University College of Life Sciences, Kampala, Uganda, <sup>5</sup>Department of Clinical Pharmacology, University of California San Francisco, San Francisco, CA, United States

Artemisinin-based combination therapy is recommended as first-line treatment for uncomplicated malaria in sub-Saharan Africa where there is high HIV and malaria coinfection. The impact of antiretroviral (ART) drug interactions on antimalarial exposure may lead to cardiotoxicity via corrected QT (QTc) prolongation, raising the risk of fatal arrhythmias. In the context of two clinical trials, we assessed the cardiac safety of artemether-lumefantrine (AL) and dihydroartemisinin-piperazine (DP) in children with and without HIV. The first trial, EXALT (Extended Duration Artemether-Lumefantrine Treatment for Malaria in Children), is a randomized, open-label, prospective pharmacokinetic (PK) and pharmacodynamic (PD) study of extended duration AL conducted in Busia, Uganda. EXALT enrolled HIV-infected children on an efavirenz-based ART and HIV-uninfected children, both with uncomplicated malaria. Participants were randomized to 3-day or 5-day treatment groups. The second trial, DPART (DP in the context of antiretroviral therapy), is an open label, prospective PK study in Kampala and Busia. The trial is enrolling HIV-infected children on lopinavir/ritonavir-, efavirenz-, or dolutegravir-based ART regimens, compared with HIV-uninfected children, all receiving a single or 3-day course of DP. ECG monitoring for QTc prolongation is ongoing at baseline, pre/post-last dose, 24-hours post last dose, and at the end of follow-up. To date, we have completed enrollment and follow-up with ECG analysis in EXALT on 42 HIV-infected children, and 107 HIV-uninfected children. For DPART, we have enrolled 30 children on efavirenz-based ART, 20 on lopinavir-ritonavir, and 30 on dolutegravir-based ART, with other groups being enrolled currently. Preliminary data suggests no significant increase in QTcF between the 5-day and 3-day AL treatment groups, no significant prolongation of QTcF in HIV-infected children receiving DP in the context of efavirenz-based ART, or single-dose lopinavir-ritonavir. Results for all groups will be presented, providing a comprehensive dataset on the use of DP with several HIV regimens, and extended duration AL.

1067

### A SECONDARY LOCUS ON CHROMOSOME 6 INTERACTS WITH PFCRT TO CONFER HIGH LEVEL CHLOROQUINE RESISTANCE

**Katrina A. Button-Simons<sup>1</sup>**, Katelyn Vendrely<sup>1</sup>, Xue Li<sup>2</sup>, Sudhir Kumar<sup>3</sup>, Lisa A. Checkley<sup>1</sup>, Nelly Carmago<sup>3</sup>, Meseret T. Haile<sup>3</sup>, Spencer Y. Kennedy<sup>3</sup>, Douglas A. Shoue<sup>1</sup>, Ann Reyes<sup>2</sup>, Marina McDew-White<sup>2</sup>, Abeer Sayeed<sup>2</sup>, François H. Nosten<sup>4</sup>, Stefan H. Kappe<sup>3</sup>, Ian H. Cheeseman<sup>5</sup>, Ashley M. Vaughan<sup>3</sup>, Timothy J. Anderson<sup>2</sup>, Michael T. Ferdig<sup>1</sup>

Is chloroquine (CQ) resistance simple or complex? Mutations in *pfcr*t have a large effect on CQ resistance. Additional transporters, such as *pfmdr*1, have been shown to influence levels of CQ resistance in some genetic backgrounds. Utilizing human liver-chimeric mice infused with human red blood cells (the FRG huHep/huRBC mouse), we can efficiently generate crosses using recent patient-derived parasite isolates to explore how loci interact and contribute to drug resistance phenotypes. We utilize a cross between lab-adapted NF54 (CQ-susceptible) and NHP4026, a recent CQ-resistant Southeast Asian isolate to search for additional loci. Initially, we used a bulk segregant approach, pressuring uncloned progeny populations with CQ followed by bulk sequencing. This reveals a strong QTL on Chr 7 (coinciding with *pfcr*t) as expected, but we also see a QTL on Chr 6. The Chr 7 NHP4026 *pfcr*t allele is in strong LD with the Chr 6 QTL allele from NHP4026. To uncover the specific genetic architecture of these QTL, we chose 16 cloned progeny bearing distinct combinations of parental alleles at the Chr 6 and 7 QTL and measured CQ IC<sub>50</sub>. These QTL interact epistatically to control variation in CQ IC<sub>50</sub> of individual progeny: the *pfcr*t locus controls 60% of the variation in CQ IC<sub>50</sub> and the Chr 6 QTL modulates resistance controlling 16% of the variation primarily in resistant progeny. The Chr 6 QTL contains an outstanding candidate locus - the amino acid transporter *pfat1* - which shows strong signals of selection and strong interchromosomal LD with *pfcr*t in natural parasite populations. This locus was identified in genome wide association analyses examining CQ-resistance, and underlies CQ-resistance in the *P. chabaudi*. CRISPR/Cas9 gene editing studies are in progress to examine the functional role of two SNPs that differentiate NF54 and NHP4026. These results (i) demonstrate the utility of identifying QTL using rapid bulk segregant analyses and determining how these QTL interact to determine phenotypes using a subset of individual progeny and (ii) reveal that CQ-resistance is oligogenic involving at least three loci - *pfcr*t, *pfmdr*1 and the chr 6 locus identified here.

### EFFECTIVENESS OF RECTAL ARTESUNATE IMPLEMENTED AS PRE-REFERRAL TREATMENT FOR SEVERE MALARIA IN CHILDREN IN THREE AFRICAN COUNTRIES

**Manuel W. Hetzel**<sup>1</sup>, Proscovia Athieno<sup>2</sup>, Phyllis Awor<sup>2</sup>, Nina Brunner<sup>1</sup>, Giulia Delvento<sup>1</sup>, Jean-Claude Kalenga<sup>3</sup>, Joseph Kimera<sup>2</sup>, Mark Lambiris<sup>1</sup>, Tristan Lee<sup>1</sup>, Jean Okitawutshu<sup>3</sup>, Elizabeth Omoluabi<sup>4</sup>, Aita Signorelli<sup>1</sup>, Antoinette Tshetu<sup>3</sup>, Valentina Buj<sup>5</sup>, Theodor Visser<sup>6</sup>, Christian Lengeler<sup>1</sup>, Christian Burri<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Makerere University School of Public Health, Kampala, Uganda, <sup>3</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Akena Associates, Abuja, Nigeria, <sup>5</sup>UNICEF, New York, NY, United States, <sup>6</sup>Clinton Health Access Initiative, Boston, MA, United States

Parenteral artesunate followed by an oral artemisinin-based combination therapy (ACT) is the recommended treatment for severe malaria. In remote settings, where most malaria deaths occur, parenteral treatment is rarely available. In a clinical trial, pre-referral treatment with rectal artesunate (RAS) reduced case fatality in children with signs of severe malaria who delayed reaching a referral facility. Regardless of potential, the real-world impact of RAS is expected to be lower due to health system constraints. In a multi-country observational study, we assessed the health status and treatment seeking of children below 5 years with suspected severe malaria 28 days after they presented to a community health worker or primary health centre ('community enrolments'), or to a referral facility. Enrolment started 10 months before and continued 15 months after the roll-out of RAS in the Democratic Republic of the Congo (DRC), Nigeria and Uganda. We included 11,952 children in the analysis (6,216 community enrolments). The case fatality in the pooled sample was 3.9% (95% CI 3.5, 4.4) in community enrolments and 2.6% (95% CI 2.3, 3.1) in referral facility enrolments. An additional 13.3% and 12.3%, respectively, were

alive but sick after 28 days. RAS use reduced the risk of dying in Uganda (adjusted risk ratio [aRR] = 0.27, 95% CI 0.09, 0.77) but only the risk of illness in DR Congo and Uganda. Completing referral did not consistently reduce the risk of dying, but administration of an ACT in Uganda (aRR = 0.23; 95% CI 0.09, 0.58) or injectable artesunate plus ACT in DRC (aRR = 0.40; 95% CI 0.23, 0.68) were protective. Oral ACT was not consistently administered following RAS and injectable artesunate treatment. This is the largest community-based study of severe febrile illnesses in highly malaria-endemic areas. A functioning continuum of care is essential for RAS to have a noticeable impact. With fluctuations in RAS use, health systems constraints and secular trends, the roll-out of RAS did not reduce case fatality in children with suspected severe malaria in the project countries, despite some evidence of a positive health effect of RAS at an individual level.

1069

### DISSECTING THE RELATIVE CONTRIBUTIONS OF PFCRT AND PLASMEPSIN II/III COPY NUMBER ON PIPERAQUINE SENSITIVITY USING A GENETIC CROSS

**Haley Dahlhoff**<sup>1</sup>, Lisa A. Checkley<sup>1</sup>, Xue Li<sup>2</sup>, Sudhir Kumar<sup>3</sup>, Puspendra P. Singh<sup>1</sup>, Katelyn M. Vendrely<sup>1</sup>, Douglas A. Kappe<sup>3</sup>, Franaois Nosten<sup>4</sup>, Ian H. Cheeseman<sup>2</sup>, Tim J. Anderson<sup>2</sup>, Ashley M. Vaughan<sup>3</sup>, Michael T. Ferdig<sup>1</sup>

<sup>1</sup>Eck Institute for Global Health, University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>3</sup>Center for Global Infectious Disease Research, Seattle Children's Research Institute, Seattle, WA, United States, <sup>4</sup>Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine Research building, University of Oxford, Oxford, United Kingdom

Piperaquine (PPQ) is widely used in combination with dihydroartemisinin (ACT) as a first-line treatment of malaria infection. Resistance to this ACT has emerged in Cambodia and is threatening to spread to other malaria endemic regions. Multiple drivers of PPQ resistance have been proposed, including mutations in the *Plasmodium falciparum* chloroquine resistance transporter (PfcRT) and increased copies of plasmepsin II/III (PM). Genetic crosses offer a unique opportunity to quantify the relative contributions of different mutations to phenotypes and have the distinct advantage of assaying the effects of naturally evolved genetic variation in genome-wide context. We crossed KH004-2-019, an isolate from a rapidly spreading multi-drug resistant Southeast Asian lineage to a generally drug susceptible Malawian isolate, Mal31. Mal31 harbors a wild-type PfcRT and one copy of PM, while KH004 has a chloroquine-resistant PfcRT and a mean of 4 copies of PM. Neither parent carried known PPQ resistance SNPs in PfcRT. We isolated 103 unique progeny from this cross and focused on a targeted set of progeny representing all possible combinations of PfcRT and PM alleles for their contribution to the PPQ Survival Assay (PSA) phenotype, standard dose-concentration effect curves, and head-to-head fitness competitions. Importantly, progeny inheriting the KH004 PM inherited a range of copies (1-5), giving us a unique opportunity to directly assess the contribution of increasing copies on the phenotypes. We find that progeny inheriting both PfcRT and PM alleles from KH004 are PPQ resistant for both drug response phenotypes, and the inheritance of KH004 PfcRT is required for resistance. Isogenic progeny that differed only in PM copy number showed that increased copies generate higher resistance, a trend not observed in progeny inheriting Mal31 PfcRT. Ongoing studies will determine whether PfcRT can, by itself, generate PPQ-R in this cross as well as the effect of copy number on competitive outcomes among these progeny clones. These data indicate that the relationship between PPQ-resistance and PM copy number is not simple and may be conditional on PfcRT genotype.

### MARKED DECREASE IN ANTIBIOTIC USAGE FOLLOWING INTENSIVE MALARIA CONTROL IN A COHORT OF UGANDAN CHILDREN

<sup>4</sup>University of Washington, Seattle, WA, United States, <sup>5</sup>Makerere University College of Health Sciences, Kampala, Uganda

Malaria control interventions reduces all-cause child mortality and hospitalizations. Acute bacterial infections are common in malaria endemic settings, and the widespread use (and overuse) of antibiotics to treat these infections, particularly in outpatient settings, drives the antimicrobial resistance. This observational study of two sequential cohorts of children aged 6 months through 10 years in Tororo District, Uganda assesses the association between malaria control and outpatient prescriptions of antibiotics from 2011 to 2019. Indoor residual spraying (IRS) beginning in December 2014 was associated with a dramatic decline in the incidence of malaria treatments, from 2.68 treatments per person-year (ppy) before IRS to an average of 0.05 ppy in years 4-5 after IRS was instituted. Antibiotic prescriptions also dropped from 4.13 ppy prior to IRS, to 1.26 ppy in years 4-5. This corresponds to a 70% decrease in the IRR (95% CI: 66% to 73%;  $p < 0.001$ ), and 2.88 fewer antibiotic treatments per person-year (95% CI: 2.54-3.21;  $p < 0.001$ ). To explore potential mechanisms for this finding, data were stratified by fever and parasitemia status at the time antibiotics were prescribed. Compared to pre-IRS, there was a small but significant increase in antibiotic treatments among children who were afebrile without parasitemia. All other categories experienced significant reductions, with the most marked declines in children who were febrile with either sub-microscopic parasitemia (IRD=1.15, 95% CI: 1.02-1.27,  $p < 0.001$ ) or clinical malaria (IRD=1.12, 95% CI: 0.99-1.25;  $p < 0.001$ ). Upper respiratory infections (URI) were the most common diagnostic category, but both annual incidence and proportion of antibiotics declined over time. Amoxicillin was the most common antibiotic prescribed throughout the study and it also declined in both incidence and proportion over time. These results demonstrate that successful efforts to control malaria in highly endemic settings may have additional benefits for child health beyond malaria with additional implications for health systems and the spread of antimicrobial resistance.

### MAPPING PARTNER DRUG RESISTANCE TO GUIDE ANTIMALARIAL COMBINATION THERAPY POLICIES IN SUB-SAHARAN AFRICA

Hanna Ehrlich, Amy K. Bei, Daniel M. Weinberger, Joshua L. Warren, Sunil Parikh

Yale University, New Haven, CT, United States

Resistance to artemisinin-based combination therapies (ACTs) threatens the global control of *Plasmodium falciparum*. Although ACTs remain widely effective in sub-Saharan Africa, long-standing circulation of parasite alleles associated with reduced partner drug susceptibility may contribute to the development of clinical resistance. Molecular markers provide rapid information on landscapes of resistance to ACTs and can protect the efficacy of artemisinin by informing regional selections of longer-acting partner drugs. We fit a hierarchical Bayesian spatial model to data from over 500 molecular surveys to predict the prevalence and frequency of four key markers in transporter genes (*pfcr1* 76T, *pfmdr1* 86Y, 184F, and 1246Y) in first-level administrative divisions in sub-Saharan Africa, from the uptake of ACTs (2004-2009) to their widespread usage (2010-2018). Our models estimated that the *pfcr1* 76T mutation decreased in prevalence in 90% of regions, the *pfmdr1* N86 and D1246 wild-type genotypes

increased in prevalence in 96% and 82% of regions, respectively, and there was no significant directional selection at the *pfmdr1* Y184F loci. Rainfall seasonality was the strongest predictor of the prevalence of wild-type genotypes, with other covariates including first-line drug policy and transmission intensity more weakly associated. We lastly identified regions of high priority for additional surveillance that could signify decreased susceptibility to the local first-line ACT. These results can be used to infer the degree of molecular resistance and magnitude of wild-type reversion in regions without survey data to inform therapeutic policy decisions. Working with global partnerships and local National Malaria Control Programs, our work can assist in efforts to sustain the use of ACTs as first-line therapies and improve disease surveillance strategies more broadly.

### ANALYSIS OF THE DISCREPANCY BETWEEN MICROSCOPY AND RAPID DIAGNOSTIC TESTS (RDTs) FOR THE DETECTION OF PLASMODIUM FALCIPARUM IN TWO DIFFERENT ENDEMIC SETTINGS OF DANGASSA AND KOILA, MALI

Fousseyni Kane, Mahamoudou Toure, Daouda Sanogo, Sory Ibrahim Diawara, Idrissa Konate, Nafomon Sogoba, Seydou Doumbia

West African International Center for Excellence in Malaria Research (ICEMR-WA), University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali

In malaria-endemic areas, early and accurate diagnosis of malaria is essential for both effective disease control and surveillance as misdiagnosis can be associated with significant morbidity and mortality. The present study aimed to analyze the discordance between the microscopy and the rapid diagnostic test (RDT) results, in two ecological settings with different transmission patterns (Dangassa and Koila in Mali). This study includes a cohort of 1400 persons followed in each of the two villages. Microscopy and RDT (Malaria HRP2/pLDH Pf) were performed on all patients received at the community health center with suspected malaria symptoms during the study period (2013-2016). Frequencies with 95% confidence intervals (CI) with the Wilson-Brown method were used for categorical variables. Discrepancies between the two methods were analyzed and estimated by odds ratio (OR) with 95%CI regarding age, parasite load, season, and geographical settings. A total of 4,666 samples tested by microscopy and RDT, were analyzed, with respectively 3,616 and 1,050 samples for Dangassa and Koila from 2013 to 2016. The average cumulative incidence per 1000 persons\*year was 34 cases  $\pm$  8.7 in Dangassa and 9 cases  $\pm$  8.06 in Koila. Compared to Dangassa, RDTs to Koila had higher sensitivity (90.17; 95% CI 87.66-92.21 vs 83.07; 95% CI 81.50-84.53, respectively). The same trend was observed with the specificity (83.8; 95% CI 79.82-92.46 vs. 63.16; 95% CI 60.47-65.78, respectively). The Likelihood Ratio (LR) showed a moderate effect in Koila (LR= 5.56) versus a weak effect in Dangassa (LR= 2.25). During the rainy seasons, 95% susceptibility was observed in Koila vs. 86% in Dangassa, with twice the disease incidence in Dangassa. Regression analysis showed an increase in discrepancy with increasing age, rainy season, and parasite load. This study showed the presence of diagnostic discrepancies between RDT and microscopy. These discrepancies can probably be influenced by factors such as age, seasonality, or malaria endemicity. However, further studies are needed to better estimate the discrepancies between all malaria diagnostic methods.

### LABORATORY DIAGNOSTIC CAPACITY AND PROFICIENCY IN MALARIA MICROSCOPY IN KENYA: IMPLICATIONS FOR ROLLOUT OF QUALITY ASSURANCE PROGRAM

Regina Kandie<sup>1</sup>, Gatakaa Hellen<sup>2</sup>, Kiplagat Rosebella<sup>3</sup>, Ngindu Augustine<sup>2</sup>, Yamo Emmanuel<sup>2</sup>, Dickson Mwakangalu<sup>1</sup>, Lolade Oseni<sup>4</sup>, Gladys Tetteh<sup>4</sup>, Ballard Sarah-Blythe<sup>5</sup>, Wacira Daniel<sup>6</sup>

<sup>1</sup>Division of National Malaria Program, Nairobi, Kenya, <sup>2</sup>PMI Impact Malaria Project, Nairobi, Kenya, <sup>3</sup>National Malaria Reference Laboratory, Nairobi, Kenya, <sup>4</sup>PMI Impact Malaria Project, Baltimore, MD, United States,

<sup>5</sup>US President's Malaria Initiative, US Centers for Disease Control and Prevention, Nairobi, Kenya, <sup>6</sup>US President's Malaria Initiative, United States Agency for International Development, Nairobi, Kenya

Quality malaria case management (CM) requires accurate diagnosis, which depends on well-trained microscopists, functional equipment, supplies, quality assurance, and consistent supervision. To assess malaria diagnostic capabilities in Kenya, Impact Malaria (IM) supported the Division of National Malaria Program (DNMP) to conduct a national cross-sectional assessment of 169 public health facilities (17 county hospitals, 47 sub-county hospitals, 100 health centres) in 43/47 counties in September 2020. A standard checklist was used to identify capacity gaps, and proficiency testing was conducted to assess performance on malaria parasite detection, species identification, and parasite quantification with a validated slide set (3 negative, 3 positive with pre-quantified parasitemia ranges, 4 species identification). Less than 50% of health centres and sub-county hospitals participated in quality assurance programs compared to 100% for county referral hospitals. Standard operating procedures were available in a third of health centres, about half of sub-county hospitals, and in all county referral hospitals. WHO-guided proficiency testing of 112 microscopists with 568 positive and 460 negative slides identified 17% false negatives and 7% false positives. Compared with the WHO-informed 80% national standard, microscopists achieved 76% agreement (A) with a Kappa (K) value of 0.52 on parasite detection (0.44 in health centres; 0.70 county referral hospitals) and A: 48%; K: 0.29 on species identification (0.25 in health centres; 0.36 county referral hospitals). Parasite quantification results were available for 125/1,028 (12%), due to lack of timers (56%) for staining and tally counters (43%) for quantification. Multi-level diagnostic inadequacies, mostly in lower level facilities where most malaria cases present, reduce malaria CM quality and can affect quality of diagnosis results. To address the gaps, IM will support the DNMP, Department of Public Health Laboratory, and Counties to improve diagnostic quality through supply chain improvements, staff training, supportive supervision, and quality assurance programs.

1074

### LEVERAGING GEOSPATIAL MAPPING TO OPTIMIZE THE CONTINUITY OF MALARIA CARE DURING COVID-19 PANDEMIC BY COMMUNITY-BASED HEALTH WORKERS IN MASHONALAND EAST, ZIMBABWE

**Busisani Dube**<sup>1</sup>, Paul Matsvimbo<sup>1</sup>, Brighton Gambia<sup>2</sup>, Munyaradzi Mareke<sup>2</sup>, George Machacha<sup>1</sup>, Abaden Svisva<sup>2</sup>, Eliza Walwyn-Jones<sup>2</sup>, Dominic Lucero<sup>2</sup>, Patience Dhlwayo<sup>1</sup>, Joseph Mberikunahe<sup>1</sup>

<sup>1</sup>National Malaria Control Program, Harare, Zimbabwe, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States

In Zimbabwe, existing gaps in access to health services have been worsened by the COVID-19 outbreak. COVID-19 related travel restrictions and inadequate personal protective equipment (PPE) threatened normal health service delivery. Community Health Workers (CHWs) substantially contribute to primary health services delivery, including providing 30% of national malaria tests. The peak malaria transmission season for 2020 coincided with the emergence of COVID-19, creating a challenge for CHWs managing malaria due to the similarity in symptoms of malaria and COVID-19 and limited PPE availability. As a result, the National Malaria Control Program (NMCP), working with partners, mobilized resources to train CHWs on the safe delivery of services during the COVID-19 outbreak and provide the required PPE for use by the CHWs. In January 2021, supportive supervision visits were conducted in four districts in Mashonaland East province to map 1,258 CHWs and understand gaps in CHW needs and accessibility at a time of increased demand for services. A data collection tool was developed to measure access to CHW services by the communities at high risk of malaria, provision of COVID-19 support by CHWs, and availability of malaria case management commodities for CHWs testing and treating for malaria. Data were collected using Survey CTO and analyzed in SPSS and QGIS. Using drive-time to the nearest health facility as a measure of access to healthcare service for the

population in the CHW catchment area, the analysis showed that 37% of CHWs were operating within 15 minutes of the nearest health facility, 31% within 30 minutes to a health facility and 32% in areas over 30 minutes away from the nearest health facility. The proportion of malaria cases tested in the community in the four districts increased steadily after the COVID-19 related lockdown, resulting in CHWs contributing 45% of 232,420 malaria rapid diagnostic tests and treating 50% of the 99,469 positive malaria cases recorded in 2020. The data also reflected gaps in the availability of PPE and commodity stock out on RDTs and ACTs, primarily driven by the unexpected surge in patient attendance at the CHW level.

1075

### ADHERENCE TO CASE MANAGEMENT GUIDELINES BASED ON RESULTS OF MALARIA RAPID DIAGNOSTIC TESTS IN SUB-SAHARAN AFRICA FROM 2010-2020: A SYSTEMATIC REVIEW

**Michael Humes**

USAID - PMI, Washington, DC, United States

In 2010, the WHO updated case management guidelines for uncomplicated malaria, recommending parasite-based diagnosis in endemic areas. As a result, the annual number of suspected malaria cases that received a diagnostic test across sub-Saharan Africa (SSA) from 2010 to 2019 increased from 51 million to 235 million, respectively. This was driven by scale-up of malaria rapid diagnostic test (RDT) use, which increased in SSA from 21 million instances in 2010 to 195 million in 2019. This scale-up was vital towards improving the quality of malaria case management, yet provider adherence to guidelines based on test results ("adherence") has not been systematically assessed across SSA. To evaluate provider adherence, determinants of provider adherence, and patient-client factors, we followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses guidelines to conduct a systematic search using Embase and Scopus, and five search engines to identify articles published from January 2010 to August 2020. Search terms included "malaria," "rapid diagnostic test," and "adherence," combined with "Africa". Bibliographies of relevant studies were checked for other publications. Of 1,463 articles identified, 324 were reviewed and results from 76 were analyzed. This review synthesizes trends of RDT adherence across SSA over the past decade and highlights key factors driving adherence issues. Adherence when RDTs were positive was universally high; adherence when RDTs were negative varied. Improved adherence for negative RDT results was associated with training and supervision, trust in RDT quality, accepted practice norms, manageable patient caseloads, and adequate RDT stock. Persistent poor adherence when RDTs are negative contributes to overuse of antimalarials, distorts malaria surveillance data, may deprive patients of treatments for non-malaria fevers, and may obscure detection of other febrile illness with pandemic potential. Information about adherence to RDTs and drivers of adherence can inform program interventions and improved case management practices and guide future studies on identified gaps.

1076

### A TABLET-BASED HEALTH NETWORK QUALITY IMPROVEMENT SYSTEM (HNQIS) FOR DATA-DRIVEN DECISION MAKING AND TARGETED OUTREACH TRAINING SUPPORTIVE SUPERVISION (OTSS+) AT LOW PERFORMING SITES IN THE DEMOCRATIC REPUBLIC OF CONGO (DRC)

**Ange Landela**<sup>1</sup>, Saraphine Kutumbakana Kimwesa<sup>1</sup>, Anselme Manyong Kapit<sup>1</sup>, Lennie Kyomuhangi<sup>2</sup>, Julie Buekens<sup>2</sup>, Jordan M. Smith<sup>2</sup>, Nicole Carbone<sup>3</sup>, Luigi Nunez<sup>3</sup>, Charlotte Eddis<sup>3</sup>, Dieudonne Mumba Ngoyi<sup>4</sup>, Godefroid Tshiswaka Bondo<sup>5</sup>, Francois-Xavier Mwema<sup>6</sup>, Eric Mukomena Sompwe<sup>6</sup>, Renion Saye<sup>7</sup>

<sup>1</sup>PMI Impact Malaria, MCDI, Kinshasa, Democratic Republic of the Congo,

<sup>2</sup>PMI Impact Malaria, MCDI, Silver Spring, MD, United States, <sup>3</sup>PMI

Impact Malaria, PSI, Washington, DC, United States, <sup>4</sup>Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo,

<sup>5</sup>USAID, Kinshasa, Democratic Republic of the Congo, <sup>6</sup>National Malaria Control Program, MOH, Kinshasa, Democratic Republic of the Congo, <sup>7</sup>PMI Impact Malaria, MCDI, Bamako, Mali

Outreach Training Supportive Supervision Plus (OTSS+) is a quality improvement approach aimed at enhancing the quality of malaria clinical and diagnostic service delivery. During OTSS+ visits to health facilities (HF), a checklist and on-site training are used to ensure procedures follow national guidelines. Diagnostic service delivery components are assessed, such as malaria microscopy (MM) skills, stock management, human resources, and quality assurance processes. PMI Impact Malaria supports the National Malaria Control Program to implement OTSS+ in nine provinces in DRC. The paper checklist used for field data collection was inefficient and did not allow for rapid corrective actions identified during field visits. The digital checklist, HNQIS, is an Android-based application which works on a DHIS2 platform. It enables clinical and laboratory (lab) data to be collected and generates competency scores in real-time, allowing supervisors to provide immediate feedback and take corrective actions. HNQIS was first used in DRC during a lab OTSS+ round in March 2020, during which 109 HF were visited. Action plans based on competency scores were developed during each visit and follow-up responsibilities were assigned. Based on the March 2020 results, 24 of the 109 (22%) HF were identified as low performing. Identified gaps included low MM skills and a lack of internal quality control processes. These HFs were targeted for additional visits in August 2020. Of these 24 HF, 16 HF (67%) showed improvement in parasite detection (PD) which ranged from 33% to 100%. The average PD scores of these 24 HFs was 62% during the initial visit and 75% after being re-visited. The 8 HF that did not show improvement had recently graduated lab technicians who have not participated in OTSS+. It is expected that new technicians will increase their MM skills with OTSS+ and Malaria Diagnostic Refresher Trainings. The feedback loop of HNQIS enabled quick turnaround of results, which were useful in making data-driven decisions to revisit low-performing facilities. HNQIS helps supervisors prioritize low-performing HFs to visit more regularly.

## IMPROVING MALARIA CASE MANAGEMENT PRACTICES AND REPORTING IN THE PRIVATE SECTOR IN UGANDA

**Robert Mugerwa**

*MOH, Kampala, Uganda*

Coverage of fever case management interventions remains low across sub-Saharan Africa, including Uganda. While many caregivers seek treatment for symptoms of fever in the private sector, private sector outlets may not have adequate fever diagnostics, training, waste management, and first line quality assured treatments to ensure appropriate case management. The National Malaria Control Division together with partners have prioritized private sector engagement by ensuring that quality of services offered by private providers is improved and they report into DHIS II. An Assessment of malaria case management in licensed/accredited private outlet types including drug shops, pharmacies, clinics and hospitals was conducted, and participating members received training on integrated case management for febrile illnesses, supportive supervision, access to quality assured malaria rapid diagnostic test kits, subsidized ACTs and self-regulation coordination mechanisms. Baseline and follow-up assessment through integrated support supervision were conducted in 2020 and follow on in 2021 to assess improvement in malaria case management in 20 districts in Uganda. Key results include overall change in reporting comprising number, completeness, timeliness and accurateness of data by private providers; Effect on the availability of quality guidelines and protocols in private outlets to provider behavior; coordination mechanisms of private sector providers at all levels and changes in case management of those who reportedly received treatment in the private sector. Implications for scaling up case management coverage through strengthening services provided by private sector providers focusing on the different outlet type will be discussed.

## DETECTING AND CLASSIFYING CELLS WITH A MULTI-CLASS MASK R-CNN IN THIN SMEAR MICROSCOPY FOR MALARIA DIAGNOSIS

**Yasmin M. Kassim<sup>1</sup>**, Hang Yu<sup>1</sup>, Feng Yang<sup>1</sup>, Kamolrat Silamut<sup>2</sup>, Richard J. Maude<sup>3</sup>, Stefan Jaeger<sup>1</sup>

<sup>1</sup>National Library of Medicine, National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Mahidol-Oxford Tropical Medicine Research Unit, Mahidol University, Bangkok, Thailand, <sup>3</sup>Centre for Tropical Medicine and Global Health, Nuffield Department of Medicine, University of Oxford, Oxford, United Kingdom

Malaria is a leading cause of death worldwide. The parasitic infectious disease can be transmitted easily to humans through mosquito bites that result in over 200 million infections and 400 thousand deaths every year, with children under five accounting for the majority of all malaria deaths. Due to the high infection rate, pathologists need to read millions of blood smears for malaria diagnosis. This manual process is time-consuming, costly, and subject to human error. Reporting accurate reading is essential for treatment, assessing effective drug doses, and determining disease severity. Computer-assisted algorithms have become a mainstay of biomedical applications to automate, simulate and standardize medical interpretations and quantification. In this study, we design a single multi-class classifier for detecting and classifying cells in thin blood smear images. We adapt a state-of-the-art instance segmentation network (Mask R-CNN) to delineate cells accurately and identify infected and uninfected red blood cells, and white blood cells. It segments hundreds of cells, in a matter of seconds and with a low memory footprint. Specifically, this approach is scalable to large blood smear images (5312×2988 pixels) featuring high cell densities, where cells are relatively small objects compared to the overall image size. We tested the method on an archived collection of human malaria smears with nearly 200,000 labeled cells across 965 images from 193 patients, acquired in Bangladesh. The cell detection accuracy is very promising and outperforms state-of-the-art methods in the literature. Our software implementation is a crucial step towards automated malaria diagnosis. It can assist microscopists in the field and in resource-poor primary care settings as a fast and affordable method for blood smear interpretation. Furthermore, it can assist researchers in major hospitals and institutes allowing a fast analysis and accurate quantification of their research experiments. Several organizations and institutes are currently helping to field-test the software developed in this study.

1079

## MALARIA DIAGNOSIS QUALITY CONTROL AT HEALTH FACILITIES IN RWANDA

**Jean-Louis Ndikumana Mangara<sup>1</sup>**, Aline Uwimana<sup>1</sup>, Michee Kabera<sup>1</sup>, Jean Damascene Niyonzima<sup>1</sup>, Aniceth Rucogoza<sup>1</sup>, Tharcisse Munyaneza<sup>1</sup>, Emmanuel Ruzindana<sup>1</sup>, Jean Bosco Mucaca<sup>1</sup>, Maurice Twahirwa<sup>1</sup>, Noella Umulisa<sup>2</sup>, Aimable Mbituyumuremyi<sup>1</sup>

<sup>1</sup>Rwanda Biomedical Center, Kigali, Rwanda, <sup>2</sup>Jhpiego/Impact Malaria, Kigali, Rwanda

Although significant progress has been made, malaria remains one of the most common diseases in Rwanda, with more than 2 million cases and more than a hundred deaths per year. To achieve Rwanda Malaria Control Program goals as a way to contribute to the socio-economic development through elimination of malaria burden, malaria diagnosis external quality assessment, quality control (EQA/QC) is conducted every quarter to evaluate and strengthen quality of diagnosis and treatment. The EQA/QC was conducted in 42 hospitals where 15 Slides were randomly collected at each hospital and retested at Rwanda Biomedical Center/ National Reference Laboratory Division by microscopists accredited by WHO (ECAMM) in Malaria microscopy. After retesting, a prompt feedback is provided so that actions can be taken to correct errors. For 1917 slides collected in 42 district hospitals in which EQA/QC of blood smears was

conducted, 2019-2020 EQA/QC was noted compared to the previous fiscal year with an improvement in overall results from 4.12% to 1.74% which remain above the cut off 5% acceptable range with 4/42 hospitals (Kabutare (8,89%), Masaka (6,67%), Muhororo (6,67%), Mibilizi (6,67%)) exceed the acceptable range. Findings from the EQA/QC has revealed that laboratory technicians at hospitals in Rwanda have high (>98%) proficiency testing -a continuous capacity building is needed to ensure and sustain accurate diagnosis for appropriate case management. Thus, Mal & OPDD will continue to work closely with NRL to correct reported discrepancies in district hospitals through formative and refresher training during the next fiscal years.

### MAGNETO-OPTICAL RESPONSE TO MAGNETIC FIELD ACROSS ALL HUMAN MALARIAS SPECIES USING GAZELLE PLATFORM

**Brian T. Grimberg**<sup>1</sup>, Tyler Witte<sup>2</sup>, Stephanie Bledsoe<sup>2</sup>, D'Arbra Blankenship<sup>1</sup>, Daren Bledsoe<sup>2</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Hemex Health, Portland, OR, United States

All malaria parasites create the by-product Hemozoin as a result of Red Blood Cell digestion. However, because of the different pathways and speed of creating the Hemozoin, the resulting iron containing crystals have slightly different sizes and shapes which theoretically translates to a different response to presence and absence of a magnetic field. Here we detect the orientation and disorganization of the Hemozoin crystals from all the human malarial species; *P. falciparum*, *P. vivax*, *P. malariae*, *P. ovale*, and *P. knowlesi* from short term cultures. Frozen samples of each of the species from BEI (Pf/Pv/Pk) or patient samples (Pm/Po) were thawed and placed in cultures of RPMI 1640 CMC (Pf) or RPMI 1640/Waymouths +10 % Human AB (Pk, Pf, Po, Pm) and grown in 5% CO<sub>2</sub> for 24hr to allow for the creation of hemozoin. Samples were then tested on the Hemex Health Gazelle platform. The platform continuously measures the transmitted light passing through blood samples as the magnetic field is repeatedly applied and removed. As the magnet is applied the hemozoin aligns blocking an amount of light equivalent to the parasitemia. As the magnetic field is removed the hemozoin becomes disorganized via Brownian motion. Analysis of the output data reveals that the Hemozoin from Pv and Po showed a much faster disorganization upon removal of the magnetic field than the other species. Other work on adjoining posters has demonstrated that this difference reliably allows for the delineation of pure Pv from Pf infections from one another in field samples. This work could allow for the diagnosis of all forms of malaria as well as treatment with Primaquine to eliminate the hypnozoites in the liver created by the Po and Pv parasites to prevent relapse infections.

### HEALTHCARE PROVIDERS CHALLENGE TO CORRECTLY INTERPRET MALARIA RDT RESULTS IN NIGERIA

**Wellington A. Oyibo**<sup>1</sup>, Sonachi Ezeiru<sup>2</sup>, Diwe Ekweremadu<sup>2</sup>, Temitope Ipinmoye<sup>2</sup>, Victor Adebayo<sup>2</sup>, Olatayo Abikoye<sup>2</sup>, Oladipo Oladosu<sup>1</sup>, Chinonye Anabike<sup>1</sup>, Simon Ijezie<sup>3</sup>, Nnenna Ogbulafor<sup>3</sup>, Emmanuel Shekarau<sup>3</sup>, Perpatua Uhomobh<sup>3</sup>, Bala Audu<sup>3</sup>

<sup>1</sup>ANDI Centre of Excellence for Malaria Diagnosis, College of Medicine of the University of Lagos, Nigeria, Lagos, Nigeria, <sup>2</sup>Catholic Relief Services (CRS)(Principal Recipient of the Global Fund, Malaria in Nigeria), Federal Capital Territory, Abuja, Nigeria, Abuja, Nigeria, <sup>3</sup>National Malaria Control Programme, Federal Ministry of Health, Abuja, Nigeria

Malaria rapid diagnostic tests (mRDTs) has become the widely used tool for the parasitological confirmation of suspected malaria cases in Nigeria. The potential of mRDTs in expanding access to malaria testing remain incontestable as it accounted for about 85% of malaria tests performed in public health facilities in Nigeria in 2019. Challenges with mRDTs have been underscored but the contribution of weak/faint lines in mRDT interpretation is unknown. Our facility, a WHO designated

mRDT lot verification Centre in Lagos, Nigeria, observed during mRDT lot assessments high frequency of "faint, very faint and very very faint lines" [weak (<1+)/very weak (<1++), extremely weak(<1+++)] in some mRDTs lots that were difficult to interpret. We hypothesized that if these test lines posed a challenge in interpretation at the level of our operations, correct interpretation by health care providers (HCPs) in downstream health facilities may be a serious challenge in effective malaria case management. Instruction for use (IFUs) for mRDTs merely require weak test lines should be read as positive without categorization. A total of 677 HCPs in three states of Nigeria namely, Katsina, Gombe, and Osun states, were assessed for correct interpretation using 21 standardized picture images of mRDTs (mRDT EQA card). Overall, 102 (15.1%) and 109 (16.1%) of the 677 HCPs correctly interpreted 15 and 16 RDT results respectively. Remarkably, 16.1% of the 677 HCPs only correctly interpreted less than 10 RDT images. HCPs that correctly interpreted above 17 of 21 RDTs in the states were: Gombe, 37(20.3%), Katsina, 36 (18.3%) and Osun, 31(10.4%). Analyses of capacity to correctly interpret mRDT test lines showed that HCPs had little challenge with clear (bold) positive tests (90.3%), but had challenge with very weak positive tests (<1++)(34.7%), All positives (27%); very faint positives [extremely weak tests(<1+++)(3.5%), and negative tests (54.1%). The consequence was that HCPs were likely to interpret most "weak" positive tests as negative. This user challenge in RDT test interpretation with false negative and false positive tests are to be identified and addressed urgently.

1082

### DEVELOPMENT OF A RAPID DIAGNOSIS TEST FOR PLASMODIUM VIVAX

**Karli Redinger**, Jürgen Bosch, Peter Zimmerman, Rajeev Mehlotra, Quentin Watson, Marlin Linger

Case Western Reserve University, Cleveland, OH, United States

The issue with current Rapid Diagnosis Test for *Plasmodium vivax* (RDTs) is that they are often not sensitive enough to detect low parasitemia or mixed infection which requires additional medication to fully eradicate liver-stage parasites. In the Bosch Lab, we have selected five *P. vivax* proteins that were expressed, refolded, and purified in the lab using self-assembled protein nanoparticles (SAPNs) to be used as antigens for the generation of antibodies in rabbits for the development of a sensitive, *P. vivax*-specific RDT. These protein antigens were chosen due to their high affinity and selectivity for *P. vivax* as opposed to other Malaria species. The majority of our work thus far has consisted of the evaluation of the polyclonal antibodies using multiple lab techniques to determine that they recognize *P. vivax*-infected cells and have limited cross-reactivity with infected cultures of other Malaria species. Initial findings using Imagestream analysis indicate the antibodies recognize and bind to infected-*P. vivax* cells at various stages of the parasite life cycle while showing low binding affinity for uninfected cells. Additionally, paper-based and ELISA assays with mixed *P. vivax* and *P. falciparum* cultures suggest all five antibodies have a higher affinity for *P. vivax* antigens as opposed to *P. falciparum*. With these initial assays, we have determined a proposed limit of detection for *P. vivax* significantly lower than that of current RDTs used in the field today. We plan on continuing these evaluation assays using flow cytometry to examine double positive red blood cells (Hoechst and antibody stain) between *P. vivax*, *P. falciparum*, and *P. knowlesi* Malaria species. Results from these experiments will be analyzed to determine which of our polyclonal antibodies have the highest specificity to then generate monoclonal antibodies to be used in a new RDT that will be designed using laminar flow or an electrophoresis based device. By developing a more sensitive and specific RDT for *P. vivax*, we in the Bosch Lab hope to bridge a gap in current endemic Malaria control efforts by designing a means by which to identify and treat an often overlooked yet devastating form of Malaria disease.

### THE STANDARD G6PD TEST (SD BIOSENSOR) SHOWS GOOD REPEATABILITY AND REPRODUCIBILITY IN A MULTI-LABORATORY COMPARISON

**Benedikt Ley**<sup>1</sup>, Ari Winasti Satyagraha<sup>2</sup>, Mohammad G. Kibria<sup>3</sup>, Jillian Armstrong<sup>4</sup>, Greg Bizij<sup>5</sup>, Germana Bancone<sup>6</sup>, Mariusz Wojnarski<sup>7</sup>, Amy K. Bei<sup>4</sup>, Marcelo Brito<sup>8</sup>, Gonzalo Domingo<sup>5</sup>, Xavier Ding<sup>9</sup>, Michael von Fricken<sup>10</sup>, Gornpan Gornsawun<sup>6</sup>, Brandon Lam<sup>11</sup>, Didier Menard<sup>12</sup>, Sampa Pal<sup>5</sup>, Sunil Parikh<sup>4</sup>, Lydia V. Panggalo<sup>2</sup>, Daniel Pfeffer<sup>1</sup>, Ric N. Price<sup>1</sup>, Alessandra da Silva Orfano<sup>4</sup>, Martina Wade<sup>4</sup>, Kuntawunginn Worachet<sup>13</sup>, Wueltton Monteiro<sup>8</sup>, Aqsa Yar<sup>12</sup>, Mohammad S. Alam<sup>3</sup>, Rosalind E. Howes<sup>9</sup>

<sup>1</sup>Menzies School of Health Research, Darwin, Australia, <sup>2</sup>Eijkman Institute of Molecular Biology, Jakarta, Indonesia, <sup>3</sup>International Center for Diarrheal Disease Research, Dhaka, Bangladesh, <sup>4</sup>Yale School of Public Health, New Haven, CT, United States, <sup>5</sup>PATH, Seattle, WA, United States, <sup>6</sup>Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Faculty of Tropical Medicine, Mahidol University, Mae Sot, Thailand, <sup>7</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>8</sup>Fundação de Medicina Tropical Dr. Heitor Vieira Dourado, Manaus, Brazil, <sup>9</sup>Foundation for Innovative New Diagnostics, Geneva, Switzerland, <sup>10</sup>George Mason University, Fairfax, VA, United States, <sup>11</sup>Johns Hopkins University School of Medicine, Baltimore, MD, United States, <sup>12</sup>Institut Pasteur, Paris, France, <sup>13</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

The introduction of short course, high dose primaquine and single dose tafenoquine for the radical cure of *Plasmodium vivax* (*P. vivax*) presents a great opportunity for more effective control of *P. vivax* malaria. Roll out of these novel regimens will require a reliable point-of-care diagnostic that can identify individuals with intermediate or severe G6PD deficiency. SD Biosensor (Republic of Korea) has developed a handheld quantitative G6PD screening device (the STANDARD™ G6PD), that demonstrated an accuracy of around 90% in field studies for identifying individuals with intermediate or severe deficiency. However, the device can only be considered for routine care if repeatability and reproducibility of the assay are high. Commercial controls (ACS Analytics, USA) with high, intermediate, and low G6PD activities were tested with ten Biosensor devices 20 times and compared to the reference method spectrophotometry (Pointe Scientific, USA). Each device was then dispatched to one of ten different laboratories with a standard set of controls. Each control was tested 40 times at each laboratory by a single experienced user and compared to spectrophotometry results. When tested at one site, the mean coefficient of variation (CV) was 11%, 17% and 26% for high, intermediate and low controls across all devices respectively; combined G6PD Biosensor readings correlated well with spectrophotometry ( $r_s = 0.859$ ,  $p < 0.001$ ). When subsequently tested in different laboratories, correlation was lower ( $r_s = 0.604$ ,  $p < 0.001$ ) and the results determined by Biosensor for the low and intermediate controls overlapped. Conversely, Biosensor G6PD readings did not differ significantly between sites ( $p = 0.436$ ), but readings differed markedly by spectrophotometry ( $p < 0.001$ ). The use of lyophilized samples derived from human blood rather than fresh blood for which the device was developed may have affected these findings. Repeatability and inter-laboratory reproducibility of the Biosensor are significantly better than those of spectrophotometry. Clinical studies are required to assess the performance of the test in clinical practice.

### DETECTION OF A SUBSTANTIAL NUMBER OF PFHRP2 GENE DELETIONS AMONG SUBMICROSCOPIC INFECTIONS IN ETHIOPIA

**Lemu Golassa**<sup>1</sup>, Gezahegn Solomon Alemayehu<sup>1</sup>, Kayla Blackburn<sup>2</sup>, Karen Lopez<sup>3</sup>, Cheikh C. Dieng<sup>3</sup>, Eugenia Lo<sup>3</sup>, Daniel Janies<sup>3</sup>

<sup>1</sup>Addis Ababa University, Addis Ababa, Ethiopia, <sup>2</sup>Department of Bioinformatics and Genomics, University of North Carolina at Charlotte, Charlotte, NC, United States, <sup>3</sup>University of North Carolina at Charlotte, Charlotte, NC, United States

Apart from parasites resistance to drugs and mosquitoes resistance to chemicals, respectively, nowadays parasite escaping detection has challenged efforts to test and treat malaria cases. HRP2-based RDTs have been challenged by *P. falciparum* deleting the gene that encodes for HRP 2 and 3 proteins leading to HRP2-based RDTs are unable to detect parasite undergoing *pfhrp2* and 3 gene deletion. A total of 218 quantitative PCR-confirmed *P. falciparum* positive samples were included for analysis of *pfhrp2* and 3 genes deletion. The prevalence of *pfhrp2* exon 2 gene deletions was 17.9% (39/218) and that of *pfhrp3* exon 2 was 9.2% (20/218). The deletions extended to the downstream (55.0%) and to the upstream (42.7%) regions in *pfhrp2*. Of eighty-six PfHRP2 RDT negative samples, thirty-six lacked the main HRP2 coding region, *pfhrp2* exon 2. Five PfHRP2 RDT negative samples had double deletions in exon 2 of both *pfhrp2* and *pfhrp3* genes. Of these double deletions, only two of the samples were positive by the microscopy. Three samples with intact *pfhrp3* exon2 but with deleted *pfhrp2* exon2 were tested positive by PfHRP2 RDT and microscopy. Of the 39 *P. falciparum* isolates without *hrp2* and 3 genes, 36 of them were submicroscopic while three of them are microscopic infections. In conclusion, this study confirms the presence of deletions of *pfhrp2* and 3 genes including the flanking regions. *Pfhrp2* and 3 gene deletions results in false-negative results undoubtedly affect the current malaria control and elimination effort in the country. Assessment of *pfhrp2* and 3 gene deletions should take account of both microscopic-and submicroscopic-infections to avoid underestimation of the true prevalence of gene deletions. *Pfhrp2* deletions were compensated by the intact *pfhrp3* regions.

### INTEGRATING G6PD POINT-OF-CARE TESTING INTO MALARIA CASE MANAGEMENT TO SUPPORT RADICAL CURE: AN ASSESSMENT OF HEALTH WORKER SKILLS AND KNOWLEDGE IN LAOS AND VIETNAM

**Emily Gerth-Guyette**<sup>1</sup>, Sarah Cassidy-Seyoum<sup>2</sup>, Huygen Nguyen<sup>3</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>UCSF Global Programs for Research and Training, Vientiane, Lao People's Democratic Republic, <sup>3</sup>PATH, Hanoi, Viet Nam

The lack of tests for glucose-6-phosphate dehydrogenase (G6PD) deficiency, an inherited condition common in malaria-endemic countries, has resulted in both an underuse of radical cure due to safety concerns in some areas and the unsafe use of these drugs with no G6PD screening in others. Recently commercialized diagnostics for G6PD deficiency have the potential to improve health outcomes, align diagnosis and treatment options in remote settings with globally recommended clinical practices, and reduce transmission through the expanded use of radical cure treatments, including Kozenis (tafenoquine). Adoption of these tests has been limited in part due to concerns around product usability in malaria case-management settings. Malaria control programs and research partners in Vietnam, and Lao PDR have undertaken operations research studies to assess the feasibility of integrating G6PD testing into malaria case management. The aim of this study is to assess whether health workers that currently diagnose and treat *P. vivax* can also use G6PD tests, and what training practices enable their effective use. District hospital laboratory and health center staff at 23 facilities in malaria-endemic regions of Laos PDR and Vietnam were trained in the use of a point of

care G6PD biosensor-based diagnostic. A mixed-methods approach to assessing user knowledge and competency was developed, which included a quantitative questionnaire and an observational component, where users completed the diagnostic workflow and interpreted the test result using control reagents. These data were collected immediately after the training and four to six months after training. Results from these assessments indicate that health workers ability to run and interpret a G6PD test varies widely across settings and is mediated by the quality of the training and by the volume of malaria patients that are seen by the health worker over time. These data provide insights into what changes to routine care, training, and supervision will be needed to accommodate G6PD testing as well as recommend specific supplementary training materials to accompany the introduction of the test.

## PAST EFFECTS OF CLIMATE AND INTERVENTIONS ON MALARIA IN UGANDA

**Margaux Sadoine**<sup>1</sup>, Audrey Smargiassi<sup>1</sup>, Ying Liu<sup>1</sup>, Grant Dorsey<sup>2</sup>, Guillaume Dueymes<sup>3</sup>, Philippe Gachon<sup>4</sup>, Adrienne Epstein<sup>2</sup>, Jaffer Okiring<sup>5</sup>, Kate Zinszer<sup>1</sup>

<sup>1</sup>School of Public Health of the Université de Montréal and Centre for Public Health Research (CReSP), Montréal, QC, Canada, <sup>2</sup>University of California, San Francisco, CA, United States, <sup>3</sup>Université du Québec à Montréal, Montréal, QC, Canada, <sup>4</sup>University of Québec at Montréal and Center for the Study and Simulation of Regional-Scale Climate (ESCCER), Montréal, QC, Canada, <sup>5</sup>Infectious Diseases Research Collaboration, Kampala, Uganda

Studies have estimated the impact of malaria control interventions on malaria incidence although few have explored the differential impact due to environmental conditions. We aimed to evaluate the influence of temperature, rainfall, humidity, and vegetation, on the relationship between insecticide-treated bednets (ITNs) and indoor residual spraying (IRS) and malaria. A longitudinal analysis was conducted, based on episodes of laboratory-confirmed malaria from a dynamic cohort of children followed from 2011 to 2017 in Uganda. Children less than 10 years were randomly selected from low, medium, and high transmission sub-counties. Participants were provided ITNs, and four rounds of spraying were conducted in one subcounty. Environmental variables were extracted from remote sensing sources and include enhanced vegetation index (MODIS), rainfall (ARC2), minimum and maximum temperature (ERA5), humidity (ERA5), averaged over different time periods. General linear mixed models were constructed based on a log-binomial distribution, accounting for repeated measures and clustering by household and non-linear associations with malaria incidence were explored. Over six years, 1,090 children were followed with a mean of 35 visits and 5 malaria episodes per individual. The best fit model was with the meteorological measures averaged over 90 days prior to the date of clinic visit. Controlling for the interventions, humidity and precipitation presented non-linear relationships with malaria incidence while increasing minimum and maximum temperatures were associated with a linear reduction of malaria risk. IRS was associated with a significant risk reduction (OR=0.21, 95% CI 0.17-0.26). An increased risk of malaria associated with increased minimal temperatures was only observed for individual who did not sleep under an ITN, demonstrating an interaction effect. Effect of minimal temperatures on malaria risk is modified by ITN. Non-linear relationship and modifying effect of climate by anti-vectorial interventions need to be considered when assessing the epidemiology of malaria.

## LONGITUDINAL GENETIC EPIDEMIOLOGY SURVEILLANCE WITH A SNP-BASED MOLECULAR BARCODE DETECTS WIDESPREAD COTRANSMISSION OF PLASMODIUM FALCIPARUM MALARIA PARASITES IN THIÈS, SENEGAL

**Wesley Wong**<sup>1</sup>, Rachel F. Daniels<sup>1</sup>, Sarah K. Volkman<sup>1</sup>, Dyann F. Wirth<sup>1</sup>, Daniel L. Hartl<sup>2</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States,

<sup>2</sup>Harvard University, Cambridge, MA, United States

Genomic epidemiology surveillance shows great potential for monitoring transmission dynamics and informing targeted public health interventions to reduce infectious disease burden. In *Plasmodium falciparum*, these surveys consistently identify a large number of polygenomic (multi-strain) infections whose complexity of infection (COI, number of strains per infection) is greater than one. While polygenomic infections in high transmission settings tend to have high COI, it is unclear to what extent COI correlates with transmission intensity. This uncertainty stems from two competing hypotheses regarding either superinfection, which predicts a positive correlation between COI and transmission due to the introduction of unrelated strains from multiple infectious bites, or cotransmission, which predicts a weak correlation due to the introduction of multiple, genetically related strains from a single bite. To address this issue, we examined a set of 2,203 infections (23.6% polygenomic) collected from Thiès, Senegal between 2006 and 2019 and genotyped at 24 single nucleotide polymorphisms (SNPs). To determine whether polygenomic infections were comprised of related strains and the result of cotransmission, we calculated an F-statistic that measures an inbreeding coefficient based on comparing the heterozygosity from single-strain and polygenomic infections. We found that polygenomic infection heterozygosity was depressed by an average factor of 0.38 (0.36, 0.40). Most polygenomic infections showed evidence of inbreeding, suggesting they were the result of at least one cycle of cotransmission. Genomic epidemiology studies should supplement COI with estimates of polygenomic relatedness to account for cotransmission when evaluating parasite transmission intensity. This study also highlights the usefulness of field-deployable SNP assays for conducting simple genomic surveillance data to inform transmission dynamics and assess the impact of interventions on parasite population structure toward malaria burden reduction.

1088

## MALARIA IN THE PERIPARTUM PERIOD AND ASSOCIATED CLINICAL OUTCOMES FOR MOTHER AND BABY IN A HIGHLY ENDEMIC REGION OF THE BRAZILIAN LEGAL AMAZON, ACRE STATE

**Mary K. Lynn**<sup>1</sup>, Julio A. Seijas Chávez<sup>2</sup>, Melissa S. Nolan<sup>1</sup>, Maria J. Francalino Rocha<sup>3</sup>, Muana da Costa Araújo<sup>4</sup>, Fernando L. Affonso Fonseca<sup>5</sup>, Gabriel Z. Laporta<sup>5</sup>

<sup>1</sup>University of South Carolina, Columbia, SC, United States, <sup>2</sup>Hospital da Mulher e da Criança do Juruá, Cruzeiro do Sul, Brazil, <sup>3</sup>Universidade Federal do Acre, Cruzeiro do Sul, Brazil, <sup>4</sup>Vigilância Entomológica da Secretaria Municipal de Saúde, Cruzeiro do Sul, Brazil, <sup>5</sup>Centro Universitário da Faculdade de Medicina do ABC, Santo André, Brazil

Deforestation in Amazonia has recently resulted in a resurgence of malaria in this region of the world, with 75% of all 2018 Latin American malaria cases occurring in Brazil and Venezuela. In Brazil, the disease burden predominantly lies in the Brazilian Legal Amazon region. Pregnant women in this region are particularly susceptible to malaria infection and clinical disease. Malaria infection in the peripartum period can lead to a range of negative maternal-child outcomes including, maternal anaemia, congenital malaria, preterm birth, and stillbirth. This study sought to understand the clinical outcomes of malaria during pregnancy on mothers and neonates in a hospital in Acre state. We enrolled 2,809 women at delivery or within 3 days post-delivery from the Women and Children's Hospital of the Juruá River Valley in Cruzeiro do Sul county of Acre state. Blood samples were taken from mothers to assess malarial status and haemoglobin levels,

questionnaires administered, and birth outcomes assessed via clinical charts. Questionnaires sought to assess maternal demographics and preventive measures including the use of DEET and insecticidal bed-nets. Further, maternal *Plasmodium* species was determined following malaria diagnosis. We found 7.2% of mothers were infected with malaria during pregnancy, and 1% were diagnosed in the perinatal period. We found similar rates of *Plasmodium falciparum* and *P. vivax* in mothers who were infected. Nearly half of mothers had been diagnosed with malaria in a previous pregnancy. Nearly half of enrolled women presented with perinatal anaemia, and those with anaemia were more likely to be infected with *P. falciparum* ( $p = 0.004$ ). Living in a rural area and diagnosis of malaria in a previous pregnancy were significantly associated with malaria diagnosis at the time of the current pregnancy ( $p < 0.001$ ,  $p < 0.001$ ). Perinatal anaemia was significantly associated with lower APGAR scores in neonates ( $p = 0.004$ ). Outcomes of this study will inform preventive efforts and clinical case management for maternal malaria infection in a particularly susceptible population in a highly endemic rural region of the Brazilian Amazon.

1089

### UnMASC: UGANDA MALARIA ACTIONABLE SURVEILLANCE IN THE TIME OF CORONAVIRUS

Jessica Briggs<sup>1</sup>, Isaac Ssewanyana<sup>2</sup>, Martha Nassali<sup>2</sup>, Samuel Gonahasa<sup>2</sup>, Isaiiah Nabende<sup>2</sup>, Emmanuel Victor Kamy<sup>2</sup>, Jane Frances Namuganga<sup>2</sup>, Catherine Maiteki-Sebuguzi<sup>3</sup>, Peter Mutungi<sup>2</sup>, Moses Kamy<sup>2</sup>, Adrienne Epstein<sup>1</sup>, Bryan Greenhouse<sup>1</sup>, Sarah Staedke<sup>4</sup>, Grant Dorsey<sup>1</sup>

<sup>1</sup>University of California, San Francisco, San Francisco, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>National Malaria Control Division, Kampala, Uganda, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

As the COVID-19 epidemic progresses in Uganda, its repercussions may affect healthcare-seeking behavior, case management, and control interventions for malaria. Improved malaria surveillance will be essential to fully understanding the effects of COVID-19 on malaria transmission, burden, and care. Our study will conduct cross-sectional surveys in communities surrounding a subset of 64 malaria reference centers (MRCs) that serve as an enhanced malaria surveillance network. Households in the catchment area of 12 MRCs have been enumerated and are currently being randomly surveyed with questionnaires on healthcare seeking behavior and household-level malaria control interventions (such as long-lasting insecticide treated net availability and use from the 2020-2021 national distribution campaign). We plan to enroll 50 households with at least one child 2-10 years of age from each catchment area. We will obtain a thick smear for microscopy and collect dried blood spots from all children in enrolled households, allowing us to calculate parasite prevalence and conduct precision serosurveillance for malaria and COVID-19 using a multiplex Luminex assay. In 2020, we recorded 952,270 outpatient visits from 64 health facilities, with 72.1% of those attending suspected to have malaria. From all 64 MRCs, we will report changes over time in the number of visits and standard malaria indicators from March 2020-October 2021 compared to prior years' data. From the subset of 12 MRCs, we will report 1) changes in healthcare-seeking behavior and household-level malaria control interventions in the context of the COVID-19 pandemic, 2) estimates of parasite prevalence using microscopy and precision serosurveillance, allowing us to contextualize the malaria indicator data collected from MRCs (which may be biased by pandemic-related factors such as health facility attendance) and 3) estimates of COVID-19 prevalence in children. Combining data from both health facilities and cross-sectional community-based surveys will allow for a robust assessment of the effects of the COVID-19 pandemic on routine malaria care and prevention.

<sup>1</sup>National Malaria Control Program, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>Jhpiego, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>4</sup>President's Malaria Initiative, USAID, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>President's Malaria Initiative, USAID, Washington, DC, United States, <sup>6</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention and President's Malaria Initiative, Dar es Salaam, United Republic of Tanzania, <sup>7</sup>United States Agency for International Development, Dar es Salaam, United Republic of Tanzania, <sup>8</sup>Jhpiego, Baltimore, MD, United States, <sup>9</sup>Imperial College, London, United Kingdom

Estimates of malaria burden and intervention uptake in Africa are primarily based upon nationally representative household (HH) surveys. However, their expense and infrequency limits their utility for timely analysis for operational action by malaria programs. We assessed whether population surveillance via women attending antenatal care (ANC), consisting of collecting data on malaria prevalence using rapid diagnostic tests and on coverage of malaria interventions among women and their households using a short questionnaire during 1<sup>st</sup> ANC visits (ANC1) could provide relevant data to guide decision-makers. Malaria prevalence from routine ANC-based surveillance in 40 health facilities (HF) in Geita Region were compared with those in children under 5 (U5) from a cross-sectional HH survey conducted in the same HF catchment areas in November-December 2019. Data on coverage of malaria control interventions and care-seeking behavior was collected routinely from women at ANC1 starting March 2020. A second cross sectional HH survey is planned for summer 2021. We fitted a linear relationship between the log odds of both ANC1 prevalence and HH prevalence with a random effect for each health facility catchment. The model showed a statistically significant positive relationship ( $p < 0.005$ ), though this relationship was non-linear ( $p < 0.0001$ ): malaria prevalence during ANC1 exceeded that in U5 in areas where U5 prevalence was low ( $< 10\%$ ), while prevalence among U5 increasingly exceeded ANC prevalence in higher prevalence areas, where multigravida have acquired substantial immunity. Prevalence in younger women ( $< 20$  yr) appeared nearly uniformly high in all HF regardless of U5 prevalence, making them and their newborns a core malaria risk group. Findings on the utility of ANC surveillance for measuring coverage of malaria control interventions and care-seeking behavior will also be presented. Our study suggests that malaria prevalence estimates derived from ANC surveillance correlate well with estimates derived from HH surveys and might be useful in informing prevention efforts when more resource-intensive HH surveys are not feasible.

Fever is a common reason for patients to seek medical care in sub Saharan Africa. In malaria endemic settings, fever is often caused by infection with *Plasmodium falciparum*. However, quantifying the fraction of fever attributable to malaria has been challenging. We used well characterized cohorts of children and adults followed from 2011 to 2019 in a historically high transmission area of Uganda to estimate the malaria attributable fraction of fever (MAFF). Standard clinic evaluations during clinic visits included documentation of a history of fever in the last 24 hours and measurement of tympanic temperature. Over the 8-year observation period, 2 rounds of universal distribution of long-lasting insecticidal nets (LLIN) and 7 rounds of indoor residual spraying of insecticide (IRS) were deployed, resulting in dramatically reduced malaria vector populations, infection and disease. We estimated and compared MAFF for self-reported vs objective fever and background vs clinical fever in younger children (<5 years old), older children (5-10 years) and in adults (over 18 years old). The study enrolled 814 participants, 32.8% younger children, 38.3% older children and 28.9% adults. Objective fever was lower than self-reported fever. After intensive vector control interventions, the MAFF for self-reported fever during scheduled visits reduced by 94%, 95% and 99% in younger children, older children and adults respectively. During the unscheduled visits, it reduced by 50%, 65% and 80% in younger children, older children and adults. During scheduled visits, objective fever was extremely rare in adults. After intensive vector control interventions, the MAFF for objective fever reduced by 72% in younger children with no significant reduction in older children. Malaria accounted for 88% of objective fever in younger children, 75% in older children and 91% in adults. In this area where IRS was deployed alongside mass LLIN distribution, the MAFF was remarkably high and fever was rare in the absence of malaria. Effective control of malaria could lead to improvement in health beyond traditional measures of symptomatic malaria.

1092

### IS ZONOTIC TRANSMISSION OF MALARIA A RISK FOR BLOOD DONATION AND ORGAN AND TISSUE TRANSPLANTATION?

Mariana Aschar<sup>1</sup>, Maria J. Costa-Nascimento<sup>2</sup>, Sandra C. Montebello<sup>3</sup>, Maria L. Farinas<sup>1</sup>, Jose E. Levi<sup>1</sup>, Silvia M. Di Santi<sup>1</sup>

<sup>1</sup>University of Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>SUCEN, Sao Paulo, Brazil, <sup>3</sup>Fundacao Pro Sangue Hemocentro of Sao Paulo, Sao Paulo, Brazil

Zoonotic transmission of malaria is described in several regions. Asymptomatic humans infected by *Plasmodium cynomolgi* and *P. knowlesi* were reported in the Asia. Human cases of *P. vivax/P. simium* and *P. malariae/P. brasilianum* were detected in the Brazilian coast, where monkeys of the genus *Alouatta* and *Callithrix* act as reservoirs of *Plasmodium*. Asymptomatic infections pose a challenge for elimination and represent a risk for blood donation and transplantation. Although guidelines recommend screening candidates from endemic areas or those with a history of malaria, the risk of asymptomatic individuals infected in areas of low endemicity with zoonotic transmission requires attention. This study was conducted in two blood centers and in hospitals in the state of Sao Paulo, Brazil. We processed 431 blood samples from candidates with displacement to areas of low endemicity with malaria zoonotic transmission, using thick blood smear (TBS), two genus-specific protocols (in house qPCR and Alethia<sup>®</sup> Malaria LAMP) and RealStar<sup>®</sup> Malaria Screen & Type PCR for determination of species. Eleven samples from donors/recipients of organs/tissues and 525 samples from blood donors who traveled to endemic regions were screened for *Plasmodium*, following the Brazilian guidelines. Among the 431 samples, two donors (0.5%) were positive for *Plasmodium* by qPCR, LAMP and TBS, both confirmed as *P. malariae*. One sample showed a single parasite-like structure in the TBS, but it was negative in all molecular tests. No positive samples were detected among the 11 donors or recipients of organs/tissues and the 525 blood donors from endemic areas. Epidemiological screening in

blood banks considers displacement to endemic regions to prevent the transmission of malaria. If infected, this population would probably present symptoms, a hypothesis corroborated by our findings, in which no donor was positive. According to our results, the risk was detected in blood donors from areas of low endemicity, where zoonotic transmission of malaria was reported. The detection of *P. malariae* coincides with reports of non-human primates infected with *P. brasilianum* in this region.

1093

### EFFICACY OF ARTEMETHER-LUMEFANTRINE FOR UNSUPERVISED TREATMENT OF UNCOMPLICATED MALARIA IN LOW AND HIGH TRANSMISSION AREAS IN GHANA

Bernice Anane Mawuli, Linda E. Amoah, Neils Quarshie, Gordon Awandare, Yaw Afrane

University of Ghana, Accra, Ghana

The Artemisinin combination therapy continues to be effective in the supervised treatment of uncomplicated malaria in Ghana. In the hospital setting however, the ACTs are administered to individuals with malaria without strict supervision of drug intake. This may not provide a true reflection of the efficacy of the ACTs under such circumstances. This study determined the response to unsupervised treatment with Artemether lumefantrine (AL). Fifty-nine individuals with uncomplicated malaria were recruited from Lekma Hospital in Accra (low transmission area; N= 23), and King's Medical Centre in Tamale (high transmission area; N= 36). Participants were followed up on day 1, 2, 3, 7, 14, 21 and 28. Presence of parasites on follow up days were determined by microscopy. Sub microscopic infections were determined by nested PCR of the *18S rRNA* gene of *Plasmodium falciparum*. Clearance of malaria parasite clones was assessed by MSP 1 and 2 genotyping. Two out of the 36 (5.56%) participants from the high transmission area showed delayed parasite clearance on day 3, but they did not have any parasite on day 7. In all prevalence of delayed parasite clearance for all study participants was 3.39%. One participant who had parasites on day 7 had no parasites on day 14 by microscopy. There was presence of parasites by microscopy on day 21 in 11.11% of participants from the high transmission area. On day 28, only one of these individuals still had parasites by microscopy. Also, one other participant whose parasites were cleared by day 1 had recurrence on day 28. Prevalence of sub microscopic infections was 16.67% in participants from the low transmission and 21.74% from high transmission areas respectively. Malaria parasite genotyping by MSP 1 and 2 indicated that all parasite clones were cleared equally after drug administration. To this end, Artemether-lumefantrine, taken under unsupervised conditions in Ghana, continues to be efficacious in the treatment of uncomplicated malaria in Ghana. However, sub-microscopic persists after treatment. This could serve as reservoirs of parasites that could be transmissible.

### IMPACT OF SIX-MONTH TRAVEL MORATORIUM ON PLASMODIUM FALCIPARUM PREVALENCE ON BIKO ISLAND, EQUATORIAL GUINEA: A DIFFERENCE IN DIFFERENCES ANALYSIS

Dianna E.B. Hergott<sup>1</sup>, Guillermo A. Garcia<sup>2</sup>, Olivier Tresor Donfack<sup>3</sup>, Carlos A. Guerra<sup>2</sup>, Jeremias Nzamio Mba Eyono<sup>3</sup>, Marcos Mbulito Iyanga<sup>3</sup>, Restituto Mba Nguema Avue<sup>3</sup>, Cristantos Nsue Abeso<sup>3</sup>, Teresa Ayingono Ondo Nfumu<sup>3</sup>, Sean C. Murphy<sup>1</sup>, Jennifer E. Balkus<sup>1</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>3</sup>Medical Care Development International, Malabo, Equatorial Guinea

Malaria control on Bioko Island, Equatorial Guinea, has substantially reduced the prevalence of *Plasmodium falciparum* (Pf) malaria, but it is still ~19%. Residents of Bioko frequently travel to the mainland, where Pf prevalence is much higher (>40%). Analyses suggest that imported infections from the mainland contribute to sustained prevalence on

Bioko Island, especially in urban areas where travel is common. Between March and September 2020, travel on major airlines and passenger ferry boats between the island and mainland was suspended in response to the Covid-19 pandemic. This, ostensibly, would have also halted the importation of *Pf* infections, and provides a natural experiment to evaluate the contribution of imported infections to *Pf* prevalence in Bioko. Data from the 2019 and 2020 malaria indicator survey (MIS) was used to evaluate whether the change in *Pf* prevalence before the travel restriction (2019) to after the travel restriction (2020), was greater in areas with a high proportion of reported travelers compared to the change in areas with a low proportion of reported travelers using a difference in differences model. Quartiles of travel prevalence were used to categorize sampling areas, and the areas in the highest and lowest quartiles were compared. The change in *Pf* prevalence over time in each travel group was compared. On average, there were 2900 individuals from 820 households in the low-travel areas per year, and 6800 individuals from 1685 households in high-travel areas. In low travel areas, *Pf* prevalence increased 5% from 2019 to 2020 (8% to 13%). Over the same time, the prevalence in high-travel areas decreased 2% (14% to 12%), for an unadjusted difference in differences of 7% ( $p < 0.005$ ). This suggests that imported infections do contribute to the overall malaria burden in areas where travel is frequent. We plan to use a weighted regression model that accounts for time-varying household and community level covariates with an interaction term for year and travel group, to estimate the reduction in malaria prevalence due to the restriction of travel and importation of malaria infections.

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>University of California, San Francisco, CA, United States, <sup>3</sup>University of Washington, Seattle, WA, United States, <sup>4</sup>Makerere University, Kampala, Uganda, <sup>5</sup>Radbaud University, Nijmegen, Netherlands, <sup>6</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>7</sup>Durham University, Durham, United Kingdom

Housing improvements may support malaria control and elimination in sub-Saharan Africa by reducing house entry by malaria vectors, but concurrent effects on other causes of child morbidity and mortality are poorly understood. We tested the hypothesis that improved housing is associated with reductions in malaria, acute respiratory infection (ARI), non-malaria fever and diarrheal disease in Nagongera, Uganda. Data were analyzed from a cohort study that followed all residents ( $n=531$ ) from 80 randomly selected households for 24 months from October 2017 to October 2019. Houses were classified as modern (cement, wood, or metal walls, tiled or metal roof, and closed eaves) or traditional (all other homes). Analyses are ongoing; results will be presented on associations between house type and human biting rate (HBR), proportion of blood fed *Anopheles* (measured every two weeks using CDC light traps in all rooms where participants slept), and between house type and malaria parasitemia, incidence of ARI, incidence of non-malaria fever and incidence of diarrheal disease (measured every four weeks using active surveillance for all enrolled participants). The findings of this study will provide important insight into the potential health benefits of housing improvements beyond reductions in malaria in rural Sub-Saharan Africa.

#### CEREBRAL MALARIA AND SEX-BASED DIFFERENCES IN RISK OF IN-HOSPITAL MORTALITY, POST-DISCHARGE MORTALITY, AND POST-DISCHARGE READMISSION IN YOUNG AFRICAN CHILDREN

Caitlin A. Bond<sup>1</sup>, Dibadyuti Datta<sup>1</sup>, Ruth Namazzi<sup>2</sup>, Robert Opoka<sup>2</sup>, Chandy C. John<sup>1</sup>

<sup>1</sup>Indiana University School of Medicine, Indianapolis, IN, United States,

<sup>2</sup>Makerere University College of Health Sciences, Kampala, Uganda

While studies report a male bias in clinical malaria among adults living in endemic regions, often attributed to behavior or sex hormones, the bias in children is less defined. We report findings from three cohort studies of Ugandan children admitted with cerebral malaria in 2003-2006 (cohort 1,  $n=92$ ), 2008-2015 (cohort 2,  $n=269$ ), and 2014-2016 (cohort 3,  $n=69$ ). In each cohort, males were disproportionately affected (58%, 59%, and 56% in cohorts 1, 2, and 3, respectively, while national census data showed proportion of males age 0-14 years to range from 49-51% during these periods). In each cohort, there were no significant sex-based differences in length of symptoms prior to seeking care, primary caregiver, or socio-economic status. To evaluate if sex related to clinical outcomes in children with cerebral malaria, we analyzed in-hospital mortality, post-discharge mortality, and readmission among children with cerebral malaria in each cohort by sex. Using data from all cohorts, overall in-hospital mortality was lower in males than females (12% vs 17%,  $p=0.10$ ) but these differences were not statistically significant. Across the 3 cohorts, there was also no significant difference by sex in post-discharge mortality (2% males, 3% females,  $p=0.72$ ). In cohort 3, males had a 3-fold increased risk of malaria readmission compared to females (IRR [95% CI]: 2.9 [1.2, 7.0],  $p=0.01$ ). Among Ugandan children, males are more often admitted for cerebral malaria than females, and have a greater risk of post-discharge readmission. Future studies should investigate the reasons for these sex-based differences in cerebral malaria morbidity.

1097

#### PREVALENCE OF ASYMPTOMATIC MALARIA IN SOUTHERN BENIN

Dossou Yannelle<sup>1</sup>, Sissinto Yolande Savi de Tove<sup>2</sup>, Gilles Cottrell<sup>3</sup>

<sup>1</sup>Clinical Research Institute of Benin, Abomey-Calavi, Benin, <sup>2</sup>University of Benin, Abomey-Calavi, Benin, <sup>3</sup>Research and Development Institute, Paris, France

With the renewed interest in malaria eradication around the world, strategies targeting the human parasite reservoir are needed to continue to reduce transmission and achieve elimination in malaria endemic area. Asymptomatic carriers of *Plasmodium* are important sources of infections for malaria vectors. The objective of this study was to assess the asymptomatic malaria case rates, during dry season, in the general population in southern Benin. From February to March 2020, 1064 inhabitants of the village of ADJRAKO, in the south of Benin, were screened for malaria, by three diagnostic methods: Rapid Diagnostic Test-RDT, microscopy, Polymerase Chain Reaction-PCR. Demographic data, vital signs, search for antecedent of taking antimalarial were recorded. Symptomatic malaria prevalence across all village in dry season was 6,3% (67/1064). The frequency of asymptomatic carriage of plasmodium was 19,3% (182/944); 18,1% (171/944); and 39,8% (376/944) by RDT, microscopy and PCR respectively. The predominant parasite is plasmodium falciparum with a proportion of 32.4% (306/944). Stratification by age group (< 5 years, 5-15 years, > 15 years), shows respectively, a frequency of carriage of microscopic malaria: 3,7% (35/944); 10,6% (100/944); 3,8% (36/944). The percentage related to asymptomatic submicroscopic malaria is respectively: 1,6% (15/944); 9,4% (89/944) et 11% (104/944). Whatever the diagnostic method used (microscopic, or PCR), the average quantitative values are higher in the age group of children under 5 years old (mean QPCR: 1720) compared to the groups of children from 5 to 15 years (mean QPCR: 710), as well as those over 15 years (mean QPCR: 108), and this significantly (Kruskal Wallis  $\chi^2 =$

60.212;  $p < 0.001$ ). Our findings show a low prevalence of clinical malaria episodes with a significant proportion of asymptomatic carriers. Therefore, the group of children under 5 years of age has a higher average parasitaemia rate than the older age groups despite a lower frequency of asymptomatic malaria.

1098

### SPATIAL HETEROGENEITY OF THE SUBMICROSCOPIC MALARIA RESERVOIR IN RURAL BAGAMOYO DISTRICT, TANZANIA

**Tyler J. Rapp<sup>1</sup>**, Cyrus Sinai<sup>1</sup>, Billy Ngasala<sup>2</sup>, Mwajabu Loya<sup>2</sup>, Christopher Basham<sup>1</sup>, Sifa Ngalasa<sup>2</sup>, Michael Emch<sup>1</sup>, Jessica Lin<sup>1</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,

<sup>2</sup>Muhimbili University of Health and Allied Sciences, Dar es Saalam, United Republic of Tanzania

Submicroscopic malaria reservoirs are composed of asymptomatic parasite carriers who are invisible to standard malaria diagnostics yet likely contribute to malaria transmission. The proportion of the asymptomatic reservoir that is submicroscopic varies by malaria prevalence – in areas of lower malaria endemicity, much of the malaria burden is submicroscopic, whereas in high transmission areas, asymptomatic malaria is more commonly patent (positive by microscopy or RDT). Since malaria transmission is highly heterogeneous even at local scales, we investigated whether variable malaria prevalence between villages in eastern coastal Tanzania translates to differences in the size of the microscopic reservoir. Malaria screening data including from rapid diagnostic tests (RDT), blood smears, and 18srRNA-based real-time PCR (qPCR) from more than 4,300 participants (median age 23.8, range 6 to 100 years) collected from October 2018 to March 2021 from 112 villages throughout rural Bagamoyo district, Tanzania, are used in this analysis. Villages include homes primarily constructed of sheet metal roofs (87%) and bamboo with mud housing material (68%). To identify differences in the submicroscopic reservoir at the local scale, we employed ArcGIS to map the ratio of RDT and blood smear positive cases to qPCR positive cases in 17 of the 112 villages (those containing >50 screened participants). The proportion of submicroscopic infections ranged from 26%–84% and, similar to trends identified on larger geographic scales, was lower in the villages with higher overall malaria prevalence. We will investigate individual risk factors associated with submicroscopic parasite carriage (age, gender, malaria prevalence in village) as well as village-level risk factors (altitude, season/rainfall, proximity to water, and distance to nearest health center) associated with the prevalence of malaria and submicroscopic carriage. While our study sample mainly draws from two locales and their surrounding villages that are just 30 km apart, significant spatial heterogeneity is present in the size of the submicroscopic reservoir.

1099

### EVALUATING THE EFFECT OF EXTRACTIVE INDUSTRIES ON MALARIA TRANSMISSION IN THE DEMOCRATIC REPUBLIC OF THE CONGO

**Cedar Mitchell<sup>1</sup>**, Mark Janko<sup>2</sup>, Melchior K. Mwandagali<sup>3</sup>, Antoinette K. Tshetu<sup>3</sup>, Jessie K. Edwards<sup>1</sup>, Brian Pence<sup>1</sup>, Jonathan J. Juliano<sup>1</sup>, Michael Emch<sup>1</sup>

<sup>2</sup>Institute for Health Metrics and Evaluation, Seattle, WA, United States,

<sup>3</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo

Extraction of natural resources through mining and logging activities provides revenue and employment across Sub-Saharan Africa, a region with the highest burden of malaria globally. The extent to which mining and logging influence malaria transmission in Africa remains poorly understood. Using malaria testing results and demographic information from 16,277 adults in the Democratic Republic of the Congo sampled across 489 nationally representative clusters in the 2013 Demographic

and Health Surveys, we evaluated the association between exposure to mining and logging concessions (residence  $\leq 15$  km from concession) and prevalence of malaria infections. We stratified analyses by urban vs. rural and employed hierarchical regression models that a) controlled for intra-cluster correlation alone, and b) additionally incorporated a spatially varying intercept to adjust for residual spatial confounding. We found that, without adjusting for spatial confounding, individuals in rural areas residing in a cluster exposed to mining had a malaria prevalence odds of 1.82 (95% uncertainty interval (UI): 1.35, 2.44) compared with residents of unexposed clusters. Adjusting for space, the effect of living close to a mine moved close to the null with an odds ratio of 0.93 (95% UI 0.69, 1.26). In urban areas, mining was unassociated with malaria prevalence regardless of adjusting for space. Logging was unassociated with malaria in urban and rural areas when controlling for intra-cluster correlation alone and when adjusting for space. For both mining and logging, models incorporating a spatially varying intercept fit the data better than models with a random intercept alone. These findings suggest that while mines are often located in areas of high transmission, mining itself may not drive the high prevalence; when controlling for spatial confounding, mining and logging operations are not associated with malaria prevalence.

<sup>1</sup>University of Basel and Children's Research Center, University Children's Hospital Zurich, Basel, Switzerland, <sup>2</sup>Department of Clinical Sciences, Tropical Diseases Research Centre, Ndola, Zambia, <sup>3</sup>Mycobacterial and Migrant Health Research Group, University of Basel Children's Hospital, and Department of Clinical Research, University of Basel, Basel, Switzerland, <sup>4</sup>United Nation High Commission for Refugees, Lusaka, Zambia, <sup>5</sup>Zambian Ministry of Home Affairs, Lusaka, Zambia, <sup>6</sup>Tropical Diseases Research Centre, Ndola, Zambia, <sup>7</sup>Department of Epidemiology and Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>8</sup>Mycobacterial and Migrant Health Research Group and Infectious Disease and Vaccinology Unit, University Children's Hospital Basel, University of Basel and Department of Pediatrics, The Royal Children's Hospital Melbourne, The University of Melbourne, Basel, Switzerland, <sup>9</sup>Johns Hopkins Malaria Research Institute, Johns Hopkins Bloomberg School of Public Health and Department of Medicine, Johns Hopkins University School of Medicine, Baltimore, MD, United States

Malaria due to *Plasmodium falciparum* is a leading cause of morbidity and mortality in children in highly endemic areas in sub-Saharan Africa. Refugees are at increased risk of various infectious diseases. Knowledge about the malaria risk in refugees compared to the general population is limited. This retrospective observational study was conducted in a high-transmission region of northern Zambia hosting Congolese refugees. They first were situated in a transit center during the acute phase of the refugee crisis, and then transferred to a refugee settlement (post-acute phase). We analyzed hospital records from October 2017 to May 2020 of children below 16 years of age from refugee sites and local villages with severe malaria, and malaria surveillance data of health centers from October 2018 to February 2021 to examine differences in demographic and clinical characteristics and identify risk factors. In-hospital mortality was assessed in multivariable logistic regression models. 2 197 hospitalized children had severe malaria. Of those 3% were refugees from the transit center ( $n=63$ ) and 5% from the post-acute settlement ( $n=110$ ). The overall in-hospital mortality was 13%, and was significantly higher in children from the refugee settlement (25%) than in children from the surrounding villages (12%) and from the acute phase transit center (14%). It was independently associated with being refugee (OR 1.7,  $p$  value=0.049) after adjustment for age, sex, and road distance from the hospital. Referral rate

from the settlement health center to the hospital was lower in refugee than in local children (0.4 vs 1.1%). The findings suggest that refugee children were referred earlier in the acute than in the post-acute phase, when the transit center was situated closer to the hospital. In the post-acute phase, the in-hospital mortality in refugee children with malaria was higher, what may be explained by late access to health care. Interventions tailored to the refugee context encouraging earlier healthcare-seeking and access to health care are required to improve malaria outcomes in this population.

### PREVALENCE OF MULTIPLE PLASMODIUM SPECIES IN UGANDA - TIME TO CONSIDER SUBMICROSCOPIC INFECTIONS AND NON-FALCIPARUM MALARIA IN THE CONTROL AND TREATMENT STRATEGIES?

Giselle Lima-Cooper<sup>1</sup>, Dibadyuti Datta<sup>1</sup>, Ruth Namazzi<sup>2</sup>, Andrea Conroy<sup>1</sup>, Robert Opoka<sup>2</sup>, Chandy C. John<sup>1</sup>

<sup>1</sup>Indiana University, Indianapolis, IN, United States, <sup>2</sup>Makerere University, Kampala, Uganda

The World Health Organization lists Uganda as one of the five countries that collectively suffers >50% of all malaria cases globally. *Plasmodium falciparum* is the predominant malaria species in Uganda, but the prevalence of *P. malariae*, *vivax*, and *ovale* infections remain unclear. In this study, we investigated the prevalence of multiple *Plasmodium* species in blood samples collected for a prospective observational study of neurodevelopmental outcomes in children (6 months - 4 years of age) with severe malaria (SM) conducted between 2014-2018 in Uganda. The study included participants with SM (n=600) and asymptomatic community controls (CC, n=120). Presence of malaria at enrollment was confirmed by microscopy for all species or PfHRP2 or pan-lactate dehydrogenase rapid diagnostic test (RDT). We later performed nested PCR (nPCR) testing on whole blood samples, targeting the 18S small subunit ribosomal RNA of the *Plasmodium* genus, followed by species-specific primers for amplification of *P. falciparum*, *malariae*, *ovale*, and *vivax*. In children with SM, prevalence of *P. falciparum* infections was 73%, 100% (for Pf or pan-malaria), and 96% by microscopy, RDT or nPCR, respectively. In asymptomatic CC, prevalence of *P. falciparum* infections was 8%, 24% (for Pf or pan-malaria), and 28% by microscopy, RDT or nPCR, respectively. The prevalence of *P. malariae* infections detected by microscopy in SM group was 0.3% and 0.8% in the asymptomatic CC group. nPCR found a prevalence of *P. malariae* in 1.2% in SM group and 1.7% in asymptomatic CC group. Testing is ongoing for *P. ovale* and *P. vivax*. Our preliminary findings suggest a need for improved detection of non-*falciparum* infections in malaria endemic countries as well as a need to understand prevalence of all-species sub-microscopic infections, which will be key in malaria transmission reduction goals.

1102

### ELUCIDATING MALARIA PLASMODIUM SPECIES COINFECTIONS ACROSS ZAMBIA USING MOLECULAR AND GENOMIC APPROACHES

Ilinca I. Ciubotariu<sup>1</sup>, Daniel J. Bridges<sup>2</sup>, Abebe A. Fola<sup>1</sup>, Mulenga C. Mwenda<sup>2</sup>, Brenda Mambwe<sup>2</sup>, Conceptor Mulube<sup>2</sup>, Moonga Havela<sup>3</sup>, Giovanna Carpi<sup>1</sup>

<sup>1</sup>Purdue University, Department of Biological Sciences, West Lafayette, IN, United States, <sup>2</sup>PATH Malaria Control and Elimination Partnership in Africa (MACEPA), Lusaka, Zambia, <sup>3</sup>National Malaria Elimination Centre, Zambia Ministry of Health, Chainama Hospital Grounds, Lusaka, Zambia

Malaria continues to be a major public health problem in sub-Saharan Africa, including in Zambia, where the majority of population is at risk. In Zambia, the *Plasmodium falciparum* parasite causes the overwhelming majority of malaria cases, but a study from Eastern and Luapula provinces found that *Plasmodium spp.* coinfections accounted for 10.6% of analyzed samples. As Zambia heavily relies on rapid diagnostic tests (RDTs) for malaria diagnosis which only detect *P. falciparum*, we hypothesize

that non-*falciparum* malaria infections are under-diagnosed, and their prevalence underestimated. This study aimed to assess the prevalence and spatial patterns of coinfections with *P. falciparum*, *P. ovale*, *P. malariae* using molecular and genomic data. We analyzed data from the Zambia 2018 Malaria Indicator Survey (MIS) with light microscopy (LM), PET-PCR, and RDT results for dried blood spots. The overall prevalence of *P. falciparum* by PET-PCR was 19.6% (747/3817). Of the PET-PCR Pf-positive samples, 3.7% (28/747) were positive for *P. ovale/P. malariae* by LM, although this is likely higher due to 13.5% of samples lacking *P. ovale/P. malariae* microscopy results. To assess whether we can untangle *Plasmodium spp.* coinfections by mining available WGS Pf genomic data, we selected a subset of samples coinfecting with *P. ovale/P. malariae* and *P. falciparum*, and samples only Pf-infected, and mapped reads to 4 reference genomes (*P. falciparum*, *P. malariae*, *P. ovale curtisi*, *P. ovale wallikeri*). Coinfected samples yielded a higher percentage of apicoplast mapped reads ( $p < 0.05$ ) for *P. ovale w.* when comparing apicoplast mapped reads for coinfecting vs. Pf-infected samples across species. Also, *P. ovale w.* and *P. malariae* had a significant difference ( $p < 0.05$ ) between percentage of bases with >5X read coverage for coinfecting relative to only Pf-infected samples, indicating these samples are likely coinfecting with *P. malariae/P. ovale w.* These results improve our understanding of prevalence and spatial distribution of coinfections across Zambia. Further analysis with more samples is needed and we will assess how coinfections impact anemia and parasitemia levels.

1103

### ENVIRONMENTAL RISK OF MALARIA INFECTION ALONG THE MOZAMBIQUE AND ZIMBABWE BORDER

Kelly M. Searle<sup>1</sup>, Alexa Steiber<sup>1</sup>, Dominique Earland<sup>1</sup>, Anísio Novela<sup>2</sup>, Albino Bibe<sup>3</sup>, João L. Ferrão<sup>4</sup>

<sup>1</sup>University of Minnesota, Minneapolis, MN, United States, <sup>2</sup>Direção Distrital de Saúde de Sussundenga, Manica, Sussundenga, Mozambique, <sup>3</sup>Escola Secundária de Sussundenga, Sussundenga, Mozambique, <sup>4</sup>Instituto Superior de Ciências de Educação, Beira, Mozambique

Mozambique currently has the 5<sup>th</sup> highest malaria prevalence globally. Malaria incidence varies within country, with it being lowest in the south and highest in the north. The central area experiences sustained high incidence and prevalence and has heterogeneous environments and ecologies. Sussundenga District in Manica Province directly borders Zimbabwe and has a varying ecology which impacts malaria transmission at the community level. We conducted a community cross-sectional survey from December 2019-February 2020 to determine the malaria prevalence, risk factors, and impacts of severe weather events. *P. falciparum* malaria prevalence in this area was high at 31%. We collected MODIS environmental data from NASA including land surface temperature (LST), evapotranspiration (ET), normalized difference vegetation index (NDVI), land use, and elevation. We joined survey data with time static environmental data (land-use and elevation) by spatial location of the household collected during the survey. We joined time varying environmental data (LST, ET, and NDVI) data to survey data by spatial location with a 2-week lag in time from survey data collection. We used mixed effects logistic regression models to estimate associations between environmental factors while controlling for individual risk factors. We investigated the impacts of malaria control interventions in varying ecologies in the area. Our analysis was done at the community level, with direct implications for identifying transmission hotspots. Along the Mozambique, Zimbabwe border differing malaria control policies are in place with heterogeneous environments, while already experiencing early impacts of climate change. Our findings will show how these control policies and environments impact malaria transmission in this setting.

1104

## SEROLOGICAL MARKERS OF PREVIOUS EXPOSURE TO *PLASMODIUM FALCIPARUM* AND *P. VIVAX* IN WESTERN ETHIOPIA

Brook Jeang<sup>1</sup>, Arlene E. Dent<sup>2</sup>, Delenasaw Yewhalaw<sup>3</sup>, James W. Kazura<sup>2</sup>, Guiyun Yan<sup>1</sup>

<sup>1</sup>University of California, Irvine, Irvine, CA, United States, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>3</sup>Jimma University, Jimma, Ethiopia

Sub-Saharan Africa sustains a disproportionate share of the global malaria burden. Malaria cases and deaths in Africa have historically been attributed almost exclusively to *Plasmodium falciparum* infections, as *Plasmodium vivax* was previously thought to be absent. With the advent of more sensitive diagnostics, *P. vivax* infections have been increasingly reported. Concerted efforts targeting *P. falciparum* and *P. vivax* are urgently needed in co-endemic areas, such as Ethiopia, in order to achieve successful malaria elimination. The purpose of this study was to identify factors associated with fine-scale heterogeneities in antibody responses to serological markers of *P. falciparum* and *P. vivax* infections. We conducted a cross-sectional immuno-epidemiological study (N=746) in two areas of western Ethiopia with contrasting malaria transmission intensities: Arjo in the Oromia Region (low transmission area) and Gambella in the Gambella Peoples' Region (high transmission area). We measured participants' antibody reactivity to a panel of 6 *P. falciparum* (AMA-1, CSP, EBA175 RIII-V, MSP-1, MSP-3, RH2ab) and 4 *P. vivax* (DBPSal-1, EBP2, MSP-1, RBP2b) antigens to gain a better understanding of cumulative and recent malaria exposure in the study area. As expected, people residing in Gambella had higher prevalence and levels of antibodies to *P. falciparum* and *P. vivax* compared to people residing in Arjo. We used mixed effects logistic regressions to assess predictors of antibody response at the species-level and for each antibody. Age and male sex were strongly positively associated with odds of seropositivity in Arjo only. Distance to nearest perennial water source or irrigation scheme was not a strong predictor of antibody seropositivity in Arjo or Gambella. Concurrent *Plasmodium* PCR infection data will be added to the model when complete. Variations in individual- and community-level antibody prevalence and levels between the low and high transmission sites suggest the potential for adapting this serological panel to monitor spatiotemporal trends in transmission intensity following implementation of malaria control interventions.

1105

## ANALYSIS OF PREDICTORS OF INSECTICIDE TREATED NET USE (ITN) IN GUINEA USING MACHINE LEARNING ALGORITHMS

Ousmane Oumou Diallo<sup>1</sup>, Ifeoma D Ozodiegwu<sup>1</sup>, Alioune Camara<sup>2</sup>, Beatrice Galatas<sup>2</sup>, Jaline Gerardin<sup>1</sup>

<sup>1</sup>Northwestern University, Evanston, IL, United States, <sup>2</sup>National Malaria Control Program, Guinea, Conakry, Guinea, <sup>3</sup>Global Malaria Programme, World Health Organization, Geneva Switzerland, Geneve, Switzerland

Malaria is the leading cause of outpatient visits (34%) and deaths (28%) among children in Guinea. The use of insecticide-treated nets (ITNs) reduces the burden of malaria. Despite very good household net ownership (61%), net use (23%) remains low in Guinea (2018 Demographic and Health Survey (DHS)). We used a machine learning model to identify predictors of ITN use to inform intervention planning. Data was obtained from the 2018 DHS. We first used a Rao Scott Chi-square test to select significant variables for inclusion in a Chi-square automatic interaction detector (CHAID) model. Region, marital status, household size, household wealth quintile, gender, place of residence, and educational level of the head of household were the significant variables. To identify the optimal predictors of ITN use, CHAID uses a multi-level successive fitting algorithm. In each level, the model identifies the predictor variable with the strongest association with the outcome. We obtained a model accuracy of 0.77 (0.767- 0.774). A logistic regression model was used to estimate odds ratios and 95% confidence intervals. Region was

the best predictor of ITN use in the general population, with greatest use in the N'zerekore region, followed by the Faranah region. Using the Boke region as reference, the odds ratio of using an ITN was 1.90 times higher in the N'zerekore region (95% CI 1.35-2.67, p<0.001) and 0.51 times lower in Labe (95% CI 0.36-0.74, p<0.001). Place of residence, household size, and household wealth quintile were other significant predictors, depending on the region. In the region of N'zerekore, place of residence (urban or rural) was the most significant predictor of ITN use. In contrast, in Boke, the predictor most associated with ITN use was household size, with households of 8 or more members having lowest ITN use. The results of this study will allow the Guinea National Malaria Control Program to understand how to target ITN distribution in different regions of Guinea. Improved targeting of distribution and communications campaigns could have a huge impact on malaria burden and potentially allow Guinea to reach Global Technical Strategy targets for 2030.

1106

## ANALYSIS OF MALARIA TRENDS WITH RESPECT TO THE IMPLEMENTATION OF CONTROL INTERVENTIONS BETWEEN 2014 AND 2020 IN DANGASSA, MALI

Mahamoudou Touré<sup>1</sup>, Fousseyni Kané<sup>1</sup>, Daouda Sanogo<sup>1</sup>, Drissa Konate<sup>1</sup>, Moussa Keita<sup>1</sup>, Salim Kanté<sup>1</sup>, Aboubakar K. Fomba<sup>1</sup>, Nafomon Sogoba<sup>1</sup>, Mahamadou Diakité<sup>1</sup>, Jeffrey G. Shaffer<sup>2</sup>, Seydou O. Doumbia<sup>1</sup>

<sup>1</sup>University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, <sup>2</sup>Tulane University, New Orleans, LA, United States

Over the past decade, three strategies have reduced severe malaria cases and deaths in endemic regions of Africa, Asia, and the Americas, specifically: 1] artemisinin-based combination therapies (ACTs), 2] insecticide-treated nets (ITNs), and 3] intermittent preventive treatment with sulfadoxine-pyrimethamine in pregnancy (IPTp). Recent studies have shown significant declines in malaria incidence between 2010 and 2018. This study aims to analyze seven years of data for Dangassa, Mali in relation to implementation of control interventions from 2014 to 2020 in an effort to facilitate evidence-based and area-specific malaria interventions. This prospective study was based on a rolling longitudinal cohort of 1,401 subjects between 2014 and 2020. Participants were screened biannually at the start and the end of the malaria transmission season for the prevalence of asymptomatic *Plasmodium (P) falciparum* infection. Incidence was assessed through passive case detection at community health centers. Electronic data capture and cloud-based databases were used for data collection, capture and management. Prevalence of infection ranged from 9.5% to 62.8% and from 15.1% to 66.7% at the start and the end of the transmission season, respectively. The incidence of uncomplicated malaria was found to remain high among children aged under five years. Starting 2015, we observed a shift in malaria prevalence, with more asymptomatic infection occurring among children aged 5 to 14 years. At baseline, prevalence of *P. falciparum* was over 60% followed by a significant year-to-year decline starting in 2015. Incidence of uncomplicated infected was greater among children aged under five years, while asymptomatic infection was more frequent among children aged five to 14 years. Efficient Implementation in 2015 of two main malaria prevention strategies in Dangassa substantially contribute to a reduction of both asymptomatic and symptomatic malaria in Dangassa from 2015 to 2020. The findings for this study are consistent with the progressive implementation of effective malaria control strategies in Dangassa.

### DECLINING MALARIA TRANSMISSION AND ANTIBODY PROFILE KINETICS TO *PLASMODIUM FALCIPARUM*: A LONGITUDINAL STUDY IN SOUTHERN ZAMBIA FROM 2008 TO 2015

Tamaki Kobayashi<sup>1</sup>, Harry Hamapumbu<sup>2</sup>, Philip E. Thuma<sup>2</sup>, Kevin Tetteh<sup>3</sup>, Chris Drakeley<sup>3</sup>, William J. Moss<sup>1</sup>

<sup>1</sup>*Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*, <sup>2</sup>*Macha Research Trust, Choma, Zambia*, <sup>3</sup>*London School of Hygiene & Tropical Medicine, London, United Kingdom*

Limited information is available on the kinetics of the antibody responses to *Plasmodium falciparum* in low transmission settings. The catchment area of Macha Hospital in Southern Province, Zambia was mesoendemic, with malaria transmission peaking during the rainy season, but transmission declined dramatically over the past two decades and the area is now approaching elimination. We collected dried blood spots from 637 individuals (median age at baseline 13 years, interquartile range = 5.6, 23) repeatedly between 2008 and 2015 when malaria transmission declined. Parasite prevalence by rapid diagnostic test (RDT) among cohort participants was 4% in 2008 and 0% in 2015. Using a subset of samples (n=12), we previously tested the use of a multiplex bead assay comprised of 19 *P. falciparum* antigens and showed that higher antibody response was associated with the age at baseline, but not to the seasonality, suggesting that the antibody response acquired before the enrolment persisted instead of exposure to the parasite between 2008 and 2015. We are expanding this analysis to the complete longitudinal cohort of 637 individuals. Our aim is to obtain information on the baseline immunological profile as well as temporal variations in antibody responses in a setting of declining *P. falciparum* transmission. For every 637 participants, demographic information and malaria-related information (RDT, microscopy, bed net use) are available, and together, these data will provide insight into the kinetics of antibody responses to falciparum malaria in a near-elimination region.

### THE EMERGENCE OF A NEW MALARIA HOTSPOT: IMPORTED AND INDIGENOUS MALARIA IN THE BORDER STATE OF RORAIMA FROM 2016 TO 2020 AND CHALLENGES DURING THE COVID-19 PANDEMIC

Paola Marchesini<sup>1</sup>, Erika Wetzler<sup>2</sup>, Leopoldo Villegas<sup>3</sup>, Sara Canavati<sup>2</sup>

<sup>1</sup>*Ministry of Health, Brasilia, Brazil*, <sup>2</sup>*World Vision, Washington DC, MD, United States*, <sup>3</sup>*ASOCIS, Tumeremo, Bolivar, Bolivarian Republic of Venezuela*

Since the political and economic crisis began in Venezuela in 2010, the country has become a hotspot for malaria in the region. The crisis has resulted in the mass migration of Venezuelans to other countries in Latin America, with over 260,000 Venezuelan migrants officially entering Brazil since 2010. Their primary entry point into Brazil is Pacaraima, in the northernmost state of Roraima. Little is known about how the epidemiology of imported and indigenous malaria in Roraima has changed since the surge in migration. Using surveillance data from the Malaria Epidemiological Surveillance and Case Notification System in Brazil (SIVEP), we describe seasonality, malaria parasite species composition, key populations, and temporal distribution of cases including imported and indigenous cases from 2016 to 2020. Using logistic regression methods, we identify risk factors associated with *Plasmodium falciparum* (Pf) and *P. vivax* (Pv) infection, and for imported versus indigenous cases. Between 2016 and 2020, there were 81,329 reported local cases compared to 15,089 imported cases. The proportion of reported cases in areas classified as indigenous increased in Roraima from 18.5% in 2017 to 63.8% in 2020. Pf cases declined from 7.4% in 2016 to 1.7% in 2017 but rose to 15.1% in 2020. The trend in imported versus autochthonous cases was highest in 2016 at 36.3%, decreasing to 3.9% in 2020. Overall, most imported cases were from Venezuela (81.8%), followed by Guyana

(17.6%), but in 2020, cases from Venezuela dropped to 74.1%. During the study period, there was an increase in the total number of malaria cases in Roraima, likely generated from the influx of Venezuelan migrants arriving in the state. However, in 2020, when the border with Venezuela closed in response to the COVID-19 pandemic, there was a marked reduction in imported cases, but an increase in the total number of cases. Additionally, species composition shifted away from Pv to Pf. Establishment of strong cross-border surveillance systems and identification of the high-risk activities and demographic groups are needed to appropriately target and tailor interventions to maximize impact.

### PREDICTORS AND ASSOCIATIONS WITH MATERNAL AND BIRTH OUTCOMES OF *PLASMODIUM FALCIPARUM* INFECTION IN THE FIRST TRIMESTER AMONG NULLIPAROUS WOMEN FROM THE DEMOCRATIC REPUBLIC OF THE CONGO, KENYA, AND ZAMBIA

Malaria infection in the first trimester of pregnancy could disrupt placentation and thus impair fetal growth. Despite the concern for adverse pregnancy outcomes associated with first-trimester malaria infection, malaria prevention measures are rarely initiated until the second trimester. We sought to (i) identify predictors of first-trimester malaria and (ii) estimate its associations with adverse maternal and birth outcomes. We studied a subset of participants from the ASPIRIN (Aspirin Supplementation for Pregnancy Indicated Risk reduction In Nulliparas) trial. Recruited from multiple sites in Democratic Republic of the Congo (DRC), Kenya, and Zambia, 1,513 nulliparous pregnant women were tested for first-trimester *Plasmodium falciparum* infection by qPCR and analyzed using parametric g-computation. First-trimester malaria prevalence among nulliparous pregnant women was 62.9% in DRC, 37.8% in Kenya, and 6.3% in Zambia. We first considered factors associated with first-trimester malaria in hopes of developing better prevention strategies. Predictors associated with higher crude first-trimester malaria prevalence included younger age (<20 years) among Kenyan women and lower education (no secondary education) among women from all three sites when pooled. We then considered associations of first-trimester malaria with pregnancy outcomes. After adjusting for confounders, first-trimester malaria was associated with higher prevalences of preterm birth (adjusted PD (aPD) = 0.06 [99% CI: -0.04, 0.16]) and low birth weight (aPD = 0.07 [99% CI: -0.03, 0.16]) among Congolese women only, and higher prevalence of anemia in late pregnancy among Kenyan (aPD = 0.05 [99% CI: -0.06, 0.17]), Zambian (aPD = 0.07 [99% CI: -0.12, 0.36]), and Congolese

women (aPD = 0.04 [99% CI: -0.09, 0.16]). In this first large multi-site study of first-trimester malaria, the high prevalence of infections in high-transmission areas along with associations of first-trimester malaria with higher prevalences of adverse maternal and birth outcomes suggest that screening women early in pregnancy may be needed to reduce the impact of first-trimester malaria.

1110

### RESIDING AND TRAVELING AT THE ZIMBABWE-MOZAMBIQUE BORDER: A STUDY OF BORDER MALARIA IN MUTASA DISTRICT, ZIMBABWE

Ellen Ferriss<sup>1</sup>, Sungano Mharakurwa<sup>2</sup>, Shungu Munyati<sup>3</sup>, Lovemore Gwanzura<sup>4</sup>, Amy Wesolowski<sup>1</sup>, William J. Moss<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Africa University, Mutare, Zimbabwe, <sup>3</sup>Biomedical Research and Training Institute, Harare, Zimbabwe, <sup>4</sup>University of Zimbabwe, Harare, Zimbabwe

International vector and human population movement are recognized as contributors to malaria transmission in border regions and impediments to national malaria elimination. However, their contribution in areas with seasonal malaria is not well characterized. In eastern Zimbabwe, border malaria with Mozambique is believed to play a key role in transmission. This study estimated parasite prevalence in Mutasa District, Zimbabwe, using community-based active surveillance data from 2012 through 2020. Changes in parasite prevalence relative to household distance to the border and self-reported travel to Mozambique were estimated using a Poisson regression model with robust variance estimation. The population attributable fraction arising from travel to Mozambique was estimated via bootstrapping. Living closer to the Zimbabwe-Mozambique border and recent overnight travel to Mozambique were significantly associated with increased parasite prevalence in Mutasa District. The relative risk of malaria declined 14% (95% confidence interval = 0.81, 0.91) with each additional kilometer from the border, while travel to Mozambique was associated with an 171% increase in risk (95% confidence interval = 1.42, 5.19). However, only roughly two percent of observed cases were estimated to be attributable to travel. Future control efforts may consider binational malaria control programming, including coordinated indoor residual spraying and long-lasting insecticide-treated net distribution, in addition to continued support for border health posts, clinics, and community health workers.

### DETERMINING ANTIGEN DIVERSITY AND IMMUNE SELECTION TARGETS OF LEADING PLASMODIUM VIVAX VACCINE CANDIDATES AND SEROSURVEILLANCE MARKERS

Paolo N. Barends<sup>1</sup>, Myo Naung<sup>2</sup>, Somya Mehra<sup>3</sup>, Alyssa E. Barry<sup>1</sup>

<sup>1</sup>Institute for Mental and Physical Health and Clinical Translation (IMPACT), School of Medicine, Deakin University, Victoria, Australia, <sup>2</sup>Division of Population Health and Immunity, Walter and Eliza Hall Institute of Medical Research, Victoria, Australia, <sup>3</sup>Life Sciences Discipline, Burnet Institute, Victoria, Australia

Attention on *Plasmodium vivax* (Pv) infection and its impact on the global malaria control and elimination campaign is limited. One of the major gaps in Pv research is the lack of information on the diversity of surface antigens, which could provide relevant details on the parasite population structure and vaccine development. Population genetic data can not only assess transmission intensity but also provide insights in detecting genes under immune selection. We, therefore, aimed to determine the global distribution of antigen diversity and identify gene regions with signature of immune selection amongst leading *Plasmodium vivax* vaccine candidate antigens and sero-surveillance markers. Several signatures of diversity and balancing selection were measured based on published sequences from multiple geographic populations such as Thailand (n=111), Peru (n=40), and Papua New Guinea (n=21). Genetic relatedness of the sequences was visualized through haplotype network diagrams. Furthermore, sequences

were mapped onto experimentally defined three-dimensional protein structures to analyze spatially derived nucleotide diversity ( $\pi$ ) and immune selection. Initial results showed low nucleotide and haplotype (Hd) diversity in *P. vivax* antigen genes *rama* ( $\pi=0.68$ ; Hd=0.71), *msp1<sub>19</sub>* ( $\pi=0.63$ ; Hd=0.19), and *csp* ( $\pi=0.20$ ; Hd=0.10); which is supported with limited immune selection hotspot. In contrast, high diversity was observed in antigen genes *rbp1a* ( $\pi=2.79$ ; Hd=0.99), *rbp2b* ( $\pi=1.52$ ; Hd=0.99), *dbpRII* ( $\pi=7.68$ ; Hd=0.96), and *ama1* ( $\pi=6.89$ ; Hd=0.99), which is consistent with the observed distantly related sequences in the haplotype network plots. Lastly, spatially-derived nucleotide diversity and Tajima's D were similar between different geographic populations suggesting that gene regions, which are the targets of protective antibodies, are potentially consistent across different populations. The data from this study will guide researchers in designing widely effective vaccines and serological tools against *P. vivax* parasites.

1112

### CONTROLLED HUMAN MALARIA INFECTIONS WITH NF54 AND 7G8 STRAINS ELICIT DIFFERENTIAL ANTIBODY RESPONSES TO PLASMODIUM FALCIPARUM PEPTIDES

DeAnna Friedman-Klabanoff<sup>1</sup>, Travis L. Jensen<sup>2</sup>, Kirsten E. Lyke<sup>1</sup>, Matthew B. Laurens<sup>1</sup>, Joana C. Silva<sup>3</sup>, Emily M. Stucke<sup>1</sup>, Amed Ouattara<sup>1</sup>, Casey E. Gelber<sup>2</sup>, Johannes B. Goll<sup>2</sup>, Jigar J. Patel<sup>4</sup>, John C. Tan<sup>4</sup>, Gregory A. Deye<sup>5</sup>, Shannon Takala-Harrison<sup>1</sup>, Mark A. Travassos<sup>1</sup>, Andrea A. Berry<sup>1</sup>

<sup>1</sup>Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>The Emmes Company, Rockville, MD, United States, <sup>3</sup>Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>4</sup>Nimble Therapeutics, Inc., Madison, WI, United States, <sup>5</sup>Parasitology and International Programs Branch, Division of Microbiology and Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Extensive genetic diversity of *Plasmodium falciparum* plays a role in immune system evasion. In endemic settings, past infection history confounds studies examining allele-specific versus cross-protective immune responses. Controlled human malaria infection (CHMI) allows the investigation of immune responses to diverse parasite proteins after a single infection with a known strain. Using a diversity-reflecting peptide microarray, we probed sera from 38 malaria naïve adults at baseline and 28 days after CHMI with *P. falciparum* (Pf) NF54 (n = 21) or Pf 7G8 (n = 17). The array contained 22,656 protein variants from 23 genome assemblies and field-derived genomic data from 411 samples for 227 Pf protein-coding loci, collected from 9 countries in 3 continents. Each variant was represented by 16 amino acid (aa) peptides with 15 aa overlap. Quantitative seroreactivity was based on average smoothed log<sub>2</sub> fold changes relative to baseline. Serorecognition was defined as post-CHMI maximum smoothed log<sub>2</sub> signal intensity >2.5 standard deviations above baseline of all subjects; a protein variant was considered serorecognized at the cohort level if signal for >15% of subjects exceeded the cutoff. All 227 proteins were assessed for target epitopes using ABCPred. The seroreactivity analysis identified 193 proteins with differential responses, of which 25 were also serorecognized. The 7G8 group had higher mean seroreactivity across all 25 proteins compared to the NF54 group. ABCPred predicted epitopes with a score of >0.8 in 52 proteins on the array; 27 overlapped with epitopes identified by our peptide array, five of which were highly cross-reactive with >95% of variants serorecognized. Overall, the peptide array discriminated strain-specific responses to peptide variants and identified cross-reactivity to predicted epitopes after a single malaria episode. Interestingly, despite earlier malaria diagnosis and antimalarial treatment (by 2.5 days), the 7G8 group had higher seroreactivity to 85% of proteins on the array. Further characterization of broadly serorecognized proteins may lead to a better understanding of acquired immunity to malaria.

### DEEP IMMUNOPROFILING OF FOLLICULAR HELPER (TFH) T CELLS ASSOCIATED WITH PLASMODIUM FALCIPARUM PFSEA-1A AND PFGARP RESPONSES FROM ADULTS AND CHILDREN IN KENYA

Catherine Suzanne Christine Forconi<sup>1</sup>, Erastus Kirwa<sup>2</sup>, Hannah W. Wu<sup>3</sup>, John Michael Onge'cha<sup>2</sup>, Jonathan Kurtis<sup>3</sup>, Ann Moormann<sup>1</sup>

<sup>1</sup>University of Massachusetts Medical School, Worcester, MA, United States, <sup>2</sup>Center for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>Department of Pathology and Laboratory Medicine, Brown University, Providence, RI, United States

Follicular Helper (TFH) T cells are essential to promote B cell class-switching and antibody production which make them a key player in the establishment of protective immunity against *Plasmodium falciparum* (Pf). However, because of their low frequency in peripheral blood, investigating human TFH cell subsets can be challenging. In this study we used OMIQ, an unbiased flow cytometry analysis platform to assess TFH cell subsets from adults and children living in a malaria holoendemic area of Kenya. Peripheral blood mononuclear cells from 15 adults and 14 children (7 years old) were stimulated *in vitro* with two malaria vaccine-candidate antigens, PfSEA-1A or PFGARP and stained with a 20-color TFH flow cytometry panel. PfSEA-1A and PFGARP specific IgG antibody levels and function were assessed by Luminescence and C1q fixation, respectively. Using unbiased analysis methods instead of conventional gating for multiparameter flow cytometry data, we found a unique TFH cell subset (CXCR5<sup>int</sup>CD45RA<sup>+</sup>CCR7<sup>+</sup>CCR6<sup>neg</sup>CXCR3<sup>neg</sup>PD1<sup>neg</sup>ICOS<sup>low</sup>) only in children, yet it did not respond to malaria-antigen stimulation. Our analysis revealed graduated CXCR5 expression (classified as high, intermediate or low) for more activated TFH cell subsets that expressed less CCR7 and more ICOS and PD-1 within adults in contrast to children. After *in vitro* stimulation, PFGARP induced IL4 production from CXCR5<sup>int</sup>CCR6<sup>neg</sup>CXCR3<sup>low</sup>PD1<sup>int</sup>ICOS<sup>high</sup>TFH2-like cells (i.e. more efficient helpers) in adults but IL-21 from CXCR5<sup>int</sup>CCR6<sup>neg</sup>CXCR3<sup>high</sup>PD1<sup>int</sup>ICOS<sup>int</sup>TFH1-like cells in children. Interestingly, upon PfSEA-1A stimulation, IFN $\gamma$  was produced by CXCR5<sup>high</sup>CCR6<sup>neg</sup>CXCR3<sup>high</sup>PD1<sup>int</sup>ICOS<sup>int</sup>TFH1-like cells only in adults, whereas we did not observe any response from children. Our findings are consistent with other studies of malaria and TFH cell subset phenotypes associated with age. However, our unbiased analysis methods revealed more granularity and antigen-specificity for TFH cell subsets. This has implications for evaluating the role of TFH cells in malaria vaccine-elicited antibody responses.

### PLASMODIUM LIVER STAGE-TARGETED ANTIBODIES CAN REDUCE PARASITE LIVER BURDEN AND SYNERGIZE WITH ANTI-CSP ANTIBODIES TO PROVIDE ENHANCED STERILE PROTECTION

Thomas Martinson<sup>1</sup>, Maya Aleshnick<sup>1</sup>, Isabella Updyke-Welch<sup>1</sup>, Alexander Watson<sup>2</sup>, Nicholas Dambrauskas<sup>2</sup>, Noah D. Sather<sup>2</sup>, Brandon K. Wilder<sup>1</sup>

Antibodies (Abs) have long been known as important for protection against *Plasmodium* infection. However, neither traditional nor emerging Ab candidates appear capable of providing sufficient protection when targeted by vaccines or monoclonal Ab. The few efforts to combine antigens have confounded by mixing of vaccine platforms and issues of apparent immune interference. To date, nearly all Ab-based efforts have focused on preventing parasite cell entry at the extracellular sporozoite, merozoite or gametocyte stages with little consideration of the multi-day intracellular liver stages—likely because they reside within a parasitophorous vacuole membrane (PVM) within the hepatocyte cytoplasm. Here, we demonstrate that the PVM protein UIS3 is susceptible

to Ab-mediated inhibition during these intracellular liver stages. Specifically, passive transfer of polyclonal anti-PfUIS3 Abs can clear >90% of liver stage parasites in mice infected with *P. berghei* parasites carrying the PfUIS3 gene as a replacement. This occurred when Abs were administered 4 hours after intravenous sporozoite injection when all parasites have left the circulation. Antibody efficacy was minimally affected by the absence of host FcRn, indicating the lack of receptor-mediated interaction with hepatocytes for parasite killing. On their own, anti-PfUIS3 Abs did not provide any sterilizing protection in this model but increased the protective capacity of a suboptimal anti-PbCSP monoclonal Ab from 0% to 60% when used in combination. Further mechanistic and monoclonal Ab studies are under way in wild type and humanized mice. These data confirm a single previous publication showing that the *Plasmodium* liver stage, and in particular PVM proteins, are susceptible to Ab-mediated inhibition. Moreover, they clearly demonstrate the potentiating power of a hereto unrealized class of Ab targets and add to a growing body of literature within and outside the malaria field indicating that combinations of Abs targeting different proteins and/or stages of infection will be needed to achieve high levels of protection.

### EVIDENCE OF ACTIVATION OF HOFBAUER CELLS IN ACTIVE PLACENTAL MALARIA

Placental malaria (PM) is characterized by *Plasmodium falciparum*-infected red blood cells sequestering in the placenta. We previously showed that placental malaria is associated with increased levels of tumor necrosis factor alpha (TNF- $\alpha$ ), gamma interferon (IFN- $\gamma$ ), CXCL9 and inflammatory cell infiltrate. Hofbauer cells (HBCs) are fetal macrophages residing in the stroma of placental villi, are generally described as M2-type macrophages. However, there have been limited studies on the HBC response to the pro-inflammatory environment during PM. Here, we assess whether there are changes in HBC polarization during inflammation associated with PM by comparing placentas from uninfected women, women infected during pregnancy and women infected at delivery. We conducted an immunohistochemical analysis of primigravid placental tissue samples using the following surface markers: IBA-1 (pan-macrophage marker), CD68 (M1, classically activated) and CD163 (M2, alternatively activated). Marker-positive areas were normalized to the total villous areas and the resulting percentage (%Area) logit transformed ( $\log[\%Area/(100-\%Area)]$ ) and compared. No significant differences ( $p < 0.05$ ) were found in the expression of CD68 and CD163 between uninfected placentas ( $n=10$ ) and those infected during pregnancy ( $n=8$ ) or at delivery ( $n=12$ ). IBA-1 adjusted signal was higher in placenta samples infected at delivery compared to uninfected placenta samples (6.5% vs 5.6% IBA-1 positive areas), but the differences did not achieve significance ( $p=0.08$ ). IBA-1 expression was also higher in placental samples from women infected during pregnancy compared to uninfected, but the differences were not

significant ( $p = 0.1$ ). The increase in IBA-1 observed in this pilot study suggests that a proinflammatory environment might modify HBCs during PM. Of note, this study did not examine whether IBA-1 signal may have changed due to an increase in HBCs numbers or IBA-1 expression. In future, we will isolate HBCs to explore changes in numbers and subtypes of HBCs using multiple surface markers.

Wilding**<sup>1</sup>, Samuel Anyona<sup>2</sup>, Evans Raballah<sup>3</sup>, Qiuying Cheng<sup>4</sup>, Ivy Hurwitz<sup>4</sup>, Alexandra Yingling<sup>4</sup>, Ananias Escalante<sup>5</sup>, Kristan Schneider<sup>6</sup>, Collins Ouma<sup>7</sup>, Benjamin H. McMahon<sup>1</sup>, Douglas J. Perkins<sup>4</sup>

<sup>1</sup>Los Alamos National Laboratory, Los Alamos, NM, United States, <sup>2</sup>Department of Medical Biochemistry, School of Medicine, Maseno University, Maseno, Kenya, <sup>3</sup>Department of Medical Laboratory Sciences, School of Health Sciences, Masinde Muliro University of Science and Technology, Kakamega, Kenya, <sup>4</sup>Center for Global Health, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>5</sup>Temple University, Philadelphia, PA, United States, <sup>6</sup>Department of MNI, University of Applied Sciences Mittweida, Mittweida, Germany, <sup>7</sup>Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Maseno, Kenya

We present a statistical analysis of the relationship between circulating inflammatory mediator production (25-plex) in children with acute malaria (day 0, pretreatment) and upon recovery (day 14, posttreatment). Children ( $n=70$ , age 3 to 36-months) were recruited at Siaya County Referral Hospital in western Kenya, a holoendemic *Plasmodium falciparum* transmission region. Fourteen of the children had severe malarial anemia (SMA), defined as presence of *P. falciparum* parasitemia (any density) and hemoglobin (Hb) levels below 5.0 g/dL, while 56 children had uncomplicated malaria (UM, *P. falciparum* parasitemia and  $Hb \geq 5.0$  g/dL). Children with SMA had elevated levels of lymphocytes and monocytes and decreased production of type-1 cytokines (i.e., IFN- $\gamma$ , IL-12, and TNF- $\alpha$ ). SMA was also defined by a strong negative correlation between monocyte counts and blood glucose levels, an important metabolite for type 1 macrophages (M1) that is necessary for appropriate effector functions. Analysis of the inflammatory mediators on day 14 revealed that cytokines/chemokines associated with SMA on day 0 retained that association on day 14, with the exception of IL-12 and IFN- $\gamma$ . Between day 0 and 14, there was a significant change in 13 of the 25 inflammatory mediators. However, other than IFN- $\gamma$ , none of the inflammatory mediators that significantly changed across the timepoints were associated with the severity of malaria. Collectively, these results suggest that the pathogenesis of SMA is associated with an inefficient (suboptimal) type-1 immune response for macrophage polarization and that the observed imbalance in M1/M2 may be impacted by glucose levels.

## A PARASITE PROTEIN THAT LOCALIZES TO THE LIVER STAGE NUCLEUS IS ESSENTIAL FOR ITS COMPLETE MATURATION

**Debashree Goswami**<sup>1</sup>, Silvia A. Arrendondo<sup>1</sup>, Janna Gibson<sup>1</sup>, William Betz<sup>1</sup>, Sean C. Murphy<sup>2</sup>, Stefan H.I. Kappe<sup>3</sup>, Ashley M. Vaughan<sup>3</sup>

<sup>1</sup>Seattle Childrens Research Institute, Seattle, WA, United States, <sup>2</sup>Department of Laboratory Medicine, University of Washington, Seattle, WA, United States, <sup>3</sup>Seattle Childrens Research Institute, Department of Pediatrics, University of Washington, Seattle, WA, United States

The biology of *Plasmodium* liver stage (LS) development remains largely unexplored. We used our curated LS transcriptome datasets to find LS-specific transcripts and identified an uncharacterized gene, PY17X\_1465200 (*Py146*). We created an mCherry tagged *Py146* (*Py146*-

mCherry) and detected mCherry expression only in the LS, starting at 36 hours post infection. *Py146*-mCherry localized to the nucleus and partially co-localized with histone markers. To further evaluate the function of *Py146* in LS development, we generated a *Py146* gene-deficient parasite strain (*Py146*<sup>-</sup>), which displayed normal blood stage and mosquito stage development. However, LS development was severely impaired and only 50% of BALB/c mice infected with 50,000 *Py146*<sup>-</sup> sporozoites transitioned from liver stage-to-blood stage. Mice that did become patent were severely delayed in their time to patency - wildtype infected mice became patent on day 3 whereas *Py146*<sup>-</sup> infected mice became patent between days 8 and 10. Late *Py146*<sup>-</sup> LS schizonts displayed abnormal plasma membrane invaginations and lacked well segregated exo-erythrocytic stage merozoites, indicating severe attenuation in completion of LS development. To investigate whether the observed defect in LS development was conserved across species, we generated a *Plasmodium falciparum* strain lacking the orthologous gene *Pf124* (*Pf124*<sup>-</sup>). LS development was evaluated by infecting FRG huHep mice with *Pf124*<sup>-</sup> sporozoites. *Pf124*<sup>-</sup> late LS schizonts also showed defects in the formation of exo-erythrocytic merozoites. Two of three mice infected with *Pf124*<sup>-</sup> sporozoites underwent liver stage-to-blood stage transition after infusion of human red blood cells, however, there was a 60,000-fold reduction in parasite load at the time of transition compared to wildtype. These results indicate that we have identified a novel candidate for the creation of a late liver stage arresting replication competent genetically attenuated parasite (LARC GAP) vaccine for pre-clinical study.

<sup>1</sup>Sanaria Inc, Rockville, MD, United States, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>3</sup>Ifakara Health Institute, Bagamoyo Research and Training Centre, Bagamoyo, United Republic of Tanzania, <sup>4</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>5</sup>Ministry of Health and Social Welfare, Malabo, Equatorial Guinea, <sup>6</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>7</sup>Marathon Oil, Houston, TX, United States, <sup>8</sup>Ragon Institute of MGH, MIT and Harvard, Cambridge, MA, United States

Studies of mechanisms of protective immunity against *Plasmodium falciparum* (Pf) infection in the field are limited, because it is impossible to know if an individual was actually exposed to Pf during surveillance. Controlled human malaria infection (CHMI) circumvents this limitation. When  $3.2 \times 10^3$  PfSPZ of the PfNF54 strain (Sanaria® PfSPZ Challenge [NF54]) were administered by direct venous inoculation to 79 previously unexposed subjects in the US and EU, 100% developed Pf parasitemia. When the same dose was administered to 287 subjects in Tanzania, Kenya, Gabon, Mali, the Gambia and Equatorial Guinea (EG), the percent developing parasitemia ranged from 53.3% to 100%, likely reflecting different levels of naturally acquired immunity (NAI). For example, in a vaccine trial in EG, 13 of 19 (68%) of controls developed Pf parasitemia. A prior study in Tanzania had indicated that in subjects with low-level malaria exposure, antibodies to PfEXP1 and PFMSP1, proteins 1<sup>st</sup> expressed in the mid to late liver stages and in blood stages developed 4 weeks after first CHMI in 90.5% and 76.2% of subjects, respectively. We, therefore, assessed antibody levels (Abs) to PfEXP1 and PFMSP1 by ELISA in sera collected at time of CHMI in the EG trial to see if they were associated with protection against detectable parasitemia. Using the serum dilution at which the optical density was 1.0 (OD 1.0), the median PfEXP1 OD 1.0s were 2,960 vs. 456 ( $p=0.0125$ ) and PFMSP1 OD 1.0s were 1,986

vs. 349 ( $p=0.0462$ ) in non-infected and infected subjects, respectively. We interpret these findings to indicate that Abs to these antigens may be a correlate of functional NAI, but cannot determine if absence of detectable asexual blood stage parasitemia resulted from sporozoite and liver stage immunity, asexual blood stage immunity or a combination of both. Assessment of pre-CHMI sera from subjects in other PfSPZ Challenge in Tanzania, Kenya, Mali, Gabon, and EG for anti-PfEXP1 and PfMSP1 antibodies and by systems serology analysis will be done and presented. The goal is to use such data to increase our understanding of the mechanisms of protective immunity against Pf.

1119

### THE IMPACT OF LOW MALARIA TRANSMISSION INTENSITY ON THE DEVELOPMENT OF ANTIBODY TO PLASMODIUM FALCIPARUM IN PREGNANCY

Meseret W. Kassa<sup>1</sup>, André Barateiro<sup>2</sup>, Jammie G. Dombrowski<sup>2</sup>, Elizabeth H. Aitken<sup>1</sup>, Cláudio R. Marinho<sup>2</sup>, Stephen J. Rogerson<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases, The Peter Doherty Institute for Infection and Immunity, University of Melbourne, Melbourne, Australia, <sup>2</sup>Department of Parasitology, Institute of Biomedical Sciences, University of São Paulo, São Paulo, Brazil

Pregnant women have increased susceptibility to *Plasmodium falciparum* malaria, caused by the placental accumulation of infected erythrocytes (IEs) via a parasite ligand called VAR2CSA. Protective antibodies targeting the variant surface antigens (VSA) expressed on IEs are acquired in successive pregnancies; however, the development of these antibodies may depend on a combination of factors, including transmission intensity. Using plasma from 408 Brazilian pregnant women (207 women with *P. falciparum* infection and 201 without infection), we explored the dynamics of the antibody acquisition to pregnancy malaria in a low transmission setting. We measured IgG antibodies to pregnancy-specific and non-pregnancy-specific *P. falciparum* antigens using flow cytometry, ELISAs and Luminex assays. Only 7.8% of subjects had developed IgG that recognizes the pregnancy-specific VSAs on IES. The levels of these antibodies were higher in multigravidae than primigravidae ( $p=0.01$ ), and malaria-infected women were more likely to have these antibodies (AOR (95% CI) = 4.1 (1.8, 9.1),  $p=0.001$ ) than uninfected women. A high proportion of women (24% to 63.7%) acquired antibodies that recognized recombinant VAR2CSA domains with the DBL5 being the most often recognized domain, however, levels of these antibodies did not differ between women with and without a history of malaria ( $p>0.052$ ). Moreover, these antibodies did not vary by gravidity ( $p>0.362$ ). As expected, malaria-infected women had significantly higher antibody levels to non-pregnancy malaria-specific antigens, MSP1, 19 (arbitrary unit median=28 vs 0.7,  $p<0.0001$ ), and schizont extract (arbitrary unit median=6 vs 0.3,  $p<0.0001$ ), compared to uninfected women. In correlation analyses, antibodies to VAR2CSA domains correlated with each other ( $r>0.55$ ,  $p<0.0001$ ) but not with the antibodies to VSAs on IEs ( $r<0.12$ ,  $p>0.06$ ). In summary, pregnant women living in a low transmission area in Brazil acquired low levels of antibodies to pregnancy-specific VSAs on IEs but more frequently recognized VAR2CSA domains and non-pregnancy associated *P. falciparum* antigens.

1120

### LIVER STAGE PLASMODIUM INFECTION-INDUCED IFN-I SIGNALING REMODELS INTRAHEPATOCYtic SIGNALING TO IMPAIR HEPATIC CD8 T CELL MEMORY

Nana K. Minkah, Laura Reynolds, Vera Okolo, Ashley M. Vaughan, Stefan H. Kappe

Seattle Children's Research Institute, Seattle, WA, United States

*Plasmodium* liver stage infection is detected by host innate immune sensing pathways to initiate type I Interferon (IFN-I) signaling. This response has limited impact in controlling a primary infection, but we recently reported that IFN-I deficient mice immunized with live, whole sporozoite vaccines generate superior CD8 T cell responses compared to immunized wildtype mice. Importantly, a hallmark feature of this IFN-I-mediated,

inferior CD8 T cell response is the increased expression of PD-1 and Lag-3, two markers of T cell dysfunction typically associated with chronic infections. We now show that T cell dysfunction is observed in hepatic memory CD8 T cells and not memory CD8 T cells in secondary lymphoid organs or in circulation, suggesting that hepatic T cell dysfunction is driven by immunological events in the liver. In support of this, we now show that immunized mice lacking the ability to propagate IFN-I signaling solely in hepatocytes do not generate significant frequencies of dysfunctional PD-1<sup>hi</sup> hepatic memory CD8 T cells. Transcriptomic analyses of hepatocytes isolated from *Plasmodium yoelii*-infected mice, show that the induction of IFN-I signaling coincides with substantial remodeling of hepatocyte gene expression. We observed the upregulation of antigen presentation pathways, immunoregulatory cytokines, chemokine transcripts to facilitate immune cell recruitment into the liver and receptors implicated in the induction of T cell exhaustion signaling. Thus, IFN-I signaling likely reshapes signaling networks in hepatocytes to establish an immunosuppressive liver microenvironment around each infected hepatocyte that in turn promotes the development of dysfunctional hepatic CD8 T cell memory. This likely encumbers natural immunity to liver stage infection and lessens the efficacy of whole attenuated parasite vaccines. Our future studies will unearth the molecular mechanisms underpinning this dysregulated immune response and identify avenues for improving the quality of vaccine engendered pre-erythrocytic immunity.

1121

### ESTABLISHING A RELIABLE PLASMODIUM KNOWLESI (PK) SPOOROZOITE (SPZ)-BASED IMMUNIZATION AND CHALLENGE MODEL IN RHESUS MACAQUES

Sumana Chakravarty<sup>1</sup>, Natasha KC<sup>1</sup>, Urvashi Rai<sup>1</sup>, Sean C. Murphy<sup>2</sup>, Stephen L. Hoffman<sup>1</sup>

<sup>1</sup>Sanaria Inc., Rockville, MD, United States, <sup>2</sup>Department of Laboratory Medicine, University of Washington, Seattle, WA, United States

We aim to improve *Plasmodium falciparum* (Pf) sporozoite (SPZ)-based vaccines against malaria, with parallel efforts focused on developing a reliable animal model to interrogate immunological mechanisms of SPZ-based vaccines in non-human primates (NHPs). To test the protective efficacy of irradiated (irr), purified, cryopreserved *P. knowlesi* (Pk) SPZ in rhesus macaques we based the immunization regimen on previous mouse studies with irr *P. yoelii* (Py) SPZ, and a recent clinical trial of PfSPZ Vaccine at the University of Tübingen in Germany in which 3 doses of  $9.0 \times 10^5$  PfSPZ Vaccine administered on days 1, 8, and 29 protected 83% of volunteers against a heterologous controlled human malaria infection (CHMI) 9.5 weeks after last dose of vaccine. We similarly immunized a total of six rhesus by DVI with  $1.0 \times 10^6$  irr PkSPZ (3 animals also received an adjuvant) on days 1, 8, and 29. As controls, 3 animals received adjuvant and 2 received diluent. Fifty days after the last dose of vaccine, the NHPs were injected with 1500 infectious PkSPZ. Of the 6 immunized animals, 3 remained parasitemia negative through the end of the study on day 21 post challenge, a highly significant 50% sterile protection by survival analysis (log rank). The mean pre-patent period for the 3 vaccinated NHPs that became infected was 13 days, compared to 8.6 days for 5 control NHPs ( $p < 0.0001$ , student's t test, unpaired). There are 8-10 merozoites in each Pk-infected erythrocyte and they rupture every 24 hours. If the replication rate every 24 hours was 5-fold, a 4.4 day increase in the prepatent period corresponds to a greater than 97.5% reduction in liver stage parasite burden in the three vaccinated NHPs that did not achieve sterile protection. In addition, this study constituted a third demonstration of the consistent infectivity of purified, cryopreserved, vialled PkSPZ. All control animals became parasitemic by day 8 or 9, with PkSPZ cryopreserved three years prior. We have now established a Pk model of immunization and challenge with Sanaria's purified, cryopreserved stocks of infectious and irradiated PkSPZ using an accelerated immunization regimen in non-human primates.

1122

### THE ECONOMIC BURDEN OF MALARIA IN PREGNANCY IN ENDEMIC COUNTRIES: EVIDENCE FROM NIGERIA AND DEMOCRATIC REPUBLIC OF CONGO

**Laia Cirera**, Elisa Sicuri, Franco Pagnoni, Clara Menendez

*ISGlobal, Barcelona, Spain*

Malaria in pregnancy is a major public health problem in sub-Saharan Africa (SSA). Intervention strategies for malaria control during pregnancy are provided for free at the antenatal care (ANC) services of public health facilities. However, the coverages of such interventions are still low. Pregnant women face different barriers regarding malaria care, including remote access to health facilities, sub-optimal care management and limited availability of drugs. Households' costs associated with malaria health care may be an additional barrier. Estimating these costs is essential to informing policy decisions aimed at increasing access to malaria control interventions in pregnancy. We estimated malaria care-seeking and morbidity costs during pregnancy through a structured exit survey administered to 933 pregnant women when leaving the ANC visits in Nigeria and DRC. Women were asked to report direct and indirect costs incurred to attend the ANC services, as well as treatment costs associated to a malaria episode. Data collection, which is ongoing in Mozambique and Madagascar, is expected to finish in July 2021. The final analysis will include a pooled analysis across the 4 study countries. Average costs of attending an ANC visit, where malaria preventive treatment is provided for free, was 5.89 international dollars (I\$). Of the 933 interviewed pregnant women, 64 sought care for severe malaria episodes (requiring hospital admission) and 304 for uncomplicated malaria episodes. The average cost associated with an episode of uncomplicated malaria was 46.97 I\$. The cost incurred of an episode of malaria requiring hospitalization was 101.8 I\$. For both complicated and uncomplicated malaria, women's indirect costs (value of the time lost in the main economic activity) constituted the largest share of total costs. Results of this study show that malaria infection imposes a high economic burden on pregnant women and their families and strengthen the importance of investing in malaria control strategies and thus reduce the burden of the disease during pregnancy.

1123

### A DESCRIPTION OF MALARIA-RELATED KNOWLEDGE, PERCEPTIONS, PRACTICES, AND TREATMENT-SEEKING BEHAVIORS OF MOBILE MIGRANTS WORKERS IN JAZAN, SAUDI ARABIA

**Shaymaa Abdalal<sup>1</sup>**, Joseph Keating<sup>1</sup>, Mohammad Shammaky<sup>2</sup>, Hassan Ozayr<sup>2</sup>, Hussan Alkhaiyri<sup>2</sup>

<sup>1</sup>Tulane University of Louisiana, New Orleans, LA, United States, <sup>2</sup>Center of Vector Borne disease, Public Health Department Ministry of Health, Jazan, Saudi Arabia

Human movement along the Saudi/Yemen border is thought to play a strong role in malaria transmission in Saudi Arabia. Although mobile populations and migrant workers are a key population to containing malaria transmission, there is a limited representation of migrants in routine surveillance data. Understanding migrant's malaria-related knowledge, risk perceptions, treatment-seeking behavior, and use of prevention methods could increase the elimination program's success. A survey of migrant workers in the rural agricultural area took place in Abu-Arish region at the southern border of Saudi Arabia, using peer navigators. A questionnaire was administered, and the data were captured electronically. Bivariate and multivariate analysis was used to determine which factors are associated with preventive measurement and malaria infection. A total of 227 participants were included in the study. Ordinal logistic regression was used to identify factors associated with correct malaria knowledge and health perceptions. 79% of migrant workers have been residents in Jazan region for more than six months. They have a 94% accuracy level of knowledge about malaria, which is considered high ( $214/227 = 94.27\%$ ). Overall, 65.2% of the participants had a positive attitude toward malaria. However, only 19% of the participants

had received health messages or malaria information in the preceding six months. Bed net ownership was extremely low among participants, 5%. Interestingly more than two-thirds of the participants reported never visiting a health facility if they had a fever. Most of the migrant's agricultural border in Abu Arish do not receive health messages, nor do they benefit from the available malaria prevention tools in the area, which puts them at greater risk of malaria infection.

1124

### A PATIENT FROM THE DEMOCRATIC REPUBLIC OF CONGO WHO TRAVELED TO CONNECTICUT THREE MONTHS AGO NOW PRESENTS WITH ARTHRALGIAS AND HEADACHE

**Jessica J. Tuan**

*Yale University School of Medicine, New Haven, CT, United States*

The patient was a 21-year-old male with no significant history originally from Kivu, Democratic Republic of Congo who reported 1-day history of joint pain. Four months prior, he traveled to Dar es Salaam, Tanzania, then Amsterdam, Netherlands. 2.5 months prior, he arrived to Connecticut, United States. One day prior, he noted 5/10 aching bilateral hip and knee pain. He reported a 1-day history of moderate headache, lower back pain, lower abdominal pain, and mild pain with urination. On exam, he was afebrile and hemodynamically stable aside from pulse of 102 bpm. He had bilateral conjunctival injection and mildly decreased range of motion with bilateral hip and knee flexion and extension. Laboratory data demonstrated low platelet count of 93,000 cells/ $\mu$ L, elevated total bilirubin of 3.1 mg/dL, hemoglobin level of 14.5 g/dL with MCV of 73 fL. Urinalysis demonstrated large ketones, trace blood. Quantitative buffy coat test was negative for parasites. Blood smear demonstrated malarial ring forms. Malaria Binax testing demonstrated <1% positive result for *Plasmodium vivax* or *Plasmodium malariae* or *Plasmodium ovale*. He was noted to be Duffy antigen Fy<sup>a+</sup> and Fy<sup>b-</sup>. He was treated with a course of atovaquone-proguanil and primaquine. In summary, malaria, caused by single-celled microorganisms, protozoans of the *Plasmodium* group, should be considered on the differential diagnosis in a traveler from a malaria-endemic area who may present with non-specific symptoms (i.e. arthralgias, headache). Classically, malaria is categorized into *P. falciparum* (more severe) and non-falciparum malaria, the latter of which includes *P. vivax*, *P. ovale*, *P. malariae*, and *P. knowlesi*. Signs and symptoms of malaria may include headache, fever, arthralgias, hemolytic anemia, jaundice, emesis. In terms of diagnostics, blood smear is the gold standard; qualitative immunochromatographic assay detecting *Plasmodium* antigens may support the diagnosis. Additionally, Duffy negativity offers protection against *P. vivax* blood-stage infection, however emerging evidence of *P. vivax* infection in Africa has been noted.

1125

### COMMUNITY MALARIA RAPID DIAGNOSTIC TESTS (RDTs) BELIEFS IN WESTERN KENYA: HOW DOES EXPERIENCE WITH TESTING AFFECT CONFIDENCE IN, AND ADHERENCE, TO RDTs?

**Judith Nekesa Mangeni<sup>1</sup>**, Indrani Saran<sup>2</sup>, Lucy Abel<sup>1</sup>, Steve Taylor<sup>3</sup>, Andrew Obala<sup>1</sup>, Wendy P. O'Meara<sup>3</sup>

<sup>1</sup>Moi University, Eldoret, Kenya, <sup>2</sup>Boston University College, Boston, MA, United States, <sup>3</sup>Duke University, Durham, NC, United States

The WHO recommends test-based management for malaria infections, a goal that has become more feasible with increasing access to malaria Rapid Diagnostic Tests (RDTs). However, community members' confidence in RDTs likely affects the success of such a policy, especially in places where many people seek treatment outside the formal health sector. We follow a cohort of 36 households (268) individuals in three villages in Western Kenya from June 2017, for a period of 30 months. We examined how experience with RDTs changes people's beliefs about RDT accuracy and how those beliefs affect behavior. Monthly surveys were conducted where questions about malaria-like illnesses experienced by household members in the past month, their treatment decisions, including whether the

individual was tested for malaria, and their beliefs about the accuracy of malaria RDT results were asked. Beliefs about RDT accuracy were elicited on a 5-point Likert scale from “very unlikely” to “very likely.” Household members could request a free RDT from the study team any time they suspected a malaria illness. Over the study period, the proportion of survey respondents that said a hypothetical negative RDT result was “very likely” to be correct increased from approximately 55% to 75%. One year into the study period, we found that, controlling for initial beliefs, people who had been tested at least once with an RDT in the past year had 2.48 times higher odds (95% CI [0.99 6.22, P=0.054]) of saying a negative RDT was “very likely” to be correct, an effect that was largely coming from people who had received at least one negative test result in the past year (OR=2.30, 95% CI [1.13 4.69, P=0.022]). We also find evidence that confidence in testing is associated with behavior: those who believed a negative RDT was “very likely” to be correct had 1.91 times higher odds (95% CI [1.21 3.03], P=0.006) of adhering to a negative RDT result (by not taking ACTs) than those who were less certain about the accuracy of negative RDTs. Our results suggest that greater experience with RDTs can not only increase people’s confidence in its accuracy but also improve adherence to the test result.

### NON-MONETARY STRATEGIES FOR MOTIVATION OF COMMUNITY HEALTH WORKERS IMPLEMENTING INTEGRATED COMMUNITY CASE MANAGEMENT OF MALARIA, PNEUMONIA AND DIARRHOEA IN UGANDA

Alex Ndyabakira<sup>1</sup>, Betty Nambuusi<sup>1</sup>, Rebecca Babirye<sup>1</sup>, Joel Kato<sup>1</sup>, Damian Rutazaana<sup>2</sup>, Henry Katamba<sup>2</sup>, Catherine Maiteki<sup>2</sup>, Jimmy Opigo<sup>2</sup>, Phellister Nakamya<sup>1</sup>, Ruth Nabwire<sup>2</sup>, Maureen Amutuhaire<sup>2</sup>, Fred Kitutu<sup>3</sup>, JohnBosco Asimwe<sup>4</sup>

<sup>1</sup>Program for Accessible Health Communication and Education, Kampala, Uganda, <sup>2</sup>Ministry of Health, Kampala, Uganda, <sup>3</sup>Makerere University School of Health Sciences, Kampala, Uganda, <sup>4</sup>School of Statistics and planning, Makerere University Kampala, Kampala, Uganda

Integrated Community Case Management (iCCM) strategy aims to provide timely access to treatment for malaria, pneumonia and diarrhoea for under-fives in vulnerable communities. From 2010-2020, iCCM had rolled out to 120/135 districts in both public and private health facilities. iCCM is implemented by community health workers (CHWs) who receive basic training in major health programs to sensitize communities, offer treatment for malaria, pneumonia and diarrhoea to under-fives. The CHWs are given antimalarials, oral rehydration solution (ORS), Amoxicillin and sulfadoxine pyrimethamine. We aimed to assess the effectiveness of CHW motivation strategies. From January 2019 to December 2020, we interviewed 362 CHWs from 15 districts implementing the iCCM strategy in Uganda. The districts were purposively selected to represent the 15 participating regions, excluding Kampala. We used multi-stage cluster sampling to select CHWs. We administered a structured questionnaire to the CHWs and captured information about sociodemographic characteristics, current and proposed motivation strategies, knowledge about iCCM strategy and medical commodities. We analysed data using STATA version 15. Three hundred and sixty-two CHWs were included in the study. Over all, CHWs implementing the iCCM strategy in the private sector felt more motivated than those in the public sector. Of these, 243 (67%) received non-monetary motivation. VHTs felt motivated by; being trusted with medical supplies, provision of branded T-shirts, face masks and bags, and knowledge acquired during trainings. Other motivators were recognition as health workers at community and national level, recognition as high priority when seeking medical care at health facilities, provision of monthly facilitation and bicycles to aid mobility during routine work. CHWs proposed starting of savings’ scheme, provision of monthly pay, and mobile phones and offering certificates after training as additional strategies. Although non-monetary incentive strategies motivated CHWs to implement iCCM strategy, regular financial compensation was suggested to achieve sufficient motivation.

1127

### THE EFFECT OF THE INTEGRATED COMMUNITY CASE MANAGEMENT STRATEGY ON UNDER-FIVE MORBIDITY IN RURAL UGANDA

Phellister Nakamya<sup>1</sup>, Alex Ndyabakira<sup>1</sup>, Betty Nambuusi<sup>1</sup>, Daniel Kyabayinze<sup>2</sup>, Ruth Nabwire<sup>2</sup>, Mathias Kasule<sup>2</sup>, Johnbosco Asimwe<sup>3</sup>, Rebecca Babirye<sup>1</sup>, Joel Kato<sup>1</sup>, Maureen Amutuhaire<sup>2</sup>, Jimmy Opigo<sup>2</sup>

<sup>1</sup>Programme for Accessible Health Communication and Education (PACE Uganda), Kampala, Uganda, <sup>2</sup>Ministry Of Health Uganda, Kampala, Uganda, <sup>3</sup>School of Statistics & Planning, Makerere University, Kampala, Kampala, Uganda

Between 2010 and 2020, integrated community case management (iCCM) strategy was rolled out in 120/135 districts in both public and private health facilities in Uganda. The strategy aims to provide timely access to treatment for malaria, pneumonia and diarrhoea for children less than 5 years of age in rural Uganda. It is implemented at community level by trained community health workers (CHWs). We compared under-five morbidity between participating and non-participating districts in rural Uganda. Between January 2019 and December 2020, we interviewed CHWs and care takers of children under five years from 20 iCCM implementing and 5 non-implementing districts. The districts were selected through stratified sampling. We abstracted data from the district health information system (DHIS2) relating to reports submitted by CHWs. We determined the trends of out-patient attendance due to malaria, pneumonia and diarrhoea in under-fives and compared with the 2016 Uganda health demographic survey (UDHS). Data was analysed using STATA version 15. We interviewed 2888 care takers and 362 CHWs. About 73% (2394/2888) of caretakers were females and 25% stayed in the same location for at least 5 years. Fifty six percent (1606/2888; 95%CI: 53.8-57.4%) of care takers and 27.1% (98/362; 95%CI: 22.7-31.9%) of the CHWs had completed primary level education only. About 29% (95%CI: 25.4-32.4%), 18% (95%CI: 15.4-20.4%) and 14% (95%CI: 11.2-15.8%) of the under-fives had presented with fever, cough or diarrhoea respectively in the two weeks prior to the survey. Between 2012 and 2018, the number of sick children reviewed by CHWs tripled from 455,667 to 1,975,823. Outpatient attendance by under-fives due to malaria, cough and diarrhoea reduced in iCCM implementing districts. The number of acute diarrhea cases in non iCCM implementing districts increased by 14% compared to 0.2% in iCCM-implementing districts. No significant differences were seen in outpatient attendance due to pneumonia across the study districts. The iCCM strategy offers innovative ways of reducing childhood morbidity due to malaria, diarrhoea and pneumonia in rural resource limited settings

1128

### STRENGTHENING POST TRAINING CONTINUOUS QUALITY IMPROVEMENT PROCESSES FOR BETTER CAPTURE AND REPORTING OF INPATIENT MALARIA DATA: A CASE FROM MIGORI COUNTY REFERRAL HOSPITAL IN KENYA

Alphonse Nyakech<sup>1</sup>, Joyce Naganga<sup>2</sup>, Fredrick Keya<sup>2</sup>, Augustine Ngindu<sup>1</sup>, Maureen Mabiria<sup>1</sup>, Dickson Mwakangalu<sup>1</sup>, Sarah-Blythe Ballard<sup>3</sup>, Gladys Tetteh<sup>4</sup>, Lolade Oseni<sup>4</sup>, Florence Ngere<sup>2</sup>

<sup>1</sup>PMI Impact Malaria Project, Nairobi, Kenya, <sup>2</sup>MOHIKEMRI Clinical Information Network, Migori, Kenya, <sup>3</sup>US President's Malaria Initiative, US Centers for Disease Control and Prevention, Nairobi, Kenya, <sup>4</sup>PMI Impact Malaria Project, Baltimore, MD, United States

Malaria is the second leading cause of pediatric morbidity and mortality in Migori County, Kenya with a 336 per 1,000 annual incidence. Migori County Referral Hospital admits an annual average of 3,000 pediatric patients, 19% with severe malaria. Impact Malaria’s (IM) cross-sectional baseline survey of 186 health facilities in Migori and 7 other western Kenya counties identified 117 (63%) facilities with missing admission registers, incomplete inpatient summary tools, or incorrectly summarized case fatality data. To improve Migori County Referral Hospital pediatric inpatient case management (CM), data capture, and reporting, IM trained

four clinician mentors in severe malaria, who mentored 4 peer cohorts (15 total peers) in the pediatric inpatient department from December 2019-February 2020. Six follow-up visits were done at monthly intervals after training completion to assess mentor and mentee competencies, conduct root cause analysis of CM errors with a structured checklist, and implement pediatric ward processes improvements using the Kenya Quality Model for Health. Service delivery data were collected and summarized in routine data collection tools from January through December 2020. At baseline visit, 6/18 (33%) randomly sampled patient records identified delays of 30-60-minutes in second artesunate dose administration following treatment initiation, indicating a lack of treatment adherence. Root cause analysis associated the delays with patient handover process failures between shifts. Two checklist-based process improvements were implemented: a artesunate stock level monitoring communication loop and nurse station reminder cards, enabling 100% on-time second-dose administration at post-training record review (15/15). The 12-month service delivery data comparison showed intervention-associated median shifts in case reporting completeness from 168/174 (96%) to 402/408 (98%) and case fatality rates from 2/15 (13%) to 1/24 (4%). Continuous quality improvement training improved data reporting gap identification, root cause identification, and action point generation to address case management gaps.

1129

### IMPROVING INPATIENT MALARIA DATA REPORTING AND OUTCOME MEASUREMENT ACCURACY THROUGH CLINICAL MENTORSHIP OF HEALTHCARE WORKERS IN KENYA, 2019-2020

**Maureen Mabiria**<sup>1</sup>, Florentius Ndinya<sup>2</sup>, Fredrick Odhiambo<sup>3</sup>, Hellen Gatakaa<sup>1</sup>, Augustine Ngindu<sup>1</sup>, Dickson Mwakangalu<sup>1</sup>, Sarah-Blythe Ballard<sup>4</sup>, Gladys Tetteh<sup>5</sup>, Lolade Oseni<sup>5</sup>

<sup>1</sup>PMI Impact Malaria Project, Nairobi, Kenya, <sup>2</sup>Jaramogi Oginga Odinga Teaching and Referral Hospital, Kisumu, Kenya, <sup>3</sup>Division of National Malaria Program, Kisumu, Kenya, <sup>4</sup>US President's Malaria Initiative, US Centers for Disease Control and Prevention, Nairobi, Kenya, <sup>5</sup>PMI Impact Malaria Project, Baltimore, MD, United States

Impact-level malaria indicator monitoring in Kenya is hampered by under-reporting of inpatient data in Kenya Health Information System (KHIS). Data challenges include stock-outs of data capture tools, discrepancies between primary source tools and KHIS, and knowledge gaps in classification and coding severe malaria (SM). A 2019 baseline assessment conducted by Impact Malaria (IM) in 10% of health facilities in the 8 supported malaria endemic Counties indicated 93 (50%) of health facilities had a healthcare worker (HCW) trained in management of SM in the past 2 years, and none had complete inpatient morbidity and mortality data in KHIS. Between August 2019 and September 2020, IM designed and supported implementation of a 3-month SM clinical mentorship program for 84 HCWs from 72 admitting facilities. Targeted cadres were clinical, nursing, and medical officers stationed at pediatric and medical inpatient wards in 16 malaria-endemic sub-counties. Focus was on improvement of SM clinical skills, case notes recording, and capturing and reporting inpatient cases and deaths. Each month during the structured mentorship visits, targeted checklist-guided supervision was conducted. Discrepancies between inpatient data in KHIS and recorded admissions in Ministry of Health inpatient data tools served as a measure of data quality intra- and post-intervention. HCW pre- and post-testing assessed competencies. Post-intervention assessment was conducted between Jan - Sep 2020. In the 72 admitting facilities, the proportion of facilities with at least one HCW trained on management of SM increased from 50% to 72% (p-value <0.05). There was an increase from 31% to 67% (p-value 0.005) in data capture between baseline and December 2020. HCW competency levels in SM management improved from 64% to 77% (p-value <0.05). Data discrepancies between primary source documents and KHIS2 decreased from 67% to 35% (p-value <0.05). The inpatient malaria case fatality rate was 1.7% at the end of the intervention. SM mentorship in Kenya improved HCW competency, data capture, and is providing Kenya's National Malaria Program more accurate data for key decision making.

1130

### A UNIQUE CHEMOPROPHYLAXIS APPROACH FOR MALARIA PREVENTION AMONG NON-IMMUNE OIL AND GAS WORKERS

**Muhammad W. Fazail**, Candace McAlester, Susan Ngunjiri, Damola Adesakin, Richard H. Gelatt, Malick Diara  
*ExxonMobil, Spring, TX, United States*

With international mobile workforces assigned or traveling to malaria-endemic countries, our company non-immune personnel are exposed to the disease with the risk of severe illness or death. To safeguard such workers from these malaria related risks, we have implemented the ABCD malaria program, which provides awareness, bite prevention, chemoprophylaxis, and early diagnosis and treatment. In addition, our malaria prevention includes a formal requirement for these non-immune travelers and assignees to take their chemoprophylaxis, with the ability for the company to confirm compliance by testing for the presence of these medications (i.e. Proguanil, Doxycycline, or Mefloquine) in the urine. Following the development of the laboratory based method for such verification, ExxonMobil (EM) formed a unique partnership with the French Army Biomedical Institute and two manufacturers in 2007. The intent was to develop a rapid detection test (RDT) using specific drug antibodies thereby replacing the more expensive and less practical laboratory method. The RDTs were validated in malaria-endemic areas with urine samples from personnel taking malaria preventive drugs, and laboratory procedures were used to confirm the findings after the initial proof of concept in the lab. The rapid detection tests were successively integrated into our workplace program with implementation completed by 2013 in all our sites located in malaria risk areas. As a result, our recent Malaria Chemoprophylaxis Compliance Program (MCCP) evaluation showed high employee compliance for the past five years (over 99% detect) and a decrease in non-immune malaria cases from over 200 in 2003 to only 1 in 2020. Overall, EM has averted over 2000 non-immune malaria cases since 2003 and has had zero deaths due to malaria among our workers since 2007. As Tafenoquine-a new chemoprophylaxis regimen is now becoming available, the challenge is to develop a test to integrate it into the panel of recommended malaria preventive medicines for our workers.

1131

### GENOTYPING PLASMODIUM FALCIPARUM MATURE GAMETOCYTES USING AMPLICON DEEP SEQUENCING

**Jimmy Vareta**, Biraj Shrestha, Amed Ouattara, Miriam Laufer, Shannon Takala-Harrison  
*University of Maryland, Baltimore, Baltimore, MD, United States*

Understanding the dynamics of *Plasmodium falciparum* gametocytes *in vivo*, including parasitological factors that promote sexual commitment and gametocyte production, requires the ability to discern asexual parasites and gametocyte clones within polyclonal infections. Genotyping gametocytes requires a marker that is expressed exclusively in this life stage and is diverse enough to distinguish multiple clones. Identifying such marker is challenging owing to the limited diversity in gametocyte-specific antigens compared to most asexual antigens. In this study, we aimed to develop and test a gametocyte genotyping assay based on deep sequencing of short amplicons from polymorphic regions of gametocyte-specific antigens. Using publicly available single cell RNA-seq data to identify antigens expressed primarily in mature gametocytes, as well as a recently published list of diverse "microhaplotypes" from the *Plasmodium falciparum* genome, we identified two regions in the gene encoding P230 and one region in the gene encoding G377 as candidate gametocyte genotyping markers. We tested the specificity of these markers to detect gametocytes, assessed their ability to distinguish minor clones, and measured their diversity compared to pre-erythrocytic and asexual blood stage markers currently being used for genotyping based on deep amplicon sequencing. Results from RT-PCR of RNA from ring stages of a *P. falciparum* strain that does not produce gametocytes and mature gametocytes from NF54 targeting the three markers indicated that these

markers are specific to mature gametocytes. Based on 205 *P. falciparum* whole genome sequences from Malawi, we observed a similar or greater number of haplotypes at these markers (G377: 24, P230: 51 and 53) compared to polymorphic regions of *csp*, *sera2*, and *ama1*, which showed 3, 23, and 18 haplotypes in the same data set, respectively. We have developed a gametocyte genotyping assay based on sequencing of short amplicons from polymorphic regions of mature gametocyte genes. This assay will be an important tool for studies that are aimed at understanding the dynamics of gametocyte production in polyclonal *P. falciparum* infections.

1132

### MAPPING HOUSE LOCATION WITH REMOTE SENSING AND MACHINE LEARNING METHOD IN WESTERN KENYA

Ming-Chieh Lee, Guiyun Yan

University of California, Irvine, Irvine, CA, United States

House location represents one of the most critical variables in the assessment of exposure to vector-borne pathogens. Accurate information on house location can improve modeling disease transmission risk and help planning interventions. However, obtaining precise house location in vast rural areas of Africa where there was no prior detailed mapping effort is labor-intensive, expensive, and time-consuming. High-resolution remote sensing images are helpful, but the traditional method to manually identify house location needs skilled technicians and prone to errors due to the morphological resemblance of ground objects to human dwellings. We conducted a case study by combining remote sensing and machine learning methods to detect human houses across the Homa peninsula in Homa Bay County, western Kenya. Using high resolution, multi-band pan-sharpened Pléiades satellite images with labeled dwellings from the ground survey, the Mask R-CNN, a deep convolutional neural network for object detection, was used to generate low-level features and high-level features. Bounded box regression and classification were conducted. The model was trained on a 0.1° x 0.1° satellite images with 22,319 labeled houses and validated on the other three adjacent 0.1° x 0.1° area. The average precision score for the potential model is 0.687, and the validation accuracy of the same images is around 99.3%. The overall accuracy of estimation is 88.2% on the adjacent area. We are currently testing several new machine learning algorithms to improve the modeling prediction precision and accuracy for different house types. A combination of remote sensing and machine learning methods is valuable to detect house location, estimate population density, and the population under risk in rural Africa.

1133

### ESTABLISHMENT AND USE OF MALARIA E-TOOLKIT TO INCREASE ACCESS TO STRATEGIC MALARIA RESOURCES IN NIGERIA

Oluwatobiloba Akerele<sup>1</sup>, Linda Okafor<sup>2</sup>, Abba Umar<sup>2</sup>, Uchenna Nwokenna<sup>2</sup>, Kazeem Ayankola<sup>2</sup>, Yakubu Cherima<sup>2</sup>, Olusesu Ishola-Gbenla<sup>2</sup>, Abimbola Olayemi<sup>2</sup>, Maya Gershtenson<sup>3</sup>, Meenakshi Mehra<sup>3</sup>, Perpetua Uhomoihi<sup>4</sup>, Chukwu Okoronkwo<sup>4</sup>, Modiu Aro<sup>4</sup>, Abel Ajeigbe<sup>4</sup>, Thomas Hall<sup>3</sup>, Ratha Loganathan<sup>3</sup>

<sup>1</sup>Management Sciences for Health, Calabar, Nigeria, <sup>2</sup>Management Sciences for Health, Abuja, Nigeria, <sup>3</sup>Management Sciences for Health, Arlington, VA, United States, <sup>4</sup>National Malaria Elimination Programme, Abuja, Nigeria

Available evidence suggests that an estimated 76% of Nigeria's population is at risk of contracting malaria because they live in high transmission areas. According to the World Malaria Report (2020), Nigeria accounted for 27% of the global malaria cases and 24% of global malaria deaths in 2019. Poor access to updated malaria strategic documents by frontline health workers and stakeholders affects the quality of service delivery which ultimately contributes to these statistics. In response to these staggering statistics, President Malaria Initiative for States (PMI-S) worked with the National Malaria Elimination Program (NMEP) to set up the NMEP

e-toolkit. The e-toolkit is a platform where all updated policies, guidelines, standard operating procedures, and job aids for malaria prevention and control are stored and accessed by malaria stakeholders, program implementers and service providers in Nigeria. The process of setting up the NMEP e-toolkit was informed by a needs assessment. The e-toolkit is divided into the six key indicators of malaria interventions and pointers to improved malaria service delivery. The components are 1) surveillance and M&E (SME); 2) program management (PM); 3) procurement and supply chain management (PSM); 4) vector control (VC); 5) case management (CM); and 6) advocacy, communication, and social mobilization (ACSM). An analysis of the e-toolkit's page views per thematic area from February 2020 to March 2021 was conducted. The number of page views per thematic areas are 358 for CM, 209 for SME, 147 for PM, 136 for VC, 129 for ACSM and 104 for PSCM. Usage analysis of the e-toolkit during the same time frame indicates that 15,000 Nigeria-based users across the 36 states and Abuja have accessed it. Triangulation of findings from in-depth interviews and analytics suggest that the technology-enabled e-toolkit is a strategic tool which enables real time access to strategic malaria documents. These findings show that technology is a driver of structural change and standardization because the e-toolkit is a reference tool to access malaria prevention and control resources toward improved malaria service delivery in Nigeria.

1134

### STRENGTHENED CAPACITY ENHANCES HEALTH WORKERS' ABILITY FOR MALARIA CASE MANAGEMENT IN CROSS RIVER STATE, NIGERIA

Etieno Etuk<sup>1</sup>, Victor Bassey<sup>1</sup>, Aniefiok Akpasa<sup>1</sup>, Linda-Kaka Enyia<sup>1</sup>, Aniefiok Akpasa<sup>1</sup>, Augustine Firima<sup>1</sup>, Kenechukwu Ugbene<sup>1</sup>, Asuquo Ekwe<sup>2</sup>, Dorathy Ekom<sup>2</sup>, Abba Umar<sup>3</sup>, Uchenna Nwokenna<sup>3</sup>, Kazeem Ayankola<sup>3</sup>, Abimbola Olayemi<sup>3</sup>, Paul Waibale<sup>4</sup>, Thomas Hall<sup>5</sup>, Ratha Loganathan<sup>5</sup>

<sup>1</sup>Management Sciences for Health, Calabar, Nigeria, <sup>2</sup>State Malaria Elimination Programme, Cross River State, Calabar, Nigeria, <sup>3</sup>Management Sciences for Health, Abuja, Nigeria, <sup>4</sup>Management Sciences for Health, Kampala, Uganda, <sup>5</sup>Management Sciences for Health, Arlington, VA, United States

WHO recommends testing all fever cases for malaria using microscopy or a rapid diagnostic test, and treating only positive cases with an Artemisinin-based Combination Therapy (ACT). However, Nigeria Demographic and Health Survey (2018) revealed that ACT was used in treatment of malaria for only 52% of children with fever in South-South, Nigeria. Only 12.4% of these under 5 years children were tested for malaria. The baseline analysis of the malaria program in Cross River showed that health workers were last trained on malaria case management in 2015, and that 85% of persons with fever were issued ACT without a malaria positive test. Consequently, there was a need to strengthen health care worker capacity to offer quality services. We used classroom training, onsite approaches, and routine mentoring of health care workers through phone calls and WhatsApp messaging to provide supportive supervision in 40% of PHCs and 75% of public secondary hospitals to build capacity of health workers on adherence to malaria case management guidelines. Data from the Nigeria Health Management Information System from January-December 2020 revealed that testing for suspected malaria cases increased from 90.7% in 2018 from the NDHS to 95% in January 2020 and further improved to 97.2% by December 2020. Similarly, treatment of confirmed cases with an ACT improved from 85% to 100% by December 2020, and clinical diagnosis dropped from 66% in January 2020 to 1.1% within the year under review. This data show improvement in malaria case management following skills transfer to healthcare workers. Trainings, mentoring and supervision visits and the mentoring outreach with the health care providers contributed to the improvement of malaria diagnosis and treatment. This approach built sustainability into the framework of our project interventions.

1135

### STRENGTHENING COORDINATION SYSTEMS AND PROCESSES FOR BETTER FINANCING OF MALARIA IN NIGERIA THROUGH THE MALARIA ANNUAL OPERATIONAL PLAN DEVELOPMENT AND MONITORING PROCESS - CASE STUDIES OF FOUR STATES

Esther Ayandipo<sup>1</sup>, Ime Akpan<sup>2</sup>, Victor Basse<sup>3</sup>, Grace Nwankwo<sup>4</sup>, Abba Umar<sup>5</sup>, Uchenna Nwokenna<sup>5</sup>, Abimbola Olayemi<sup>5</sup>, Kazeem Ayankola<sup>5</sup>, Paul Waibale<sup>6</sup>, Oyewole Lawal<sup>7</sup>, Iwara Iwara<sup>8</sup>, Michael Urom<sup>9</sup>, Godfrey Akro<sup>10</sup>, Emeka Nsofor<sup>11</sup>, Muyiwa Tegbe<sup>12</sup>, Thomas Hall<sup>13</sup>, Ratha Loganathan<sup>13</sup>

<sup>1</sup>Management Sciences for Health, Ibadan, Nigeria, <sup>2</sup>Management Sciences for Health, Uyo, Nigeria, <sup>3</sup>Management Sciences for Health, Calabar, Nigeria, <sup>4</sup>Management Sciences for Health, Abakaliki, Nigeria, <sup>5</sup>Management Sciences for Health, Abuja, Nigeria, <sup>6</sup>Management Sciences for Health, Kampala, Uganda, <sup>7</sup>State Ministry of Health, Oyo State, Ibadan, Nigeria, <sup>8</sup>State Ministry of Health, Cross River State, Calabar, Nigeria, <sup>9</sup>State Ministry of Health, Ebonyi State, Abakaliki, Nigeria, <sup>10</sup>State Ministry of Health, Akwa Ibom State, Uyo, Nigeria, <sup>11</sup>ThinkWell, Lagos, Nigeria, <sup>12</sup>ThinkWell, Baltimore, MD, United States, <sup>13</sup>Management Sciences for Health, Arlington, VA, United States

Nigeria's State Malaria Elimination Programs (SMEP) and their partners undertake Annual operational planning every fiscal year to identify high priority malaria control and elimination activities. The Annual Operational Plan (AOP) developed from the process is meant for integration in the annual health sector budget plan and formulation of the annual state budget. The planning should achieve three objectives: (1) link prioritized activities to strategic pillars of the State/National Strategic Health Development Plans which enables a connection between the strategic priorities and budgeting, (2) generate an implementation plan for the fiscal year, and (3) provide a monitoring framework comprising performance indicators against which implementation can be measured. SMEPs are chronically underfunded, making them dependent on donors to finance key functions and limiting their capacity to effectively steward malaria control efforts. AOP development workshops were held using a four step approach, which included: conducting situational analyses of the SMEP performance; prioritization/ranking of selected activities; cost estimation of the prioritized activities and the development of performance monitoring plans. The intervention states completed the operational planning early enough for its inclusion in the health sector plan and budget for 2021. Prioritized activities were successfully mapped to strategic priorities of the state health development plans, resources, funding sources were assigned to activities, and the resource gaps determined for each state. Findings from the cost estimation revealed cost of new activities accounted for 44% of the AOP, costs for procurement supply chain management activities accounted for upward of 75% of the cost of prioritized activities across all the states.

1136

### RELIABILITY OF MALARIA INDICATORS IN HEALTH DISTRICTS IN BURKINA FASO: EFFECTS OF AN INTEGRATED QUALITY ASSURANCE PROGRAM

Siaka Debe<sup>1</sup>, Christelle Gogue<sup>2</sup>, Rene N. Kinda<sup>1</sup>, Sonia Ilboudo<sup>1</sup>, Gerard W. Nonkani<sup>1</sup>, Adama Ganou<sup>1</sup>, Gauthier Tougri<sup>3</sup>, N'Fale Sagnon<sup>1</sup>, Moussa W. Guelbeogo<sup>1</sup>, Molly Robertson<sup>4</sup>, Adama Gansane<sup>1</sup>

<sup>1</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>2</sup>PATH, Washington, DC, United States, <sup>3</sup>Programme National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso, <sup>4</sup>PATH, Seattle, WA, United States

High quality data is important for appropriate decision-making and to evaluate health interventions. For this purpose, a baseline data quality assurance (DQA) of malaria indicators was performed in 2019 in Orodara, Gaoua, and Banfora, three health districts in Burkina Faso, prior to the distribution of Interceptor® G2 (BASF) insecticide-treated nets (ITNs) as

part of the New Nets Project. Based on results obtained in 2019, a DQA plan integrating trainings, supervision, and meetings was implemented immediately to enhance the capacity of health workers to provide better quality malaria data. The effect of these capacity strengthening activities on the reliability of malaria data transmitted to District Health Information Software 2 (DHIS 2) was then monitored. Health facilities were randomly selected for malaria DQA in 2019 and 2021. Source data were collected through source document review, such as health facility registers, while transmitted data were extracted from DHIS 2. The assessments focused on 10 key malaria indicators before and after the one-year continuous DQA plan. Reliability was assessed using the interclass correlation coefficient (ICC) between source and DHIS 2 data. Each ICC was compared between reviews through confidence intervals at 95%. Data were analyzed with SPSS software using parallel model, two-way mixed and absolute agreement type. A total of 45 health facilities were assessed. For seven indicators the ICC was significantly higher after than before the DQA plan. Most of the ICC were greater than 0.9 ( $p < 0.001$ ). However, there was no change for overall presumptive malaria cases (ICC=0.4 [95% CI: 0.2-0.6]) and severe malaria cases in pregnant women (ICC=0.7 [95% CI: 0.4-0.8]). The ICC for the malaria lethality indicator was 1 during the two surveys. DQA activities improved the reliability of seven malaria indicators. Thus, it is recommended to maintain these capacity strengthening activities in health facilities in Burkina Faso.

We describe a case of a 2 year old female given a full course of Dihydroartemisin-piperazine (DP) dosed at a tablet of 320/40mg per day for 3 days during a mass treatment campaign in Uganda. This child was not taking any other medications prior to DP ingestion. She developed a progressive skin rash and blisters which later formed painful raw areas associated with a low grade fever 7 days after DP ingestion. Blood work performed (CBC, RFTs/LFTs) was basically unremarkable apart from hypoproteinemia of 4.63(6.6-8.7 g/dl). Her constellation of symptoms and presentation were consistent with Toxic Epidermal Necrolysis (>30% TBSA). The causality was established as 'probable' to DP with both Naranjo scale and World Health Organization causality assessment scale. It could not be established whether the offending molecule was dihydroartemisinin or piperazine but the child had previously taken artemether-lumefantrine for malaria with no reported complaints. The child was admitted to the burns unit, and managed basically with supportive treatment which included: steroids, anti-histamines, tetracycline ointment for eye care, prophylactic antibiotics, twice daily dressing with neomycin cream and plenty of fluids and high protein diet until she was discharged after 2 weeks. The child was monitored for re-appearance of lesions for up to 6 months but none were observed. The child and her caregivers were given a laminated card to be used at all health facilities, advising against any retreatment with DP.

### EFFECTIVENESS AND SAFETY OF INTERMITTENT PREVENTIVE TREATMENT FOR MALARIA USING EITHER DIHYDROARTEMISININ-PIPERAQUINE OR ARTESUNATE-AMODIAQUINE IN REDUCING MALARIA RELATED MORBIDITIES AND IMPROVING COGNITIVE ABILITY IN SCHOOL-AGED CHILDREN IN TANZANIA: A CONTROLLED RANDOMISED TRIAL

**Geofrey Makenga**<sup>1</sup>, Vito Baraka<sup>1</sup>, Filbert Fransis<sup>1</sup>, Samwel Gesase<sup>1</sup>, George Mtove<sup>1</sup>, Rashidi Madebe<sup>1</sup>, Edna Kyaruzi<sup>2</sup>, Daniel T. Minja<sup>1</sup>, John P. Lusingu<sup>1</sup>, Jean-Pierre Van geertruyden<sup>3</sup>

In high transmission settings, majority of school-aged children harbour malaria parasites (*Plasmodium*) without showing symptoms (asymptomatic), thus, acting as a relevant reservoir for malaria transmission. Asymptomatic *Plasmodium* infections induce inflammation leading to anaemia that may impair cognitive levels. A clinical trial [NCT03640403] was conducted in Muheza, Tanzania (from March 2019 to Dec 2020), to determine the effectiveness and safety of two antimalarial drugs Dihydroartemisinin-piperazine (DP) and Artesunate-amodiaquine (ASAQ) in preventing malaria-related morbidity in school-aged children (IPTsc) living in highly endemic areas. In this trial, 1563 schoolchildren aged 5-15 years were recruited from seven primary schools located in villages with high malaria prevalence. These children were individually randomised to receive either DP (n=526) or ASAQ (n=525), or control (standard of care, n=512), that was given three times a year at a 4-month interval. The primary endpoints were change from baseline in mean haemoglobin (Hb) concentration at month 12 and the number of malaria illness cases accrued from baseline to month 12 of follow up. Four months after one, two and three rounds of DP or ASAQ dosing; the respective mean Hb differences between DP and Control arms were 0.45g/dl (95% CI 0.26-0.65, P<0.0001), -0.74 g/dl (95% CI -0.94--0.54, P<0.0001) and 0.59g/dl (95% CI 0.23-0.94, P=0.0011), while for ASAQ and Control arms, the respective mean Hb differences were, -0.21g/dl (95% CI -0.40--0.02, P=0.029), 0.80g/dl (95% CI 0.59-1.02, P<0.0001) and 0.53g/dl (95% CI 0.17-0.89, P=0.0043). At month 12, malaria prevalence reduction was 16% (95% CI 9-23, P=0.002) and 8.8% (95% CI 1.3-16, P=0.0036) for DP and ASAQ arms respectively. Further analysis on impact of IPTsc on cognitive, malaria incidence and rebound effect is ongoing but will be available during the conference. In this study, both DP and ASAQ offered a safe protection against malaria parasitaemia, anaemia and clinical malaria, and were pragmatically feasible for scale up on malaria intervention in adoption to school health programmes when IPTsc becomes a policy.

### PRELIMINARY FINDINGS ON IMPACT OF SEASONAL MALARIA CHEMOPREVENTION ON MALARIA INCIDENCE AMONG CHILDREN 5 TO 10 YEARS OF AGE IN A HIGH MALARIA PREVALENCE REGION IN MALI (SIKASSO)

**Beh Kamate**<sup>1</sup>, Mohamadine A. Maiga<sup>1</sup>, Chebou Diallo<sup>1</sup>, Samba Coumare<sup>1</sup>, Abdrahamane Diallo<sup>2</sup>, Renion Saye<sup>3</sup>, Oumar Yattara<sup>1</sup>, Curt von Boguslawski<sup>4</sup>, Jules Mihigo<sup>5</sup>, Aliou Diallo<sup>5</sup>, Diahara Traore<sup>6</sup>, Vincent Sanogo<sup>6</sup>, Charlotte Eddis<sup>7</sup>, Tabitha Kibuka<sup>7</sup>, Jadmin Mostel<sup>7</sup>, Idrissa Cisse<sup>6</sup>

<sup>1</sup>PMI Impact Malaria, PSI, Bamako, Mali, <sup>2</sup>PMI Impact Malaria, Jhpiego, Bamako, Mali, <sup>3</sup>PMI Impact Malaria, MCDI, Bamako, Mali, <sup>4</sup>PSI, Bamako, Mali, <sup>5</sup>USAID, Bamako, Mali, <sup>6</sup>National Malaria Control Program, MOH, Bamako, Mali, <sup>7</sup>PMI Impact Malaria, PSI, Washington, DC, United States

In Mali, SMC campaigns target children less than 5 years once a month for four months to prevent malaria during the high transmission season. Because the burden of malaria appears to be shifting to older children (Touré et al., 2016), the National Malaria Control Program decided to

expand SMC to children up to ten in two health districts in the high burden region of Sikasso in 2020, with the first cycles starting at the end of July. In June 2020, the NMCP also distributed second-generation (IG2) long-life insecticide-treated nets (LLIN) to one of the two health districts that expanded SMC to older children, while the other received standard LLINs. To assess the relative contributions of IG2 and the expansion of SMC up to ten years (SMC10), we extracted 2019 and 2020 data from the national health information system to compare the incidence of uncomplicated and severe malaria in children aged 5-14 years in four health districts. Selingue received IG2 and SMC10; Koutiala standard LLINs and SMC10; Kadiolo IG2 and SMC up to age 5 (SMC5); and Kolondieba standard LLINs and SMC5. All districts have been implementing SMC5 since at least 2015. In August 2020, Selingue (IG2 and SMC10) saw 6.6 confirmed uncomplicated malaria cases per 1000 vs 11.4 in August 2019; Koutiala (standard LLIN and SMC10) saw 4.6 per 1000 in 2020 vs 12.4 in 2019; Kadiolo (IG2 and SMC5) saw 10.2 in 2020 vs 19.8 in 2019; and Kolondieba (standard LLIN and SMC5) saw 4.8 in 2020 vs 10.9 in 2019. For severe malaria cases per 100,000, comparison of August 2020 to August 2019 were as follows: Selingue (IG2 and SMC10), 60.5 in 2020 vs 100.2 in 2019; Koutiala (standard LLIN and SMC10), 34.3 in 2020 vs 67.5 in 2019; Kadiolo (IG2 and SMC5), 77.5 in 2020 vs 107.2 in 2019; and Kolondieba (standard LLIN and SMC5), 89.7 in 2020 vs 120.4 in 2019. The incidence of confirmed uncomplicated and severe malaria in children aged 5-14 during August 2020 was lower than the same period in 2019 in all four districts, so it is not necessarily the case that it was due to the SMC treatment of older children. As SMC in children up to 10 years is expanded in 2021 further monitoring will be needed to determine the impact of this intervention.

### MOLECULAR MECHANISMS OF PLASMODIUM CANDIDATE PROTEINS INTERACTION DURING PARASITE INVASION OF MIDGUTS

**Yacob Keleta**, Guodong Niu, Jun Li

Florida International University, Miami, FL, United States

Malaria is a mosquito-borne deadly infectious disease caused by *Plasmodium* parasites. Malaria claims nearly half a million lives every year. Most malaria eradication programs have been concentrated on eliminating the asexual stage of the parasite and controlling the mosquito population using insecticides. However, the increased parasite drug resistance and mosquito insecticide resistance are calling for alternative approaches. Hence, the research focus has shifted to transmission-blocking strategies. The sexual stages of the parasite are key for successful mosquito infection and malaria transmission. Ookinetes are the invasive form of the parasite that interacts with midgut proteins to penetrate the peritrophic matrix and midgut epithelial cells. Therefore, understanding the molecular mechanisms of interaction between the malaria parasite proteins and mosquito midgut proteins is crucial for developing an appropriate intervention. Our lab has identified six sexual stage parasite proteins that bound to the mosquito midgut and this research focuses on elucidating the molecular mechanisms of these proteins during parasite midgut invasion. We have cloned and expressed these genes in *E. coli* and insect cells. To study the mechanisms of interaction and identify the interacting partner, we will perform protein-protein interaction assays using pull-down, far-western blot, and western blot. We will also study the localization of these proteins using indirect immunofluorescence assay. Moreover, we will conduct a transmission-blocking assay to determine the role of these proteins in malaria transmission. These identified parasite proteins and their binding partners will be ideal candidates to block malaria transmission.

**TRENDS IN COVERAGE, OWNERSHIP AND USE OF LONG-LASTING INSECTICIDAL NETS WITH, AND WITHOUT, PIPERONYL BUTOXIDE AFTER A UNIVERSAL COVERAGE CAMPAIGN IN UGANDA: A SECONDARY ANALYSIS OF DATA FROM A PRAGMATIC CLUSTER-RANDOMIZED TRIAL USING OF LONG LASTING INSECTICIDAL NETS**

Samuel Gonahasa<sup>1</sup>, Catherine Maiteki-Sebuguzi<sup>2</sup>, Grant Dorsey<sup>3</sup>, Jimmy Opigo<sup>2</sup>, Simon Peter Kigozi<sup>1</sup>, Janet Hemingway<sup>4</sup>, Moses R. Kanya<sup>1</sup>, Martin Donnelly<sup>4</sup>, Sarah G. Staedke<sup>5</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>Ministry of Health (MOH/INMCD), Kampala, Uganda, <sup>3</sup>University of California, San Francisco, San Francisco, CA, United States, <sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>5</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

To evaluate ownership, coverage, and use of long lasting insecticidal nets (LLINs), we conducted surveys as part of a cluster-randomised trial embedded in Uganda's national LLIN distribution campaign in 2017-18. In total, 104 clusters (health sub-districts) were included. Proportionate randomisation was used to assign clusters to one of four arms; in total 52 clusters were assigned to the piperonyl butoxide (PBO) arm, and 52 to non-PBO. At baseline, 6, 12, and 18 months after LLIN distribution, 50 randomly selected households per cluster were surveyed (5,200 households and ~28,000 residents per survey) using two-staged cluster sampling. Multivariate logistic regression was used to evaluate associations between predictors of interest and LLIN coverage and use at 18 months. LLIN ownership and coverage rose from baseline levels of 65.0% and 17.9%, to 96.6% and 71.3%, respectively, after 6 months. LLIN ownership remained high (>80%) during follow-up, while coverage and use declined to 50.9% and 73.0% respectively. In the adjusted analysis, the strongest predictors of adequate LLIN coverage were smaller household size (2-4 vs ≥7: 66.4% vs 32.5%; aOR 5.30, 95% CI 4.46-6.29, p<0.001) and fewer residents (<3 per sleeping space) (aOR: 1.59, 95% CI 1.41-1.80, p<0.001). Compared to non-PBO households, those in the PBO arm had higher odds of adequate coverage (52.5% vs 49.2%; aOR 1.22, 95% CI 1.08-1.37, p=0.001) and residents were more likely to use LLINs (74.3% vs 71.8%; aOR: 1.13, 95% CI 1.03-1.25, p=0.01), although these differences were small. Heads of households were more likely to use LLINs than their 2nd degree relatives (81.9% vs 66.1%; aOR 1.94, 95% CI 1.72-2.18, p<0.001) while children aged 5-15 years were less likely to use LLINs (<5yrs vs 5-15yrs: 77.8% vs 67.1%; aOR 1.77, 95% CI 1.66-1.89, p<0.001). LLIN attrition following mass distribution is a major issue. LLINs may need to be distributed more frequently than every 3 years. Efforts are needed to ensure larger households are adequately covered, and school-aged children and extended family members should be targeted.

**FINDINGS FROM AN EFFECTIVENESS-IMPLEMENTATION HYBRID TYPE I EVALUATION OF THE FEASIBILITY, ACCEPTABILITY AND PROTECTIVE EFFICACY OF SEASONAL MALARIA CHEMOPREVENTION IN TWO DISTRICTS IN KARAMOJA, UGANDA**

Anthony Nuwa<sup>1</sup>, Jimmy Opigo<sup>2</sup>, Maureen Nakirunda<sup>1</sup>, Kevin Baker<sup>3</sup>, David Salandini<sup>1</sup>, Tonny Kyagulanyi<sup>1</sup>, Craig Bonnington<sup>3</sup>, Christian Rass<sup>3</sup>, Madeleine Marasciulo-Rice<sup>4</sup>, Godfrey Magumba<sup>1</sup>, Musa Odongo<sup>1</sup>, Jane Achan<sup>3</sup>, Sol Richardson<sup>3</sup>, Jane Nabakooza<sup>2</sup>, Denis Rubahika<sup>2</sup>, James Tibenderana<sup>3</sup>

<sup>1</sup>Malaria Consortium Uganda, Kampala, Uganda, <sup>2</sup>National Malaria Control Division, MOH, Kampala, Uganda, <sup>3</sup>Malaria Consortium UK, London, United Kingdom, <sup>4</sup>Malaria Consortium US, Raleigh, NC, United States

To date, due to widespread prevalence of markers especially pfdhps540E, pfdhps581G, Pfmdr1 and Pfcr1 mutants associated with sulfadoxine-pyrimethamine (SP) and amodiaquine (AQ) resistance, Seasonal Malaria Chemoprevention (SMC) has not been implemented at scale in East and Southern Africa. Although the effectiveness of SMC to reduce malaria

incidence has been demonstrated in areas of low resistance to SP in the Sahel region, the feasibility, acceptability, and protective efficacy of SMC implemented in areas with high resistance to SP are unknown. Malaria Consortium in collaboration with Ministry of Health, Uganda, has implemented a five-months cycle effectiveness-implementation hybrid type 1 SMC project in 3 districts of Karamoja region, Uganda to assess the protective effectiveness of SMC as a complementary malaria control intervention. The evaluation components involved quasi-experimental non-randomized study in Kotido and Moroto as intervention districts and Nabilatuk as a control to understand: 1) the adaption of SMC to the Ugandan context; 2) acceptability and feasibility of SMC intervention, 3) coverage and quality of SP+AQ delivery using a cross sectional end-of-round survey; 4) baseline prevalence of SP and AQ resistance associated genotypes (including Pfdhps, Pfdhfr, Pfcr1 and Pfmdr1 mutants); 5) monitor the safety of repeated use (for 5 months) of SP and AQ when used in SMC among children 3-59 months and 6) reduction in odds of clinically-significant malaria outcomes associated with receipt of SP+AQ based on a non-randomised controlled trial with eligible children in the two intervention districts and control district. Results on the following output and outcomes measures will be presented; malaria incidence, feasibility of SMC implementation in terms of coverage and quality of implementation, prevalence of resistance markers for SP and AQ among the children 3-59 months, malaria parasite prevalence, acceptability of SMC, adverse events related to SP and AQ.

**MALARIA CHEMOPREVENTION IN KENYAN CHILDREN WITH SICKLE CELL ANEMIA: A RANDOMIZED, OPEN-LABEL, TWELVE-MONTH TRIAL COMPARING DAILY PROGUANIL, MONTHLY SULFADOXINE-PYRIMETHAMINE/AMODIAQUINE, AND MONTHLY DIHYDROARTEMISININ-PIPERAQUINE**

Steve M. Taylor<sup>1</sup>, Sarah Korwa<sup>2</sup>, Cindy Green<sup>3</sup>, Sheila Clapp<sup>3</sup>, Angie Wu<sup>3</sup>, Joseph K. Kirui<sup>2</sup>, Wendy P. O'Meara<sup>1</sup>, Festus M. Njuguna<sup>2</sup>

<sup>1</sup>Duke University, Durham, NC, United States, <sup>2</sup>Moi University, Eldoret, Kenya, <sup>3</sup>Duke Clinical Research Institute, Durham, NC, United States

Children with sickle cell anemia in areas of Africa with endemic malaria transmission are commonly prescribed malaria chemoprevention. The comparative efficacy of prevention regimens is largely unknown. We enrolled 246 Kenyan children aged 1-10 years with HbSS disease confirmed by electrophoresis in a single-site, randomized, open-label, 12-month trial. Patients were assigned in a 1:1:1 ratio to receive daily Proguanil (the standard of care), monthly sulfadoxine/pyrimethamine plus amodiaquine (SP-AQ), or monthly dihydroartemisinin-piperaquine (DP). The primary outcome was the incidence of clinical malaria, defined as fever with peripheral parasitization or as severe malaria, and the main secondary outcome was painful events, defined as pain lasting 2 hours or more that did not have an obvious cause. The incidence of these and other secondary tertiary outcomes in the SP-AQ and DP arms was compared to those in the Proguanil arm using generalized regression models to estimate incidence rate ratios. We also compared safety outcomes between prevention arms. The primary analysis set consisted of children in the As-Treated population. Planned subgroup analysis were also conducted based on enrollment values for age, sex, hydroxyurea use, sickle cell severity, and hemoglobin concentration. Clinical followup completed in December 2020, study closeout is in progress, and results will be available by mid-2021. The comparative effectiveness of alternate regimens on malaria and painful event prevention will help guide evidence-based care for children with sickle cell anemia in malaria-endemic areas.

### EFFECT OF LARGE-SCALE MASS DRUG ADMINISTRATION FOR MALARIA ON MORTALITY AND MORBIDITY IN ANGUMU HEALTH ZONE, ITURI, DEMOCRATIC REPUBLIC OF CONGO

Yves Katuala<sup>1</sup>, **Lise Grout**<sup>2</sup>, Trish Newport<sup>3</sup>, Priscillah Gitahi<sup>4</sup>, Tom Adoum Mahamat<sup>4</sup>, Jean Jacques Mandagot<sup>4</sup>, Michel Quere<sup>3</sup>, Sophie Wodon<sup>3</sup>, Iza Ciglenecki<sup>3</sup>, Mathieu Bastard<sup>5</sup>, Francis Baelongandi<sup>6</sup>, Louis Tshulo<sup>7</sup>, Herman Jakisa<sup>7</sup>, Esther Sterk<sup>3</sup>, Etienne Gignoux<sup>5</sup>

<sup>2</sup>Epicentre, Paris, France, <sup>3</sup>Médecins Sans Frontières, Geneva, Switzerland,

<sup>4</sup>Médecins Sans Frontières, Bunia, Democratic Republic of the Congo,

<sup>5</sup>Epicentre, Geneva, Switzerland, <sup>6</sup>Ministry of Public Health, Kisangani,

<sup>7</sup>Ministry of Public Health, Bunia, Democratic Republic of the Congo

WHO recommends mass drug administration (MDA) for malaria in extreme complex emergencies. Angumu health zone in Ituri, DRC, a highly malaria-endemic area, has been hosting internally displaced persons (IDP) from lower-endemicity zones, with health system overburdened. Three MDA rounds (2 amodiaquine-artesunate + 1 artesunate-pyronaridine) were implemented with high coverage from September 2020 to January 2021 by Ministry of public health and Médecins sans Frontières for >2 months-old living in 4 health areas. We compare reported mortality and morbidity in locations where MDA has been performed and locations where it has not. A cross-sectional population-based retrospective mortality survey was conducted in March 2021, stratified by villages/IDP sites and MDA/non-MDA locations. For the villages, two-stage cluster sampling methodology was used; all IDP sites were surveyed with a systematic random sampling. The main outcome was crude and under-5 mortality in the different strata. Morbidity in the 2 weeks prior to the survey was also calculated. 2554 households were interviewed, and data collected for 15470 individuals, whom 721 died in the 18 month recall period. In the villages, the under-5 mortality decreased from 2.06 [1.22-2.9] deaths/10,000 people/day before the MDA to 0.91 [0.4-1.41] after the MDA in the MDA villages whereas it increased from 2.23 [1.33-3.12] to 2.83 [1.77-3.89] in the same time periods in the non-MDA villages. In IDP sites, the under-5 mortality decreased from 2.54 [0.4-4.68] deaths/10,000 people/day before MDA to 0.57 [0-1.36] after MDA in the MDA sites while it remains stable in the non-MDA sites. All-cause and malaria-specific morbidity in the 15 days before the survey appears lower in MDA villages and sites than in non-MDA ones: reported malaria-specific morbidity was 14.7% [11-18] and 30.4% [27-33] respectively in MDA and non-MDA villages, 25.0% [19-31] and 49.3% [45-54] respectively in MDA and non-MDA sites. The observed sharp decrease of under-5 mortality and morbidity after the MDA confirms that MDA has the potential to become an important malaria-control tool in emergency settings.

### ASSESSING COVERAGE OF SEASONAL MALARIA CHEMOPREVENTION IN GHANA IN 2020

**George Adu**<sup>1</sup>, Nana Pephrah<sup>1</sup>, Boakye-Yiadom Adomako<sup>1</sup>, Mohammed Wahjib<sup>1</sup>, Sammy Opong<sup>1</sup>, Abubakari Ihsan<sup>1</sup>, Ibrahima MBaye<sup>2</sup>, Abena Poku-Awuku<sup>3</sup>, Andre-Marie Tchouatieu<sup>3</sup>, Corinne Merle<sup>4</sup>, Paul Milligan<sup>5</sup>, Susana Scott<sup>5</sup>, Jean Louis NDiaye<sup>2</sup>, Keziah L. Malm<sup>1</sup>

<sup>1</sup>National Malaria Control Programme, Accra, Ghana, <sup>2</sup>Université de Thiès,

Thiès, Senegal, <sup>3</sup>Medicines for Malaria Venture, Geneva, Switzerland,

<sup>4</sup>UNDP/UNICEF/World Bank/WHO Special Programme for Research and

Training in Tropical Diseases (TDR)/ World Health Organization (WHO),

Geneva, Switzerland, <sup>5</sup>London School of Hygiene&Tropical Medicine,

London, United Kingdom

Seasonal Malaria Chemoprevention (SMC) was introduced in Ghana in 2015 in Upper West region, expanded to include Upper East region in 2016, and, in 2019, Northern region (now Northern, Savannah and North East regions), the same regions being included in 2020. Community Health

Volunteers (CHVs) use Android phones to register eligible children in each household and record daily doses administered. In 2020, blister packs were given to the caregiver who was asked to administer the first daily doses observed by the CHV, and the remaining doses at the same time on each of the next two days. The date was written in the child's health record booklet. CHVs visited again on the second and third day, to check that doses were given by inspecting blister packs, and to give treatment for any eligible children who were not present on the first day. The Sicapp android app allows staff to monitor the number of treatments each day and compare with daily targets. Supervisors can then consider corrective actions if necessary. In 2020, a total of 4.1million treatment courses were administered over 4 months to a population of 1.08million children. A household survey was conducted to assess coverage with support from the OPT-SMC project. A total of 2100 households were visited in 150 clusters. Children aged 3-84 months at the last cycle were included, to assess coverage in the target age group and to assess whether older children were treated. Dates of SMC treatments were determined from the child's health record booklet, or from the Sicapp database if the booklet was not available, and caregivers were asked about adherence to daily doses. Focus groups with caregivers and interviews with CHVs were held to understand barriers to SMC uptake. A total of 87.6% of children eligible for four cycles, received four treatments. Very few (1%) of the older age group were treated. The percentage of day1 treatments that were directly observed, in cycle 4, was 95.8%. Limitations included lack of time for call-back visits to non-responders due to limited funds. Side effects of SMC drugs, taste of tablets, and charging costs for management of side effects, and over-tasking of volunteers, were identified as barriers to SMC uptake.

### A RECOMBINATION SYSTEM FOR THE CREATION OF STABLE ANTIPLASMODIAL PARATRANSGENIC *ASAIA SP.*

**Thomas P. Kelly**, David J. Lampe

Duquesne University, Pittsburgh, PA, United States

Malaria, a disease caused by the parasite *Plasmodium sp.* and spread by the bite of infected female *Anopheles* mosquitoes, is responsible for hundreds of thousands of deaths each year. Reduction of global malaria cases has stagnated in recent years, highlighting the need for new control strategies. One such strategy, paratransgenesis, involves engineering mosquito symbionts to secrete antiplasmodial effectors within the midgut to kill parasites post infected blood meal. The bacterium *Asaia bogorensis* has been identified as an ideal candidate for antiplasmodial paratransgenesis, as it efficiently colonizes the midgut, ovaries, and salivary glands of *Anopheles* mosquitoes. Paratransgenic *A. bogorensis* strains have previously been developed which were shown to be effective at reducing oocyst prevalence within infected mosquitoes. However, the paratransgenic components of these strains are located on plasmids and rely on drug-selection for stability, which is unsuitable for field-release. One way to develop stable strains of paratransgenic *A. bogorensis* is to insert the antiplasmodial effectors into the chromosome. To this end, a site-specific recombination technique has been adapted for use in *A. bogorensis* in which I-SceI mediated recombination is linked to *sacB* counterselection. This technique was used to create several strains in which the general antimicrobial peptide scorpine driven by a previously identified blood meal induced promoter was inserted within neutral sites of the *A. bogorensis* chromosome. In this study, we analyze these strains in comparison to their plasmid counterparts.

### IDENTIFYING AN OPTIMAL DIHYDROARTEMISININ-PIPERAQUINE DOSING REGIMEN FOR MALARIA PREVENTION IN YOUNG UGANDAN CHILDREN

Erika Wallender<sup>1</sup>, Ali Mohamed Ali<sup>1</sup>, Emma Hughes<sup>1</sup>, Abel Kakuru<sup>2</sup>, Prasanna Jagannathan<sup>3</sup>, Mary Kakuru Muhindo<sup>2</sup>, Bishop Opira<sup>2</sup>, Meghan Whalen<sup>1</sup>, Liusheng Huang<sup>1</sup>, Moses Kanya<sup>4</sup>, Grant Dorsey<sup>1</sup>, Francesca Aweeka<sup>1</sup>, Philip J. Rosenthal<sup>1</sup>, Rada Savic<sup>1</sup>

<sup>1</sup>University of California, San Francisco, San Francisco, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>Stanford University, Palo Alto, CA, United States, <sup>4</sup>Makerere University and Infectious Diseases Research Collaboration, Kampala, Uganda

Intermittent preventive treatment (IPT) with dihydroartemisinin-piperazine (DP) is highly protective against malaria in children, but is not standard in malaria-endemic countries in Africa. Infants are at highest risk of malaria complications, but drug exposure-response relationships for piperazine (PPQ), the drug responsible for the preventive efficacy of DP, are poorly characterized for this population. We identified for Ugandan infants optimal IPT-DP dosing regimens to maximize malaria preventive efficacy and reduce toxicity and antimalarial resistance selection. Among 280 infants, we analyzed PPQ concentrations (n=4,506), malaria incidence data (n=326), and *P. falciparum* drug resistance markers (n=143) from a trial of children 2-24 months of age randomized to IPT with DP every 12 weeks (n=184) or every 4 weeks (n=96). DP was administered daily for 3 days and the first dose was directly observed. Nonlinear mixed effects modeling was used to quantify malaria protective PPQ levels and risk factors for suboptimal protection. DP was associated with 95% protective efficacy (95% CI: 84-99%) when administered every 4, compared to every 12 weeks. A PPQ level of 15.4 ng/mL reduced the malaria hazard by 95%. Malnutrition reduced PPQ bioavailability by 10.2% for each standard deviation decrease in WHO height-for-age z-score. Adherence was lower than expected in the study, with 61% lower PPQ exposure when DP was taken without directly observed therapy. PPQ level was not associated with parasite genetic markers associated with decreased aminoquinoline sensitivity. In simulations, DP every 4 weeks was optimal for malaria prevention across a range of malaria transmission intensities. Age-based dosing, with dose increases at 6 and 18 months, improved malaria protection in young or malnourished infants. Age-based, rather than the currently recommended weight-band based dosing of DP improved PPQ exposure for malnourished Ugandan infants and may have operational benefits for community implementation of IPT in children.

### PERSPECTIVES OF HEALTHCARE PROVIDERS ON FACTORS ENABLING OR INHIBITING THE UPTAKE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA FOR PREGNANT WOMEN IN OYO STATE, NIGERIA

Olabisi Kalejaye<sup>1</sup>, Taiwo Olarinde<sup>1</sup>, Abba Umar<sup>2</sup>, Paul Waibale<sup>3</sup>, Kazeem Ayankola<sup>2</sup>, Uchenna Nwokenna<sup>2</sup>, Esther Ayandipo<sup>1</sup>, Elizabeth Adeleke<sup>4</sup>, Abimbola Olayemi<sup>2</sup>, Thomas Hall<sup>5</sup>, Ratha Loganathan<sup>5</sup>

<sup>1</sup>Management Sciences for Health, Ibadan, Nigeria, <sup>2</sup>Management Sciences for Health, Abuja, Nigeria, <sup>3</sup>Management Sciences for Health, Kampala, Uganda, <sup>4</sup>State Ministry of Health, Oyo State, Ibadan, Nigeria, <sup>5</sup>Management Sciences for Health, Arlington, VA, United States

Malaria remains one of the highest contributors to the precarious maternal mortality figures in Sub-Saharan Africa. In Nigeria, 11% of maternal deaths are attributed to malaria. To mitigate the risk of malaria in pregnancy (MIP), intermittent preventive treatment of malaria in pregnancy (IPTp) with Sulphadoxine-Pyrimethamine (SP) is recommended. First dose is to be administered in the second trimester and monthly until delivery, with a minimum of three doses given. In Oyo State, despite these recommendations, only 64.7% of pregnant women received second dose and beyond (IPTp2+) and the drop-out rate between first (IPTp1) and third (IPTp3) doses was 86%. We surveyed health providers' perception

of the barriers and enablers to IPTp uptake using a structured self-administered questionnaire. Data was collected from healthcare providers in selected primary health centers in the state electronically using Google forms. All 82 consenting healthcare providers rendering ante-natal care (ANC) services were enrolled and responded to the survey. Questions were structured to elicit responses on inhibitors and enablers to the administration of IPTp by healthcare providers. Analysis revealed factors such as routine ANC counselling, Directly Observed Treatment (DOT), capacity building, availability of MIP tools (SOPs, Job Aids, Algorithm) and guidelines coupled with a regular supply of SP were key enablers. All respondents claimed that routine ANC counselling is essential in ensuring improved IPTp uptake while 80% of respondents stated that regular supply of SP facilitated the uptake of IPTp in their facilities. Late booking of pregnant women at ANC was identified as the most common inhibiting factor (66%) alongside high patronage of traditional birth attendants (62%). Other inhibiting factors included stock out of SP, inadequate knowledge of pregnant women on MIP and non-availability of guidelines. Key enablers, such as counselling and supply of SP should be reinforced in health facilities. Factors inhibiting IPTp uptake could be addressed through community sensitization and dissemination of MIP guidelines to health facilities.

### IN HOSPITAL UTILIZATION OF LLIN IN THE NORTHWEST OF DEMOCRATIC REPUBLIC OF THE CONGO

Nono Mvuama<sup>1</sup>, Josué Zanga<sup>2</sup>, Patricia Konga<sup>3</sup>, Emery Metelo<sup>4</sup>, Philippe Lukanu<sup>5</sup>, Paul Mansiangi<sup>1</sup>

<sup>1</sup>Kinshasa School of Public Health, Faculty of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Department of Tropical Medicine, Faculty of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Provincial Health Division of Mongala, Lisala, Democratic Republic of the Congo, <sup>4</sup>Faculty of Medicine, University of Bandundu, Kwilu, Democratic Republic of the Congo, <sup>5</sup>SANRU asbl, Kinshasa, Democratic Republic of the Congo

The promotion of LLIN utilization has become the main preventive measure against malaria in many LMICs. This has been expanded to specific households to improve coverage. We evaluated the utilization of LLINs in the hospital setting in the cities of Lisala and Bumba, in the northwest of the DRC. These facilities received donation of LLINs during the mass campaign in July 2016. Between October and November 2017, we conducted a cross-sectional study in 13 states, church-owned and private health facilities in the above setting. Institutional managers and 227 inpatients were interviewed. The available LLINs were directly assessed. Overall, the facilities surveyed received a total of 544 LLINs during the distribution campaign. 14 months later, 8 out of the 13 visited facilities had no remaining LLINs, representing an attrition rate of 74.4%. Lost LLINs were reportedly taken away by patients upon discharge from hospital. A total of 153 LLINs were used in the visited health facilities the night before the survey, of which only 30% were owned by the health facilities. The frequency of cleaning of LLINs in the visited health facilities was not regulated. It was done with mild soap either monthly, or when the LLIN looks dirty, or when the patient who had used it was discharged. Of 227 surveyed patients, 66.5% were female, 73.6% over 15 years old, and 67.4% (CI95%: 60.8-73.5) had spent the night before under LLINs. Inpatient use of LLINs was influenced by place of residence (AOR=17.1; 95% CI: 7.2-40.7); gender, men being more compliant than women (AOR=2.5; 95% CI: 1.1-5.7); previous use of LLINs at home (AOR=5.5; CI95%: 1.2-25.4); and by facility type, inpatients in private facilities being less likely to sleep under LLINs (AOR=0.3; CI95%: 0.1-0.9). The use of LLINs in hospital remains below 80%. The survival time of LLINs in health facilities seems to be lower than the survival time at the household level. Hence, there is a need to find mechanisms for more frequent LLIN renewal in order to maintain coverage. There is also a need to find an adequate means of cleaning that balances the need for effective vector control with minimizing the risk of spreading nosocomial infections.

### MALARIA PLASMODIUM CARRIAGE AFTER THE IMPLEMENTATION OF SEASONAL MALARIA CHEMOPREVENTION IN SENEGAL: CASE OF THE SARAYA HEALTH DISTRICT FROM 2013 TO 2015

Isaac Akhénaton Manga<sup>1</sup>, Fassia Tairou<sup>1</sup>, Khadime Sylla<sup>1</sup>, Marie Pierre Diouf<sup>1</sup>, Babacar Faye<sup>1</sup>, Omar Gaye<sup>1</sup>, Jean Louis Ndiaye<sup>2</sup>

<sup>1</sup>Service de parasitologie et mycologie UCAD, Dakar, Senegal, <sup>2</sup>Service de parasitologie et mycologie UFR Santé Université de Thiès, Thiès, Senegal

Seasonal malaria chemoprevention is a strategy adopted and implemented in Senegal since 2013 in the southern regions of the country in children aged between 3 months and 10 years old. The scaling up of this strategy requires its evaluation to assess its impact. This study was carried out to determine the dynamics of *Plasmodium falciparum* carriage after two years of implementation. Four household surveys were conducted in villages located in the Saraya health district which is a SMC implementation zone in Senegal. These villages were selected based of the proportional probability of the population. Each of the selected villages was divided into segments that had to contain at least 50 children. In the selected segment, a household questionnaire was administered to collect to parents or legal representative of children aged 3 to 120 months. Blood sample was collected to determine *Plasmodium falciparum* prevalence and hemoglobin level. A total of 2577 children were included in our study with an average age of 4.81 (+/-2.73) years. Children over 5 years of age represented 50.33% of our study population and male children 50.32%. The overall coverage of LLINs was 83.39%. Net ownership was 99.62%, 99.79%, 69.46% and 45.76% respectively in August 2013, January 2014, July and December 2015. Anemia prevalence was 79.08% and it was higher in children under 5 years of age. *Plasmodium falciparum* carriage was 9.42%. Parasite prevalence after SMC scaling had decreased from baseline (6.1% in January 2014 and 4.93% in July 2015 compared to 10.68% in 2013) before increasing in December 2015 (15.25%). Malaria prevalence was more important in children over 5 years old and boys. The overall prevalence of gametocytes carriage was 5.76% and it was more important in children under 5 years old. When the MSC was first scaled up in Saraya, there was a decrease in *Plasmodium falciparum* parasite carriage, which subsequently increased. The presence of gametocytes in children raises the question of whether primaquine should be added to this strategy for better.

### ENGAGING THE PRIVATE SECTOR IN ACHIEVING ZERO MALARIA, COUNTRY CASE STUDIES FROM COTE D'IVOIRE, DRC, LIBERIA AND UGANDA

Sophie Faye, Catherine Clarence, Awa Dieng, Mignote Haile, Lisa Nichols

Abt Associates, Rockville, MD, United States

The ongoing fight against malaria has resulted in a 60% decrease in deaths from malaria and a 40% drop in malaria cases over the last two decades (2000-2020). However, malaria continues to remain a major health issue in many countries, with pregnant women and children under 5 being the most at risk. Thus, the journey towards elimination is far from over, and countries and development partners are increasingly looking at market-based approaches and investments from the private sector to help bridge gaps in both resource and expertise to sustain results to date and accelerate progress. The private sector is engaged in malaria control through various ways. For example, strengthened public-private partnerships (PPP) enable resource mobilization to scale up implementation of effective malaria interventions. However, many of their activities are not tracked by National Malaria Control Programs and this lack of information often prevents alignment with national goals and strategies. Given the important role of the private sector in the sustainable development of countries, and in line with USAID's Private Sector Engagement (PSE) Policy, the USAID-funded Local Health System Sustainability project is implementing a PMI-funded activity in four selected PMI priority countries,

Cote d'Ivoire, DRC, Liberia, and Uganda, to: 1- do a landscape analysis of private sector contributions to malaria programming, and 2- Identify potential strategic opportunities to strengthen PSE. The methodology for this activity is a mix of literature review and in-country key informant interviews. The results of this activity are expected in August 2021. In each country we will develop a set of strategies to engage the private sector more efficiently and ultimately accelerate progress towards malaria elimination. This activity will also produce global learnings on PSE for malaria programming, especially the contextual factors to account for when designing collaborative activities with the private sector and advocating for more private sector funding for malaria in Low- and Middle-Income Countries.

### IMPROVING PREDICTION OF POPULATION LOCATION FOR HOUSE-HOLD BASED SERVICE DELIVERY: DESCRIPTIVE ANALYSIS AND MODELING USING GEOTEMPORAL DATA

Anne C. Martin<sup>1</sup>, James Nyirenda<sup>1</sup>, Hannah Meridith<sup>2</sup>, Christina Riley<sup>1</sup>

<sup>1</sup>Akros, Lusaka, Zambia, <sup>2</sup>Duke Global Health Institute, Duke University, Durham, NC, United States

Mass campaigns consistently struggle to obtain good coverage for several reasons: poor planning and management of field teams, the lack of population knowledge of the intervention, and challenges in determining the location of eligible populations. These challenges could be addressed with a tool for locating eligible populations and predicting their movement: campaigns could be planned and deployed more efficiently, with sensitization efforts better targeted, and instances of missing subpopulations due to regular movement or permanent relocation reduced. The Reveal tool facilitates geospatial population estimation to reduce uncertainty in the volume and location of the population and has been applied in mass campaigns such as IRS, MDA, and vaccinations, but does not yet incorporate temporal dynamics. The Reveal Population Movement (RPM) project, funded by the Gates Foundation as a Grand Challenge Exploration (GCE) aims to address the challenge human movement poses to service delivery in two key ways. First, we are conducting a descriptive analysis of existing data, to understand temporal patterns in households being present and able to receive services. These data collected through implementations of house-to-house service delivery campaigns with the Reveal tool, contain geotags and timestamps on each household level data point, allowing granular exploration of temporal patterns. From this we will develop qualitative recommendations to inform deployment timing strategies. Second, we are constructing models of population movement based on cell phone provider data, to understand trends and build models that reveal spatio-temporal patterns in human movement. This model will provide a theoretical framework to make adjusted predictions in populations needing services in given areas at given times of year. We will present initial results from these two specific objectives and their proposed application to an implementation of the Reveal tool in a health service delivery campaign.

### PRIVATE SECTOR ENGAGEMENT TOWARDS MALARIA CONTROL: PERSPECTIVES FROM STATE ACTORS AND ASSOCIATIONS OF PRIVATE HEALTHCARE PROVIDERS IN AKWA IBOM STATE, NIGERIA

Ime Akpan<sup>1</sup>, Enobong Ndekhedehe<sup>1</sup>, Augustine Firima<sup>2</sup>, Abba Umar<sup>3</sup>, Uchenna Nwokenna<sup>3</sup>, Kazeem Ayankola<sup>3</sup>, Abimbola Olayemi<sup>3</sup>, Paul Waibale<sup>4</sup>, Oluwatosin Adeyemo<sup>5</sup>, Ndifreke Mbaba<sup>6</sup>, Matt Griffith<sup>5</sup>, Thomas Hall<sup>7</sup>, Ratha Loganathan<sup>7</sup>

<sup>1</sup>Management Sciences for Health, Uyo, Nigeria, <sup>2</sup>Management Sciences for Health, Calabar, Nigeria, <sup>3</sup>Management Sciences for Health, Abuja,

Nigeria, <sup>4</sup>*Management Sciences for Health, Kampala, Uganda*, <sup>5</sup>*Banyan Global, Washington, DC, DC, United States*, <sup>6</sup>*Banyan Global, Uyo, Nigeria*, <sup>7</sup>*Management Sciences for Health, Arlington, VA, United States*

Nigeria accounts for about 27% of global malaria cases and 23% of deaths. Private health facilities (PHF) play an important role in expanding access to malaria case management (MCM). In 2020, the USAID President's Malaria Initiative for States (PMI-S) project conducted a mapping study to identify opportunities to improve provision of high quality MCM, intermittent preventive treatment of malaria in pregnancy (IPTp), and data reporting among PHFs in Akwa Ibom State, Nigeria. The study included a review of relevant literature and in-depth interviews with seven state actors and four representatives of Associations of Private Healthcare Providers. The study found that a lack of awareness on guidelines on MCM and capacity deficits in the private sector have affected the delivery of high quality MCM and data reporting as seen in 13.9% of PHFs offering IPTp and 41.9% not using or not reporting on NHMIS. Not all private providers belong to these associations. There is a need to sensitize, train and retrain private health practitioners on MCM protocols. The associations expressed readiness to support MCM awareness creation within their memberships, as well as support efforts to increase compliance to national guidelines. Inclusion of MCM topics in continuing medical education (CME) based on the newly revised guidelines would be beneficial. Another recommendation is making CME programs on MCM mandatory for practitioners' license renewals. Given the importance of commodity supply and data management in ensuring delivery of quality-assured MCM and IPTp, access to state-sponsored commodity supply mechanisms at subsidized rates may incentivize private sector providers to report data. PMI-S is working closely with the state ministry of health to incorporate these recommendations into a private sector engagement strategy.

#### UNLOCKING THE POTENTIAL OF PRIVATE SECTOR HEALTH FACILITIES IN MALARIA CONTROL: FINDINGS FROM A MAPPING STUDY IN OYO STATE, SOUTH WEST NIGERIA

**Taiwo Olarinde**<sup>1</sup>, Esther Ayandipo<sup>1</sup>, Augustine Firima<sup>2</sup>, Abba Umar<sup>3</sup>, Paul Waibale<sup>4</sup>, Uchenna Nwokenna<sup>3</sup>, Kazeem Ayankola<sup>3</sup>, Olubunmi Ayinde<sup>5</sup>, Olusesan Ishola-Gbenla<sup>3</sup>, Abimbola Olayemi<sup>3</sup>, Titilayo Famade<sup>6</sup>, Oluwatosin Adeyemo<sup>7</sup>, Matt Griffith<sup>8</sup>, Thomas Hall<sup>9</sup>, Ratha Loganathan<sup>9</sup>

<sup>1</sup>*Management Sciences for Health, Ibadan, Nigeria*, <sup>2</sup>*Management Sciences for Health, Calabar, Nigeria*, <sup>3</sup>*Management Sciences for Health, Abuja, Nigeria*, <sup>4</sup>*Management Sciences for Health, Kampala, Uganda*, <sup>5</sup>*State Ministry of Health, Oyo State, Ibadan, Nigeria*, <sup>6</sup>*Banyan Global, Ibadan, Nigeria*, <sup>7</sup>*Banyan Global, Brighton, United Kingdom*, <sup>8</sup>*Banyan Global, Washington DC, MD, United States*, <sup>9</sup>*Management Sciences for Health, Arlington, VA, United States*

Nigeria accounts for 27% of global malaria cases and 23% of global malaria deaths. Private sector health facilities (PHF) play an important role in expanding access to malaria case management (MCM). In 2020, we conducted a mapping study to identify opportunities to improve provision of high quality MCM, intermittent preventive treatment of malaria in pregnancy (IPTp), and data reporting among PHFs in Oyo State, Nigeria. The study involved a desk review and a survey of 509 PHFs out of 733 identified in the state. Slightly over half (58%) of PHFs offered malaria rapid diagnostic testing (mRDT), while only 16.7% of PHFs offered microscopy, suggesting many PHFs still rely on clinical diagnosis to initiate malaria treatment. Findings revealed a low rate of provision of IPTp (30.6%) by the PHFs. Almost all PHFs (99%) offered Artemisinin-based Combination Therapy (ACT) for the treatment of uncomplicated malaria. Larger number of PHFs offered ACT than mRDT. Over half (54%) did not have the national guidelines on MCM available for use, raising quality concerns. Commodity stock out was highlighted as a prevalent problem by 60% of PHFs. Non-reporting of malaria data on the National Health Management Information System (NHMIS) was also quite common, as 35.5% of PHFs had never reported. The mapping team produced

several recommendations for addressing these challenges. MCM and MIP guidelines should be made available to all PHFs to improve compliance and promote widespread use of mRDTs. Guidelines on management of malaria in pregnancy should also be made available to PHFs especially those offering maternity services. The state can consider extending subsidized commodity supply mechanisms to PHFs that regularly report health data as an incentive and motivation for others.

#### PREVALENCE OF MALARIA INFECTION AND COVERAGE OF MALARIA CONTROL INTERVENTIONS AMONG PREGNANT WOMEN ATTENDING THEIR FIRST ANTENATAL CARE VISIT IN THREE HEALTH DISTRICTS OF BURKINA FASO: INTERIM RESULTS

**Rene N. Kinda**<sup>1</sup>, Christelle Gogue<sup>2</sup>, Siaka Debe<sup>1</sup>, Adama Ganou<sup>1</sup>, Sonia Ilboudo<sup>1</sup>, Aladari Sagnon<sup>1</sup>, Casimir Tarama<sup>1</sup>, Mafama Siribie<sup>1</sup>, Gauthier Tougri<sup>3</sup>, N'Fale Sagnon<sup>1</sup>, Moussa W. Guelbeogo<sup>1</sup>, Julie R. Gutman<sup>4</sup>, Molly Robertson<sup>5</sup>, Adama Gansane<sup>1</sup>

<sup>1</sup>*Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso*, <sup>2</sup>*PATH, Washington, DC, United States*, <sup>3</sup>*Programme National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso*, <sup>4</sup>*Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States*, <sup>5</sup>*PATH, Seattle, WA, United States*

Health indicators are collected via household surveys and routine health surveillance activities. Data collected on malaria prevalence and coverage of malaria control interventions during antenatal care (ANC) clinic visits may provide an easily accessible, reliable, and representative source for monitoring population trends for select malaria prevalence and intervention coverage indicators. We assessed the potential to use pregnant women as a pragmatic sentinel population to collect health indicators in the health districts of Banfora, Gaoua, and Orodara, Burkina Faso. All pregnant women attending their first ANC visit in 21 randomly selected facilities in 3 health districts (7 per district) who gave informed consent were administered a standardized questionnaire and were tested for malaria infection using HRP-2-based rapid diagnostic tests. We analyzed preliminary data collected over 6 months (September 2020 to March 2021). In total, 4,587 pregnant women were enrolled. The proportion of pregnant women reporting that they owned an insecticide treated net (ITN) was 87.1% (95% CI, 85-89), 62.9% (60-65%), and 80.24% (78-82%) in Banfora, Gaoua, and Orodara, respectively. Among those possessing an ITN, the proportion of women reporting having slept under an ITN on the preceding night was 79.7% (77-82%) in Banfora, 58.8% (56-61%) in Gaoua, and 76.9% (75-79%) in Orodara. The prevalence of malaria infection among first ANC attendees was 27.5% (25-29%), 39.1% (36-41%), and 19.1% (17-21%) in Banfora, Gaoua, and Orodara, respectively. Comparison of data from ANC attendees with data from household surveys, to be collected in June 2021, will enable validation of the ANC platform for malaria surveillance. If validated to represent population-level trends, data from pregnant women attending ANC could provide a useful, routine data source to allow continuous monitoring of the coverage and impact of interventions.

1156

#### IMPACT OF TARGETED DELIVERY OF INTERVENTIONS TO MALARIA HIGH RISK POPULATIONS IN NAMIBIA

**Jennifer L. Smith**<sup>1</sup>, Henry Ntuku<sup>1</sup>, Francois Rerolle<sup>1</sup>, Cara Smith-Gueye<sup>1</sup>, Jerry O. Jacobson<sup>1</sup>, Petrina Uusiku<sup>2</sup>, Immo Kleinschmidt<sup>3</sup>, Davis Mumbengegwi<sup>4</sup>, Roly Gosling<sup>1</sup>, Adam Bennett<sup>1</sup>

<sup>1</sup>*University of California San Francisco, San Francisco, CA, United States*, <sup>2</sup>*National Ministry of Health and Social Services, Windhoek, Namibia*, <sup>3</sup>*London School of Hygiene & Tropical Medicine, London, United Kingdom*, <sup>4</sup>*University of Namibia, Windhoek, Namibia*

Seasonal agricultural workers and cattle herders in northern Namibia have been identified as populations at higher risk of malaria, due to their

mobility, occupational exposures, and low access to effective malaria prevention. A quasi-experimental study using a matched pair pre-post-intervention design was used to evaluate the impact of targeted delivery of a package of interventions on coverage and malaria prevalence in these populations in the Ohangwena and Zambezi regions. A baseline cross-sectional survey was conducted between November 2019 and January 2020 in eight health facility catchment areas (HFCAs). A package of four interventions was rolled out at worksites in a random subset of four of the eight areas between January and March 2020, including: presumptive treatment with artemether lumefantrine, targeted IRS mop up with Actellic, a vector control pack (LLINs and topical repellents) and malaria education. Main outcomes (PCR-based *P. falciparum* prevalence and coverage of interventions) were assessed through an endline cross sectional survey conducted amongst 1,691 participants in May-June 2020. The secondary outcome was passively detected case incidence derived from health facility records. A generalized difference-in-difference approach using two-way fixed effects regression was used to compare change (baseline to endline) in intervention coverage, infection prevalence and HFCA-level incidence between intervention and control areas, adjusting for environmental covariates. Preliminary results suggest that the intervention resulted in an absolute increase of 57% (95% CI 51.7 - 63.5%) increase in coverage with an effective intervention ( $p < 0.0001$ ) in the target population, from an overall baseline of 26%, after controlling for age, gender and HFCA. There was 3.5% (95% CI 0.2 - 6.9) decrease in infection prevalence by RDT ( $p = 0.04$ ) in the target population, reducing it from 4% to 0.5%, and an overall decline in incidence of malaria in intervention areas ( $p = 0.02$ ). Final analyses will be presented describing impact on PCR-based infection prevalence, and an assessment of heterogeneity of impact.

1157

#### THE IMPACT OF POPULATION-BASED INDOOR RESIDUAL SPRAYING, WITH AND WITHOUT A MASS TREATMENT CAMPAIGN, ON KEY MALARIA INDICATORS IN A HIGH TRANSMISSION SETTING IN NE UGANDA

**Dorothy C. Echodu**<sup>1</sup>, Adoke Yeka<sup>2</sup>, Kathryn Colborn<sup>3</sup>, Benjamin Amoah<sup>4</sup>, Humphrey Wanzirah<sup>5</sup>, Thomas Eganyu<sup>5</sup>, Richard Elliott<sup>6</sup>, Fred Bukenya<sup>5</sup>, Wycliff Odude<sup>5</sup>, Kilama Maxwell<sup>7</sup>, Joaniter Nankabirwa<sup>7</sup>, Ronald Mulebeke<sup>7</sup>, Samuel Gonahasa<sup>7</sup>

<sup>1</sup>Pilgrim Africa, Seattle, WA, United States, <sup>2</sup>University of Makerere, Kampala, Uganda, <sup>3</sup>Department of Biostatistics, University of Colorado Denver, Denver, CO, United States, <sup>4</sup>University of Lancaster, Lancaster, United Kingdom, <sup>5</sup>Pilgrim Africa, Kampala, Uganda, <sup>6</sup>Boise State University, Boise, ID, United States, <sup>7</sup>IDRC, Kampala, Uganda

We describe results of a 32-month, prospective, controlled before and after trial investigating the impact of co-timed antimalarial mass drug administration (MDA) with population-based indoor residual spraying (IRS) on malaria burden in a high transmission region of NE Uganda. The study began in November 2016, and all arms had universal campaign coverage with non-PBO nets delivered by the Ministry of Health in April 2017. The study interventions were 4 rounds of IRS with pirimiphos methyl, alone or in combination with a simultaneous MDA with dihydroartemisinin-piperazine. The third reference arm had nets alone. The study population was an open cohort of approximately 52,000 people in Katakwi District, Uganda. The three arms of ~16,000-18,000 persons each were contiguous sub-counties with heavy entomological pressure. Prevalence in children under 5 measured by qPCR at baseline ranged from 48.5% to 58.4%. All households in the study area were mapped and enumerated twice yearly. In the MDA arm, all medically screened persons over 6 months were eligible, and all households in intervention arms were eligible for IRS. MDA was directly observed day 1, and followed up after. Coverage of MDA was ~80%, and IRS coverage was ~98%. 6 cross-sectional prevalence surveys using rapid diagnostic tests, expert microscopy and qPCR were conducted during the study period, and a spatio-temporal geostatistical analysis was performed on the survey and household data for qPCR. Residence in the IRS arm was found to confer 64.7% reduced odds of infection with malaria compared with residence in the LLIN only

arm, while residence in the MDA + IRS arm conferred an 80.1% reduction in the odds of being found infected. The additional protective impact of a single, co-timed round of MDA was detected via surveys performed (with one exception) more than 6 months after the MDA round. This shows that a single treatment round of antimalarials in a very high burden population, when combined with indoor spraying, can provide significant and prolonged protection from malaria infection. Limitations include non-random assignment to arm and the presence of only one cohort per arm.

1158

#### PERFORMANCE OF ZAMBIA'S NATIONAL MALARIA ELIMINATION PROGRAMME COMMUNITY HEALTH WORKERS

**Travis Porter**<sup>1</sup>, Elizabeth Chiyende<sup>2</sup>, Todd Jennings<sup>2</sup>, Marie-Reine Rutagwera<sup>2</sup>, Chris Lungu<sup>2</sup>, Michael Hainsworth<sup>3</sup>, Busiku Hamainza<sup>4</sup>, Thomas P. Eisele<sup>1</sup>, John M. Miller<sup>2</sup>

<sup>1</sup>Tulane University, New Orleans, LA, United States, <sup>2</sup>PATH, Lusaka, Zambia, <sup>3</sup>PATH, Seattle, WA, United States, <sup>4</sup>National Malaria Elimination Centre, Lusaka, Zambia

As Zambia's National Malaria Elimination Programme (NMEP) continues to invest resources into community health workers (CHWs) as part of its strategy for achieving malaria elimination, understanding performance of these individuals and factors that influence outputs becomes increasingly important. Previous research has demonstrated competency of CHWs in conducting diagnostic tests and administering anti-malarials, though less work has been done to describe and assess CHW outputs. To provide further insight into NMEP CHWs performance, we first review performance in terms of both passive and active malaria testing rates between 2013 and 2019 across the entire population of CHWs. Using a subset of 404 CHWs drawn from a simple random sample for whom additional data were available regarding supervision, community support, incentive satisfaction, time demands, and other demographic characteristics, we assess relationships between these factors and individual CHW performance. The average number of passive tests conducted per month followed seasonal trends in malaria transmission, increasing as local malaria incidence increased. Active testing rates remained the same and the proportion of households followed up decreased during higher incidence periods, however. Zero-inflated negative binomial regression models showed that lower quality of supervision, lower incentive satisfaction, interest in monetary compensation, less time as a CHW, access to a bicycle, being single, and no access to electricity at home were individually associated with higher passive and/or active testing rates. After controlling for seasonal and geographic differences in local malaria incidence rates, greater satisfaction with current incentives was associated with lower (IRR: 0.69;  $p: 0.008$ ) passive testing rates; active testing rates were higher (IRR: 1.47;  $p: 0.041$ ) among CHWs specifically expressing interest in receiving monetary incentives. Understanding performance expectations and limitations of this largely voluntary workforce is important to optimize engagement and determine realistic assumptions for elimination timelines.

1159

#### FREEDOM FROM MALARIA INFECTION: A NOVEL FRAMEWORK FOR QUANTIFYING MALARIA ELIMINATION, AN EXAMPLE FROM INDONESIA

**Luca Nelli**<sup>1</sup>, Henry Surendra<sup>2</sup>, Riris Andono Ahmad<sup>3</sup>, Risalia Reni Arisanti<sup>3</sup>, Dyah Ayu Shinta Lesmanawati<sup>3</sup>, Jason Matthiopoulos<sup>1</sup>, Isabel Byrne<sup>4</sup>, Elin Dumont<sup>4</sup>, Chris Drakeley<sup>4</sup>, Lindsey Wu<sup>5</sup>, Gillian Stresman<sup>4</sup>

<sup>1</sup>University of Glasgow, Glasgow, United Kingdom, <sup>2</sup>Eijkman-Oxford Clinical Research Unit, Jakarta, Indonesia, <sup>3</sup>Universitas Gadjah Mada,

Yogyakarta, Indonesia, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>5</sup>WHO Global Malaria Program, Geneva, Switzerland

The “freedom from infection” (FFI) framework is an approach, designed and used in veterinary epidemiology, to provide a quantitative estimate of the probability of detecting an infection in a population, if present above a predefined threshold. Here we show that the FFI method can be applied to the context of malaria to assess the sensitivity of the malaria surveillance system (S<sub>Se</sub>), a critical component in how likely it is an infection will be detected, and the corresponding probability of freedom (P<sub>Free</sub>). We collected monthly routinely reported malaria surveillance data from January 2017 to December 2019 and conducted semi-quantitative health systems surveys from 46 health facilities in Kulon Progo and Magelang Districts in Indonesia. The surveillance system sensitivity (S<sub>Se</sub>) was estimated, by conditionally modelling the flow of a potentially infected individual through the system (from the infection to being detected) and simultaneously modelling the underlying expected malaria cases in the population, using autoregressive spatio-temporal models in a joint inferential Bayesian framework based on the data collected. There was a high heterogeneity in the estimated probability of care seeking for malaria (P<sub>Seek</sub>; Mean=0.087, Min=0.012, Max=0.190), and the probability of being tested for malaria (P<sub>Test</sub>; Mean=0.17, Min=0.000, Max=1.000). This corresponded to the S<sub>Se</sub> per facility and P<sub>Free</sub> for detecting 1 or more cases, ranging between 0.00 and 0.14 (Mean=0.018) and 0.00 and 1.00 (Mean=0.277), respectively. Our results highlight that the FFI framework can be meaningfully applied to the context of malaria. Quantifying the S<sub>Se</sub> provides an approach to identify specific areas that can strengthen the malaria surveillance system and provide quantitative benchmarks for tracking progress, at all transmission intensities. Furthermore, the use of P<sub>Free</sub> can complement and guide malaria elimination decision-making by quantifying how likely it is that elimination has been achieved for better resource allocation.

1160

### DOES REBOUND MALARIA EXPLAIN THE HETEROGENEITY IN RTS,S/AS01 MALARIA VACCINE EFFICACY?

**Griffin J. Bell<sup>1</sup>**, Stephaney Gyaase<sup>2</sup>, David Dosoo<sup>2</sup>, Musah Osei<sup>2</sup>, Kenneth Wiru<sup>2</sup>, Paulin Essone<sup>3</sup>, Fabrice Mougéni<sup>3</sup>, Pamela Minsoko<sup>3</sup>, Bright Adu<sup>4</sup>, Benedicta Mensah<sup>4</sup>, Cyrus Sinai<sup>5</sup>, Varun Goel<sup>5</sup>, Karamoko Niare<sup>6</sup>, Jonathan Juliano<sup>7</sup>, Michael Hudgens<sup>1</sup>, Anita Ghansah<sup>4</sup>, Portia Kamthunzi<sup>8</sup>, Selidji Todagbe Agnandji<sup>3</sup>, Kwaku Poku Asante<sup>2</sup>, Michael Emch<sup>1</sup>, Jeffrey Bailey<sup>6</sup>

<sup>1</sup>UNC Gillings School of Global Public Health, Chapel Hill, NC, United States, <sup>2</sup>Kintampo Health Research Centre, Kintampo, Ghana, <sup>3</sup>Centre de Recherches Médicales de Lambaréné, Lambaréné, Gabon, <sup>4</sup>Noguchi Memorial Institute for Medical Research, Accra, Ghana, <sup>5</sup>UNC Chapel Hill, Chapel Hill, NC, United States, <sup>6</sup>Brown University, Providence, RI, United States, <sup>7</sup>UNC School of Medicine, Chapel Hill, NC, United States, <sup>8</sup>UNC Project - Malawi, Lilongwe, Malawi

RTS,S/AS01 is the first vaccine against malaria to undergo pilot implementation. Trials reported lower vaccine efficacies in higher-incidence sites, potentially due to a “rebound” in malaria cases in vaccinated children. The rebound hypothesis posits that immune protection in the unvaccinated (acquired from natural infections) can temporarily rise above waning vaccine protection in the vaccinated, leading to a negative vaccine efficacy. Whether natural protection in the unvaccinated is superior to waning vaccine protection at certain time points is likely dependent on the level of malaria exposure. Using data from the 2009-2014 phase III trial (NCT00866619) in Lilongwe, Malawi; Kintampo, Ghana; and Lambaréné, Gabon, we evaluate the rebound malaria hypothesis by estimating malaria incidence over time by vaccination status and estimated malaria exposure. The phase III trial included two age groups: infants, who will not be vaccinated during pilot implementation, and children 5-17 months. Restricting to follow-up of unvaccinated infants after they reached 5 months of age, we fit a random forest model to estimate the relationship between malaria incidence and the following ecological predictors: rainfall,

temperature, elevation, several vegetation indices, population density, nighttime lights, evapo-transpiration, aridity, household construction, and bed net use. Then, we apply our fitted model to estimate the malaria exposure for children in the phase III trial and fit a negative binomial model with a three-way interaction between vaccine group, time since vaccination, and estimated malaria exposure. We use the output from this model to calculate the incidence rate of malaria over time in each vaccine group and several malaria exposure settings. Malaria incidence in the unvaccinated decreased while vaccine efficacy waned, causing a rebound effect which increased with greater malaria exposure. For example, when exposure was set at 3 cases per-person-year (CPPY), modeled incidence in the three-dose vaccine group at 1 and 4 years post-vaccination was 2.01 and 3.19 CPPY, respectively, compared to 3.38 and 2.66 in the unvaccinated.

### HUMAN-CENTERED DESIGN PROCESS AND SOLUTIONS TO PROMOTE MALARIA TESTING AND TREATMENT-SEEKING BEHAVIOR IN GUYANA HINTERLANDS

**Joann Simpson<sup>1</sup>**, Shirley Yan<sup>2</sup>, Lyndsey Mitchum<sup>2</sup>, Jennifer Orkis<sup>2</sup>, TrishAnn Davis<sup>2</sup>, Sean Wilson<sup>1</sup>, Neil Trotman<sup>3</sup>, Helen Imhoff<sup>3</sup>, Horace Cox<sup>3</sup>, Gabrielle Hunter<sup>2</sup>, Bolanle Olapeju<sup>2</sup>, Camille Adams<sup>1</sup>, Douglas Storey<sup>2</sup>

<sup>1</sup>Breakthrough ACTION Guyana, Georgetown, Guyana, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Guyana National Malaria Program, Georgetown, Guyana

Malaria remains common among Guyana gold-mining populations. To address this public health challenge, an interdisciplinary team of public health professionals, graphic designers, and mining organizations collaborated on a human-centered design (HCD) process, including the i) Define and 2) Design & Test phases, facilitated by the USAID-funded Breakthrough ACTION Guyana and the MoH. In the Define phase, we conducted 108 qualitative interviews to understand experiences and challenges when seeking malaria testing and treatment services. These interviews were synthesized into 11 actionable insights on issues such as risk perception, malaria knowledge, preventive behaviors, traditional and self-treatment, testing, adherence to the correct treatment, and coordination and communication gaps. From these insights, during the Design & Test phase, we developed 33, “How might we...?” questions to stimulate creative thinking about potential solutions to the existing challenges. Five final prototypes included: (1) a “Little Mosquito, Big Problem” social behavior change campaign to address risk perception and other behavioral barriers; (2) rapid counseling cards to improve quality of malaria services; (3) branded malaria testing and treatment services located in mining areas; (4) innovations to improve treatment adherence; and (5) an integrative “participants, content, and logistics” strategy to ensure supply could meet demand. When applying HCD to public health issues, there are both opportunities and challenges to reconcile gaps that may exist between the two disciplines. HCD provides a new set of tools and mindsets that are not typically part of public health strategies. The synthesis produces innovative, feasible ways to organize work with migrant and mobile mining communities to encourage malaria testing and treatment services.

### DESIGN AND CHARACTERIZATION OF SELF-ASSEMBLING PROTEIN NANOPARTICLE PRESENTING PLASMODIUM FALCIPARUM PLASMODIUM FALCIPARUM THROMBOSPONDIN-RELATED ADHESION PROTEIN (TRAP) SUBDOMAINS IN CROSS-TERMINI DISPLAY

Cosette G. Schneider<sup>1</sup>, Justin A. Taylor<sup>1</sup>, Ishita N. Waghela<sup>1</sup>, Xiaoyan Zou<sup>2</sup>, Peter Burkhard<sup>3</sup>, Evelina Angov<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>3</sup>Alpha-O Peptides, Riehen, Switzerland

Malaria remains a major health concern in tropical regions, causing an estimated 229 million clinical cases and 409,000 deaths in 2019 alone despite the development of novel prophylactic anti-malarial drugs and vector control efforts. Thus, a highly efficacious vaccine is critical to the control and eradication of malaria. Preclinical testing of novel malaria vaccine strategies achieved through rational antigen selection and particle-based delivery platforms is yielding encouraging results; however, to date, there is no licensed, efficacious vaccine for malaria. One promising particulate delivery system, the self-assembling protein nanoparticle (SAPN), has the potential to overcome limited vaccine efficacy through repetitive, high-density epitope display. Here, the von Willebrand factor A (VWA) and thrombospondin repeat (TSR) domains of *Plasmodium falciparum* thrombospondin-related adhesion protein (TRAP), an essential protein for sporozoite motility and liver-stage infection, were engineered onto the termini of a SAPN monomer, and particle formation was characterized. Contrasting previous SAPN requiring lengthy refolding processes in denaturing conditions, TRAP-SAPN monomers spontaneously formed into a particle after a one-step purification under non-denaturing conditions, likely due to the hydrophobic interactions between the continuous domains displayed across termini. Proper folding was confirmed by DLS, TEM, and epitope mapping by dot blot with conformation-specific monoclonal antibodies. Furthermore, stability testing indicated that TRAP-SAPN is stable at 4°C for one year, unlike most vaccine platforms requiring storage at -80°C. Current preclinical studies are exploring the functionality of this novel chimeric particle *in vivo* through immunization of BALB/c mice and *in vitro* through ELISA, ILSDA, and sporozoite gliding motility assays.

### INFLUENCE OF TRUST ON THE ACCEPTANCE OF THE MALARIA VACCINE IN THE KASSENA-NANKANA DISTRICTS OF GHANA

Eustace Bugase, Paulina Tindana

University of Ghana, Accra, Ghana

The availability of a malaria vaccine for routine use will be a major milestone for the eradication of malaria mortality among children of under five years. Nonetheless, trust by the public for the vaccine could pose a major challenge for its comprehensive acceptance referencing documented evidence from the oral polio vaccine boycott in northern Nigeria and the failure of the Ebola vaccine trial in Ghana among others. A total of 390 structured questionnaires were administered to mothers and caregivers of children of under five years and 15 in-depth interviews were conducted with mothers and health workers. The data was analyzed using STATA Version 16.0 and QSR NVivo 12 software. We performed a bivariate and multivariate regression analysis to determine the influence of trust on vaccine acceptance. The results were further explained and affirmed by the qualitative data. We found that knowledge about the vaccine was widespread (95.4%) and uptake of the vaccine was high (82.4%). In a bivariate analysis, health education about the vaccine and perceived ineffectiveness were found to be associated with acceptance of the vaccine. A multivariate regression of the factors found trust for the malaria vaccine as the main factor that positively influenced the acceptance of the vaccine among the mothers in the district (OR= 0.55[95% CI 0.30-0.84] P<0.001). This was confirmed by the qualitative data which similarly

revealed trust for the vaccine as the main determinant of uptake. The results of this study suggest that trust for the malaria vaccine is critical for its uptake. Therefore, efforts towards improving comprehensive acceptance of the malaria vaccine and other vaccines should be focused on building and sustaining trust for the vaccine among mothers and community members.

### IMPACT OF A DELAYED AND FRACTIONATED THIRD DOSE OF R21/MATRIX-M ADJUVANT IN UK ADULTS

Duncan G. Bellamy, Lisa Stockdale, Mehreen Dato, Jeremy Aboagye, Helen Sanders, Rebecca Makinson, Navin Venkatramann, Meera Madhavan, Amy Flaxman, Nick Edwards, Ian Poulton, Megan Baker, Fernando Ramos-Lopez, Jenny Reimer, Umesh Shaligram, Adrian V. Hill, Katie J. Ewer

University of Oxford, Oxford, United Kingdom

Malaria remains a leading cause of childhood mortality, highlighting the need for an effective vaccine. R21 is a virus-like particle (VLP) vaccine displaying the immunodominant NANP repeat region and C-terminus of the circumsporozoite protein (CSP) of *Plasmodium falciparum*. R21 is novel in that CSP epitopes cover the particle surface of Hepatitis B surface antigen (HBsAg), whereas the current leading malaria vaccine candidate, RTS,S, has a much higher ratio of HBsAg to CSP. R21, combined with the saponin-based Matrix-M adjuvant (MM) has been assessed previously in Phase I and Phase II trials to determine safety, immunogenicity and efficacy with different vaccine doses but in this study the effect of a delayed and fractionated third dose is investigated. In a Phase I controlled human challenge model in Oxford, R21/MM, induced high levels of anti-CSP-specific IgG when administered to malaria naïve adults. Protection against clinical malaria after being immunized with the standard dose regimen of 3 low doses of R21/MM (10,10,10µg) administered one month apart was 63%. In the Phase I/IIa study to be presented here, dose and regimen timing are investigated. We compare immunogenicity and efficacy of the standard dose regimen (10,10,10µg – Group 3) with a delayed third dose (given at 6 months – Group 2). Additionally, a delayed fractional dose regimen with a lower final dose given at 6 months (10,10,2µg – Group 5) and a higher delayed fractional dose regimen (50,50,10µg – Group 4) were investigated. Data that will be presented support antigen dose-sparing, thereby impacting access and having economic implications of vaccine delivery. Regardless of dose, volunteers with an antibody response greater than 1100 ELISA units were significantly more likely to be protected when challenged with *P. falciparum*, making this a potential correlate of protection for R21/MM. Further work to assess antibody isotype and subclass, in addition to humoral and cellular responses to other vaccine constituents, will be presented. Lastly, a direct comparison of immunogenicity between R21/MM and another vaccine candidate, RTS,S/AS01, will be presented.

### A NOVEL PHYSIOLOGICAL MODEL TO STUDY PLASMODIUM FALCIPARUM INTERACTIONS IN PLACENTAL MALARIA

Rebecca Reif, Sumaiyah Shaha, Yuliya Fakhr, Catherine Mitran, Madeleine Wiebe, Denise Hemmings, Stephanie Yanow

University of Alberta, Edmonton, AB, Canada

Placental malaria poses a major health threat to women, resulting in fetal morbidity and low birth weight infants. It develops when infected red blood cells (iRBCs) adhere to chondroitin sulfate A (CSA) glycosylated syndecan-1 (SDC-1) on placental syncytiotrophoblasts (ST) via VAR2CSA, a parasite protein localized to the iRBC surface. Current vaccine efforts are directed at VAR2CSA to disrupt the interaction with CSA glycosylated SDC1 on the ST for protection against placental malaria. Current assays use CSA-coated plates; these are non-physiological and prone to high inter- and intra-assay variability. A more relevant tissue-based iRBC binding model will close the gap between *in vitro* assays, vaccine development and human clinical trials. We developed a new model using villous tissue

explants from human term placentas. We first confirmed that SDC-1 localized to the apical membrane of ST layer in villous explants, making it a suitable tissue for this model. iRBCs were stained with ethidium bromide to detect parasite DNA and uninfected RBCs were stained with DiD. Infected or uninfected RBCs were added to explants and rocked. After washing, explants were fixed, whole mounted and RBC binding was quantified manually in 5 fields of view using fluorescent microscopy. The iRBC n=3 binding between assays varied 19.7(%CV). ST area will be quantified since different levels could explain this high variability in binding. Controls include chondroitinase cleavage of CSA from explants and soluble CSA competition. Blocking iRBC binding with rabbit anti-VAR2CSA IgG validated the assay. Specific iRBC binding to SDC-1 on villous explants was reduced with chondroitinase treatment by 76.02±15.3%. Preincubation of iRBCs with soluble CSA or rabbit anti-VAR2CSA IgG reduced binding by 80.19±15.3% and 93.94±17.1%, respectively. Average background binding levels of uninfected RBCs was 28.89±19.4 compared to bound iRBCs 127.3±19.4 in 5 fields of view. This study presents a more physiological model to test the functional activity of antibodies from pre-clinical vaccine studies and human trials with candidate vaccines against placental malaria.

### POTENT HUMAN MONOCLONAL ANTIBODIES TARGET DIFFERENT DOMAINS OF MALARIA TRANSMISSION BLOCKING VACCINE CANDIDATE PFS48/45

Amanda Fabra-García<sup>1</sup>, Roos de Jong<sup>1</sup>, Marta Szabat<sup>2</sup>, Stefanie Vogt<sup>2</sup>, Aoise O'Neill<sup>2</sup>, Stephanie Pfaffen<sup>2</sup>, Sherie Duncan<sup>2</sup>, Veronique Lecault<sup>2</sup>, Carl Hansen<sup>2</sup>, Karina Teelen<sup>1</sup>, Rianne Stoter<sup>1</sup>, Marga van de Vegte-Bolmer<sup>1</sup>, Geert-Jan van Gemert<sup>1</sup>, Judith Bolscher<sup>3</sup>, Martijn Vos<sup>3</sup>, Marloes de Bruijn<sup>3</sup>, John Rek<sup>4</sup>, Margaret Feeney<sup>5</sup>, Bryan Greenhouse<sup>5</sup>, Rick King<sup>6</sup>, Randall MacGill<sup>6</sup>, Robert Sauerwein<sup>3</sup>, Teun Bousema<sup>1</sup>, **Matthijs Jore**<sup>1</sup>

<sup>1</sup>Radboudumc, Nijmegen, Netherlands, <sup>2</sup>AbCellera, Vancouver, BC, Canada, <sup>3</sup>TropiQ Health Sciences, Nijmegen, Netherlands, <sup>4</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>5</sup>UCSF, San Francisco, CA, United States, <sup>6</sup>PATH Malaria Vaccine Initiative, Washington, DC, United States

Malaria continues to be one of the most devastating infectious diseases worldwide. The spread of malaria parasites is highly efficient and occurs through bites of infected *Anopheles* mosquitoes. Malaria transmission blocking vaccines (TBVs) aim to interrupt malaria parasite development in the mosquito and thereby provide powerful tools for malaria elimination efforts. The sexual stage protein Pfs48/45 is a leading TBV candidate and will soon be evaluated in Phase I clinical trials. We previously demonstrated that naturally acquired polyclonal antibodies against Pfs48/45 reduce transmission *ex vivo*. However, little is known about the epitope specificity and potency of monoclonal antibodies (mAbs) that make up this functional polyclonal response in humans. Following single cell sorting and screening of B-cells from two donors with naturally acquired transmission reducing activity, we identified a panel of 100 Pfs48/45-specific human monoclonal antibodies. We characterized these antibodies in terms of affinity, epitope specificity and potency, and defined novel protective epitopes. Affinity was determined using surface plasmon resonance and native antigen recognition was confirmed in surface-immunofluorescence assays with live gametes. While western blot analyses demonstrated most mAbs were conformation dependent, some targeting the N-terminal domain of Pfs48/45 (domain I) were not. Competition experiments showed the mAbs can be grouped into four large clusters, targeting domains I, II or III, or both domains I and III. Interestingly, only domain I- and domain III-specific mAbs strongly reduced transmission in standard membrane feeding assays. MAbs against domain III, also known as the 6C domain, reduced transmission up to 95% at 2 µg/mL. This observation aligns with the activity of the known domain III mAb TB31F, and domain III targeting mAbs are the most potent human transmission blocking mAbs described to date. Altogether we provide unprecedented insight in protective and non-protective epitopes on Pfs48/45 which will inform the design of this important transmission blocking vaccine.

<sup>1</sup>National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Sanaria Inc., Rockville, MD, United States

Preclinical studies of *Plasmodium falciparum* (Pf) pre-erythrocytic stage vaccines have been hindered by the limitations of existing models that require engineered parasites or hosts; there are no available nonhuman primate (NHP) models for assessing the PfNF54-based vaccines being clinically evaluated world-wide. Aotus monkeys are a well-established NHP model that supports Pf and *P. vivax* blood stage infections. However, success with Pf sporozoite (SPZ)-induced infections has been variable in previous studies. We examined *Aotus lemurinus griseimembra*, which are known to support PfSPZ infection with the Santa Lucia parasite but not the NF54 strain of Pf, as a model for pre-erythrocytic infection using aseptic, purified, cryopreserved PfSPZ. In an initial comparative pilot study, one *A. griseimembra* and one *A. nancymaae* monkey (both splenectomized) were each inoculated with 5.4x10e6 PfSPZ; two needle biopsies of liver were collected on day 6 and daily blood samples on days 6-10 post-challenge. Both liver biopsy samples from *A. griseimembra* were PCR-positive with comparable estimated parasite burdens per gram of tissue; blood samples from days 6-9 were PCR-positive for low-level parasitemia which cleared without treatment. All samples from the *A. nancymaae* monkey were negative. To our knowledge, this is the first demonstration of infection of any Aotus with PfNF54 SPZ. We will report further development of the *A. griseimembra*/PfSPZ NF54 model as a platform to assess pre-erythrocytic stage malaria vaccines.

<sup>1</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Structural Biology Section, Research Technologies Branch, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>3</sup>Protein Chemistry Section, Research Technologies Branch, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>4</sup>Vaccine Research Center, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Malaria is a mosquito-borne disease caused by the intracellular growth of protozoan parasites in RBCs. Development of a vaccine that blocks transmission of malaria parasites to humans and mosquitoes is considered critical for elimination and eradication efforts. A vaccine against Pfs25, a glycosylphosphatidylinositol (GPI) anchored protein on the surface of zygotes and ookinetes, is being evaluated for development of a transmission-blocking vaccine that would interrupt mosquito transmission to humans. The most extensively studied Pfs25 transmission-blocking vaccine is comprised of recombinant forms of Pfs25 expressed as a secreted protein without the GPI anchor in *Pichia pastoris* that are chemically conjugated to a recombinant carrier protein, ExoProtein A. Pfs25 contains four epidermal growth-factor like domains. The first-generation recombinant Pfs25, identified as Pfs25H, contained 14

heterologous amino acids positioned at the amino- or carboxyl-termini. A second-generation recombinant protein has been produced to remove the 14 non-native amino acids and is identified as Pfs25M. The purified forms of both were characterized biochemically and biophysically for identity, purity, biological activity and integrity including protein structure. The biological activity of Pfs25H and Pfs25M generated by monomeric forms or conjugated nanoparticles appeared similar. However, fine mapping studies with two transmission-blocking monoclonal antibodies detected fine structural and immunological differences. An evaluation of nonhuman primate antisera generated against conjugated Pfs25H or Pfs25M also identified these unique structural differences. Small modifications in amino acid content may modify recombinant forms of vaccine immunogens and should be made with thoughtful consideration or empirical comparisons.

*P. falciparum* circumsporozoite protein (PfCSP) and P25 (Pfs25) are leading candidates for development of pre-erythrocytic and transmission-blocking vaccines (TBV), respectively. Although considerable progress has been made in developing PfCSP and Pfs25 vaccines, neither has elicited complete protection or transmission-blocking activity (TBA) in clinical trials. The combination of antigens from various life stages is an alternative strategy to develop an effective malaria vaccine targeting multiple stages. In this study, female and male Balb/c mice were immunized with DNA plasmids encoding PfCSP and Pfs25, administered alone or in combination via *in vivo* intramuscular electroporation. Antigen-specific antibodies were analyzed by ELISA, and splenic T cell populations by flow cytometry. Immune protection against sporozoite challenge, using transgenic *P. berghei* expressing both PfCSP and luciferase (Pb-PfCSP-Luc), was assessed by *in vivo* bioluminescence imaging and blood-stage parasite growth. TBA was evaluated in standard membrane feeding assays. High levels of PfCSP- and Pfs25-specific antibodies were induced in mice immunized with either antigen alone or in combination. No difference in antibody levels were observed for both PfCSP and Pfs25 between the single antigen and combined antigen immunization groups. When challenged by PbPfCSP-Luc parasites, mice immunized with PfCSP (alone or combined with Pfs25) revealed significantly reduced liver-stage parasite burden as compared to mice immunized with Pfs25 alone (PfCSP:  $p < 0.05$ ; Combined:  $p < 0.01$ ). Furthermore, parasite liver burdens were negatively correlated with PfCSP-specific antibody levels (Ab concentration:  $p = 0.0117$ ; Ab titer:  $p < 0.0001$ ). The evaluation of TBA of Pfs25-specific Abs is still in progress. Our studies reveal that the combination of PfCSP and Pfs25 DNA vaccines does not compromise the immunogenicity and protective efficacy when compared with mice immunized with each antigen individually. Our studies pave the way for further evaluation of other multi-stage and multi-antigen combined DNA vaccines against *P. falciparum*.

### IDENTIFICATION OF A NOVEL EPITOPE IN THE CIRCUMSPOROZOITE PROTEIN C-TERMINAL REGION BOUND BY RTS,S AS01 INDUCED HUMAN ANTIBODIES

Randall S. MacGill<sup>1</sup>, Tossapol Pholcharee<sup>2</sup>, David Oyen<sup>3</sup>, Nathan Beutler<sup>2</sup>, Wayne Volkmuth<sup>4</sup>, Daniel Emerling<sup>4</sup>, Thomas Rogers<sup>3</sup>, C Richter King<sup>1</sup>, Ian Wilson<sup>3</sup>

<sup>1</sup>PATH, Washington DC, MD, United States, <sup>2</sup>The Scripps Research Inst, La Jolla, CA, United States, <sup>3</sup>Scripps Research Inst, La Jolla, CA, United States, <sup>4</sup>Atreca Inc., South San Francisco, CA, United States

The mechanism of protection for RTS,S/AS01 remains an active area of research and is widely expected to be linked to antibody responses to the repeat region of the circumsporozoite protein (CSP). Multiple reports have also indicated a possible role for C-terminal region antibody responses. These include association of higher levels of vaccine efficacy against strain matched parasites, as well as the induced antibody magnitude, avidity, and isotype of C-term antibodies. At present however, the evidence for a mechanistic link to protection is considered less definitive than for antibodies to the repeat region. The lone study to date of structure-function relationships for C-terminal binding monoclonal antibodies induced by PfSPZ vaccination with chloroquine prophylaxis indicated the two induced mAbs did not have infection blocking functional activity. In our studies of antibodies induced in humans by RTS,S/AS01, we describe a family of mAbs that bind to a similar epitope to that previously described. Additionally, we identify new mAbs that bind to a novel C-term epitope which is structurally distinct. The novel epitope primarily contains the sequence invariant  $\beta$ -sheets of the C-terminal region of CSP on the opposite side of the CSP molecule. The mAb binding residues of the epitope were also independent of the critical residues associated with vaccine escape identified by sieve-analysis of field isolates in RTS,S/AS01 clinical efficacy studies. We hypothesize this novel epitope could be the site of reactivity that contributes to the repertoire of RTS,S/AS01 induced functional activity against the C-terminal region of CSP. We propose these findings should be considered for structure-based vaccine designs of next-generation CSP-based vaccines.

1171

### OPEN LABEL TRIAL TO ESTABLISH A BLOOD-STAGE CONTROLLED HUMAN MALARIA INFECTION MODEL AND DETERMINE ITS SAFETY IN HEALTHY TANZANIAN ADULTS WITH VARYING PRIOR EXPOSURE TO PLASMODIUM FALCIPARUM (VAC 083).

Florence Milano, Neema Balige, Saumu Ahmed, Kamaka Kassimu, Ally Olotu

Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania

*Plasmodium falciparum* malaria still remains a disease of public health significance. This has been caused by the waning effectiveness of currently registered antimalarial drugs due to fast emergence and spread of resistance and the absence of an effective vaccine hence need for new malaria disease fighting tools to be used in the eradication program. The Controlled Human Malaria infection (CHMI) model is one of latest tools for evaluation of candidate malaria vaccines and antimalarial drugs. It provides a cost-effective method to down-select potential candidate malaria interventions. CHMI studies can also facilitate assessment of immune correlates of protection in participants to inform development of effective malaria vaccines and monoclonal antibodies. However, this model has not been used in Africa, due to difficulty in accessing viable PfIRBC, lack of necessary technical expertise and infrastructure to support these kinds of studies. Therefore, the purpose of this study is to assess the safety and feasibility of controlled blood-stage *P. falciparum* human malaria infection in healthy Tanzanian adults with prior exposure to *P. falciparum*. The design for this study is a single-centre, open label trial to determine the safety and feasibility of CHMI model using *Plasmodium falciparum*-infected cryopreserved erythrocytes administered to 12 healthy Tanzanian adults aged 18 to 35 with varying prior exposure to *P. falciparum*. Safety

analysis will consist of descriptive summaries for high and low exposure groups. The overall percentage of volunteers with at least one local adverse event and the percentage with at least one general adverse event (solicited and unsolicited) during the post-CHMI period will be tabulated. Comparisons between groups will be made based on a two-sided Fisher's Exact Tests. Haematological and biochemical laboratory parameters will be measured at specific time points. Clinically relevant abnormal values will be graded, tabulated and a trend analysis could be performed if deemed necessary. The monitored data of this study will be available in September 2021.

1172

### EVALUATION OF IMMUNOGENICITY AND PROTECTIVE EFFICACY OF DNA VACCINES ENCODING FULL LENGTH AND TRUNCATED PLASMODIUM FALCIPARUM CIRCUMSPOROZOITE PROTEIN ADMINISTERED VIA IN VIVO ELECTROPORATION

Clifford Hayashi<sup>1</sup>, Yi Cao<sup>1</sup>, Hayk Simonyan<sup>2</sup>, Colin N. Young<sup>2</sup>, Yukari Usuda<sup>1</sup>, Fidel Zavala<sup>3</sup>, Nirbhay Kumar<sup>1</sup>

<sup>1</sup>Department of Global Health, Milken Institute School of Public Health, George Washington University, Washington, DC, United States, <sup>2</sup>Pharmacology and Physiology, School of Medicine, George Washington University, Washington, DC, United States, <sup>3</sup>Johns Hopkins Malaria Research Institute, Baltimore, MD, United States

*Plasmodium falciparum* circumsporozoite protein (PfCSP) is the leading pre erythrocytic vaccine target, however PfCSP subunit vaccines have not reached success in eliciting complete protection. PfCSP contains three major domains: an N terminal domain (NTD), a central repeat domain, and a C terminal domain (CTD). Sequences in the repeat domain and in the upstream junctional region are the major targets of protective antibodies. The majority of T cell epitopes are located within the CTD, and as such may account for genetic restriction of immune responses. Also, antibodies targeted against this domain have been identified to be non-protective. We sought to evaluate immunogenicity and strain specificity of PfCSP in the form of DNA vaccines. Balb/c and C57Bl/6 mice were immunized with DNA plasmids encoding full length CSP (aa 1-397) and 3 different CTD truncated CSP: SS/NR/C12 (aa 1-284, truncated 12 amino acids downstream of the repeat domain); SS/NR/Th-Tc (aa 1-337, retaining Th-Tc and T\* cell epitope); and SS/NR/Th3R (aa 1-370, retaining CTD up to the Th3R T cell epitope) via *in vivo* intramuscular electroporation (EP). Immunogenicity of the DNA vaccines was evaluated by analyzing PfCSP specific antibody levels. Immune protection from sporozoite challenge using transgenic *P. berghei* expressing PfCSP and luciferase (Pb-PfCSP-Luc) was assessed by *in vivo* bioluminescence imaging and blood stage parasitemia. In C57Bl/6 mice, high levels of specific antibodies were induced by all four DNA vaccines. However, in Balb/c mice, full length, SS/NR/Th-Tc, and SS/NR/Th3R induced high antibody levels while SS/NR/C12 induced significantly lower levels. When challenged by Pb-PfCSP-Luc parasites, all C57Bl/6 mice had reduced liver burdens compared to the control. In Balb/c mice, Full length, SS/NR/Th-Tc and SS/NR/Th3R groups had reduced liver burdens compared to the control, while SS/NR/C12 showed no statistical difference. Our study demonstrates markedly improved functional immunogenicity of PfCSP DNA vaccines by EP and also reaffirms the importance of T cell epitopes in the CTD for species transcending immunogenicity.

1173

### PROLONGING MALARIA IMMUNITY WITH MOUSE CYTOMEGALOVIRUS VACCINATION

Komi Gbedande<sup>1</sup>, Samad A. Ibitokou<sup>1</sup>, Michael G. Brown<sup>2</sup>, Mariapia Degli-Esposti<sup>3</sup>, Robin Stephens<sup>1</sup>

<sup>1</sup>Department of Internal Medicine, Division of Infectious Diseases, University of Texas Medical Branch, Galveston, TX, United States,

<sup>2</sup>Department of Medicine, University of Virginia, Charlottesville, VA, United States, <sup>3</sup>Centre for Experimental Immunology, Lions Eye Institute, Nedlands, Australia

Development of a long-lived vaccine against malaria remains a major priority. Immunity to *Plasmodium* infection and vaccination both decay. In mouse models, both B and T cells are required for immunity. However, decay of protection correlates with loss of malaria-specific T cells, not antibody. Whole parasite vaccines, like infection and drug cure, protect. However, sterile immunity from infection or vaccination last less than 200 days, while effector T cells (Teff) decay. Therefore, we have reverse-engineered a vaccine strategy to induce a long-lived antibody response with live malaria vaccination, followed by a boost to the Teff response to prolong protection. Cytomegalovirus (CMV) is a chronic vaccine vector that induces T cell-mediated immunity and shows promise against SIV, tuberculosis and liver-stage malaria. Therefore, we used MCMV to test our hypothesis that chronic stimulation of Teff activation would prolong protection by a live parasite vaccine. MCMV encoding *P. chabaudi* MSP-1 epitope B5 (MCMV-B5) and B5 TCR Transgenic T cells were used to follow the MCMV vector-induced malaria-specific T cell response. We observed that Chronic MCMV infection protected mice from parasite upon *P. chabaudi* infection. Consistent with this protection, vaccination with MCMV-B5 activated and maintained B5 T cells, and promoted generation of Teff, which we have previously shown to be protective, for 2.5 months. Importantly, boosting the live malaria vaccine with MCMV synergistically led to longer protection from *P. chabaudi* parasitemia. In investigating the mechanisms of protection, we found that IFN $\gamma$  maintained by MCMV is required for prolonged protection. Furthermore, blocking IFN $\gamma$  before challenge led to lower IL-12 production upon infection. As IL-12 is known to boost enhance antigen-presenting cell function and phagocytosis, we are currently investigating these pathways. Our findings suggest methods and mechanisms to effectively prolong immunity to *Plasmodium* infection with CMV vectored chronic vaccines to redress the problem of short-lived protection to malaria infection and vaccines which is known to be due to decay of T cell memory.

### ANTI-PFGARP IS ASSOCIATED WITH DECREASED PLASMODIUM FALCIPARUM PARASITEMIA IN KENYAN CHILDREN

Hannah W. Wu<sup>1</sup>, Sunthorn Pond-tor<sup>1</sup>, Fredrick Olewe<sup>2</sup>, Christina Nixon<sup>1</sup>, Ronald Stuart<sup>1</sup>, Jenna Zuromski<sup>1</sup>, Jennifer F. Friedman<sup>1</sup>, Catherine Forconi<sup>3</sup>, Ann Moorman<sup>3</sup>, Bernhards Ogutu<sup>4</sup>, John M. Ong'echa<sup>5</sup>, Jonathan D. Kurtis<sup>1</sup>

<sup>1</sup>Center for International Health Research, Brown University Medical School, Providence, RI, United States, <sup>2</sup>Ahero Clinical Trials Unit, Kenya Medical Research Institute, Ahero, Kenya, <sup>3</sup>Department of Medicine, UMass Medical School, Worcester, MA, United States, <sup>4</sup>Centre for Clinical Research, Kenya Medical Research Institute, Kisumu, Kenya, <sup>5</sup>Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya

In prior studies, we identified PfGARP as a target of antibodies which induce parasite programmed cell death. Vaccination with PfGARP induces significant protection against *Plasmodium falciparum* challenge in non-human primates and anti-PfGARP antibody levels are associated with decreased parasitemia in adolescents and adults. In the current study, we measured anti-PfGARP IgG antibody levels in N=394 children, ages 2-7 yrs living in a holo-endemic region of western Kenya and related these levels to parasite prevalence in a cross-sectional analysis. When analyzed as a continuous variable, even after adjusting for potential confounders including age and sex, higher anti-PfGARP IgG levels were significantly related to lower parasitemia ( $P = 0.04$ ). When analyzed as tertiles, children with low levels of anti-PfGARP IgG (n=129) had 7.6-fold higher parasitemia levels compared to children with high levels of anti-PfGARP IgG (n=134),  $P = 0.002$ . This result remained significant even after we restricted the analysis to those children who were parasitemic at the time of sample collection. These results demonstrate that PfGARP antibody

levels are associated with protection from parasitemia in young children and further support targeting PfGARP as a vaccine candidate for pediatric falciparum malaria.

### ROLE OF CD4 T CELLS IN PFS230 VACCINE ANTIBODY RESPONSE

**Bergeline C. Nguemwo Tentokam**<sup>1</sup>, Charles Anderson<sup>1</sup>, Zoltan Beck<sup>2</sup>, Lynn Lambert E. Lambert<sup>1</sup>, Kelly M. Rausch<sup>1</sup>, Olga Muratova<sup>1</sup>, Emma Barnafo<sup>1</sup>, David L. Narum<sup>1</sup>, Irfan Zaidi<sup>1</sup>, Gary R. Matyas<sup>2</sup>, Mangala Rao<sup>2</sup>, Carl R. Alving<sup>2</sup>, Alan Sher<sup>3</sup>, Dragana Jankovic<sup>3</sup>, Patrick E. Duffy<sup>1</sup>

<sup>1</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>U.S. Military HIV Research Program, Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>3</sup>Immunobiology Section, Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

One of the most promising strategies to prevent *Plasmodium falciparum* in endemic areas is the implementation of malaria transmission-blocking vaccines (TBV). TBV act by preventing the development of *P. falciparum* in the mosquito vector and limit further malaria transmission. Pfs230 is a *P. falciparum* gamete antigen and the most advanced TBV candidate. The development of TBV malaria vaccines is challenging, due in part to the difficulty to induce sustained high-titer antibody responses. To address this problem, adjuvants and carrier proteins are employed to enhance immunogenicity of parasite targets. We investigated the role of CD4 T cells in vaccine-induced immune responses to Pfs230 domain 1 (Pfs230D1) conjugated with Exoprotein A carrier and formulated with ALFQ (an AS01B biosimilar) adjuvant in C57BL/6 mice. By depleting CD4 T cells at different times during the immunization, we demonstrated Th lymphocytes are required for optimal increase in antibody titers after the 2<sup>nd</sup> but not the 3<sup>rd</sup> vaccination. Moreover, injection of Pfs230D1 monomer at the time of the 3<sup>rd</sup> immunization was sufficient to induce peak titers and enhance antibody functional activity to the same levels observed when Pfs230D1 plus the carrier were injected. Taken together these findings suggest that the formulation of vaccine with the carrier may not be beneficial after 2<sup>nd</sup> immunization because although help provided by CD4 T cells play an essential role in enhancing humoral response after the first two doses vaccination, it is dispensable for the boost effect after the third. On-going experiments include mouse and monkey studies to extend these initial findings and to evaluate the role of different adjuvants at the time of 3<sup>rd</sup> immunization. This study highlights the ability to efficiently boost with monomer as opposed to conjugate; and describes the requirement for T cell help for vaccine boosting and maturation during Pfs230D1 vaccination. Defining the characteristics of T cells required for efficient boosting of the vaccine response in preclinical studies can inform the design of more potent combinations of vaccine and adjuvants to overcome malaria-induced immunoregulation.

1176

### DEVELOPMENT OF AN INTRANASAL/ORAL SPIRULINA-BASED PFCSP MALARIA VACCINE

**Annette M. Seilie**<sup>1</sup>, Chaitra Parthiban<sup>1</sup>, Tracy Saveria<sup>2</sup>, James M. Roberts<sup>2</sup>, Michael Tasch<sup>2</sup>, Sean C. Murphy<sup>1</sup>

<sup>1</sup>Department of Laboratory Medicine and Pathology, University of Washington, Seattle, WA, United States, <sup>2</sup>Lumen Bioscience Inc., Seattle, WA, United States

Antibodies against the *Plasmodium falciparum* circumsporozoite protein (PfCSP) can block hepatocyte infection by sporozoites and protect against malaria. Most PfCSP-targeted vaccines like RTS,S require needle-based administration. Needle-free vaccination strategies are desirable. Here, we evaluated *Arthrospira platensis* algae (commonly called 'spirulina') as a malaria vaccine platform. Spirulina has a strong safety profile and is widely

used as a human food source. Lumen Bioscience genetically engineered spirulina to express virus-like particles (VLPs) consisting of woodchuck variant (WHcAg) of the human hepatitis B core (HBcAg) bearing a (NANP)<sub>15</sub> PfCSP antigen on its surface. Experimental vaccine biomass consisting of spirulina bearing WHcAg VLPs bearing externally-facing PfCSP was dried and remained stable for one year without refrigeration. PfCSP-spirulina biomass administered three times orally to BALB/cj mice was safe and moderately immunogenic, with low rates of protection (20%) against challenge with PfCSP-expressing *P. yoelii* sporozoites. To enhance priming, PfCSP-spirulina was administered intranasally, resulting in uniformly strong anti-PfCSP antibodies that were enhanced by a oral PfCSP-spirulina booster. Intranasal priming was stronger using an extract of the PfCSP-spirulina biomass than raw biomass. Upon challenge, female BALB/cj mice showed high titer PfCSP responses from the intranasal priming/oral boosting regimen and were highly protected against subcutaneous challenge with PfCSP-expressing *P. yoelii* two- or twelve-weeks post-vaccination (70%). The intranasal/oral PfCSP-spirulina vaccine was also safe and highly immunogenic in C57BL/6 mice. Thus, our data demonstrates that intranasal/oral spirulina vaccination induces protective PfCSP antibodies in rodent models of malaria and warrants further development as a promising candidate malaria vaccine platform.

### EVALUATING THE ENTOMOLOGICAL IMPACT OF THE 2019 PMI-SUPPORTED ITS CAMPAIGN IN ZAMBIA ON MALARIA TRANSMISSION PARAMETERS

**Mohamed N. Bayoh**<sup>1</sup>, Nduka Iwuchukwu<sup>1</sup>, Rabbecca Ngwira<sup>1</sup>, Willy Ngulube<sup>2</sup>, Allison Belemvire<sup>3</sup>, Paul Psychas<sup>4</sup>, Daniel Impoinvil<sup>5</sup>, Ben Johns<sup>6</sup>, Kelley Ambrose<sup>7</sup>, Aklilu Seyoum<sup>6</sup>

<sup>1</sup>U.S. President's Malaria Initiative (PMI) VectorLink Project, Abt Associates, Lusaka, Zambia, <sup>2</sup>National Malaria Elimination Program, Lusaka, Zambia, <sup>3</sup>PMI, USAID, Washington, DC, United States, <sup>4</sup>PMI, Malaria Branch, Centers for Disease Control and Prevention (CDC), Lusaka, Zambia, <sup>5</sup>PMI, Malaria Branch, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, <sup>6</sup>U.S. President's Malaria Initiative (PMI) VectorLink Project, Abt Associates, Rockville, MD, United States, <sup>7</sup>U.S. President's Malaria Initiative (PMI) VectorLink Project, Abt Associates, Cambridge, MA, United States

Entomological monitoring of vector control interventions is vital for impact evaluation. The Zambian National Malaria Elimination Program rotated clothianidin-based insecticide from Actellic CS. In October/November 2019, the U.S. President's Malaria Initiative (PMI) funded the VectorLink project to support clothianidin-based indoor residual spraying (IRS) in 17 districts in Zambia for the first time. Entomological monitoring was conducted monthly or bi-monthly 4 months before and 5 months after IRS at sentinel sites in 5 districts, with one unsprayed (control) site per district. Indoor density (ID), human biting rate (HBR), parity rate, and sporozoite rate (SR) were determined. The two main vector complexes found were *Anopheles funestus* s.l. (80.4%) and *An. gambiae* s.l. (19.3%). Seasonal increases in vector abundance were seen in both sprayed and control sites after IRS. The pre- and post-IRS mean ID of *An. funestus* s.l. increased at sprayed (2.9 to 3.6 vectors/house) and control (4.2 to 5.0) sites; *An. gambiae* s.l. ID also increased at sprayed (0.1 to 1.0) and control (0.02 to 0.6) sites. The pre- and post-IRS *An. funestus* s.l. HBR increased at sprayed (21.0 to 21.3 bites/night) and control (5.5 to 35.5) sites; *An. gambiae* s.l. HBR also increased at sprayed (0.7 to 12.0) and control (0.1 to 3.2) sites. Biting times and location did not shift post-IRS. *An. funestus* s.l. parity decreased (56% to 39%, p<0.001) at sprayed sites and increased (52% to 57%) at control sites. *An. gambiae* s.l. parity decreased (48% to 39%) at sprayed sites and increased (33% to 56%) at control sites. The SR for *An. funestus* s.l. was lower at sprayed vs control sites (2.9% vs 3.5%; p=0.635) but SR for *An. gambiae* s.l. was higher at sprayed vs control sites (0.9% vs 0.6%, p=0.673). Clothianidin IRS may not overcome the seasonal increases in vector abundance in sprayed areas. However, vector parity, a key IRS metric in entomological impact evaluation, was reduced.

Similar results have been observed using Actellic CS-based IRS over 4 years of past use. Alternative interventions such as ITNs and complementary interventions such as larval source management should be considered.

### OPTIMISATION OF SGRNA EXPRESSION WITH RNA POL III REGULATORY ELEMENTS FOR THE DEVELOPMENT OF A SPLIT DRIVE IN ANOPHELES STEPHENSI

**Joshua X. Ang**, Estela Gonzalez, Katherine Nevard, Lewis Shackleford, Mireia Larrosa, Matthew Edwards, Michelle A. Anderson, Luke Alphey

*The Pirbright Institute, Pirbright, United Kingdom*

*Anopheles stephensi* is a competent vector for *Plasmodium falciparum* and *P. vivax*. It is the main vector of urban malaria in South-east Asia and since 2012 has invaded into several countries in East Africa. The invasion and spreading of this mosquito in Africa threatens all the current efforts for malaria control which rely mainly on extensive insecticide spraying and insecticide-treated bed nets. Although these methods have shown to be highly efficient and have helped to reduce malaria incidence, the occurrence and increase of insecticide resistance as well as environmental risks have weakened their use. Researchers have therefore turned to genetic approaches such as CRISPR/Cas9-based gene drives in recent years and were successful in developing such drives in *An. gambiae* and *An. stephensi*. We are interested in the development of a geographically confineable gene drive system that would allow a local and transient control of a mosquito population. In our study, we assessed two components of the split drive system: the A element, located in the cardinal (*cd*) locus, being an sgRNA expressed by an endogenous RNA pol III regulatory element (U6A, U6B, U6C, or 7SK), and the B element being a zero-population growth (*zpg*)-driven Cas9 which would drive the A element. Using a series of experimental crosses, we were able to determine factors which may affect the viability of the drive. Inheritance rates of the A element was found to be increased up to 71-100% and that the increment depended highly on the pol III promoters driving the sgRNA. Results also show lower homing rates to be associated with lower cutting rates and vice versa, indicating the significance of optimising sgRNA expression levels to improve homing efficiency. Interestingly, maternal deposition of Cas9 was also found to induce both cutting and/or homing of up to 100% in the germline of individuals inheriting only the A element. Taken together, the conclusions obtained from this study will be used to inform future designs and development of confineable gene drives in *An. stephensi*.

### ADVANCING EVIDENCE FOR THE GLOBAL IMPLEMENTATION OF SPATIAL REPELLENTS (AEGIS)

**John P. Grieco**<sup>1</sup>, Eric Ochomo<sup>2</sup>, Steve Harvey<sup>3</sup>, Suzanne Van Hulle<sup>4</sup>, Issaka Sagara<sup>5</sup>, Korelege Hasitha Aravinda Tissera<sup>6</sup>, D. S. Anoja F. Dheerasinghe<sup>6</sup>, Nicole L. Achee<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health and Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, <sup>4</sup>Catholic Relief Services, Baltimore, MD, United States, <sup>5</sup>Malaria Research and Training Center, University of Science, Techniques and Technologies, Bamako, Mali, <sup>6</sup>National Dengue Control Unit, Epidemiology Unit, Ministry of Health, Colombo, Sri Lanka

Goals of malaria elimination and eradication and the expanding scope of *Aedes*-borne viruses (ABVs) like dengue require the development of new, vector control tools to complement available interventions in order to meet public health demands. Spatial Repellents (SR) are one such tool. SRs are products designed to release volatile chemicals into the air and prevent human-vector contact within the treated space thus reducing pathogen transmission. A number of clinical trials have demonstrated positive impact against malaria using SRs, however data is still lacking to confidently support use for public health. The AEGIS program will evaluate a novel,

scalable SR vector control product with the potential to contribute to dramatic gains in malaria and ABV control in a variety of relevant contexts. This will be achieved through three cluster-randomized-controlled trials in Kenya, Mali, and Sri Lanka, one operational research study in Uganda, and the integration of social science at several study sites. The evidence generated is meant to provide data on SR impact, feasibility, and safety to fill the current gaps required for an endorsement by the WHO for a global SR policy recommendation. Such a recommendation will support disease endemic countries in the adoption and implementation of SR products and strategies in national vector control programs.

### FIVE-YEAR IMPACT OF TARGETED INDOOR RESIDUAL SPRAYING WITH PIRIMIPHOS-METHYL IN AN AREA OF HIGH MALARIA TRANSMISSION IN LUAPULA PROVINCE, ZAMBIA

**Jessica L. Schue**<sup>1</sup>, Mike Chaponda<sup>2</sup>, Mbanga Muleba<sup>2</sup>, Jean-Bertine Kabuya<sup>2</sup>, James Sichivula Lupiya<sup>2</sup>, Tamaki Kobayashi<sup>3</sup>, Amy Wesolowski<sup>3</sup>, Timothy Shields<sup>3</sup>, Jennifer C. Stevenson<sup>4</sup>, Douglas E. Norris<sup>4</sup>, William J. Moss<sup>3</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health Department of International Health, Baltimore, MD, United States, <sup>2</sup>Tropical Diseases Research Centre, Ndola, Zambia, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health Department of Epidemiology, Baltimore, MD, United States, <sup>4</sup>Johns Hopkins Bloomberg School of Public Health Department of Molecular Microbiology and Immunology, Baltimore, MD, United States

A strategy of targeted indoor residual spraying (IRS) was adopted in Nchelenge District, Zambia, when the program switched to a long-lasting form of pirimiphos-methyl (Actellic 300CS) in 2014 and conducted five rounds of annual spraying prior to the annual rainy season. Malaria transmission in Nchelenge District is holoendemic and the two primary vector species, *An. funestus* and *An. gambiae*, peak at different times of the year. Parasite prevalence by rapid diagnostic test (RDT) and vector abundance in households were measured in the community from April 2012 - November 2019 from monthly cross-sectional surveys. Weekly malaria cases from passive surveillance at the health centers were also collected. In an adjusted analysis of households within the targeted spray areas that compared the pre-Actellic years to the last year of Actellic use, there was a slight but insignificant reduction in the odds of being RDT positive in households that received IRS compared to households that did not (OR: 0.83, 95% CI: 0.63 - 1.07). IRS did not reduce the number of *An. funestus* caught within a household (IRR: 1.33 95% CI: 0.91 - 1.94) however there was a moderate but insignificant reduction in *An. gambiae* counts (IRR: 0.68, 95% CI: 0.41, - 1.11). Similar results were found when the analysis was expanded to include unsprayed households outside of the targeted IRS areas. In an adjusted model using serial cross-sectional data for the years of Actellic use (2014-2019), there was a protective effect of living in a targeted spray area on the odds of being RDT positive (OR: 0.74 95% CI: 0.59 - 0.91) but no reduction in the odds of being RDT positive in sprayed vs unsprayed households. There was a 25% reduction in the incidence of malaria at clinics located in the targeted areas compared to clinics outside of targeted areas after 4 years Actellic use (IRR: 0.75, 95% CI: 0.71 - 0.80), although this model does not account for other changes in malaria control interventions that occurred during this time. The targeted IRS strategy used in this high transmission area had limited impact on vector counts and parasite prevalence in the community, but overall malaria incidence in health centers declined.

### COMPARATIVE EFFICACY OF SIX DIFFERENT TYPES PYRETHROID PIPERONYL BUTOXIDE (PBO) AGAINST PYRETHROID RESISTANT MALARIA VECTORS IN WEST AND CENTRAL AFRICA

Abel Agbevo<sup>1</sup>, Benjamin Menze<sup>2</sup>, Augustin Fongnikin<sup>1</sup>, Alphonsine Koffi<sup>3</sup>, **Corine A. Ngufor**<sup>1</sup>

<sup>1</sup>CRECILSHTM Collaborative Research Programme, Cotonou, Benin, <sup>2</sup>Centre for Research in Infectious Diseases, Yaounde, Cameroon, <sup>3</sup>Institute Pierre Richet, Bouake, Côte D'Ivoire

Pyrethroid-PBO nets have become available for malaria vector control and are being deployed in Africa. Several brands of these nets with varying characteristics and technical specifications have been developed presenting extra choice to vector control programs. Studies investigating the comparative performance of these different types of pyrethroid-PBO nets in different settings are essential. We performed a series of experimental hut trials to compare the efficacy and wash resistance of six types of pyrethroid-PBO nets (Olyset Plus, PermaNet 3.0, Duranet Plus, Duranet Plus 2.0, Veeralin and Tsara Boost) against wild pyrethroid resistant malaria vectors (*Anopheles gambiae* s.l and *Anopheles funestus*) in experimental huts in Cameroon, Cote D'Ivoire and Benin. Comparisons were also made with pyrethroid-only nets. Susceptibility bioassays showed that the vector populations in all three study sites were highly resistant to pyrethroids and resistance could be mitigated by pre-exposure to PBO. Mosquito mortality was higher in huts with pyrethroid-PBO nets compared to pyrethroid-only nets in all study sites (20-40% vs. 10-25%). The levels of improved effect observed varied between sites and between the different types of pyrethroid-PBO nets and were substantially low compared to other newly developed types of dual insecticide ITNs tested in these sites. Wash resistance depended on the type of pyrethroid and the initial dose of both active ingredients on the net. DuraNet Plus, DuraNet Plus 2.0, Veeralin and Tsara Boost showed non-inferiority in terms of mosquito mortality and/or blood-feeding inhibition to at least one of the two brands which have so far demonstrated an improved epidemiological impact in community randomised trials (Olyset Plus and PermaNet 3.0). The laboratory bioassays (cone bioassays and tunnel tests) and chemical analysis results corroborated the findings in the experimental huts. Considering the low levels of improved effect observed, it is not clear whether either of these nets would have the same epidemiological impact against malaria demonstrated with pyrethroid-PBO nets in trials in East Africa.

### UNIVERSAL LONG-LASTING INSECTICIDAL NETS COVERAGE ON BIKO ISLAND: THE CHALLENGE OF THE NET USE GAP

**Carlos A. Guerra**<sup>1</sup>, Olivier Tresor Donfack<sup>2</sup>, Marcos Mbulito Iyanga<sup>2</sup>, Jordan M. Smith<sup>1</sup>, Restituto Mba Avue<sup>2</sup>, Liberato Motobe Vaz<sup>2</sup>, Lucas Ondo<sup>2</sup>, Jose Antonio Mba Ela<sup>2</sup>, Jeremias Nzamio Mba Eyono<sup>2</sup>, Godwin Fuseini<sup>2</sup>, Wonder P. Phiri<sup>2</sup>, Guillermo A. García<sup>1</sup>

<sup>1</sup>Medical Care Development International, Silver Spring, MD, United States,

<sup>2</sup>Medical Care Development International, Malabo, Equatorial Guinea

Despite the known community effects of long-lasting insecticidal nets (LLINs) against malaria, achieving and maintaining universal coverage remains a challenge in many settings. Particularly challenging is narrowing the net use gap, which in most cases appears linked to lack of access more than to behavioral factors. In 2015, vector control on Bioko Island shifted towards maximizing LLIN coverage through triennial, mass-distribution campaigns (MDC) to guarantee LLIN access accompanied by intensive behavior change and communication efforts to promote use. We assessed LLIN coverage and the net use gap using malaria indicator survey (MIS) and MDC data to estimate standard LLIN indicators at a 1x1 km area grid. Data from the 2018 MDC provided the number of LLINs distributed while the 2018 and 2019 MIS data allowed quantification of LLINs observed by surveyors and of population use. On average, the 2018 and 2019 MIS took place 4.2 [range: 1.2 to 7.4] and 16.3 [range: 13.2 to 20.0] months post MDC. Following the MDC, virtually 100% of the Bioko population

had access to LLINs. Mean population access based on LLINs observed declined to 48.4% [IQR: 21.5-70.9] in 2018 and remained at similar levels a year later (52.8% [IQR: 30.8-80]). Median LLIN use amongst respondents was 51.1% [IQR: 33.3-68.3] in 2018 and 40.0% [IQR: 19.4-55.0] in 2019. Median LLIN use to access ratio based on observed LLINs was 1.0 and 0.8, respectively, but in many areas this ratio was higher than 1, suggesting that there was an over demand of nets among those using them. Despite universal LLIN coverage was guaranteed during MDC, substantial LLIN loss occurred soon after the campaign, leaving around half of the population without access to a LLIN. There was considerable spatial variation in LLIN coverage, with some communities better protected than others. These findings corroborate that the net use gap in some areas of Bioko Island cannot be explained by lack of access. This translates into sub-optimal impact of LLINs and calls for a change in current integrated vector control strategies on Bioko Island that focuses on other mainstream interventions.

### CHALLENGE OF ESTABLISHING AN EXPERIMENTAL MOSQUITO FEEDING MODEL OF PLASMODIUM FALCIPARUM IN AN URBAN CENTER IN MALAWI

**Jessy Goupeyou-Youmsi**<sup>1</sup>, Joyce Nyirongo<sup>1</sup>, Lauren L. Cohee<sup>2</sup>, Karl Seydel<sup>3</sup>, Robert S. McCann<sup>2</sup>, Mark L. Wilson<sup>4</sup>, Edward D. Walker<sup>3</sup>, Clarissa Valim<sup>5</sup>, Don P. Mathanga<sup>1</sup>, Themba Mzilahowa<sup>1</sup>, Miriam K. Laufer<sup>2</sup>

<sup>1</sup>College of Medicine University of Malawi, Blantyre, Malawi, <sup>2</sup>University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Michigan State University, East Lansing, MI, United States, <sup>4</sup>University of Michigan School of Public Health, Ann Arbor, MI, United States, <sup>5</sup>Boston University School of Public Health, Boston, MA, United States

Characterizing the infectious reservoir of *Plasmodium* is an active area of research with potential to contribute to malaria elimination. A critical component of defining the infectious reservoir is identifying who is carrying gametocytes. Beyond that, mosquito membrane feeding assays (MFAs) are a commonly used technique to assess human-to-mosquito transmission. To validate and optimize MFAs in Malawi, we sought gametocyte donors in Southern Malawi during two rainy seasons (December 2019 to May 2020, and November 2020 to March 2021). Patients diagnosed with malaria by rapid diagnostic tests (RDTs) at health centers (HCs) within 20 km of our insectary facilities in urban Blantyre, were screened for gametocytes using blood smears performed at the time of RDT diagnosis and read by expert research microscopists. Out of the 1008 blood smears collected in three HCs, 35 (4%) were found positive for gametocytes. The gametocyte carriage rate among patients was high at the onset of the rainy season and gradually decreased over time (7%, 7%, 1%, 5%, 3%, 2% and 0%, for November, December, January, February, March, April and May, respectively). The median gametocyte density (interquartile range) was 128 (-432 to 848) gametocytes/ $\mu$ L. For the two HCs closer to the insectary facilities (within a radius of 5.4 km), participants were asked to provide venous blood for MFAs; only 6 out of 14 consented. The main reason of refusals was fears concerning SARS-CoV-2 as the venous blood draw would occur at the district referral hospital, the center of COVID-19 care, which is adjacent to the insectary. Overall, rates of gametocyte carriage and willingness to participate were lower than anticipated. The preliminary results of this study show the difficulty in establishing MFAs in an urban center with low transmission intensity.

### PILOTING A NOVEL GEOSPATIAL PLATFORM TO SUPPORT INDOOR RESIDUAL SPRAYING (IRS) FOR MALARIA CONTROL IN CUANDO CUBANGO, ANGOLA

Christina Riley<sup>1</sup>, Alinda Lauer<sup>1</sup>, Franco Martin<sup>2</sup>, Cani Pedro<sup>2</sup>, Sérgio Lopes<sup>3</sup>, Ana Direito<sup>3</sup>, Manuel Lando<sup>3</sup>

<sup>1</sup>Akros, Lusaka, Zambia, <sup>2</sup>National Malaria Control Program, Luanda, Angola, <sup>3</sup>The MENTOR Initiative, Luanda, Angola

Reveal is an open-source platform and digital global good that puts geospatial technology in the hands of Indoor Residual Spray (IRS) teams to support campaign delivery and management. The platform uses satellite imagery and enumerated residential structures to guide the movement of spray teams and collect data while enabling real-time monitoring of IRS delivery. Here we discuss the coverage and user experience of piloting Reveal during the IRS campaign in Menongue Sede in Cuando Cubango province, Angola from December 2020 through March 2021. Field teams were trained to use the platform to identify residential structures for spray and record structure spray status. Reveal-generated data guided campaign decisions to improve coverage and efficiency. Using Reveal, teams visited 58,418 of 76,177 total enumerated structures, indicating a total found coverage of 76.3%. Of those visited, 1,223 structures were ineligible for spraying. Of the remaining 57,208 structures, 53,543 were sprayed yielding a spray success rate of 93.6%. Real-time spatial representation of implementation progress enabled field teams to deploy their resources with greater efficiency and precision. Supervisors used Reveal to identify areas with low coverage and subsequently prioritize areas to be revisited. Daily syncing of data into custom web dashboards strengthened communication between supervisors, field teams, and local authorities. Custom safeguarding mechanisms strengthened data quality by reducing opportunity to capture inaccurate data. Challenges included limited connectivity, which reduced the frequency with which field teams were able to sync their data and review spray progress. However, teams overcame this barrier through novel strategies such as sending individual team members to locations with connectivity to sync devices. Factors that were critical to the overall success of this pilot include careful selection and thorough training of data collectors, and meticulous logistical planning to ensure proper handling of the mobile client. The Reveal approach can be used in future campaigns to continue to strengthen precision and increase impact.

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>3</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>4</sup>Rwanda Biomedical Centre Malaria and Other Parasitic Diseases Division, Ministry of Health, Kigali, Rwanda, <sup>5</sup>University of Rwanda, Kigali, Rwanda, <sup>6</sup>National Malaria Control Program, Ministry of Health, Maputo, Mozambique, <sup>7</sup>Tropical Health LLP, Baltimore, MD, United States, <sup>8</sup>National Malaria Elimination Programme, Federal Ministry of Health, Abuja, Nigeria, <sup>9</sup>Iboda Health International, Abuja, Nigeria

Global progress in the fight against malaria has stalled due in part to increased resistance to pyrethroid insecticides in key vector populations. New, dual-active ingredient insecticide-treated nets (ITNs) that are effective against insecticide-resistant mosquitos have been developed. The New Nets Project, funded by a partnership between Unitaid and the Global Fund to Fight AIDS, Tuberculosis and Malaria and led by IVCC, is

conducting observational analyses accompanying the pilot distribution of these new ITNs in Burkina Faso, Mozambique, Nigeria, and Rwanda to generate evidence on their effectiveness and cost-effectiveness. One study component uses quantitative and qualitative methods to observe and describe time spent in and out of ITNs and to explore the determinants of ITN use through key informant interviews and focus group discussions with community members. Results will be used to inform and refine transmission dynamics model and to augment epidemiological and entomological findings by providing additional context. Participants described getting ITNs primarily through government distribution campaigns. There was variability across and within countries on whether households felt they received enough ITNs for their household and at the desired frequency. There was also variability in whether participants felt they could access ITNs through other means, with some participants having bought ITNs at pharmacies, while others said that the campaigns were the only way they could get an ITN. The inability to replace old, torn ITNs was repeatedly noted as a barrier to using ITNs. Other barriers included excessive heat and the smell of the ITNs. Benefits to using ITNs included protection from malaria, protection from mosquitoes and other insects, and warmth. Heterogeneity in access, perception, and barriers to use could have substantial impact on ITN effectiveness. This interim analysis highlights the importance of tracking qualitative evidence over time in pilot areas. Interview and focus group discussion guides have been refined based on findings from this interim analysis and will be used in subsequent rounds of data collection.

### DEVELOPMENT OF A SUSTAINABLE ALTERNATIVE MATERIAL FOR LONG-LASTING INSECTICIDAL NETS: CELLULOSE-BASED INSECTICIDAL FIBER YARN FOR MALARIA CONTROL

Sydney Brake<sup>1</sup>, Diego Gomez Maldonado<sup>1</sup>, Sarah Zohdy<sup>2</sup>, Maria S. Peresin<sup>1</sup>

<sup>1</sup>Auburn University, Auburn, AL, United States, <sup>2</sup>President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

Long-lasting insecticidal nets (LLINs) are an essential vector control tool for the prevention of malaria. These nets exhibit prolonged insecticidal properties even after constant exposure to environmental factors and repeated washing. Using material processing techniques, long-lasting insecticidal activity has been achieved through migration of insecticide particles to the surface of the filaments over time. These nets have contributed to great successes in malaria control and will continue to be distributed as countries make progress towards universal coverage; however, existing LLINs are made from nonbiodegradable and nonrenewable petroleum-based polymers. Alternatively, cellulose, an abundant natural polymer, is evaluated in this study due to its favorable properties which allow it to perform similarly to common synthetic polymeric materials. Green chemistry approaches, including the use of deep-eutectic solvents and ionic liquids, were used to disperse the cellulose pulp, and various modern fiber-spinning methods, including wet-spinning, were employed to create a cellulose yarn. The pyrethroid insecticide deltamethrin and the synergist piperonyl butoxide (PBO) were evaluated for their stability in the solvents to ensure the effectiveness of the processing parameters. Techniques such as Fourier-transform infrared spectroscopy (FTIR) and nuclear magnetic resonance spectroscopy (NMR) were used to characterize the resultant fiber yarn and fundamental interactions with pyrethroids and evaluate slow release time scale. This work describes the development and evaluation of a cellulose-based renewable and biodegradable fiber yarn. These findings can be considered for the production of novel LLINs for effective and sustainable global malaria control.

## LEVERAGING ROUTINE DATA FOR MALARIA VECTOR CONTROL EVALUATION: METHODOLOGICAL CONSIDERATIONS FOR CONDUCTING OBSERVATIONAL ANALYSES

Emily Beylerian<sup>1</sup>, Christelle Gogue<sup>2</sup>, Sarah Burnett<sup>2</sup>, Molly Robertson<sup>1</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>PATH, Washington, DC, United States

As new vector control tools become available, national malaria programs (NMPs) need to make data-driven decisions to inform their deployment. While randomized controlled trials provide high quality evidence on intervention efficacy, they are costly and sparse. The availability and quality of routine epidemiological and entomological surveillance data continues to improve and could provide a continual information source for decision-making. While broad guidance exists for evaluating malaria interventions using routine data, there is little guidance on best practices for vector control evaluations, which are particular in their entomological and ecologic scope and periodicity. We will present a framework for designing vector control evaluations using routine data sources. Through this framework, NMPs and partners can rapidly and consistently gain insights into the impact of vector control interventions in their countries. Analyses have been published or are underway by the Next Generation Indoor Residual Spray Project and the New Nets Project partnerships to document the impact of indoor residual spraying and various insecticide-treated net types in seven countries in sub-Saharan Africa. These evaluations have used a combination of programmatic epidemiological and entomological surveillance data to assess the impact of the interventions on vectors and disease burden. Based on these experiences, we will provide practical guidance on the design and implementation of vector control evaluations using routine data. Specific topics will include considerations for selecting and using interrupted time series (with or without a control group), difference-in-difference, counterfactual models, and other common designs; options for managing data quality issues; common covariates, their calculations, and data sources; and considerations for selecting follow-up periods for each intervention. These recommendations are designed to increase the frequency and rigor of vector control evaluations using available data sources, so that these evaluations can effectively support national and subnational vector control decisions.

## ABUNDANCE, BITING ACTIVITY AND PREFERENCE OF ANOPHELES SPECIES IN TWO IMPORTANT MALARIA ENDEMIC REGIONS OF COLOMBIA

Stefani Piedrahita<sup>1</sup>, Nelson Naranjo-Diaz<sup>1</sup>, Juan Camilo Hernandez<sup>1</sup>, Daniela Castañeda<sup>1</sup>, Gabriela Bolaños<sup>1</sup>, Vanessa Vargas<sup>1</sup>, Natalí Alvarez<sup>1</sup>, Sara Bickersmith<sup>2</sup>, Dra. Jan Conn<sup>2</sup>, Margarita Correa<sup>1</sup>

<sup>1</sup>Grupo de Microbiología Molecular, Escuela de Microbiología, Universidad de Antioquia, Medellín, Colombia, <sup>2</sup>The Griffin Laboratory, Wadsworth Center, New York State Department of Health, Albany, NY, United States

In Colombia, malaria is an important problem of public health and the Bajo Cauca-BC and Pacific region-PAC are currently the most malarious endemic areas in the country. Components of vector capacity are assessed to estimate the ability of mosquitoes to transmit pathogens. This work evaluated abundance, biting activity and preference of *Anopheles* mosquitoes collected in Bagre-BC, and in Buenaventura and Istmina-PAC, during 2018-2022, between 18:00 and 24:00 hours, using 70% barrier screens and protected human bait placed indoors and outdoors. A census was performed on the animals present at the sampling site on a 1 Km radius. Specimens were identified using morphological keys and molecularly confirmed by PCR-RFLP-ITS2. Biting activity and human biting rate (HBR) were determined. In addition, blood-sources were identified by PCR-Cytb in DNA extracted from midgut of resting mosquitoes. A total of 1987 *Anopheles* were collected, 528 specimens from Bagre-BC, 167 from Istmina and 1292 from Buenaventura-PAC. *Anopheles darlingi* and *An.*

*nuneztovari* were the most abundant species in BC and PAC, respectively. The HBR values were, for *An. nuneztovari*, 94 bites/person/night (b/p/n) in PAC, and 19.8 b/p/n for *An. darlingi* in BC; both had activity mainly indoors. The preferred blood-source for both mosquito species was humans; this predominantly anthropophilic preference supposes a high risk for humans. Other vertebrate sources included pigs, dogs and cows, which also indicates an opportunistic behavior. These findings should direct the implementation of control measures to minimize human-vector contact.

## OVERVIEW OF MALARIA TRANSMISSION FROM AN OBSERVATIONAL STUDY IN FOUR SUB-SAHARAN AFRICAN COUNTRIES

Julia Mwesigwa<sup>1</sup>, Christelle Gogue<sup>2</sup>, Joseph Wagman<sup>2</sup>, Kenzie Tynuv<sup>2</sup>, Peder Digre<sup>3</sup>, Baltazar Candrinho<sup>4</sup>, Aimable Mbituyumuremyi<sup>5</sup>, Joseph S. <sup>1</sup>PATH, Kampala, Uganda, <sup>2</sup>PATH, Washington, DC, United States, <sup>3</sup>PATH, Seattle, WA, United States, <sup>4</sup>National Malaria Control Program, Ministry of Health, Maputo, Mozambique, <sup>5</sup>Rwanda Biomedical Centre Malaria and Other Parasitic Diseases Division, Ministry of Health, Kigali, Rwanda, <sup>6</sup>PATH, Maputo, Mozambique, <sup>7</sup>National Malaria Elimination Programme, Federal Ministry of Health, Abuja, Nigeria, <sup>8</sup>Iboda Health International, Abuja, Nigeria, <sup>9</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>10</sup>IVCC, Liverpool, United Kingdom

Emergence of insecticide resistance in vector populations continues to threaten the effectiveness of malaria vector control tools, including insecticide-treated nets (ITNs) resulting in slowed progress toward malaria control and elimination. Through the New Nets Project, dual active ingredient ITNs (Interceptor® G2 [IG2] [BASF] and Royal Guard® [RG] [Disease Control Technologies]) have been piloted in several countries, alongside pyrethroid-piperonyl butoxide (PBO) and standard ITNs. Observational studies in Burkina Faso, Mozambique, Nigeria, and Rwanda aim to assess the effectiveness of these dual active ingredient ITNs. Sixteen districts from the four countries had baseline cross-sectional surveys to assess malaria prevalence, household ITN ownership from previous net campaign, and ITN use the previous night. In Rwanda, all household members were included, while other countries sampled only children under five. Two districts in Rwanda and one in Burkina Faso had surveys during and after net campaign, respectively. Malaria prevalence was categorized as high (>50%), moderate (>20-50%), or low (<20%). Random effects meta-analysis computed the overall odds of effectiveness of ITNs for all countries combined adjusted for district, household ITN ownership, and use at night. Prevalence was low in 4 of 16 districts in Rwanda (2) and Mozambique (2), moderate in 7 of 16 districts in Burkina Faso (2), Nigeria (2) and Mozambique (3), and high in 5 of 16 districts in Burkina Faso (1), Nigeria (2), Mozambique (2). Household ITN ownership varied from 8% to 100% and was above 80% in 5/16 districts in Rwanda and Burkina Faso, below <30% in 4 of 16 districts in Mozambique and Nigeria. The population who slept under an ITN the previous night varied from 3% to 79%. Malaria prevalence decreased as the proportion of ITN use the previous night increased (coefficient = 0.63, p=0.003). The diversity in baseline prevalence and net use is important in understanding the geographic diversity of this study and will be important in generating data on effectiveness of IG2, RG and PBO ITNs, which will inform decisions on malaria vector control tools.

### ESTIMATING THE MALARIA PREVENTION IMPACT OF NEW NETS: BASELINE RESULTS FROM OBSERVATIONAL ANALYSES TO EVALUATE THE EVIDENCE GENERATED DURING PILOTTED DUAL ACTIVE INGREDIENT INSECTICIDE-TREATED NET DISTRIBUTION IN NIGERIA

**Okefu O. Okoko**<sup>1</sup>, Peder Digre<sup>2</sup>, Perpetua Uhomobhi<sup>1</sup>, Ibrahim Maikore<sup>1</sup>, Emmanuel Obi<sup>1</sup>, Adedapo Adeogun<sup>3</sup>, Ali Onoja<sup>4</sup>, Dele Babarinde<sup>4</sup>, Ibrahim Abdulrahman<sup>4</sup>, Sylvanus Otikwu<sup>4</sup>, Samson Awolola<sup>3</sup>, Babatunde Salako<sup>3</sup>, Adesola Musa<sup>3</sup>, Hannah Koenker<sup>5</sup>, Christelle Gogue<sup>6</sup>, Joseph Wagman<sup>6</sup>, Molly Robertson<sup>2</sup>, Audu B. Mohammed<sup>1</sup>

<sup>1</sup>National Malaria Elimination Programme, Federal Ministry of Health, Abuja, Nigeria, <sup>2</sup>PATH, Seattle, WA, United States, <sup>3</sup>Nigerian Institute of Medical Research, Lagos, Nigeria, <sup>4</sup>Ibolda Health International, Abuja, Nigeria, <sup>5</sup>Tropical Health LLP, Baltimore, MD, United States, <sup>6</sup>PATH, Washington, DC, United States

The Nigeria National Malaria Elimination Programme is leading an evaluation of the impact of dual active ingredient insecticide-treated nets (ITNs) and pyrethroid + piperonyl butoxide (PBO) ITNs in comparison to standard pyrethroid-only ITNs on malaria transmission as part of the New Nets Project. The project will occur over three years in four high-burden local government areas (LGAs) in Nigeria with insecticide resistance: Ejigbo (alpha-cypermethrin ITNs) and Ife North (alpha-cypermethrin + PBO ITNs) in Osun State, and Asa (chlorfenapyr + alpha-cypermethrin ITNs) and Moro (pyriproxyfen + alpha-cypermethrin ITNs) in Kwara State. Following ITN distributions in late 2020, epidemiological, entomological, and anthropological methods are collecting data on several indicators, including malaria prevalence in children under five and ITN ownership and use. The baseline cross-sectional survey was conducted in October 2020 in 420 households per LGA and the collection of entomological data began in September 2020. The baseline cross-sectional survey revealed that ITN ownership ranged from 8.0% in Asa to 43.1% in Ejigbo. ITN use during the previous night ranged from 3.0% in Asa to 24.2% in Ife North. Malaria prevalence ranged from 38.4% in Ejigbo to 63.1% in Asa. Baseline human-baited CDC light trap collections indicate that *Anopheles gambiae* s.l. is the most abundant vector species group in Ejigbo (88% of all *Anopheles* spp. collected), Asa (100%), and Moro (100%), while in Ife North *An. funestus* s.l. (82%) was the most abundant. Molecular analysis shows the *An. gambiae* s.l. collected were predominately *An. gambiae* s.s. (70%) and *An. coluzzii* (27%), with very few *An. arabiensis* collected. The pyrethroid susceptibility of *An. gambiae* s.l., varied across the districts, from 12%-38% in Asa to 73%-94% mortality in Ejigbo. Baseline results show there is high malaria burden in these LGAs and malaria vectors are resistant to pyrethroids. The results also indicate some epidemiological and entomological differences across study LGAs which should be considered in future analyses.

### BED NET INDICATORS AND MALARIA PREVALENCE AMONG CHILDREN AGED 6 TO 59 MONTHS ONE YEAR AFTER INTRODUCTION OF DUAL ACTIVE INGREDIENT INSECTICIDE-TREATED BED NETS IN THREE HEALTH DISTRICTS AREAS OF BURKINA FASO: PRELIMINARY RESULTS

**Harouna Sore**<sup>1</sup>, Christelle Gogue<sup>2</sup>, Siaka Debe<sup>1</sup>, René N. Kinda<sup>1</sup>, Adama Ganou<sup>1</sup>, Casimir Tarama<sup>1</sup>, Gauthier Tougri<sup>3</sup>, N'Fale Sagnon<sup>1</sup>, Moussa W. Guelbeogo<sup>1</sup>, Molly Robertson<sup>4</sup>, Adama Gansané<sup>1</sup>

<sup>1</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>2</sup>PATH, Washington, DC, United States, <sup>3</sup>Programme National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso, <sup>4</sup>PATH, Seattle, WA, United States

Using insecticide-treated nets (ITNs) has contributed significantly to reducing malaria burden worldwide since 2000. However, since 2015, resistance to pyrethroids in mosquito populations has occurred in many

malaria-endemic countries including Burkina Faso. New, dual active ingredient ITNs, Interceptor G2®(BASF) (IG2) (pyrethroid+chlorfenapyr) and pyrethroid+PBO ITNs were deployed in 2019 in the districts of Gaoua, Banfora, and Orodara through a pilot study as part of the New Nets Project (funded by Unitaid and the Global Fund). The effectiveness and cost-effectiveness of ITNs in Burkina Faso will be evaluated over three years. As part of the evaluation, a household questionnaire was administered to capture data on demographic, socioeconomic and malaria prevention practices from 190 households per district in 2019 and 2020. Both surveys occurred before the annual seasonal malaria chemoprevention campaign and during the high malaria transmission season. Malaria prevalence among children aged from 6 to 59 months, using HRP2 based rapid diagnostic tests, was assessed during the surveys. At baseline, household ITN use was 20.8% (18.6-23.1%), 67.7% (64.9-70.3%), and 78.8% (76.1-81.2%) respectively in Gaoua, Banfora, and Orodara. These proportions increased respectively to 44.2% (40.9-47.5%), 90.4% (88.5-92.1%) and 84.8% (82.3-87.0%) the following year. The highest malaria prevalence was in Gaoua, at 81.0% (74.9-86.0%) in 2019, which decreased to 49.0% (41.9-56.1%) in 2020. Similarly, significant decreases in malaria prevalence were also observed in Orodara (PBO ITNs) and Banfora (IG2 ITNs) from 28.4% (22.4-35.3%) to 3.6% (1.8-7.5%) and 39.6% (33.0-46.6%) to 18.4% (13.5-24.6%), respectively. The preliminary results showed an improvement in ITN use and a decrease of malaria prevalence in children one year after mass distribution of ITNs in the three districts.

### ENTOMOLOGICAL SURVEY IN THREE HEALTH DISTRICTS IN BURKINA FASO WITH PYRETHROID, PIPERONYL BUTOXIDE-PYRETHROID, AND INTERCEPTOR G2 ITNS DEPLOYED

**Madou Tapsoba**<sup>1</sup>, Joseph Wagman<sup>2</sup>, Antoine Sanou<sup>1</sup>, Soumanaba Zongo<sup>1</sup>, Hyacinthe K. Toe<sup>1</sup>, René N. Kinda<sup>1</sup>, Fatoumata Cisse<sup>1</sup>, Gauthier Tougri<sup>3</sup>, Christelle Gogue<sup>2</sup>, N'Fale Sagnon<sup>1</sup>, Adama Gansané<sup>1</sup>, Molly Robertson<sup>4</sup>, Moussa W. Guelbeogo<sup>1</sup>

<sup>1</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>2</sup>PATH, Washington, DC, United States, <sup>3</sup>Programme National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso, <sup>4</sup>PATH, Seattle, WA, United States

Insecticide resistance threatens the efficacy of standard, pyrethroid-only insecticide-treated nets (ITNs) in Burkina Faso. Experimental huts trial results suggest that dual active ingredient ITNs could increase mosquito mortality and reduce malaria transmission in areas with pyrethroid resistance. Two varieties of dual active ingredient ITNs (Interceptor® G2 [IG2] [BASF]: alphacpermethrin + chlorfenapyr, and Olyset Duo® [Sumitomo Chemical Company Ltd.]: permethrin + piperonyl butoxide [PBO]) were distributed in select health districts during the 2019 distribution campaign while the rest of the country was provided with standard ITNs. The large-scale adoption and deployment of new ITN types requires additional evidence to prove their effectiveness in killing pyrethroid-resistant mosquitoes within real-life conditions of use. As part of a larger observational study being conducted by the New Nets Project to measure the impact of the various 2019 ITN distributions, mosquito collections began in nine villages (three villages in each of three study health districts) prior to the deployment of nets (June to July 2019), and are still ongoing. They consist of regular mosquito collections using human landing capture and CDC light traps, once a week, in each village for three years. A total of 24,360 malaria vectors were collected during the first five months (July to September 2019, during "baseline" and September to December 2019 for the initial "post-distribution" period). From these, the dominant species were *Anopheles gambiae* s.l. (80%) and *An. funestus* (11%). Peak vector abundance was observed from August to October. More than half (57.1%) of the vectors were collected host-seeking outdoors, a trend that was consistent across study districts. The overall human biting rate was ~2 bites/person/night in the pyrethroid-only area, ~1b/p/n in the PBO-pyrethroid area and ~4 b/p/n, in the IG2 area. Vector abundance and the human biting rates varied according to study

district, with a consistent preference for outdoor biting. The entomological inoculation rate is not yet available, and the sporozoite infection analysis is ongoing.

### OBSERVATIONAL ANALYSIS OF THE IMPACT OF INSECTICIDE ROTATION FOR AN INDOOR RESIDUAL SPRAYING PROGRAM IN THE UPPER WEST REGION OF GHANA 2016-2019

**Kenzie Tynuv<sup>1</sup>**, Joseph Wagman<sup>1</sup>, Julia Mwesigwa<sup>2</sup>, Christelle Gogue<sup>1</sup>, Andrew Saibu<sup>3</sup>, Keziah Malm<sup>4</sup>, Ignatius Williams<sup>5</sup>, Samuel Asiedu<sup>5</sup>, Titus Tagoe<sup>6</sup>, Christen Fornadel<sup>7</sup>, Molly Robertson<sup>8</sup>

<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>PATH, Kampala, Uganda, <sup>3</sup>IVCC, Accra, Ghana, <sup>4</sup>National Malaria Control Program, Ministry of Health, Accra, Ghana, <sup>5</sup>AngloGold Ashanti Malaria Control Limited, Obuasi, Ghana, <sup>6</sup>Ghana Health Service, Accra, Ghana, <sup>7</sup>IVCC, Liverpool, United Kingdom, <sup>8</sup>PATH, Seattle, WA, United States

Two indoor residual spraying products, Actellic® 300CS (Act.) and SumiShield® 50WG (SS), were recently used in Upper West Region (UWR), Ghana as part of the Next Generation IRS Project. In 2016 and 2017 all 11 districts in UWR sprayed Act., in 2018 4 districts switched to SS, and in 2019 all 11 districts sprayed SS. The observational, retrospective analysis presented here explores the effect of switching from Act. to SS on malaria cases as reported to the District Health Information Management System 2 from 2016 to 2019. Cases represent all patients who sought care at public health facilities and tested positive. Monthly malaria incidence rates were calculated for all 11 districts, and differences in monthly incidence rates for each 6-month post spray window were calculated. Districts were then stratified into Group 1 or 2 based on their differing 2018 insecticide designation (Act. or SS). A two-sample t test at  $\alpha=0.05$  was used to determine the mean change in malaria incidence rate between years for each group, and linear regression accounting for clustering was used to compare differences in the means between the two groups. Between 2016 and 2017, when both Group 1 and 2 sprayed Act. during both years, malaria incidence increased by around 18% in Group 1 and 6% in Group 2, a non-significant difference-in-differences effect of 11% ( $p=0.473$ ). Between 2017 and 2018 when Group 1 switched from Act. to SS and Group 2 continued using Act., malaria incidence decreased by around 29% in Group 1 and 48% in Group 2, a significant difference-in-differences effect of 19% ( $p=0.001$ ). Between 2018 and 2019 when Group 1 used SS both years and Group 2 switched from Act. to SS, malaria increased by around 27% in Group 1 compared to 64% in Group 2, a significant difference-in-differences effect of 36% ( $p<0.001$ ). These results suggest that IRS with either product is likely efficacious but that SumiShield may have had an attenuated impact on malaria reduction compared to Act., results that should be interpreted with caution given that a comparable no-IRS control area was not available and the general impact of IRS in this area, relative to no intervention, could not be quantified.

1194

### BASELINE ENTOMOLOGICAL LANDSCAPE ACROSS SIXTEEN NEW NETS PROJECT PILOT DISTRICTS: PRELIMINARY DATA ON VECTOR BIONOMICS

**Joseph Wagman<sup>1</sup>**, Moussa W. Guelbeogo<sup>2</sup>, Antoine Sanou<sup>2</sup>, Madou Tapsoba<sup>2</sup>, Adama Gansana<sup>2</sup>, Sagnon N'Fale<sup>2</sup>, Emmanuel Hakizimana<sup>3</sup>, Aimable Mbituyumuremyi<sup>3</sup>, Dulcisaria Jotamo<sup>4</sup>, Baltazar Candrinho<sup>4</sup>, Okefu O. Okoko<sup>5</sup>, Perpetua Uhomoibhi<sup>5</sup>, Emmanuel Obi<sup>5</sup>, Audu B. Mohammed<sup>5</sup>, Adedapo Adeogun<sup>6</sup>, Samson Awolola<sup>6</sup>, Adesola Musa<sup>6</sup>, Babatunde Salako<sup>6</sup>, Julia Mwesigwa<sup>7</sup>, Christelle Gogue<sup>1</sup>, Kenzie Tynuv<sup>1</sup>, Peder Digre<sup>8</sup>, Christen Fornadel<sup>9</sup>, Molly Robertson<sup>8</sup>

<sup>1</sup>PATH, Washington, DC, United States, <sup>2</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>3</sup>Rwanda Biomedical Centre Malaria and Other Parasitic Diseases Division, Ministry of Health, Kigali, Rwanda, <sup>4</sup>National Malaria Control Program, Ministry of

Health, Maputo, Mozambique, <sup>5</sup>National Malaria Elimination Programme, Federal Ministry of Health, Abuja, Nigeria, <sup>6</sup>Nigerian Institute of Medical Research, Lagos, Nigeria, <sup>7</sup>PATH, Kampala, Uganda, <sup>8</sup>PATH, Seattle, WA, United States, <sup>9</sup>IVCC, Liverpool, United Kingdom

Through the New Nets Project, dual active ingredient (AI) ITNs (Interceptor® G2 [BASF] and Royal Guard® [RG] [Disease Control Technologies]) have been piloted in several countries, alongside pyrethroid-piperonyl butoxide (PBO) and standard pyrethroid-only ITNs. To help generate evidence on the impact of these dual AI ITNs in real-world implementation settings, data on several indicators of malaria transmission is being collected in five pilot study areas composed of 16 districts across four countries: Burkina Faso, Mozambique, Nigeria, and Rwanda. Observational studies will evaluate the effect of the ITNs, relative to standard pyrethroid-only ITNs, through 2022. The ecological diversity in these geographies is critical in understanding the effectiveness of dual AI ITNs across a range of settings, and here results of baseline entomological surveillance across all study districts are presented. Malaria vector bionomics are varied both between and within each evaluation context, with *An. gambiae* s.s. the dominant vector in 9 of 16 districts overall and in at least one study district from each of the pilot countries. Other dominant vectors include *An. funestus* s.l. (4 districts, at least one in each country except Burkina Faso), and *An. coluzzii* (3 districts). Variation in indoor-to-outdoor biting ratios was also noted by district, ranging from 0.5 to 10.0, but in 10 of 16 districts the ratio was not significantly different from 1.0. Also highly variable was the baseline pyrethroid susceptibility status of primary vectors across districts: WHO tube test mortality rates ranged from 12% to 94% in Nigeria, from 86% to 100% in Rwanda, from 60% to 100% in Mozambique, and were less than 50% in all sites in Burkina Faso. Exposure to PBO completely restored susceptibility in Rwanda and Mozambique, but only partly so in Nigeria and Burkina Faso. The rich diversity and variation in vector bionomics present across the pilot study districts will provide important real-world context that accurately reflects the dynamic reality of malaria transmission in Africa and the complexities of estimating vector control impact.

1195

### THE POPULATION INTERPLAY OF TWO MALARIA VECTORS IN NE UGANDA AND THEIR MEASURED DECLINES WITH VECTOR CONTROL

**Richard Elliott<sup>1</sup>**, Wycliff Odude<sup>2</sup>, Kilama Maxwell<sup>2</sup>, Thomas Eganyu<sup>2</sup>, Kathryn Colborn<sup>3</sup>, Humphrey Wanzira<sup>2</sup>, Fred Bukenya<sup>2</sup>, Ronald Mulebeke<sup>4</sup>, Adoke Yeka<sup>4</sup>, Dorothy Echodu<sup>5</sup>

<sup>1</sup>Boise State University, Boise, ID, United States, <sup>2</sup>Pilgrim Africa, Kampala, Uganda, <sup>3</sup>University of Colorado Anschutz Medical Campus, Aurora, CO, United States, <sup>4</sup>Makerere University School of Public Health, Kampala, Uganda, <sup>5</sup>Pilgrim Africa, Seattle, WA, United States

Entomological surveillance has been a component of an ongoing, multi-year study of malaria transmission and its control in a region of high transmission of NE Uganda. The *An. gambiae* and *An. funestus* mosquito species complexes are the primary malaria vectors in the area and we report on their seasonal and locational trends, and associated patterns of malaria transmission. As part of the study, two of three connected subcounties received indoor residual spraying (IRS) with pirimiphos methyl, while all received bednets through a universal campaign from Uganda's Ministry of Health. Mosquitoes in the subcounties, with and without these interventions, are collected for a single night at monthly intervals with CDC light traps in 90 sentinel huts for nearly three years. Evident in these collections are two time-ordered, independent vector density peaks, and each is strongly dominated by a single species. These sequential, species-specific population trends are repeated annually, an apparent interspecific interaction. Despite this seasonal coordination, a spatially complex picture of the mosquito densities is also found, indicating both species are frequently sympatric, but not syntopic, in the study area. The impacts of IRS are strongly evident on the mosquito densities, with percentage reductions generally around 70-80% compared to neighboring regions with only the universal bednets, and it is somewhat more effective on the

An. funestus population. The high spatial and temporal resolution of the research setting allows a practical estimation of the number of observation huts sufficient to infer different vector control impacts, with implications for programmatic entomological surveillance.

1196

### MALARIA PARASITES CAN BE KILLED NON THERMALLY WITH MICROWAVES

**Carmenza Spadafora**<sup>1</sup>, Lorena Coronado<sup>1</sup>, Kevin Chaw<sup>1</sup>, Jose Stoute<sup>2</sup>, Carlos Donado<sup>1</sup>

<sup>1</sup>INDICASAT AIP, Panama City, Panama, <sup>2</sup>Penn State University, Hershey, PA, United States

Abstract textThe WHO has reported a shortfall in meeting the internationally agreed goals of curbing malaria. To add to this, the SARS-CoV-2 pandemic fallout could worsen the situation in the coming years. This adds to the ever present concerns of resistance to current treatments in South Asia. Our group embraced the need to find an alternative way of fighting against the disease. Using microwave energy (MW), we generated conditions in which more than 90% of the parasites that cause malaria are killed *in vitro*. This was achieved not by a thermal effect but via a MW field-induced programmed cell death that did not affect mammalian cell lines. Transmission electron microscopy revealed that exposure to MW leads to destruction of the hemozoin-containing food vacuole, consistent with the observation of leakage of calcium from the vacuole and acidification of the cytoplasm. Furthermore, parasites were protected from the effects of MW by calcium channel blockers, calmodulin, and phosphoinositol. As previously reported by our group, direct current electric fields cause the opposite effect, i.e., proliferation of the parasites by means of the same calcium signaling molecules. We found early evidence that a yet unidentified protein in *P. falciparum* could be involved in the differential inhibitory effect of MW on the pathogen. Finally, we have designed a MW applicator for testing the technology *in vivo* and have obtained results that prove that the inhibition of growth obtained *in vitro* with this applicator is reproduced *in vivo* without affecting the animals. Our findings open the door to a possible new paradigm for the treatment of malaria,

1197

### MICROBIOLOGICAL QUALITY CONTROL OF INTENSIVE CARE UNIT ENVIRONMENT AT THE EPIDEMIC TREATMENT CENTER OF COVID IN ARISTIDE LE DANTEC HOSPITAL

**Ousseynou Gueye**

Aristide Le Dantec University Hospital Center, Dakar, Senegal

Health care-associated infections (HCAIs) is a serious public health problem in the world. With the COVID, pandemic where severe cases are being treated in intensive care units, strict hygiene measures should be taken to prevent bacterial infections of patients with this disease. The objective of this study was to control microbiological quality environment of intensive care unit in Le Dantec hospital. Technical sedimentation was used and air environmental was collected in petri dish about twenty minutes before and after cleaning and antiseptic pulverization. Bacteria such as *Staphylococcus aureus* and *Klebsiella pneumoniae* were isolated before and after cleaning and antiseptic pulverization. Antibiotic susceptibility testing showed a broad-spectrum beta-lactamase-producing for *K. pneumoniae*, which was resistant to aminoglycosides and fluoroquinolones but susceptible to carbapenem. For *S. aureus* strains, most antibiotics were active excepted penicillin. In conclusion, cleaning and disinfection protocols should be reinforced to limit secondary bacterial infections cases. **Keys words:** COVID, infection, Health care-associated infections.

### PILOT RETROSPECTIVE MOLECULAR DIAGNOSIS OF NEGATIVE GENEXPERT AND AFB SPUTA OF TB SYMPTOMATIC PATIENTS IN MANILA PHILIPPINES

**Crespo Mbe-cho Ndiabamoh**

Biotechnology Center, Yaounde Cameroon, Cameroon

In 2019, the Philippines was amongst the seven countries accounting for the greatest burden (90%) of tuberculosis (TB) in the world. We sought to investigate the presence of other potentially pathogenic organisms and their clinical features in archived sputum samples from acutely unwell patients clinically diagnosed with TB and admitted to a TB ward at San Lazaro Hospital Manila and not on treatment. These patients however, had a negative Xpert® MTB/Rif assay and Acid-Fast Bacilli (AFB). A pilot retrospective molecular analytical cross-sectional study on 82 sputa samples was carried out. DNA was extracted using a QIAGEN kit. Positive controls prepared from blood culture isolates were extracted using the same kit above following manufacturers protocol. Three multiplex Polymerase chain reactions (PCR) were designed for *Hemophilus influenzae*, *Moraxella catarrhalis*, *Streptococcus pneumoniae*, *Mycoplasma pneumoniae*, *Legionella pneumoniae*, *Chlamydia pneumoniae*, and *Burkholderia pseudomallei*, *thailandensis*. Shimadzu MultiNA Microchip Electrophoresis System was used for DNA analysis. Statistics analysis was done on STATA® 15. The prevalence of bacteria was 74/82(90.24%). *Burkholderia pseudomallei* 72/82(87.80%) and *Hemophilus influenzae* 22/82(26.83%) were most prevalent. The prevalence of an over 2-week cough duration was 51/82(76.12%) while that for x-ray findings consistent with TB was 59/76(86.76%). The odds of a cough of over two weeks and weight loss were about six {OR 5.70(CI: 1.79, 18.09)}, p=0.0008 and four folds {OR 4.44(95%CI:1.56, 12.62)} p=0.0022 respectively greater in those with positive Xpert/AFB compared to those negative. There can be other bacterial infections in patients suspected and/or diagnosed of PTB. This however, warrants more research to identify types and prevalence of bacteria. Clinical manifestations like cough of over 2 weeks, fever, chest x-ray lesions, and weight loss can be present in other lung affections/diseases. In bacteriologically confirmed TB cases, a cough of over two weeks and weight loss were the most determining factors.

1199

### DOES FIBERSOL-2 EFFICACIOUS IN REDUCING DURATION OF WATERY DIARRHOEA AND STOOL OUTPUT IN CHILDREN 1-3 YEARS OLD? A RANDOMIZED, PARALLEL, DOUBLE-BLINDED, PLACEBO- CONTROLLED, TWO ARM CLINICAL TRIAL

**Abu Sadat Mohammad Sayeem Bin Shahid**, Abu Syed Golam Faruque, Mohammad Jobayer Chisti

icddr,b, Dhaka, Bangladesh

Fibersol-2 has innumerable beneficial effects on human health. It is a fermentable, non viscous, water-soluble, indigestible dextrin containing 90% dietary fiber produced from corn starch. We aimed to evaluate whether additional intake of Fibersol-2 along with oral rehydration solution treatment can reduce the duration of watery diarrhoea and stool output in children 1-3 years. This placebo-controlled double-blinded, randomized parallel two arm trial conducted in Kumudini Women's Medical College Hospital in rural Bangladesh between March and October, 2018 used 5 gm of either Fibersol-2 or placebo, dissolved in 50-ml drinking water which was given orally to 92 children with watery diarrhoea on enrolment twice daily for a period of 7 days. Randomization was done using a randomization table. We randomly allocated 45 (49%) and 47 (51%) children in Fibersol-2 and placebo groups, respectively. Primary outcome measures were duration of resolution of watery diarrhoea, the proportion of patients recovered within 72 hours, and daily stool output. Primary and safety analyses were by intention to treat. This trial is registered at ClinicalTrials.gov, number NCT03565393. The mean duration of resolution of watery diarrhoea, the proportion of children recovered from watery diarrhoea within 72 hours and total watery stool output between Fibersol-2 and placebo were (35.86±25.06 hrs vs. 44.99±36.24

hrs;  $p=0.335$ ); (91% vs. 82%;  $p=0.312$ ) and (1095.32±522.78 gram vs. 1322.93±797.58 gram;  $p=0.259$ ); respectively. No beneficial role of Fibersol-2 was seen in reducing duration of watery diarrhoea and stool output, compared to placebo in children 1-3 years old.

## 2100

### CHANGES IN THE GUT MICROBIOME IN ANGOLAN CHILDREN WITH SICKLE CELL DISEASE

**Miguel Brito<sup>1</sup>**, Mariana Delgado<sup>2</sup>, Catarina Ginete<sup>1</sup>, Jocelyne Vasconcelos<sup>3</sup>, Brigida Santos<sup>3</sup>

<sup>1</sup>ESTeSLI/PL - Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, Lisbon, Portugal, <sup>2</sup>ESTeSLI/PL - Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, Lisbon, Portugal, <sup>3</sup>CISA -Angolan Health Research Center, Caxito, Angola

Sickle cell disease (SCD) is one of the most prevalent genetic diseases, affecting between 20 and 25 million people worldwide and with an incidence of approximately 300,000 births per year. It is particularly common in the African continent, with nearly 80% of the SCD births occurring in Sub-Saharan Africa, contributing to 50-80% of under-5 mortality. Clinical manifestations of SCD are very heterogeneous and the intestinal microbiome seems to be crucial in the modulation of inflammation, cell adhesion and induction of aged neutrophils, which are the main interveners of recurrent vaso-occlusive crisis (VOC). Recent studies have reported frequent microbial and pathophysiologic changes in the intestines of SCD patients, and these include enterocyte injury, altered microbial composition, increased permeability and bacterial overgrowth. Moreover, it has been suggested that Hydroxyurea (HU), the only FDA-approved drug for SCD, shows a multimodal action and may reduce microbiome dysbiosis and aged neutrophils, which could explain the decreasing of VOC occurrences. In this project, we use Next-Generation Sequencing to sequence bacterial 16S rRNA in order to characterize the gut microbiome of SCD Angolan children and healthy siblings before and after HU administration. The aim is to understand how the disease and the HU treatment modulates the microbiome and if these changes are related with severity. Our preliminary results showed an increase in Actinobacteria phylum and a decrease of Proteobacteria in homozygous SCD patients. In the same group of patients, it was also observed a reduction of Gammaproteobacteria class and an increase of Coriobacteriales order. Understanding the epidemiology and host-microbe interactions can demonstrate the importance of specific bacteria and their function in this disease and provide new insights for attenuating symptoms. This work is supported by FCT/Aga Khan (project n°330842553) and FCT/MCTES (UIDB/05608/2020 and UIDP/05608/2020) -H&TRC.

## 2101

### TRENDS IN ANTIMICROBIAL RESISTANCE OF PATHOGENS CAUSING SURGICAL SITE INFECTIONS IN EGYPT

**Rania Nada<sup>1</sup>**, Alaa Ismail<sup>2</sup>, Noha Asem<sup>3</sup>, Samia Girgis<sup>2</sup>, Hanan El Mohammady<sup>1</sup>, Isabelle Nakhla<sup>1</sup>

<sup>1</sup>U.S. Naval Medical Research Unit - No. 3, Cairo, Egypt, <sup>2</sup>Faculty of Medicine, Ain Shams University, Cairo, Egypt, <sup>3</sup>Faculty of Medicine, Cairo University, Cairo, Egypt

Surgical site infections (SSI) accompanied with antimicrobial resistance (AMR) cause high morbidity and mortality rates. This study aimed to evaluate AMR in subjects presenting with SSI at two University Hospitals in Egypt. From March 2018 to March 2021, 119 subjects were enrolled. Identification and antibiograms of isolated wound pathogens were done by VITEK2. In total, 145 pathogens were isolated from 88 subjects. A single pathogen was identified in 48 (40.3%) subjects, whereas, up to four pathogens were co-identified in 40 (33.6%) patients. *E. coli* (34.4%), *K. pneumoniae* (27.7%), *A. baumannii* (13.4%) and *P. aeruginosa* (11.7%) were the main pathogens isolated. Overall, high AMR rates were observed among the isolated pathogens with 10% pan-drug resistant (PDR), 32.9% extensively drug resistant (XDR) and 36.4% multi-drug resistant (MDR). Of the *Enterobacteriaceae* isolates, 14% were PDR, 24.7% XDR and 40.9%

MDR. The lowest resistance rates of *Enterobacteriaceae* were against amikacin (25%) and meropenem (27.2%), whereas, >80% of the isolates were resistant to 3<sup>rd</sup> and 4<sup>th</sup> generation cephalosporins. AMR profiles of *E. coli* were XDR (29%), MDR (56.1%) and Extended Spectrum Beta-lactamase producer (ESBL) (59%). *K. pneumoniae* displayed higher level of AMR with PDR (36.4%), XDR (24.2%), MDR (18.2%); ESBL producers (30.3%) and resistance against tested antibiotics ranged from 52% to 88%, in levofloxacin and ceftriaxone, respectively. All *A. baumannii* isolates were either PDR (6.3%), XDR (81.3%) or MDR (12.5%), with one colistin resistant strain. For *P. aeruginosa*, 64.3% were XDR and colistin was the effective antibiotic against all its isolates. Importantly, 117 subjects received surgical prophylaxis, of whom, 89% were administered cephalosporins and 5.8% amikacin, which matches antibiograms noticed in *Enterobacteriaceae*. In conclusion, the excessive use of cephalosporins in surgical prophylaxis in Egypt might have contributed to the remarkably high rates of AMR observed in *Enterobacteriaceae*. The reported high rates of antimicrobial resistance highlights the urgent need for multidisciplinary actions for successful SSI prophylaxis.

## 1202

### IMMUNOMODULATORY EFFECT OF LEPIDIUM MEYENII IN THE INFLAMMATORY RESPONSE OF HUMAN MACROPHAGES TO MYCOBACTERIA

**Jorge Cervantes**, Habiba Khan, Jose Barragan, Esdras Rodriguez, Carlos Hernandez, Jessica Hungate

Paul L. Foster School of Medicine, El Paso, TX, United States

*Lepidium meyenii* (L.m.), also known as maca, is an Andean crop used medicinally for multiple purposes. Studies have shown an immunomodulatory anti-inflammatory effect in murine macrophages. Bacillus Calmette-Guérin (BCG) is the vaccine used to prevent non-pulmonary forms of tuberculosis. We aimed to assess the effect of L.m. on the inflammatory response of human macrophages to mycobacteria. Human monocytic THP-1 cells bearing two plasmid reporter systems for NF- $\kappa$ B and IRF activation, were differentiated into macrophages and then treated with L.m. at concentrations of 1ug/ml, 5ug/ml and 10 ug/ml for 48 hours. Cells were then infected with *Mycobacterium tuberculosis* (Mtb) strain H37Rv, *Mycobacterium smegmatis*, and BCG for 24 hours. L.m.-treated cells showed a decrease in NF- $\kappa$ B activation in a dose-dependent manner. No effect was observed in IRF activation. Phagocytosis was increased in L.m.-treated cells at any concentration compared to untreated cells. A decrease in the number of internalized Mtb, but an increase in internalized *M. smegmatis* and BCG were observed in L.m.-treated cells. Our results indicate that L.m. exerts an immunomodulatory effect on the NF- $\kappa$ B activation of human macrophages upon mycobacteria challenge, while at the same time improving phagocytosis. Our findings suggest a beneficial effect in active TB where an exacerbated inflammatory response is observed.

## 1203

### SUSCEPTIBILITY AND EXPOSURE TO LEPROSY: AN EXAMINATION OF NUTRIENT DEFICIENCIES, PARASITIC COINFECTION, AND WATER, SANITATION AND HYGIENE (WASH) CONDITIONS

**Megan K. Wasson<sup>1</sup>**, Cassidy Whitson<sup>1</sup>, Bridget Miller<sup>1</sup>, Wondwossen Abebe<sup>2</sup>, Belay Tessema<sup>2</sup>, Lisa E. Emerson<sup>1</sup>, Puneet Anantharam<sup>1</sup>, Annisa B. Tesfaye<sup>2</sup>, Jessica K. Fairley<sup>3</sup>

<sup>1</sup>Emory University Rollins School of Public Health, Atlanta, GA, United States, <sup>2</sup>University of Gondar, Gondar, Ethiopia, <sup>3</sup>Emory University School of Medicine, Atlanta, GA, United States

Despite control measures and a declining number of human reservoirs, continued incidence of leprosy in excess of 200,000 new infections each year suggests that alternative pathways may play a role in continued endemicity. Nutritional deficiencies, parasitic coinfection, and limited access to safe water, sanitation and hygiene (WASH) have been suggested to predispose individuals to *M. leprae* infection. To further explore this

hypothesis, leprosy cases and uninfected controls were recruited from areas around North Gondar, Ethiopia throughout 2019. Participants completed dietary and WASH surveys in addition to providing stool for Kato Katz, urine for Schisto POC-CCA™ rapid diagnostic testing, and blood for micronutrient biomarker testing. A total of 80 men (59%) and women (41%) participated in this study with an average age of 40 (SD 15.0 years). Most leprosy cases were multibacillary (93.3%). There was a high prevalence of undernutrition among cases and controls, with 32.1% of participants classified as underweight. Food shortage [OR 4.57, 95% CI (1.62, 12.89)] and fewer meals consumed per day [OR 3.85, 95% CI (1.17, 12.67)] were both significantly associated with leprosy in the univariate analysis. Additionally, 64.1% of the study population tested positive for a helminth and WASH insecurities were widespread. On multivariate analysis, lack of soap for handwashing [aOR 2.53, 95% CI (1.17, 5.47)] and lack of toilet facilities [aOR 2.32, 95% CI (1.05, 5.12)] were significantly associated with leprosy. Positive directionality was identified for a number of other inputs, including helminth infection [aOR 3.23, 95% CI (0.85, 12.35)]. Taken together, these findings strengthen previous research conducted in 2018 implicating WASH as a driver of leprosy infection. Subsequent micronutrient results will be integrated to further explore nutritional risks and build upon the significant macronutrient findings from this analysis. Given that leprosy remains the leading infectious cause of disability in the world, future research should explore all of the above susceptibilities in more depth in order to curtail the global burden of disease.

1204

#### CHARACTERIZATION OF MRSA AND ESBL PATHOGENS FROM PATIENTS WITH SURGICAL SITE INFECTIONS IN ACCRA, GHANA

Terrel Sanders<sup>1</sup>, Beverly Egyir<sup>1</sup>, Anne Fox<sup>1</sup>, Naiki Attram<sup>1</sup>, Jeannette Bentum<sup>1</sup>, Edward Nyarko<sup>2</sup>, Chaselynn Watters<sup>1</sup>

<sup>1</sup>NAMRU-3, Accra, Ghana, <sup>2</sup>Ghana Armed Forces 37 Military Hospital, Accra, Ghana

Among syndromes involving AMR/MDR, surgical site infections remain a significant clinical concern—posing challenges to patients who undergo surgery by causing delayed wound healing and increasing healthcare costs. Unfortunately, throughout Ghana, treatment of SSI is often empirical and not based on knowledge of the organisms infecting surgical sites and their susceptibility patterns. In this study, we sought to characterize *S. aureus*, *E. coli*, *K. pneumoniae* and *P. aeruginosa* recovered from patients diagnosed with SSIs in Ghana to provide antimicrobial susceptibility data. This cross-sectional study is being conducted at the 37-Military Hospital and Korle-Bu Teaching Hospital in Accra, Ghana. All organisms were identified by MALDI-TOF-MS and susceptibilities interpreted according to the CLSI 2018 guidelines. From a total of 90 patients recruited, 69 bacteria species have been identified; *E. coli* (33%), *P. aeruginosa* (21%), *K. pneumoniae* (20%) and *S. aureus* (2%). *S. aureus* isolates were susceptible to clindamycin, erythromycin, gentamicin, linezolid, rifampicin and norfloxacin but resistant to penicillin. *E. coli* and *K. pneumoniae* were resistant to tetracycline (85.4%), trimethoprim/sulfamethoxazole (81%), ciprofloxacin (75%), cefuroxime (69%), cefotaxime (69%), gentamicin (63%) and chloramphenicol (56%) but sensitive to meropenem (92%) and amikacin (88%). *P. aeruginosa* showed sensitivity to amikacin (89%), meropenem (79%), ceftazidime (79%), piperacillin-tazobactam (89%), cefepime (74%), gentamicin (63%) and ciprofloxacin (63%). ESBL-phenotype was detected in 53% of *E. coli* and 83% of *K. pneumoniae* isolates. *CTX-M* was the dominant ESBL gene in *E. coli* isolates. Of the 19 *P. aeruginosa* isolates, 2 harbored the *TEM* gene. From the preliminary data, we found an over representation of Gram-negatives compared to Gram-positives in the SSI samples analyzed. These findings further demonstrate the need for effective surveillance to monitor the rise and spread of MDR pathogens and guide stewardship best practices.

1205

#### GENOMIC EPIDEMIOLOGY AND ANTIMICROBIAL RESISTANCE IN NEISSERIA GONORRHOEAE ISOLATES FROM GHANA

Terrel Sanders<sup>1</sup>, Bright Agbodzi<sup>1</sup>, Beverly Egyir<sup>2</sup>, Helena Dela<sup>1</sup>, Clara Yeboah<sup>1</sup>, Selassie Kumordjie<sup>1</sup>, Eric Behene<sup>1</sup>, Anne Fox<sup>1</sup>, Michael Wiley<sup>1</sup>, Naiki Attram<sup>1</sup>, Chaselynn Watters<sup>1</sup>

<sup>1</sup>NAMRU-3, Marion, SC, United States, <sup>2</sup>NMIMR, Marion, SC, United States

Tracking *Neisseria gonorrhoeae* antibiotic resistance rates provides combatant commands with insights into antibiotics effectiveness in specific countries. Therefore, this study sought to perform whole genome characterization of *N. gonorrhoeae* collected in Ghana to identify lineages of circulating strains and their phenotypic and genotypic antimicrobial resistance profiles. Whole genome sequencing was performed on 56 isolates using both the Oxford Nanopore MinION and Illumina MiSeq sequencing platforms. A total of 22 STs were identified by MLST, with ST-14422 (n=10), ST-1927 (n=8) and ST-11210 (n=7) being the most prevalent. Six novel STs were also identified and submitted for assignment of new sequence types (ST-15634-115641). Seven clusters of isolates with distinct AMR genotypes were identified after the wgMLST analysis, highlighting the presence of genome wide genetic variation. All isolates harboured chromosomal AMR determinants that confer resistance to beta-lactam antimicrobials and tetracycline. A total of (49/56)87.5% and (13/56)23% isolates contained fluoroquinolone and macrolide resistance markers, respectively. NG-STAR AMR typing identified 29 unique sequence types, with ST-464 (n=8) and the novel ST-3366 (n=8) being the most prevalent. Notably, 20 of the 29 STs were novel, indicative of the unique nature of molecular AMR determinants in the Ghanaian isolates. The novel sequence types were submitted for assignment of new sequence types (ST-3352-3353). Plasmids were highly prevalent: pTetM and pblaTEM were found in 96% and 92% of isolates, respectively. The TEM-135 allele, identified in 28.5% isolates, is a cause for concern because further changes to specific amino-acids might lead to the emergence of a stable extended-spectrum β-lactamase that could result in complete cephalosporin resistance. This study highlights the need for constant genomic surveillance with the looming possible emergence of extended-spectrum cephalosporin resistant bacterial isolates.

1206

#### OVERCOMING THE UTILITY BARRIERS OF MICROSCOPIC AGGLUTINATION TEST FOR THE DIAGNOSIS OF LEPTOSPIROSIS IN LOW INCOME SETTINGS

Shalka Srimantha Lanka Acharige, Dinesha Jayasundara, Janith Warnasekara, Farika De Silva, Chamila Kappagoda, Indika Senevirathne, Suneth Agampodi

Rajarata University of Sri Lanka, Anuradhapura, Sri Lanka

Microscopic Agglutination Test (MAT) is still the standard diagnostic test for the diagnosis of leptospirosis; a neglected infectious disease in tropical and sub-tropical regions. MAT involves a time consuming, laborious procedure and expensive consumables, making it challenging to use in low and middle-income settings where the disease burden is highest. This study aimed to improve the efficiency and reduce the cost of MAT procedure, sustaining the validity to minimize the burden of Leptospirosis. We tested an extensive collection of serum samples from suspected cases of Leptospirosis, using a mixed approach to optimize the MAT panel. First, the WHO recommended *Leptospira* reference panel was obtained from the Centres for Disease Control and Prevention (CDC). Four laboratory strains isolated from Sri Lanka were also included in the panel to test the available samples. The second step involves analyzing the most suitable *Leptospira* antigen panel without compromising the representativeness of serogroups and local *Leptospira* isolates. Statistical analysis was done to select the maximum number of *Leptospira* antigens to achieve the highest sensitivity. Four hundred four samples were then tested using the new antigen panel. The final scheme included 14 strains (of the 24 tested). Of the selected 14 antigens, only 11 were required to complete the MAT quantitation. MAT

screening was done according to the standard protocol followed by MAT quantitation using a single diagnostic titre of 1/400. Antigens were used in a serial manner rather than a parallel manner for MAT quantitation. In the novel approach, 404 serum samples were tested, and 126 (31.1%) were screened positive, while 49 (12.1%) had a diagnostic titre of 1/400. This method reduced >40% of the *Leptospira* culture maintenance and test consumable costs along with 37.5% of microscopic observation time. These findings suggest that the proposed method will improve the current practice of MAT in resource-limited laboratories by saving consumables and time, thus serving the clinical diagnostic procedures better to minimize the burden of Leptospirosis.

1207

### STAPHYLOCOCCUS AUREUS BACTERIURIA IS MORE COMMON IN MALES. PERSISTENT AND RECURRENT INFECTIONS ARE UNCOMMON WITH A HIGHER INCIDENCE IN OLDER AGE GROUPS: A STUDY OF 633 CASES

**Don W. Kannagara**, Dhyanes Pandya, Roopa Anmolasingh  
St Luke's University Health network, Warren Campus, Phillipsburg, NJ, United States

Urinary infections are more frequent in young women. Recurrences are common. In a study of 633 *Staphylococcus aureus* culture positive patients, we found more infections in males. Persistent or recurrent infections were uncommon. There were more older patients. Methods: We studied *S. aureus* urine cultures of 633 patients reported by our network laboratory for a period of 3 years beginning January 2016. There were 344 males and 290 females aged 1-118. Only 22/633 (3.47%) had more than 1 positive culture. Of these the second positive culture was reported after 24 hours in 11, 48 hours in 5, 96 hours in 2 and 1 each on day 7, 14, 19 and 28. Only the last 4 was likely to have a recurrence or persistent infection (0.63%). Nine urine culture positive patients had positive blood cultures (1.42%). Two had positive wound cultures and 1 had a positive joint fluid culture. Only 69/633 (10.9%) were below age 30 and 84 (13.7%) below age 50. Three hundred and ninety-nine were above age 60 (63%). The median age was 67. All except one had multiple co-morbidities: diabetes 11, chronic Foley catheter 7, urinary retention 4, stones 4, bladder cancer 2, benign prostatic hypertrophy 2, suprapubic catheter 2, hydronephrosis 2, epidural abscess/paraplegia 1, prostatic abscess 1 cerebrovascular accident 1. All 22 with more than 1 positive culture were methicillin susceptible. Nine had minimal inhibitory concentration (MIC) to ampicillin  $\leq 2$  mcg/ml, 1 with MIC 4 mcg/ml and the remainder had MIC  $\geq 8$  mcg/ml. All were susceptible to cefazolin, gentamicin, nitrofurantoin, tetracycline, trimethoprim/sulphamethoxazole and vancomycin. Susceptibilities were checked repeatedly for accuracy. In a 5-year Irish study out of 425,013 urine cultures 542 were *S. aureus* positive (0.13%) and 151 were methicillin resistant (.036%). Thus *S. aureus* bacteriuria is uncommon. In our study *S. aureus* bacteriuria was more prevalent in older patients with a male preponderance and persistent and recurrent infections were rare, differing from common uropathogens such as *E. coli*. In the sub group of 22 with more than 1 positive culture, there was no methicillin resistance which could be due to small numbers.

1208

### DEVELOPMENT OF A NANOPORE SEQUENCING ASSAY FOR THE QUANTIFICATION OF HOST-RESPONSE FEATURES THAT PREDICT MORTALITY IN SEPSIS SUBJECTS

**Josh G. Chenoweth**<sup>1</sup>, Thomas Hall<sup>2</sup>, Gary Fogel<sup>3</sup>, Christine Marzan<sup>2</sup>, Derren Barken<sup>3</sup>, Joost Brandsma<sup>1</sup>, Deborah Striegel<sup>1</sup>, Misato Miyamasu<sup>1</sup>, Kevin Schully<sup>4</sup>, Charmagne Beckett<sup>5</sup>, Benjamin Espinosa<sup>4</sup>, Danielle Clark<sup>1</sup>

<sup>1</sup>Henry M. Jackson Foundation for the Advancement of Military Medicine, Bethesda, MD, United States, <sup>2</sup>Janus-I Science, Inc, Vista, CA, United States, <sup>3</sup>Natural Selection, Inc, San Diego, CA, United States, <sup>4</sup>Biological

Defense Research Directorate, Naval Medical Research Center-Frederick, Ft. Detrick, MD, United States, <sup>5</sup>Naval Medical Research Center, Infectious Diseases Directorate, Silver Spring, MD, United States

Early recognition and characterization of infectious disease threats and improved clinical care to mitigate the effects of infection constitute two key components of our defense-in-depth approach to biological threats. The Austere environments Consortium for Enhanced Sepsis Outcomes (ACESO) aims to improve survival of patients with severe infections by focusing on the generation of new knowledge that can rapidly translate into preventing and improving the outcome of sepsis in the austere setting. ACESO seeks to identify host-response biomarkers that are predictive of clinical severity of sepsis that can be deployed on fieldable devices. Towards this goal, recruitment was performed for an observational study of sepsis at sites in Cambodia (n=208), Ghana (n=202) and the USA (n=185). Host RNA sequencing data were generated. We used topological data analysis (TDA) to cluster patients in an unsupervised manner as a means of stratifying subjects, identifying differences between patient groups of interest (28-day mortality) and as input for regression models. Fifteen gene expression features were identified in a model termed Predict\_d28 that were predictive of outcome in the subgroups. To develop a sequencing assay capable of profiling the host response in sepsis subjects in a rapid fashion we chose the Oxford Nanopore Technologies MinION that is amenable to field applications. An assay that uses amplicon preparation and nanopore sequencing of RNA isolated from sepsis subject peripheral blood to quantify 15 features for the purpose of predicting outcomes was pursued. Automated software was developed (SepsiProgDx) to analyze the resulting sequence data to yield a risk score from the Predict\_d28 model. To gauge the correlation between the output of the Predict\_d28 prognostic assay between nanopore and real-time RT-PCR quantification of the same genes, ten clinical samples were measured using the nanopore sequencing assay and with real-time RT-PCR. Model weights were similar for all ten samples tested. Next steps include continued assay validation prior to field testing.

1209

### A CASE OF STREPTOCOCCUS VIRIDANS MULTIFOCAL ABSCESES WITHOUT BACTEREMIA AND ENDOCARDITIS

**Amanda Winn**, Keely Johnson, Marilyn Fabbri  
Elmhurst Hospital, Queens, NY, United States

*Streptococcus viridans* is an  $\alpha$ -hemolytic streptococci part of the normal oral flora and a common cause of subacute bacterial endocarditis from dental caries. *S. viridans* is responsible for 40-60% of endocarditis on normal valves, particularly in males over 45-years-old. *Streptococcus intermedius* is one of the most common microbes associated with brain and liver abscesses and pulmonary empyema. Mucosal disturbance and liver abscess may predispose patients to *S. intermedius* brain abscesses. We present a 47-year-old male patient with alcohol use disorder and diabetes with a pulmonary empyema and multiple liver abscesses with positive body fluid cultures showing *S. intermedius* in the lungs and *S. viridans* in the liver without any antibiotic use prior to admission. Exam demonstrated generalized poor dentition with multiple reconstructive dental implants placed five years prior and no acute odontogenic infection clinically or radiographically. Two sets of blood cultures were negative and TTE and two TEE procedures demonstrated no vegetations. Ophthalmology confirmed no Roth spots and exam showed no Osler nodes. On day nine, he felt dizzy and fell with subsequent MRI brain showing several ring-enhancing brain abscesses in the left thalamus measuring up to 3.1 cm, right parieto-occipital region measuring up to 3.4 cm and right frontal lobe associated with mass effect and hydrocephalus. Body fluid for *S. viridans* showed a MIC 0.5 for ceftriaxone. For treatment of abscesses and to ensure penetration into the central nervous system, patient was started on ceftriaxone 2g q12h, vancomycin 1250mg q12h and flagyl 500 mg q8h for 6 weeks. This case demonstrates the importance of considering hematogenous seeding of *S. viridans* when presented with multiorgan abscesses to liver, lungs and brain in the immunocompetent host without positive bacteremia or endocarditis. Patients with more than one organ

affected by *S. viridans* may benefit from full body CT or PET scan to further elucidate embolization or hematogenous seeding of other organs. This case supports European standards for PET scans in all patients with suspected endocarditis or multiple abscesses.

1210

### CHANGE IN SEROLOGICAL METRICS FOR CHLAMYDIA TRACHOMATIS BEFORE AND AFTER MASS DRUG ADMINISTRATION WITH AZITHROMYCIN IN KIRIBATI

Brook Goodhew<sup>1</sup>, Rabebe Tekeraoi<sup>2</sup>, Raebwebwe Taoaba<sup>2</sup>, Rab Tun<sup>2</sup>, Ana Bakhtiari<sup>3</sup>, Robert Butcher<sup>4</sup>, Chrissy H. Roberts<sup>4</sup>, Sarah Guagliardo<sup>1</sup>, Sarah Gwyn<sup>1</sup>, Anthony W. Solomon<sup>5</sup>, Emma Harding-Esch<sup>4</sup>, Diana L. Martin<sup>6</sup>

<sup>1</sup>CDC, Atlanta, GA, United States, <sup>2</sup>Kiribati Ministry of Health and Medical Services, Tarawa, Kiribati, <sup>3</sup>Task Force for Global Health, Atlanta, GA, United States, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>5</sup>WHO, Geneva, Switzerland, <sup>6</sup>CDC, Decatur, GA, United States

Trachoma, caused by ocular infection with *Chlamydia trachomatis*, is the leading infectious cause of blindness and is targeted for elimination as public health problem by 2030. One elimination target is for each formerly endemic district (evaluation unit [EU]) to achieve a prevalence of the clinical sign trachomatous inflammation—follicular (TF) of <5% in children 1-9 years old. A key intervention to help reach this target is district-wide mass drug administration (MDA) with azithromycin to clear infection. Serology may be a useful alternative indicator to TF for assessing ongoing transmission in children and monitoring recrudescence (TF ≥5%) after elimination, when resources for implementation may be more scarce. Here, we measured antibodies to *C. trachomatis* in children before and after two rounds of MDA in two EUs in Kiribati (Tarawa and Kiritimati Island). Baseline surveys to determine the need for MDA were conducted in 2015, resulting in two MDA rounds, and trachoma impact surveys (TIS) to determine if MDA could be stopped were done in 2019. Dried blood spots were analyzed by multiplex bead assay (MBA), ELISA, and lateral flow assay (LFA). Age-adjusted seroprevalence and seroconversion rates (SCR, number of seroconversions/100 children/year) were reported. In Tarawa, seroprevalence declined from 52.7% (95% CI: 43.3-61.9) at baseline to 31.4% (95% CI: 23.4-40.3) at TIS. SCR declined from 18.8% (95% CI: 16.7-20.8) to 8.8% (95% CI: 7.6-10.2) at TIS. In Kiritimati Island, seroprevalence was 46.8% (95% CI: 33.9-60.0) at baseline and 30.2% (95% CI: 22.1-40.1) at TIS; SCR was 16.9 (95% CI 13.7-23.1) at baseline and 8.9 (95% CI 7.5-10.7) at TIS. Among positive samples, the intensity of responses (represented by median fluorescence intensity, MFI) was lower at TIS compared with baseline in both sites (p<0.0001). Seroprevalence and SCR estimates derived from ELISA and LFA data were similar to those derived from MBA. Overall, reduction in antibody metrics after MDA was seen across assays in both EUs. Longitudinal data are critical to understanding antibody dynamics following interventions.

### SEROLOGICAL RESPONSES TO TRACHOMA ANTIGENS PRIOR TO THE START OF MASS DRUG ADMINISTRATION: RESULTS FROM POPULATION-BASED BASELINE SURVEYS, NORTH DARFUR STATE, SUDAN

Angelia M. Sanders<sup>1</sup>, Balgesa E. Elshafie<sup>2</sup>, Zeinab Abdalla<sup>3</sup>, Erica B. Goodhew<sup>4</sup>, Andrew W. Nute<sup>1</sup>, Nabil A. Aziz<sup>2</sup>, E. Kelly Callahan<sup>1</sup>, Diana L. Martin<sup>4</sup>, Scott D. Nash<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>Sudan Federal Ministry of Health, Khartoum, Sudan, <sup>3</sup>The Carter Center, Khartoum, Sudan, <sup>4</sup>United States Center for Disease Control and Prevention, Atlanta, GA, United States

After years of programmatic inaccessibility to the Darfur region, in 2019-2020 the Sudan Federal Ministry of Health Trachoma Control Program conducted population-based trachoma surveys in 3 localities (districts) in North Darfur state, Sudan. The goals of the baseline surveys were to

determine the current prevalence of trachomatous inflammation-follicular (TF) among children ages 1-9 years and to further use serological markers to understand the historical trachoma burden within this mass drug administration (MDA)-naïve area. Multi-stage cluster random sampling was used to select 30 villages (clusters), with 25 households per locality. In addition to the collection of trachoma clinical data by trained and certified graders, trained nurses collected dried blood spot (DBS) samples from individuals of all ages within the selected households. DBS were assayed on a multiplex bead array for antibody responses to the *Chlamydia trachomatis* antigen Pgp3. Across the three localities, 8,325 individuals aged 1-99 years in 2,189 households were examined for trachoma clinical signs and 8,324 DBS were collected, including 3,674 DBS samples from children ages 1-9 years. The prevalence of TF among children 1-9 years was endemic (>10%) in 2 localities (El Seraif, and Saraf Omrah) and below the elimination as a public health problem threshold (<5%) in the third (Kotom). The Pgp3 seroprevalence among children ages 1-9 years was 35.9% in El Seraif, 32.2% in Saraf Omrah, and 13.8% in Kotom. Within this age group, by age 9 years seroprevalence reached as high as 48% and 59% in Saraf Omrah and El Seraif, respectively, and reached 29% in Kotom. Across the whole age-range sampled, the seroprevalence was 40.4% in El Seraif, 41.9% in Saraf Omrah, and 36.8% in Kotom. Starting at age 20-29 years, the age specific seroprevalence was ≥40% among all age groups in all localities. Serological data collected within these trachoma surveys has demonstrated that all three localities have had a long history of exposure to *Chlamydia trachomatis*. Research is needed in Kotom to understand the potential epidemiological shift that may have taken place in the last 10 years.

### ENDOTHELIAL ACTIVATION IS REDUCED BY HYDROXYUREA THERAPY AND PREDICTS TRANSCRANIAL DOPPLER VELOCITY IN THE NOHARM STUDY: A PROSPECTIVE CLINICAL TRIAL OF HYDROXYUREA IN UGANDAN CHILDREN WITH SICKLE CELL ANEMIA

Thomas F. Siegert<sup>1</sup>, Robert O. Opoka<sup>2</sup>, Teresa Latham<sup>3</sup>, Adam Lane<sup>3</sup>, Russell E. Ware<sup>4</sup>, Chandy C. John<sup>5</sup>, Andrea Conroy<sup>5</sup>

<sup>1</sup>Division of Medicine-Pediatrics, Department of Pediatrics, The Warren Alpert Medical School of Brown University, Providence, RI, United States, <sup>2</sup>Department of Paediatrics and Child Health, Makerere University College of Health Sciences, Kampala, Uganda, <sup>3</sup>Cincinnati Children's Hospital Medical Center, University of Cincinnati College of Medicine, Cincinnati, OH, United States, <sup>4</sup>Division of Hematology, Department of Pediatrics, Cincinnati Children's Hospital Medical Center, Cincinnati, OH, United States, <sup>5</sup>Department of Pediatrics, Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States

Inflammation and endothelial activation play a key role in sickle cell anemia (SCA) pathogenesis. However, there are limited data on endothelial activation in children with SCA in low-and-middle-income-countries (LMIC) where SCA disease-burden is highest. We evaluated longitudinal changes in biomarkers of endothelial activation and inflammation in children enrolled in a randomized double-blind placebo-controlled trial of hydroxyurea (HU) as a disease modifying therapy for children with SCA (NOHARM study). A total of 205 Ugandan children aged 1.00 to 3.99 years were enrolled with routine hematologic monitoring and a transcranial doppler (TCD) exam at one-year follow-up to assess cerebral blood flow velocity. Increased TCD velocity is associated with stroke risk in children with SCA. We measured plasma levels of C-reactive protein, angiopoietin-2 (Angpt-2), soluble E-Selectin (sE-Selectin), P-Selectin, soluble ICAM-1, and soluble VCAM-1 by ELISA at enrollment, 2, 4, and 12 months follow-up. At enrollment, Angpt-2 levels were elevated in children with a history of blood transfusion, as well as ischemic vascular complications of SCA including vaso-occlusive crises, acute chest syndrome, and dactylitis (p<0.05 for all). Using linear mixed effects models to evaluate longitudinal changes in biomarkers, there was a significant reduction in Angpt-2, sE-Selectin and P-Selectin with HU therapy with differences evident by four months follow-up (p<0.01 for all). At both

enrollment and 12 months follow-up, Angpt-2 and sE-Selectin were independently associated with TCD velocity. We conducted longitudinal correlation analyses and generated a heat map between biomarkers of endothelial activation and hematologic parameters modified by HU over time. There was evidence that P-Selectin, Angpt-2 and sE-Selectin concentrations are associated with changes in fetal hemoglobin in children treated with HU. Additional studies are needed to understand the mechanisms of reduced endothelial activation and lower TCD velocity in children treated with HU.

## 1213

### BIOLOGICAL AND CLINICAL CHARACTERISTICS OF SUBJECTS TESTED POSITIVE FOR LEPTOSPIROSIS AMONG ACUTELY FEBRILE OUTPATIENTS ATTENDING PRIMARY CARE CLINICS DURING THE RAINFALL SEASON IN BURKINA FASO, WEST AFRICA

Sylvie Zida<sup>1</sup>, Dramane Kania<sup>2</sup>, Karine Bollore<sup>3</sup>, Oussani Bandaogo<sup>2</sup>, Amadou Dicko<sup>2</sup>, Bachirou Tinto<sup>2</sup>, Jacques Traore<sup>2</sup>, Henri Gautier Ouedraogo<sup>1</sup>, Edouard Tuailon<sup>3</sup>

<sup>1</sup>Institut de Recherche en Sciences de la Sante, Ouagadougou, Burkina Faso, <sup>2</sup>Centre Muraz, Bobo Dioulasso, Burkina Faso, <sup>3</sup>UMR 1058 INSERM/ EFS/Montpellier University, Montpellier, France

Leptospirosis has a significant public health impact worldwide and is suspected to be endemic in Burkina Faso. However, in the absence of systematically collected data on fever etiology, biological and clinical data are scarce. The present study aimed to explore the biological and clinical characteristics of subjects tested positive for leptospirosis IgM and DNA among acutely febrile outpatients attending primary care clinics during the rainfall season in Burkina Faso. Patients were recruited from primary health care centers in Bobo-Dioulasso. Patients tested negative for malaria using a rapid diagnostic test (SD Bioline malaria<sup>®</sup>, Standard Diagnostics Inc, South Korea) were considered as eligible and further explored for leptospirosis. Subjects tested positive for leptospira IgM using a rapid diagnostic test (Leptocheck<sup>®</sup>, Zephyr Biomedicals, India) or an ELISA kit (Serion<sup>®</sup>, Serion Diagnostics, Germany), or for leptospira DNA by PCR, were considered as probable leptospirosis cases. Of 350 patients screened, 170 met eligibility criteria and were enrolled. Among 170 participants, 48 (28.23%) at least one leptospirosis positive test and were considered as probable leptospirosis cases. A flu-like syndrome was observed in most cases, including fever, headache, cough, muscle pain, vomiting and diarrhea. Most of the patients had a mild form of the disease, generally not requiring hospitalization. The biological profiles of leptospirosis IgM positive people were variable and not significantly different from people tested negative for leptospirosis. On bivariable regression, variables associated with leptospirosis included water = (OR 4.70; 95% confidence intervals (CI): 2.39-9.24;  $p \leq 0.001$ ) and animal exposure (OR 2.63; CI: 1.36 - 4.09;  $p \leq 0.01$ ), and the presence of a skin wound (OR 2.81; CI: 1.27 - 6.23;  $p \leq 0.01$ ). Diagnostic testing of leptospirosis may be requested when there is a suspicion for leptospirosis based on symptoms and exposure to animal and water environments. Other epidemiological aspects of the disease such as the carriage of leptospira in domestic animals, slaughterhouse workers, muddy soils and surface water.

## 1214

### DOOR-TO-DOOR CHILD IMMUNIZATION: AN ACCEPTABLE ALTERNATE WAY TO CONTINUE CHILD IMMUNIZATION SERVICES FOR VULNERABLE POPULATION OF INFORMAL SETTLEMENTS IN NAIROBI, KENYA

Rashed Shah<sup>1</sup>, Abraham Rono<sup>2</sup>, Misiko Linda<sup>2</sup>

<sup>1</sup>Save the Children, Washington DC, DC, United States, <sup>2</sup>Save the Children International, Nairobi, Kenya, Kenya

In the first quarter of 2020, due to COVID-19 pandemic, there was a considerable disruption of immunization services in the informal settlements of Kibra and Langata in Nairobi county along with a raising concern for outbreaks of vaccine-preventable diseases. Given the high

population density within informal settlement areas in Nairobi county, we facilitated and supported Nairobi County's Ministry of Health (MOH) to conduct door-to-door immunization outreach services to vulnerable children as well as to locate, trace and vaccinate missed children. Reportedly, 710 children under five received immunization services, 277 children were dewormed, and 211 children received vitamin A supplementation during these door to door campaigns. A total of 403 missed children were all successfully traced and received vaccines too. Child immunization session data from three counties within project area revealed minimal observed disruption to outreach immunization activities, with a considerable increase in both planned and delivered outreach sessions during March to October 2020, corresponding time period when we facilitated the door to door campaigns. However, there was a slight decline in numbers of children vaccinated in 2020 compared to 2019. The physical distancing requirements as well as community reluctance affected immunization sessions and given the challenges during COVID-19 pandemic days, these achievements are potentially attributable to the adopted strategy for organizing door-to-door immunization outreach immunization session as well as the uninterrupted support offered to Nairobi County MOH and local partners within the project area. Community members in informal settlements of Kibra and Langata sub-counties were also found extremely supportive to these door-to-door immunization campaigns. While collaboration with MOH and local partners are mandatory for continuing such community focused alternate business model to keep the essential services available to vulnerable population, it is also important to ensure community support and community participation in those adopted strategy implementation steps.

## 1215

### ESTIMATING THE PROPORTION OF CHILDREN LESS THAN FIVE YEARS OLD WHO ARE FULLY IMMUNIZED ACCORDING TO EXPANDED PROGRAMME ON IMMUNIZATION IN THIRTEEN HIGH MALARIA TRANSMISSION COMMUNITIES IN MALABO DISTRICT, BOKO ISLAND

Esther L. Eburi-Losoha<sup>1</sup>, Maria Silvia A. Lopez Mikue<sup>2</sup>, Vicente Urbano<sup>2</sup>, Ali Hamad<sup>3</sup>, Antonio Enrique N. Sama<sup>1</sup>, Wonder P. Phiri<sup>1</sup>, Guillermo A. Garcia<sup>4</sup>, Thomas Richie<sup>5</sup>, Peter F. Billingsley<sup>5</sup>, Thabit Athuman<sup>3</sup>, Juan Carlos Momo<sup>2</sup>, Bonifacio Manguire<sup>6</sup>, Kamaka Ramadhani<sup>3</sup>, Marcel Tanner<sup>7</sup>, Salim Abdulla<sup>3</sup>, Stephen Hoffman<sup>5</sup>, Said Jongo<sup>3</sup>, Claudia Daubenberger<sup>7</sup>, Sonja Merten<sup>7</sup>

<sup>1</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>2</sup>Ministry of Health and Social Welfare of Equatorial Guinea, Malabo, Equatorial Guinea, <sup>3</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>4</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>5</sup>Sanaria, Rockville, MD, United States, <sup>6</sup>Marathon Oil Corporation, Malabo, Equatorial Guinea, <sup>7</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

According to the United Nations International Children's Emergency Fund (UNICEF), between 2009 and 2018 the coverage of routine immunization has been declining at an estimated rate of 10%-20% in Equatorial Guinea (EG). Although the national Expanded Programme of Immunization (EPI) with UNICEF has made progress in the elimination of polio in 2019, there is still a lack of quality immunization data in the country. The purpose of this study is to improve the quality of the data estimating routine coverage, which then will help to identify the risk factors that contribute to children not being vaccinated at the community level. The objective is to describe socio-demographic status and determine the actual EPI coverage rate among participants using both estimated national census data and Bioko Island Malaria Elimination Project (BIMEP) census data. In addition we will determine the associated factors for routine immunization rate among participants of a pilot study (EG-RESPAR) that aims to optimize recruitment and screening procedures to create a registry of ~3000 potential research participants for a future Phase III clinical trial of PfSPZ Vaccine in Malabo district. A descriptive cross-sectional assessment of routine immunization data of children <5 years old that reside in both urban and rural high malaria transmission communities will be undertaken. Caregivers will provide immunization history of children

and data verification will be done by vaccination card or by a recall, including vaccination health clinics used for the children. The proportion of children <5 years old who are fully immunized will be evaluated according to the national routine vaccination schedule. These results will address the knowledge gap and help to identify potential factors that lead to low immunization coverage among children <5 years old. The study will provide information for decision-makers to identify policy gaps and develop public health strategies to improve immunization adoption among those most vulnerable to vaccine-preventable diseases.

1216

### INTEGRATED MANAGEMENT OF CHILDHOOD ILLNESS: DANGER SIGNS AND PAEDIATRIC SEVERITY SCORES IN INPATIENT AND OUTPATIENT FEBRILE CHILDREN FROM FOUR COUNTRIES IN AFRICA AND ASIA

**Shunmay Yeung<sup>1</sup>**, Quique Bassat<sup>2</sup>, Oliver Baerenbold<sup>1</sup>, Sham Lal<sup>1</sup>, Elizabeth J. Fitchett<sup>3</sup>, Sara Ajanovic Andelic<sup>2</sup>, Núria Balanza<sup>2</sup>, John A. Crump<sup>4</sup>, Samantha Lissauer<sup>5</sup>, Ruud Nijman<sup>6</sup>, Heidi Hopkins<sup>1</sup>, David C. Mabey<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine (LSHTM), London, United Kingdom, <sup>2</sup>ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, <sup>3</sup>UCL GOS Institute of Child Health, London, United Kingdom, <sup>4</sup>Centre for International Health, University of Otago, Dunedin, New Zealand, <sup>5</sup>Malawi Liverpool Wellcome Clinical Research Programme, Blantyre, Malawi, <sup>6</sup>Imperial College London, London, United Kingdom

Identifying which febrile children can be safely sent home, and which require prioritized care can be challenging, especially in resource-constrained settings. Along with IMCI guidelines 'danger signs,' several paediatric severity scores have been developed to guide acute management decisions. However, most scores have only been validated among inpatients, where the decision to admit has already been made. Using prospectively collected data from the Febrile Illness Evaluation in a Broad Range of Endemicities (FIEBRE) study, we evaluated IMCI danger signs, and existing severity scores among both in- and outpatient children <16 years presenting with fever in Lao PDR, Malawi, Mozambique and Zimbabwe. We estimated discriminative performance using areas under the receiver-operative curve (AUC) and the positive and negative likelihood ratios for each of the following scores: LODS, LqSOFA, ED-PEWS, qPELOD-2 and modified FEAST-PET; at previously published cut-off-points. Of 3,425 children (1,412 inpatients; 2,013 outpatients) 725 were enrolled in Lao PDR, 876 in Malawi, 937 in Mozambique and 887 in Zimbabwe. Median (IQR) age was 4.3 (2.0-7.9) years. Treatment with antimicrobials varied by site, from 46 to 90% of first encounters. Of 2,946 children with complete follow-up data at 28 days, there were 22 (1.6%) and 3 (0.2%) deaths among inpatients and outpatients, respectively. At least one IMCI danger sign was present in 669 (33%) outpatients and 861 (61%) inpatients. Yet, 6 (24%) of the 25 children who died had no documented danger signs. Most severity scores demonstrated moderate-to-low discriminative performance, and were especially limited in ruling out mortality risk. The ED-PEWS and LODS scores had the highest AUCs; 0.81 (95% CI 0.71 - 0.90) and 0.80 (95% CI 0.71 - 0.90), respectively. The AUC was 0.74 (95% CI 0.62 - 0.86) for the modified FEAST-PET score. The LqSOFA and qPELOD-2 scores performed relatively poorly in this cohort (AUCs 0.66 (95% CI 0.55 - 0.76) and 0.57 (95% CI 0.48 - 0.67)). As continued progress is made to reduce child mortality, better risk-stratification tools are urgently required to guide management decisions.

1217

### DIAGNOSIS AND MANAGEMENT OF ENTEROBIOSIS IN MILITARY TREATMENT FACILITIES

**Madeline Renee Fleit<sup>1</sup>**, Jamie Fraser<sup>2</sup>, Patrick Hickey<sup>3</sup>, Edward Mitre<sup>4</sup>

<sup>1</sup>Walter Reed National Military Medical Center, Bethesda, MD, United States, <sup>2</sup>The Henry M. Jackson Foundation for the Advancement of Military Medicine, Inc., Bethesda, MD, United States, <sup>3</sup>Department of Pediatrics,

Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>4</sup>Department of Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD, United States

*Enterobius vermicularis* is one of the most common nematode infections in the world, as well as in individuals within the Military Health System (MHS). An average of over 4300 pinworm infections are diagnosed in the MHS per year. Despite being a common disease that is frequently encountered in clinical practice, few studies have evaluated current clinical practice. To determine the practices being used in the diagnosis and treatment of individuals with pinworm infection, we conducted a retrospective analysis of 112 patients diagnosed with enterobiasis from 2011 to 2018. The patient population was approximately 58% female with a median age of 8 years old (range: less than 1 year to 59 years). Signs or symptoms of infection were present in 82% (92/112) of cases, while 17.8% (20/112) of people presented for empiric treatment due to proximity to an individual with symptomatic enterobiasis. Of the symptomatic cases, a clinical diagnosis was made in 89.1% (82/92) of cases. Diagnostic studies were ordered in 25.0% (23/92) of symptomatic cases. Diagnostics included pinworm paddles, or similar adhesive preparations (52.1%, 12/23), as well as studies not geared towards the diagnosis of pinworm, such as ova and parasite exams (34.8%, 8/23), stool cultures (13.0%, 3/23), and enteric parasite PCR panels (8.7%, 2/23). Initial treatment consisted primarily of albendazole (67%), mebendazole (17.9%), and pyrantel (9.8%). Empiric retreatment 2 weeks after the initial dose was prescribed or recommended in 85.5% of cases, and empiric treatment of household members was prescribed or recommended in 45.5% of cases. Counseling on hygienic measures was documented in approximately a quarter of cases: washing sheets or bedclothes (26.1%), washing pajamas or underclothes (16.2%), hand hygiene (21.6%), clipping fingernails (12.6%). These results are preliminary, with plans to review a total of 200 charts. Thus far, our findings suggest there is an opportunity for education efforts to be made in the future with regard to best diagnostic and treatment options for pinworm, as well as highlighting pyrantel as a cost-effective therapeutic option.

1218

### ADDRESSING THE MENTAL HEALTH OF PERSONS LIVING WITH LYMPHATIC FILARIASIS IN LEOGANE, HAITI: EVALUATION OF A CHRONIC DISEASE SELF-MANAGEMENT PILOT PROGRAM

**Sarah Bazur-Leidy<sup>1</sup>**, Luccene Desir<sup>1</sup>, Martha Desir<sup>1</sup>, Samhita Kumar<sup>1</sup>, Tsion Horra<sup>1</sup>, Mary Ottley<sup>1</sup>, Rebecca Castor<sup>1</sup>, Paul Weiss<sup>2</sup>, Marc-Aurele Telfort<sup>3</sup>, Murielle Gilbert<sup>1</sup>, Gregory Noland<sup>1</sup>, Eve Byrd<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>Emory University, Atlanta, GA, United States, <sup>3</sup>Haiti Ministry of Health, Leogane, Haiti

There is mounting evidence that persons living with chronic illness resulting from neglected tropical diseases (NTDs) are at risk of mental illness, and many are living with the comorbidity of depression. There is also growing recognition of the importance of mental well-being in NTD prevention, elimination, and eradication efforts. Yet, there are few validated interventions for addressing the burden of chronic NTDs and co-morbid common mental disorders, especially in contexts affected by poverty, insecurity, and fragility. This study aims to fill this gap by determining the prevalence of depressive symptoms among persons with lymphatic filariasis in Leogane, Haiti and assessing the effectiveness of a chronic disease self-management (CDSM) intervention in improving mental health outcomes. CDSM is a six-session intervention delivered by peer facilitators within Hope Clubs. The study, carried out between July 2019 and April 2021, employed a randomized, waitlist-controlled design to assess the effect of CDSM on the treatment arm 1 (n=118) and the waitlisted treatment arm 2 (n=82) on symptoms of depressive illness, using the Zanmi Lasante Depression Symptom Inventory (ZLDSI) tool, which was created and validated in Haiti. Baseline data revealed half of respondents in Arm 1 (48%) and Arm 2 (52%) screened positive for symptoms of depressive illness, defined as a mean ZLDSI score >13 (Arm 1, 14.2, SD. 9.0; Arm 2, 13.8, SD. 8.2). At midpoint, following CDSM intervention

in Arm 1, prior to Arm 2, mean ZLDSI scores decreased in both Arm 1 (10.8, SD. 7.2) and Arm 2 (11.7, SD. 7.2). At endpoint, following CDSM intervention in Arm 2, mean ZLDSI scores again decreased in both Arm 1 (10.2, SD. 8.4) and Arm 2 (10.7, SD. 6.5). Amid limitations to the study, including delays imposed by COVID-19, these pilot data suggest overall trends that the CDSM intervention in the Hope Club setting promotes a reduction in symptoms of depressive illness among persons living with lymphatic filariasis. These findings should be considered observational, hypothesis-generating and encourage further research into the integration of mental health care into NTD care management.

1219

### ROUTINE IMMUNIZATION STATUS AND FACTORS ASSOCIATED WITH TIMELY IMMUNIZATION AMONG CHILDREN AGED 10 -17 MONTHS OLD IN BAGAMOYO, TANZANIA

**Neema Emmanuel Balige**, Florence Milando, Ally Olotu, Kamaka Kassim

*Ifakara Health Institute, Dar es salaam, United Republic of Tanzania*

Universal immunization of children against vaccine-preventable diseases (VPDs) is the most cost-effective public health intervention to reduce childhood mortality and morbidity across the world. The challenges remain in ensuring wide vaccine coverage. World Health Organization (WHO) targeted coverage for the routine immunization program is at least 90%. Also, WHO recommends that every child should receive every dose of vaccines at recommended ages and intervals to get the best protection possible. However, according to TDHS 2014-2015, the immunization coverage in Tanzania is 75%. Little data (if any) is available to explain local factors for this low coverage below the target. This information is vital for the development and implementation of appropriate solutions. Therefore, this study is designed to fill this lacuna in knowledge by investigating the current status of routine immunization and factors associated with timely immunization among Children aged 10 –17 Months Old residing in Bagamoyo district, Tanzania. This study is based on a secondary analysis of cross-sectional data from the dataset of the study entitled “A Phase Ib age de-escalation dose-escalation open-label study of the safety and immunogenicity of RH5.1/Matrix-M, administered intramuscularly in healthy adults and infants in Tanzania (NCT04318002)”. The population of this study is healthy adults (18-45 years) and infants (5-17 months) residing in Bagamoyo district, Tanzania. All data will be analysed by using SPSS computer software. Information on immunization coverage will be obtained from the child's health card and will be expressed in terms of percentage. Descriptive and analytical statistics including bivariate and multivariable analysis will be performed. Bivariate and multivariate analyses will be used to examine the association between dependent (timely immunization) and independent variables (sociodemographic variables). A corresponding P-values of  $\leq 0.05$  will be considered significant. The study started in January 2021 and screening visit monitored data is expected to be available in September 2021.

1220

### AN INVESTIGATION OF PREGNANCY OUTCOMES AMONG LASSA FEVER PATIENTS IN SIERRA LEONE

**Madison S. Drogy**<sup>1</sup>, Donald Grant<sup>2</sup>, Lansana Kanneh<sup>2</sup>, Veronica Koroma<sup>2</sup>, Fatima Kamara<sup>2</sup>, Emily Engel<sup>1</sup>, Nell G. Bond<sup>1</sup>, Jeffrey G. Shaffer<sup>3</sup>, John Schieffelin<sup>1</sup>

<sup>1</sup>Tulane University School of Medicine, New Orleans, LA, United States, <sup>2</sup>Kenema Government Hospital, Kenema, Sierra Leone, <sup>3</sup>Tulane University School of Public Health, Department of Biostatistics and Data Science, New Orleans, LA, United States

Lassa fever (LF) is a rodent-borne zoonotic disease endemic to West Africa. LF infected pregnant women are more likely to die than non-pregnant women. However, the cause of this increased mortality is not understood. In this study we characterize the relationship between pregnancy and severe outcomes of LF and present two case studies of LF in pregnancy.

The study population consisted of 53 pregnant and 250 non-pregnant women of reproductive age who were admitted to the Lassa Fever Ward at Kenema Government Hospital (KGH) in Sierra Leone between 2010 and 2019. Two cases from this study population are presented in depth. Statistical analysis was conducted in SAS, using Chi square tests to compare groups. In all, 58.49% of pregnant patients died compared to 24.20% of non-pregnant patients ( $p < 0.001$ ). Based on an ELISA test, 53.85% of pregnant patients tested positive for LASV antigen compared to 27.35% of non-pregnant patients ( $p < 0.001$ ). Among the cohort of pregnant women with accessible patient charts ( $n = 24$ ), absent uterus movement ( $p = 0.001$ ), malaise ( $p = 0.01$ ), and abdominal tenderness ( $p = 0.02$ ) were associated with increased rates of maternal and fetal death. Patient A was a 38-year-old woman from Pujehun District admitted to KGH after transfer from a local clinic. Upon exam, the gestational age was 38 weeks and no fetal heartbeat was detected. On hospital day 2 (HD2) Patient A went into labor and experienced convulsions, hemorrhaging, and expelled a macerated fetus and placenta. Patient A received a blood transfusion but died before receiving a full course of ribavirin. Patient B was a 22-year-old woman from Kenema District admitted to KGH presenting with anemia and swelling. The fundal height indicated the fetus was 28 weeks and the fetal heart rate was strong. Patient B went into labor on HD 7 and the neonate received a 9/10 Apgar score. The mother was discharged on HD 11 after receiving a full course of ribavirin. The findings of this study underscore the risks pregnant women with LF experience. The disparate outcomes between Patients A and B highlight the importance of treatment for successful maternal and fetal outcomes in the context of Lassa fever.

1221

### UPDATE ON ENVIRONMENTAL TRAITS, FREQUENCY AND LIVING CONDITIONS ASSOCIATED WITH RICKETTSIA AND LEPTOSPIRA INFECTIONS IN YUCATAN, MEXICO

**Emiliano Rivero Otamendi**<sup>1</sup>, Hannia R. Echazarreta Bolado<sup>1</sup>, Claudia D. Fuentelzas Rosado<sup>1</sup>, Brenda J. Marín Valenzuela<sup>1</sup>, Karla R. Dzul Rosado<sup>2</sup>, Nina Méndez Domínguez<sup>3</sup>

<sup>1</sup>Marist University of Merida, Mérida, Mexico, <sup>2</sup>CIR Hideyo Noguchi, Mérida, Mexico, <sup>3</sup>Hospital Regional de Alta Especialidad de la Península de Yucatán, Mérida, Mexico

Many houses located in rural areas of Yucatan still have no access to running water, and thus, cenotes are one of their sources for freshwater. Nevertheless, their underwater connection makes them vulnerable to contamination by human activities. Domestic dogs in rural Yucatan spend most of the time in public areas and defecate freely in any place since no measures for collecting feces are implemented. During the rainy season, water is not easily absorbed by the rough soil, generating puddles where animals find their drinking source. In 2011, in a reservoir seroprevalence study, the majority of dogs and cats slept outdoors of which 45.2% and 15.2% respectively were found positive for *Leptospira*, an anaerobic spirochete. *Leptospirosis* prevalence in humans in the region was reported to be 14.2% in 2002, with more prevalence in rural areas and 74.3% cases during the rainy season. However, as dogs are in contact with other dogs, wild animals, cattle and their owners, it's not uncommon to find them carrying ectoparasites such as ticks which may transmit *Rickettsia*. *Rickettsial* and *Leptospiral* infections have been continuously increasing during the last decade in Yucatan, Mexico, and therefore, the objective of this case report is to update the frequency, seasonality and trends of both diseases in the context of rural Yucatan, Mexico. This is an observational epidemiological surveillance-based study that includes all official epidemiological registries reported in 2020 in Yucatan, Mexico. A total of 187 confirmed cases of *Rickettsia* infections were reported in Mexico, two (1.06%) of them occurred in Yucatan during the dry and rainy season. Additionally, 104 new cases of *leptospirosis* were confirmed nationwide of which four (4.16%) were from Yucatan in the rainy season. Coinfections between *Rickettsia* and *Leptospira* are uncommon, but may be included in differential diagnosis when poor sanitation and cohabitation with infested animals converge. Both conditions may or may not coexist, but when

clinical manifestations in patients with environmental determinants are present, due to their incidence in the region, should both be considered and tested.

1222

### A COMPARISON OF THREE NUTRITIONAL ASSESSMENT TOOLS AMONG RENAL PATIENTS AT THE KOMFO ANOKYE TEACHING HOSPITAL, GHANA

**Marina A. Tandoh<sup>1</sup>**, Lydia Manu<sup>1</sup>, Justina Owusu<sup>2</sup>, Odeafio Asamoah-Boakye<sup>1</sup>

<sup>1</sup>Department of Biochemistry and Biotechnology (Human Nutrition and Dietetics), Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, <sup>2</sup>Department of Nutrition and Food Science, University of Ghana, Legon, Accra, Ghana

The study aimed at comparing three nutritional assessment tools; Minimal Nutritional Assessment (MNA), Subjective Global Assessment (SGA), and Malnutrition Universal Screening Tool (MUST) among renal patients at the Komfo Anokye Teaching hospital (KATH), Ghana. In a cross-sectional study, 110 renal patients aged 18 years and above and diagnosed with renal impairment were recruited from the Nephrology Unit of KATH. The MNA, SGA and MUST were used to obtain nutritional status data of the participants. According to the MNA, SGA and MUST, 49.1%, 12.7% and 16.4% of the renal patients were malnourished respectively. The MNA showed significant potential for predicting clinical outcomes such as decline in food intake ( $k = 0.972$ ,  $p = 0.015$ ), weight change ( $k = 0.827$ ,  $p = 0.024$ ) and change in body mass index (BMI) ( $k = 1.00$ ,  $p = 0.048$ ) in patients. The MUST showed a significant difference in change in BMI of patients ( $p = 0.011$ ), while no significant clinical outcome was observed in patients using the SGA tool. Thus, the MNA tool may be a better alternative to SGA and MUST for the assessment of the nutritional status of renal impaired patients. Additionally, the Ghana Health Service should provide regular training of health workers on the nutritional assessments of renal patients to enable effective identification and management of individuals who may be at risk of malnutrition.

1223

### OTORHINOLARYNGOLOGICAL SERVICE ON SPECIAL NEEDS INDIVIDUALS: OTOSCOPIC APPROACH

**Immaculata Ogechi Akpalaba**

University of Medical Sciences, Ondo State, Ondo, Nigeria

The aim was to identify common Otolological conditions in special needs and to proffer solutions to them. Special needs are neglected group in the society dependent on others for their day to day activities. They are usually stigmatized and denied medical care. This study availed them the opportunity to have medical attention through Otorhinolaryngological service to improve their hearing. This was a 4 year prospective case-control study from May 2014 to August 2018. The study centre was at Project Chari-love. The study population was special needs whose parents gave written informed consents. sampling technique was total population technique. Stratified technique was used for the control. The control was Sunday-school children attending St. Albert Catholic Church, University of Benin, Benin city. Ethical clearance and permissions and consents were duly obtained. Health talks on the aims of the study, the ear, care of the ear and hearing hygiene and possible interventions were given. Questionnaires were filled by the researchers and their trained research assistants. Otoscopy was done. Each ear was regarded as a separate entity. Speculum used for each participant was disinfected before re-use on another participant. Wax and foreign body seen were removed. Those that had ear pathologies were referred to centres with otorhinolaryngological facilities for further evaluation and management. There were 60 cases and controls, aged 1 to 18 years for the cases and the control. 16 males and 44 females in the cases while the control was 23 males, 37 female. They were pupils from pre- KG class to senior secondary 3, with consent. Mean ages were 4.80 +/- 4.50 years for the cases and 2.00 +/- 3.60 for the control. Common ear conditions identified in the cases were impacted

cerumen auris, Otitis Media with effusion, Eustachian tube dysfunction and chronic Suppurative otitis media. In contrast, the control recorded both Otomycosis and foreign body in the ears. From this study, Otolological conditions are common in special needs. It demonstrated that much can be achieved with Otoscopy.

1224

### COVID-19 SEROPREVALENCE IN TWO MALARIA ENDEMIC RURAL COMMUNITIES IN MALI, WEST AFRICA

**Bourama Kamate<sup>1</sup>**, Kourane Sissoko<sup>1</sup>, John Woodford<sup>2</sup>, Mahamadou Hamady Assadou<sup>1</sup>, Abdoulaye Katile<sup>1</sup>, Amatique Zeguime<sup>1</sup>, Mamady Kone<sup>1</sup>, Jacquelyn Lane<sup>2</sup>, M'Bouye Doucoure<sup>1</sup>, Sara Healy<sup>2</sup>, Jennifer Kwan<sup>3</sup>, Jennifer Hume<sup>2</sup>, David Cook<sup>2</sup>, Aye Sousa<sup>2</sup>, Michal Fried<sup>2</sup>, Amagana Dolo<sup>1</sup>, Mahamadou S. Sissoko<sup>1</sup>, Abdoulaye Djimde<sup>1</sup>, Alassane Dicko<sup>1</sup>, Patrick Duffy<sup>2</sup> and Issaka Sagara<sup>1</sup>.

<sup>1</sup>Malaria Research and Training Center, Mali-NIAID ICER, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali. <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland, USA. <sup>3</sup>Laboratory of Clinical Immunology and Microbiology, National Institute of Allergy and Infectious Diseases, Bethesda, Maryland, USA.

In collaboration with the Mali Ministry of Health, the Malaria Research and Training Center and the Laboratory of Malaria Immunology and Vaccinology conducted a longitudinal seroprevalence study COVID-19 epidemiology in two malaria endemic rural communities, Bancoumana and Doneguebougou, located 60 km and 30km from Bamako respectively. Participants aged  $\geq 6$  months of age completed two study visits between July and September 2020, and December 2020 and January 2021. At each visit a serum sample for SARS-CoV-2 serology testing was collected. In Doneguebougou, the seropositivity rate was 4.1% (95% CI: 2.9-5.2) at Survey 1 (n=1109) and 25.8% (95% CI: 23.2-28.4) at Survey 2 (n=1088). After adjustment, it was 4.7% (95% CI: 2.6-6.8) at Survey 1 and 34.4% (95% CI: 27.4-41.4) at Survey 2. In Bancoumana, at survey 1 (n=963) and survey 2 (n=904), the seropositivity rates were 5.3% (95% CI: 3.9-6.7) and 35.5% (95% CI: 32.4-38.6) respectively. After adjustment, the rates were 6.4% (95% CI: 4.0-8.8) and 47.6% (95% CI: 38.2-57) These results may reflect the spread of SARS-CoV-2 from urban to more rural regions as they are lower than the seroprevalence estimates of over 50% that we have previously reported in Bamako. Keywords: COVID-19, Seroprevalence, Age. Rural, Mali West Africa.

### RICKETTSIA AND LEPTOSPIRA COINFECTION IN A TWELVE-YEARS-OLD FEMALE FROM YUCATAN, MEXICO: CLINICAL CASE REPORT

**Jairo Isaih Mendoza Argáez<sup>1</sup>**, Karla R. Dzul Rosado<sup>2</sup>, Maria Fidelia Cardenas Marrufo<sup>3</sup>, Cesar Lugo Caballero<sup>2</sup>, Alberto Álvarez Baeza<sup>1</sup>, Nina Méndez Domínguez<sup>4</sup>, Fernando Puerto Manzano<sup>3</sup>, Juan José Arias León<sup>3</sup>

<sup>1</sup>Universidad Marista de Mérida, Mérida, Mexico, <sup>2</sup>Center for Regional Research "Dr. Hideyo Noguchi" Biomedical Unit, Mérida, Mexico, <sup>3</sup>Faculty of Medicine, Universidad Autónoma de Yucatán, Mérida, Mexico, <sup>4</sup>Hospital Regional de Alta Especialidad de la Península de Yucatán, Mérida, Mexico

It is estimated that approximately 75% of emerging and reemerging infection diseases worldwide are zoonotic. Rocky Mountain spotted fever is a disease caused by *Rickettsia rickettsii*, a gram-negative bacteria transmitted by an arthropod, while Leptospirosis is a zoonotic disease caused *Leptospira spp.*, a gram-negative spirochete. *Rickettsia* and Leptospirosis are not a first line diagnoses, even though Mexico show ecologic and socioeconomic characteristics that favor their transmission. The objective of the present case report is to document an unusual case of *Rickettsia* and *Leptospira* coinfection with emphasis on clinical manifestations and epidemiological context that may orient future multidisciplinary measures and diagnosis. Here we present the case of a

12-year-old female, whose mother had a history of recent a Rickettsial infection. The patient debuted with fever, developed unspecific signs and symptoms of infection, but quickly deteriorated with gastrointestinal, hepatic, renal, and neurological dysfunction. After discarding rabies, the patient was tested for *Leptospira* approaching antibodies using Microscopic Agglutination Test (MAT), which reported positive with 1:400 to *L. Interrogans* serovar Australis. Also serologic and molecular diagnosis of *Rickettsia* were performed. Immunofluorescence reagent for *R. rickettsii* IgM 1:256 and IgG 1:512 resulted positive and CSF was positive to *R. rickettsii*. Despite antibiotic treatment was indicated, the patient died due to septic shock after 33 days at the intensive care unit. This case exemplifies the possible clinical course in a probable coinfection between *Rickettsia* and *Leptospira* in a pediatric patient. When signs and symptoms, cannot fully be explain by a single pathogen and epidemiological and clinical context suggest more than one possible causal agent, coinfection should be included in differential diagnosis when poor sanitation and cohabitation and infested animals converge. In conclusion simultaneous instead of sequential diagnosis is recommended in order to prevent future fatal outcomes in patients.

1226

#### EPIDEMIOLOGICAL CHARACTERIZATION OF HUMAN SETTLEMENTS EXPOSED TO TRIATOMINAE SPECIES AND TRYPANOSOMA CRUZI IN THE COLOMBIAN CARIBBEAN

Margarita M. Ochoa-Diaz<sup>1</sup>, Monica Suarez-Sotomayor<sup>2</sup>, Melisa Eyes Escalante<sup>3</sup>

<sup>1</sup>Post-Doctoral in Tropical Medicine, Research Group Biodiversidad del Caribe Colombiano, Universidad del Atlántico, Barranquilla, Colombia, <sup>2</sup>Faculty of Medicine, Universidad del Sinú seccional Cartagena, Research Group GIBACUS, Cartagena, Colombia, <sup>3</sup>Faculty of Basic Science, Biology Program, Tropical Medicine Doctorate, Research Group Biodiversidad del Caribe Colombiano, Universidad del Atlántico, Barranquilla, Colombia

Chagas disease or American trypanosomiasis is caused by the protozoan parasite *Trypanosoma cruzi* which represents a public health problem because it is part of the group of Neglected Tropical Diseases (NTD). Chagas disease affects annually approximately 6 to 8 million people worldwide, with an estimated 50.000 deaths; likewise, between 60 to 100 million people live in risk areas around the world including Colombian Caribbean region. As part of the response for the control of CD the research groups in Tropical Medicine of the Colombian Caribbean proposed to analyze epidemiologically and serologically the human settlements exposed to Triatominae species, the presence of *Trypanosoma cruzi* and Chagas disease in municipalities of the Atlantic Department in Colombia. This was a descriptive epidemiological study of prevalence with prospective data collection. Patients with suspected diagnosis or risk factor of Chagas disease were included due their environmental risk of exposure to Triatominae located in the department of Atlantico such as the municipality of Corral de San Luis. A serum sample was taken and / or whole blood for the application of serological tests aimed to characterize patients as carriers or not of IgG antibodies against *T. cruzi*. As part of the results the serological profile of the recruited patients in relation to Chagas disease was described for the first time for a municipality in the Atlantic department where the parasite and the transmitting vector of the disease has been described in the past. This information is of relevant importance as a public health surveillance measure since, up to the date of this work, no cases of Chagas disease have been notified in government reports in the region of study, but there have been positive cases in neighboring municipalities therefore with this work a response is given to a population with many risk factors for the presence of this vector borne disease.

1227

#### DISCOVERY FOR LOA LOA CROSS-REACTIVE BIOMARKERS RESPONSIBLE FOR FALSE-POSITIVE LYMPHATIC FILARIASIS RAPID DIAGNOSTIC TESTS

Linda Yemeli Djune<sup>1</sup>, Marla Hertz<sup>2</sup>, Hugues Clotaire Nana-Djeunga<sup>1</sup>, Robert Sprung<sup>3</sup>, Jean Gabin Bopda<sup>1</sup>, Joseph Kamgno<sup>1</sup>, Philip Budge<sup>2</sup>

<sup>1</sup>Centre for Research on Filariasis and other Tropical Diseases, Yaounde, Cameroon, <sup>2</sup>Division of Infectious Diseases, Department of Medicine, Washington University School of Medicine, St. Louis, Missouri, USA, St Louis, MO, United States, <sup>3</sup>Division of Endocrinology, Metabolism and Lipid Research, Department of Internal Medicine, Washington University School of Medicine, St. Louis, MO, USA., St Louis, MO, United States

Reactivity of *L. loa* antigens (LAg) to lymphatic filariasis (LF) rapid tests (LF-RDT) (Immunochromatographic test, ICT and Filariasis Test Strip, FTS) is a hindrance to LF elimination in West and Central African countries. Previous attempts to characterize those Ags were inconclusive due to the limited number of cross-reactive sera analyzed. To determine which LAg are consistently present in cross-reactive sera, we collected sera from 73 FTS-positive individuals and 13 FTS-negative controls, both groups harboring high *L. loa* microfilariae counts, and with no evidence of LF infection. Immunoprecipitation was used to isolate cross-reactive antigens. Western blot, using the monoclonal antibody (AD12) was employed to detect the different proteins present in those samples, and liquid chromatography-electrospray ionization-tandem mass spectrometry was used for the identification and characterization of those proteins. The AD12 western blot showed that cross-reactive sera contain multiple LAg, the most common one being a ~80 kDa protein. Interestingly, the ~80kDa protein was also detectable by western blot in 92.3% FTS-negative samples. Mass spectrometry of a set of 20 FTS-positive samples already analyzed revealed the presence of 23 proteins, including two proteins present in >80% of samples. The comparison of this antigen profile with that of FTS-negative controls is ongoing and will help classifying the antigens as sole markers of cross-reactivity or as more broadly applicable antigen biomarkers for loiasis. To the best of our knowledge, this is the first large-scale proteomic identification of *L. loa* antigens in cross-reactive sera.

1228

#### EXPRESSION AND CHARACTERIZATION OF OV-103 AND OV-RAL-2, TWO LEADING VACCINE CANDIDATES FOR ONCHOCERCIASIS

Bin Zhan<sup>1</sup>, Wen\_Hsiang Chen<sup>1</sup>, Junfei Wei<sup>1</sup>, Zhuyun Liu<sup>1</sup>, Peter J. Hotez<sup>1</sup>, Sara Lustigman<sup>2</sup>, Maria Elena Bottazzi<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>New York Blood Center, New York, NY, United States

Ov-103 and Ov-RAL-2 are two vaccine candidates for onchocerciasis that induce significant protection against *Onchocerca volvulus* L3 infection in the mouse model. To produce large quantity of recombinant proteins with high purity and stability for testing in a clinical trial for efficacy in calves against natural infection with *Onchocerca ochengi* that in endemic in sub Saharan regions of Africa, the large scale production of recombinant proteins of these two antigens was carried out at 10L fermentation. Recombinant Ov-103 was highly expressed in yeast *PichiaPink* strain#1 at the 10 L scale under induction of methanol, and purified by one-step ion exchange chromatography. The recombinant Ov-RAL-2 was expressed in *E. coli* BL21 under induction of 1 mM IPTG at the 10 L scale with estimated raw yield of up to 1.0 g/L, then purified by IMAC as first capture step followed by a Q column polishing step. By these simplified two-steps purification, the purity of rOv-RAL-2 was over 97% with low contamination of endotoxin. Both recombinant proteins could be recognized by the sera from infected patients living in endemic areas. Far-UV CD spectrum analysis reveals that both Ov-RAL-2 (*E. coli*) and Ov-103 (yeast) have similar  $\alpha$ -helical structure with a typical positive peak at 193 nm and a negative peak at 202-208 nm. Stability studies showed that Ov-RAL-2 was stable at 4°C and 37°C for at least 14 days, and remained

stable for 35 months so far at -80°C; no significant changes were observed in its visual appearance, concentration and purity. For Ov-103, it has a trend to form aggregation over time even when stored at -80°C. The efficacy in the vaccinated calves co-administered with these two vaccine antigens will be also presented.

1229

### INCREASING IMMUNE ACTIVATION IN PATIENTS WITH ADVANCED STAGE FILARIAL LYMPHEDEMA

Sacha Horn<sup>1</sup>, Anja Feichtner<sup>1</sup>, Abdallah Ngenya<sup>2</sup>, Max Demetrius<sup>2</sup>, Yussuf Mgaya<sup>2</sup>, Jubin Osei-Mensah<sup>3</sup>, Vera S. Opoku<sup>3</sup>, Ute Klarmann-Schulz<sup>4</sup>, Janina Kuehlwein<sup>4</sup>, Manuel Ritter<sup>4</sup>, Achim Hoerauf<sup>4</sup>, Michael Hoelscher<sup>1</sup>, Akili Kilinga<sup>2</sup>, Alexander Y. Debrah<sup>3</sup>, Inge Kroidl<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Tropical Medicine, Medical Center of the University of Munich (LMU), Munich, Germany, <sup>2</sup>National Institute for Medical Research (NIMR), Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Kumasi Centre for Collaborative Research in Tropical Medicine (KCCR), Kumasi, Ghana, <sup>4</sup>Institute for Medical Microbiology, Immunology and Parasitology (IMMIP), University Hospital Bonn (UKB), Bonn, Germany

Filarial lymphedema is caused by the adult worm of *Wuchereria bancrofti*, which can live for up to seven years in the human body. Worldwide, around 68 million people are infected with this helminth and approximately 25 to 30 million suffer from this chronic pathology. Treatment of filariasis commonly consists of antihelminthic drug combinations (Albendazole plus Ivermectin and/or Diethylcarbamazine) which diminishes microfilariae – the larval stage – but has only minimal effects on the adult worm of *W. bancrofti*. Other treatment options are under investigation. As part of an ongoing clinical trial testing the efficacy of Doxycycline to improve filarial lymphedema, individuals with different stages of lymphedema were recruited in Tanzania and Ghana. Four hundred twenty participants per country were characterized at baseline using the lymphedema staging (stage 0-7) according to Dreyer *et al.* (2002), circumference measurements with a tape measure, and an infrared scanner (LymphaTech®, Atlanta, Georgia, USA). Apart from clinical characteristics, immunological aspects of the different treatment groups were measured at baseline. Full blood from the participants was characterized for the presence of memory CD4 or CD8 T cells (CD45, CD27), regulatory CD4 T cells (FoxP3, CD25) and immune activation markers (CD38, HLADR). Data from the first 94 patients in Tanzania and 59 patients in Ghana show increased levels of CD38<sup>+</sup>/HLADR<sup>+</sup> CD4<sup>+</sup> T cells in participants with advanced stage lymphedema (stage 4 to 7), compared to participants with early lymphedema (stage 2 to 3). The increased immune activation in patients with advanced disease emphasizes the role of the immune system in the process of lymphedema development, which might lead to new treatment opportunities.

1230

### DEVELOPMENT OF A MULTIPLEX BEAD ASSAY FOR DETECTION OF SPECIFIC ANTI-ONCHOCERCA VOLVULUS IMMUNOGLOBULIN IN HUMAN SERA

Sylvia Ossai, Yong Wang, John Noh, Olga Stuchlik, Matthew S. Reed, Pavel Svoboda, Jan Pohl, William E. Secor, Sukwan Handali  
Centers for Disease Control and Prevention, Atlanta, GA, United States

Onchocerciasis elimination programs are hampered by the lack of effective tests for making mass drug administration stopping decisions and conducting surveillance. All current tests for onchocerciasis-specific IgG4 use recombinant antigen Ov16. Although anti-Ov16 testing is useful for community screening and mapping of endemic areas, it was not developed under an elimination use case and lacks the sensitivity and specificity for making treatment stopping decisions in Africa. Therefore, identification of additional antigens that could be used alone or in combination with Ov16 to improve diagnostic accuracy and routine serosurveillance is needed. We conducted biomarker discovery to find potential targets for detecting antibodies to *Onchocerca volvulus*.

Soluble fractions of homogenized adult worms were separated by size-exclusion liquid chromatography and 1-D gel electrophoresis. Protein immunoblots were used to identify reactive bands after the disruption of carbohydrate moieties. Fractions with reactive bands were subjected to tandem mass spectrometry. We identified 136 peptide sequences and selected 28 proteins using bioinformatic screening. These proteins were expressed, purified, and tested by immunoblot using known *Onchocerca*-positive patient sera. Specific IgG1 and IgG4 reactivity were observed for 5 proteins: Ov16, OvMSA-1, OvFABP, Ov33.3, and OvMSP3 with no reactivity in negative control sera. Ov16, OvMSA-1, OvFABP, and Ov33.3 demonstrated high (500-5000) signal-to-noise ratio (S/N) compared to potentially cross-reactive sera from persons with *Wuchereria bancrofti* infection using bead conjugated antigens either alone or in a multiplex assay. OvMSP3 showed a lower S/N ratio (~40) than other antigens but remains a viable candidate. Several of these antigens have been identified by other laboratories, and their combined use has been proposed for onchocerciasis mapping activities. Independent identification of the same antigens in our studies strengthens their likely utility. Characterization of the target antigens' performance for the onchocerciasis elimination use case is currently ongoing.

1231

### SURVIVAL OF ADULT FEMALE WORMS OF ONCHOCERCA OCHENGI IN GERBILS AND HAMSTERS: IMPLICATIONS FOR THE DEVELOPMENT OF AN IN VIVO MACROFILARICIDE SCREENING MODEL

Glory E. Mbah<sup>1</sup>, Rene B. Ayiseh<sup>2</sup>, Faustin P. Manfo<sup>2</sup>, Tessa-Koko Kulu<sup>2</sup>, Fabrice N. Njotu<sup>2</sup>, Elvis Monya<sup>2</sup>, Emmanuel M. Ndi<sup>2</sup>, Evans N. Mainsah<sup>2</sup>, Judy Sakanari<sup>3</sup>, Sara Lustigman<sup>4</sup>, Fidelis Cho-Ngwaa<sup>5</sup>

<sup>1</sup>Department of Biology, Higher Teacher Training College, University of Bamenda, Bamenda, Cameroon, <sup>2</sup>ANDI Centre of Excellence for Onchocerciasis Drug Research, Biotechnology Unit, Faculty of Science, University of Buea, Buea, Cameroon, <sup>3</sup>Department of Pharmaceutical Chemistry, University of California, San Francisco, CA, United States, <sup>4</sup>New York Blood Center, Lindsey F. Kimball Research Institute, New York City, NY, United States, <sup>5</sup>National Higher Polytechnic Institute (NAHPI), University of Bamenda, Bamenda, Cameroon

Onchocerciasis, the second leading infectious cause of blindness, afflicts approximately 21 million people globally. Its control is limited to the use of the microfilaricidal drugs, ivermectin and moxidectin. Both drugs are unable to kill the adult worms which can survive for up to 15 years in patients, justifying the urgent need for potent and novel microfilaricides that kill adult worms. The development of such drugs has been mired by the lack of an appropriate small laboratory animal model to evaluate potential drug candidates *in vivo*. This study assessed the survival of *O. ochengi* female worms and their embryos over time in two laboratory rodents: gerbils and hamsters and tested using 'proof-of-concept' studies, whether known macrofilaricidal drugs can kill these worms. Gerbils and hamsters were surgically implanted with mechanical or enzyme-liberated adult *O. ochengi* female worms, and sacrificed at various time points (days 7 to 60 post-transplantation) to test for survival. Recovered worms were assessed for viability by biochemical analysis (MTT/formazan assay) or for their fecundity (embryogram). By day 26 post-implantation, 58.6±7.5% were recovered from hamsters, and 20±3.5% from gerbils. Those recovered from gerbils were mostly disintegrated or fragmented, with significantly higher (p<0.05) fragmentation observed with enzymatically-liberated worms. From day 3 post-implantation, flubendazole (FBZ) at 20 mg/kg body weight was administered subcutaneously at the nape for 7 days, to validate both rodent models. FBZ had no significant effect on the number and/or viability of worms recovered. However, embryo degradation was observed among some embryonic stages recovered from FBZ-treated gerbils (p<0.05). This exploratory study has revealed the gerbil and hamster as permissible rodents to adult female worms of *O. ochengi*. The hamsters appeared to maintain the infection longer, compared to gerbils. In gerbils, the worm isolation method significantly affected worm survival rate compared to the survival rate in hamsters.

## COMPARISON OF STANDARD AND MODIFIED HUMAN LANDING CATCH TECHNIQUES FOR BLACKFLIES IN THE ERA OF ONCHOCERCIASIS ELIMINATION

Kareen Atekem<sup>1</sup>, Philippe Nwane<sup>2</sup>, Ruth Dixon<sup>3</sup>, Rogers Nditanchou<sup>1</sup>, Aude Wilhelm<sup>3</sup>, Elena Schmidt<sup>3</sup>, Daniel Boakye<sup>4</sup>

<sup>1</sup>Sightsavers, Yaounde, Cameroon, <sup>2</sup>Centre for Research on Filariasis and other Tropical Diseases (CRFiMT), Yaounde, Cameroon, <sup>3</sup>Sightsavers, Haywards Heath, United Kingdom, <sup>4</sup>The End Fund, New York, NY, United States

Entomological evaluations of large fly catches are required for stopping mass drug administration (MDA) and verification of Onchocerciasis elimination. Human landing catch (HLC) is the standard sampling method for collecting human-biting blackflies for these purposes. Despite ethical concerns regarding the exposure of vector collectors to infective flies, the method is still commonly used, as no suitable alternative has been found to replace it. With many countries entering elimination phase, alternative and safer methods are needed. This study aimed to evaluate a modified HLC where vector collectors are protected by coloured-trousers attractive to blackflies allowing them to land on them but prevent biting. The study was conducted in Massangam district, Cameroon in October - November 2020 (rainy season) and January -February 2021 (dry season). Four points 50 meters apart along the banks of river Mbam known to contribute to onchocerciasis transmission, were selected corresponding to four collection arms - standard HLC (sHLC) and three modified versions, - collectors wearing blue (bHLC), black (nHLC) and blue-black pattern trousers (bnHLC). The collectors were rotated amongst collection points to minimize bias. Collection took place for four consecutive days per month between 7am and 5pm by two individuals interchangeably. All flies caught were dissected. Mann Whitney U test was used to compare the mean proportion of flies collected. A total of 17,246 flies were caught over the 4-month period. There was no statistical difference between proportions of flies caught between nHLC (29.9%; n=5,148) and sHLC (29.7%; n = 5,130) (P=0.13 and P=0.14) during both seasons. sHLC collected significantly more flies than bHLC (21.6%; n=3717; P<0.01) and bnHLC (18.9%; n=3251; P<0.01). A total of 673 (15.8%) were parous, 4 (2.1%) of parous flies were infected and 1 (0.5%) infective. There was no significant difference in the proportion of parous collected in the different arms. The study suggests using black colour-coated material for blackfly collection is a potential alternative to replace a sHLC, reducing the risk of exposure of collectors to fly bites.

## METALLOPROTEASE INHIBITORS AS POTENTIAL MACROFILARICIDAL TREATMENTS FOR LYMPHATIC FILARIASIS

Matthew S. Moser<sup>1</sup>, Christina Bulman<sup>2</sup>, Chelsea Fischer<sup>2</sup>, Judy Sakanari<sup>2</sup>, Edward Mitre<sup>1</sup>

<sup>1</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>University of California, San Francisco, San Francisco, CA, United States

Lymphatic filariasis is a neglected tropical disease that affects over 60 million people in tropical regions. While there are several medications with activity against microfilariae, development of short course medications with activity against adult stages would enhance global efforts to eliminate LF. In this study, we screened various classes of protease inhibitors and observed substantial macrofilaricidal effect with the matrix metalloprotease (MMP) inhibitor 1,10 phenanthroline. Biochemical analyses confirmed that inhibition of MMP activity occurs when 1, 10 phenanthroline is applied to worm homogenate. On the basis of these results, we then tested several agents that are approved for human use and have MMP inhibitor function for activity against adult *Brugia malayi* worms. Worm motility was quantified using the computer-based screening application, *The Worminator*. Agents that demonstrated effects at 100uM were then tested at a range of concentrations to determine daily EC50's from day 1

to day 7. Two flavonoid supplements, luteolin and quercetin, were found to have EC50s of 36.4uM and 25.9uM at day 7. Both of these agents are safe for human consumption at high concentrations. Additionally, the MMP inhibitors, 1,10-Phenanthroline and its analog 4,7-dimethyl 1,10-phenanthroline were also shown to be highly potent against *B. malayi* adults (EC 50 of 0.9uM and 0.3uM at day 7, respectively). Effects on third-stage larvae (L3) were even more pronounced, as 10uM of luteolin and quercetin were sufficient to kill most L3 within 3 days, as was 1uM of 1,10-phenanthroline and 4,7-dimethyl 1,10-phenanthroline. The effects of these compounds on microfilariae as well as on the endosymbiotic *Wolbachia* bacteria are under investigation. The results of this study suggest that matrix metalloprotease inhibitors may be promising macrofilaricidal agents for lymphatic filariasis. Disclaimer: The opinions and assertions expressed herein are those of the author(s) and do not necessarily reflect the official policy or position of the Uniformed Services University, the Henry M. Jackson Foundation, or the Department of Defense.

## REPLACEMENT OF MISSING VALUES FOR ONE-TIME-MEASUREMENT OUTCOMES IN ONCHOCERCIASIS CLINICAL TRIALS

Barbara Gruetzmacher<sup>1</sup>, Sabine Specht<sup>2</sup>, Alexander Y. Debrah<sup>3</sup>, Matthias Schmid<sup>4</sup>, Achim Hoerauf<sup>5</sup>, Ute Klarmann-Schulz<sup>5</sup>

<sup>1</sup>Institute for Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Bonn, Germany, <sup>2</sup>Institute for Medical Microbiology, Immunology and Parasitology, University Hospital Bonn, Bonn, Germany; Drugs for Neglected Diseases initiative (DNDi), Geneva, Switzerland, <sup>3</sup>Faculty of Allied Health Sciences, Kwame Nkrumah University of Science and Technology; Kumasi Center for Collaborative Research (KCCR), Kumasi, Ghana, <sup>4</sup>Institute for Medical Biometry, Informatics and Epidemiology, University Hospital Bonn, Bonn, Germany, <sup>5</sup>Institute for Medical Microbiology, Immunology and Parasitology, University Hospital Bonn; German Center for Infection Research (DZIF), Bonn-Cologne site, Bonn, Germany

To reach the goal of the WHO road map for NTDs 2021-2030 to eliminate onchocerciasis and lymphatic filariasis, alternative treatment strategies are needed with the aim to sterilize or kill the adult worms. To test new drugs or drug combinations, clinical trials are carried out most likely in onchocerciasis patients because there the drug effect on the adult worm can directly be assessed in the onchocerca nodules in which the worms reside. The nodules are surgically extirpated (nodulectomies) at the end of a clinical trial and afterwards histologically evaluated. Intention-to-treat (ITT) analyses are the standard for clinical trials. In this case, all randomized participants have to be analyzed and missing values should be replaced. Data from participants, who missed the nodulectomy are difficult to replace with common methods, because no data regarding the direct drug effect on the adult worms but only baseline data are available. The aim of our project is the replacement of missing data in the best suitable manner. Onchocerciasis nodule data are structured on patient-, nodule- and worm-levels, with possible dependencies between the outcome variables, which makes any quick imputation difficult. Two datasets from different clinical trials were used to implement the approaches on all three levels, facing the challenges concerning the additive and level dependencies between worm, nodule and patient data. All approaches were done with a stepwise multiple imputation with predictive mean matching (PMM-MI) and subsequent averaging to the mean with exception of the last step on worm level where a classical multiple imputation for the embryogenesis outcome was used. The PMM-MI-method showed, compared to a worst-case imputation, a much more suitable approach to replace missing data. The approach first on patient and secondly on worm level was the only possibility to impute all variables on worm level. In a last step validation of the method will be done by using a test dataset with randomly removed patients, which will be compared to the original observed data after imputation.

### MODELLING THE MASS DRUG ADMINISTRATION AND ALTERNATIVE INTERVENTIONS FOR THE ELIMINATION OF LYMPHATIC FILARIASIS IN AMERICAN SAMOA: AN AGENT-BASED SIMULATION STUDY

Angus McLure<sup>1</sup>, Patricia M. Graves<sup>2</sup>, Callum Shaw<sup>1</sup>, Colleen Lau<sup>3</sup>, Kathryn Glass<sup>1</sup>

<sup>1</sup>Australian National University, Canberra, Australia, <sup>2</sup>James Cook University, Cairns, Australia, <sup>3</sup>University of Queensland, Brisbane, Australia

Lymphatic filariasis (LF) is a mosquito-borne parasitic helminth, endemic to >70 countries in tropical and sub-tropical regions. In 2000 the World Health Organization began a campaign for the global elimination of LF as a public health problem, using annual MDA as the primary tool for interrupting transmission. Though 17 countries have successfully achieved WHO elimination targets by 2020, others have reported resurgence after completing the prescribed rounds of MDA. American Samoa underwent seven rounds of MDA from 2000-2006 which greatly reduced prevalence of circulating filarial antigen (Ag) from 16.5% in 1999 to 2.3% in 2007, but subsequent surveys found that Ag prevalence had rebounded to 6.2% by 2016, prompting two further rounds of MDA with a triple-drug combination (ivermectin, diethylcarbamazine, albendazole) in 2018 and 2019. We used GEOFIL, a spatially-explicit agent-based model of LF transmission in American Samoa, to model the effects of these additional rounds of MDA and to compare MDA scenarios by varying the number of rounds (2-7), treatment regime (two-drug vs triple-drug), MDA coverage (55%-75%), and assumptions around drug efficacy. We compared annual MDA to alternative intervention scenarios, including ongoing targeted drug administration delivered by teams embedded in the community. Our model predicts that the two additional rounds of triple-drug MDA in 2018 and 2019 are unlikely to be sufficient to interrupt transmission and that at least six annual rounds of triple-drug MDA at 75% coverage would be required to ensure more than 50% probability of elimination by 2035. Our findings have major implications for LF elimination efforts in American Samoa and other Pacific Islands with similar LF challenges, and calls for a reevaluation of end-game strategies in these settings.

### STRONGYLOIDES STERCORALIS, STILL A PROBLEM IN THE SOUTHEAST UNITED STATES?

Almutasem Hamed, Katelyn E. Madigan, John W. Sanders  
Wake Forest University, Winston Salem, NC, United States

*Strongyloides stercoralis*, a parasitic nematode transmitted through skin penetration after contact with contaminated soil. It is estimated to affect 100 million people worldwide annually. In the United States, Strongyloidiasis is thought to be relatively rare, although there have been endemic foci, notably in the Appalachian region. The region is believed to harbor a higher prevalence of strongyloidiasis for numerous reasons. First, the rugged landscape of the area became a center for resource extraction in the early 1900s leading to subsequent water pollution. The mining industry contributed to long hours in difficult work conditions with defecation common within the mines providing an optimal environment for the free-living form of the parasite. Second, the heat in the summer months in the South contributed to a higher cultural acceptance of not wearing shoes, facilitating the transmission of the parasite. Third, many rural states lagged in the development of proper waste systems, such as disposal of the sewage directly into ditches or streams and reliance on outhouses. For example, the 1990 North Carolina census showed 1.8% of residential units lacked indoor plumbing. A retrospective chart analysis of 97 patients with *Strongyloides stercoralis* diagnosed by serology or direct parasite identification was performed from records at Wake Forest Baptist Medical Center in Winston-Salem, North Carolina. This 885-bed tertiary care teaching hospital with around 40,000 inpatient admissions annually encompasses a catchment area of 27 counties ranging from southern West Virginia to South Carolina. Data extraction included demographics (i.e. gender, age) as well as, place of birth, and travel and exposure history.

Complete analysis of this information is underway and the final results will be available before the date of the conference. The goal of this study is to investigate the current prevalence of *Strongyloides stercoralis* in the southern Appalachia in order to fill an important gap in the literature and explore whether it's still a problem in our present day.

1237

### COMPARISON BETWEEN QUANTITATIVE POLYMERASE CHAIN REACTION AND SODIUM NITRATE FLOTATION MICROSCOPY IN DIAGNOSING SOIL-TRANSMITTED HELMINTH INFECTIONS

Adam W. Bartlett<sup>1</sup>, Rebecca Traub<sup>2</sup>, Salvador Amaral<sup>3</sup>, Sze Fui Hii<sup>2</sup>, Naomi Clarke<sup>1</sup>, Patsy Zendejas-Heredia<sup>2</sup>, Paul Arkell<sup>3</sup>, Merita Monteiro<sup>4</sup>, Virginia da Conceicao<sup>3</sup>, Carolina da Costa Maia<sup>5</sup>, Maria Imaculada Soares<sup>5</sup>, Josefina D. Prisca Guterres<sup>5</sup>, Joshua R. Francis<sup>3</sup>, Susana Vaz Nery<sup>1</sup>

<sup>1</sup>Kirby Institute, Sydney, Australia, <sup>2</sup>University of Melbourne, Melbourne, Australia, <sup>3</sup>Charles Darwin University, Darwin, Australia, <sup>4</sup>Ministry of Health, Dili, Timor-Leste, <sup>5</sup>National Health Laboratory, Dili, Timor-Leste

There is evolving interest in alternate microscopy techniques and quantitative polymerase chain reaction (qPCR) to evaluate soil-transmitted helminth (STH) burden. Using data from a cross-sectional survey of 540 schoolchildren across 6 primary schools in 3 municipalities of Timor-Leste, we compared the performance of microscopy using sodium nitrate flotation (SNF) and qPCR in determining STH prevalence and infection intensity. Prevalence by qPCR was higher than SNF for *Ascaris lumbricoides* (17.5% vs 11.2%), hookworm (8.3% vs 1.2%) and *Trichuris trichiura* (4.7% vs 1.6%). Agreement between SNF and qPCR was moderate for *A. lumbricoides* ( $\kappa = 0.59$ ) and *T. trichiura* ( $\kappa = 0.44$ ), and fair for hookworm ( $\kappa = 0.21$ ). Nearly all infections were light intensity by SNF, whereas qPCR identified 36.1% as moderate or heavy infections using cycle threshold to eggs per gram conversion formulas. qPCR is a promising diagnostic technique, though further studies validating infection intensity correlates are required.

1238

### USING POPULATION-BASED SURVEY DATA TO MAKE EVIDENCE-BASED PROGRAMMATIC DECISIONS TOWARD THE ELIMINATION OF SOIL-TRANSMITTED HELMINTHIASIS

Sultani H. Matendechero<sup>1</sup>, Denver Mariga<sup>1</sup>, Cara Tupps<sup>2</sup>, Sanjaya Dhakal<sup>2</sup>, Stephen Mwatha<sup>1</sup>, Joseph Otieno Oloo<sup>1</sup>, Josephine Ihahi<sup>1</sup>, Paul Emerson<sup>2</sup>

<sup>1</sup>Division of Vector Borne and Neglected Tropical Diseases, Kenya Ministry of Health, Nairobi, Kenya, <sup>2</sup>Children Without Worms at the Task Force for Global Health, Atlanta, GA, United States

The Kenya Ministry of Health initiated a strategy to break community-wide transmission of soil transmitted helminthiasis (STH) in 2018. Knowledge of the community-wide epidemiology of STH is necessary to plan and direct resources toward this goal. We conducted the first population-based STH survey in Vihiga county in 2019 using multi-stage cluster sampling and Kato Katz to assess prevalence and intensity for STH among pre-school age children (PSAC; 2-4 years), school age children (SAC; 5-14 years), and all adults >14 years. The survey was powered to give representative estimates for each target group and the whole population of the county. The overall prevalence of STH (9.5%) was below the 10.0% WHO threshold for annual preventive chemotherapy treatment (PCT) indicating that PCT once per two years is warranted. Prevalence of moderate-to-heavy intensity infection (MHII) was 2.5%, which is above the WHO 2.0% elimination threshold, indicating continued annual PCT. We found that PSAC had the highest overall and MHII prevalence (14.6% and 5.6%), followed by SAC (8.3% and 2.3%), and adults (4.3% and 1.0%). There was no significant difference in prevalence by sex in any age group ( $p=0.06$ ), and the prevalence and intensity among women of reproductive age (15-49 years) was similar to that of all adults. Participants with finished flooring had a 54% lower prevalence than those with unfinished flooring ( $p<0.001$ ), and

those who reported regular use of shoes had a 74% lower prevalence than those who did not ( $p < 0.001$ ). Half of all participants reported having an improved toilet facility at home, and their prevalence was 40% lower than those with unimproved or no facilities ( $p = 0.001$ ). Prevalence among those who use toilet paper was 47% lower than those who used other materials ( $p < 0.001$ ). Surveys such as these provide valuable insight into target-group specific prevalence of infection and risk factors, and STH surveys of two additional endemic counties are underway in Kenya. Input from experts and opinion leaders is sought to inform what multi-sectoral interventions should be conducted and how future PCT should be targeted to those at risk of morbidity from STH.

1239

### PREVENTIVE CHEMOTHERAPY FOR THE CONTROL OF STRONGYLOIDIASIS IN SCHOOL-AGE CHILDREN: ESTIMATING THE IVERMECTIN NEED

Donal Bisanzio<sup>1</sup>, Antonio Montresor<sup>2</sup>, Michael French<sup>1</sup>, Richard Reithinger<sup>1</sup>, Paola Rodari<sup>3</sup>, Zeno Bisoffi<sup>3</sup>, Dora Buonfrate<sup>3</sup>

<sup>1</sup>RTI International, Washington, DC, United States, <sup>2</sup>Department of Control of Neglected Tropical Diseases, World Health Organization, Geneva, Switzerland, <sup>3</sup>Department of Infectious – Tropical Diseases and Microbiology, IRCCS Sacro Cuore Don Calabria Hospital, Negrar, Verona, Italy

*Strongyloides stercoralis* is a soil-transmitted helminth (STH) that affects approximately 600 million people worldwide. Interventions targeting *S. stercoralis* have not been implemented yet. Specific treatment (ivermectin) could be included in already ongoing preventive chemotherapy (PC) campaigns targeting other STHs. The aim of this study was to estimate the quantity of ivermectin needed for an integrated STH/*S. stercoralis* control program. Our study targeted school-age children (SAC), usually the focus of STH deworming campaigns. The normal approximation of the binomial distribution was adopted to calculate the hypothetical prevalence distribution in each endemic country. Considering prevalence thresholds for PC equal to 10%, 15%, and 20%, we estimated the number of SAC in need of treatment. We adjusted the estimates accounting for ivermectin distributed in lymphatic filariasis and onchocerciasis elimination programs and excluded from our calculation areas where *Loa loa* is endemic. The global number of SAC that should be targeted in PC campaigns was estimated at 42.8M (95% CI: 25.1-58.0), 31.1M (95% CI: 24.1-57.8), and 24.1M (95% CI: 12.9-33.8) when the threshold for intervention was set to 10%, 15%, and 20%, respectively. India, China, Indonesia, Bangladesh, and Nigeria accounted for about 50% of the global SAC would have to be covered by PC intervention. Our analysis may support endemic countries to evaluate the ivermectin quantity needed for integrating strongyloidiasis in the existing STH programs. These estimates might also show to generic drug manufacturers the size of the potential market for ivermectin and encourage its production.

### USING DEEP AMPLICON SEQUENCING TO SCREEN FOR THE PRESENCE OF BENZIMIDAZOLE RESISTANCE IN HOOKWORM POPULATIONS IN NORTHWEST ETHIOPIA

Abhinaya Venkatesan<sup>1</sup>, Russell Avramenko<sup>1</sup>, Rebecca Chen<sup>1</sup>, Abebe Bayih<sup>2</sup>, Ayalew Zeleke<sup>2</sup>, Solomon Afework<sup>2</sup>, John Gilleard<sup>1</sup>

<sup>1</sup>University of Calgary, Calgary, AB, Canada, <sup>2</sup>University of Gondar, Gondar, Ethiopia

The hookworm, *Necator americanus*, causes severe anemia in school-aged children and pregnant women. Control in endemic regions is achieved by Mass Drug Administration (MDA) programs using the benzimidazole drugs, albendazole and mebendazole, which have variable efficacy. Mebendazole, in particular, is often reported to have low efficacy in clinical studies and the extent to which this is due to anthelmintic resistance is as yet unclear. Benzimidazole resistance is widespread in many species of gastrointestinal nematodes of veterinary importance with mutations at codons 167, 198 and 200 of the isotype-1  $\beta$ -tubulin gene commonly

occurring in resistant populations. Although some of these mutations have been described in *N. americanus*, their prevalence, distribution and contribution to low drug efficacy is poorly studied. We have developed deep amplicon sequencing assays to enable large scale screening of *N. americanus* populations for benzimidazole resistance mutations at codons 167, 198 and 200 in both the isotype-1 and isotype-2  $\beta$ -tubulin genes. Here we describe their application to investigate whether the low efficacy of mebendazole in an efficacy study in NW Ethiopia could be due to the presence of these mutations. Fecal samples were collected and parasite prevalence was determined from study participants in four districts - Chuahit, Debark, Sanja, and Maksegnit - in the Gondar region of Ethiopia. Following a single dose of mebendazole, the cure rate and egg reduction rate for hookworms were 23.1% and 49.6%, respectively. Deep amplicon sequencing was performed on hookworm positive fecal DNA samples from 26 and 44 participants from Chuahit and Sanja districts, respectively. No mutations were detected at any of the three codons of interest in either  $\beta$ -tubulin gene in any of the samples. These results demonstrate that mebendazole efficacy in this particular trial was not associated with the presence of previously described benzimidazole resistance mutations. This work illustrates the value of deep amplicon sequencing to screen parasite populations in individual stool samples for the presence of known benzimidazole resistance mutations.

### DEVELOPMENT OF CRYSTAL PROTEIN TREATMENTS FOR GASTROINTESTINAL NEMATODES

Jeffrey Chicca, Carli Garceau, Florentina Rus, Ernesto Soto-Villatoro, Nicholas Cazeault, Hanchen Li, Kelly A. Flanagan, David Gazzola, Gary Ostroff, Raffi V. Aroian

University of Massachusetts Medical School, Worcester, MA, United States

Gastrointestinal nematode (GIN) parasitic infections are one of many neglected tropical diseases urgently needing new treatments due to increasing resistance to current anthelmintics. One and a half billion people worldwide are infected with GIN parasites, which can lead to malnutrition, anemia, growth stunting, cognitive deficits, and significant reductions in future earnings and education in children. Crystal proteins (cry) produced by *Bacillus thuringiensis* (Bt), a natural soil bacterium, have been used safely in agriculture for over half a century. We have previously reported that Cry5B cures parasitic nematode infections *in vivo*, including hookworm, *Ascaris suum*, *Parascaris sp.*, and *Haemonchus contortus*. More recently we reported on a new way to produce and deliver cry proteins to nematodes, as a cytosolic crystal protein expressing paraprotective (Cry5B IBaCC) that is effectively ingested by hookworms and ascarids. However, delivery of Cry5B in the form of IBaCC to whipworm has proven to be ineffective because whipworms can't ingest such large particles. Finding superior treatments against whipworm is of great importance due to the lack of effective current anthelmintics. To address this problem, we have developed new methods of processing purified Cry5B cytosolic crystals that are highly active against whipworms *in vitro*, while retaining activity against hookworm and ascarids. Additionally, we are exploring the mining of cry variants with various amino acid changes which may lead to the discovery of more potent crystal proteins.

### RETROSPECTIVE REVIEW OF TOXOCARIASIS AT TEXAS CHILDREN'S HOSPITAL

Mary B. Fortini, Megan N. Carey, Karina M. Robinson, Timothy A. Erickson, Sarah M. Gunter, Jill E. Weatherhead  
Baylor College of Medicine, Houston, TX, United States

*Toxocara (T. cati, T. canis)* is a zoonotic helminth found in cats and dogs. Accidental ingestion of eggs in contaminated soil causes toxocariasis, which can be asymptomatic, cause covert disease, ocular larva migrans or visceral larva migrans in humans, leading to long-term morbidity. The aim of this study was to characterize *Toxocara* cases in Houston, Texas and identify risk factors in those seeking care at Texas Children's Hospital

(TCH). An observational retrospective review was performed from January 1, 2010-April 9, 2021 in patients 0-18 y/o with corresponding *Toxocara* ICD 9/10 codes or those who had positive *Toxocara* serologies identified via the TCH microbiology laboratory. Demographics, laboratory analysis, symptoms, and risk factors were noted. A total of 48 cases were found with an average age of infection of 6.6 years; 44% of patients were female. Most cases were of Hispanic/Latino ethnicity (30/48; 62.5%) and white race (41/48; 85%). Using geospatial analysis, a toxocariasis hot spot was identified in Northeast Houston. An initial AEC <500 was found in 6/48 cases (12.5%); all were symptomatic, with 4/6 (67%) having vision loss/impairment. A total of 12/48 (25%) had mild eosinophilia (AEC  $\geq$ 500 but < 1500). Of these, 50% were symptomatic; wheezing/coughing (4/12; 33%) was the most common symptom. Over 35% (17/48) had moderate eosinophilia (AEC  $\geq$ 1500 but < 5000) of which 8/17 (47%) had symptoms, most commonly abdominal complaints (6/17; 35%). Lastly, 10/48 (21%) had severe eosinophilia (AEC  $\geq$ 5000), of which 6/10 (60%) had symptoms including 33% with skin lesions and 50% with abdominal complaints. Three patients had unknown AECs. Animal exposure occurred in 37/48 (77%); most had close contact with either dogs (19/37; 51%) or with both cats and dogs (46%). The majority of children had unknown pica behavior. Toxocariasis is the most common zoonotic infection in the U.S. We identified a *Toxocara* hot spot in the Northeast region of Houston. Contact with dogs was also an important risk factor for the development of infection. This information should guide future "one health" efforts to reduce the risk of toxocariasis in children in the Houston area.

1243

#### DETERMINING EFFICACY OF ALBENDAZOLE IN DAK LAK PROVINCE, VIETNAM, USING QUANTITATIVE PCR

Clare E. Dyer<sup>1</sup>, Naomi E. Clarke<sup>1</sup>, Dinh Ng-Nguyen<sup>2</sup>, Dilrukshi Herath<sup>3</sup>, Rebecca J. Traub<sup>3</sup>, Susana Vaz Nery<sup>1</sup>

<sup>1</sup>University of New South Wales Sydney, Sydney, Australia, <sup>2</sup>Tay Nguyen University, Buôn Ma Thuột, Viet Nam, <sup>3</sup>University of Melbourne, Melbourne, Australia

Soil-transmitted helminths (STHs) are parasitic worms infecting over 1 billion people worldwide. Regular large-scale deworming is the main strategy to control STH-associated morbidity. Dak Lak province, Vietnam, has implemented large-scale deworming of primary school-age children with mebendazole or albendazole since 2007 as part of the national STH control program. We tested the efficacy of one locally manufactured brand of albendazole ("Zentel"), used as part of a large clinical trial we are conducting (the Community Deworming against STH (CoDe-STH) trial). Quantitative PCR (qPCR) was used to detect and quantify infections; infection intensity in eggs per gram of faeces (EPG) was calculated from cycle threshold (Ct values) using conversion formulas derived from egg-seeding experiments. We also tested the chemical composition of Zentel compared with FDA-approved "Eskazole". Baseline stool samples were collected and assessed for infection status and intensity from 4 hamlets in Dak Lak province in April-May 2020. Individuals providing a baseline stool sample were given a single dose of Zentel. 14 days post-treatment, all individuals who provided a stool sample and took Zentel were asked to provide a second stool sample, to determine drug efficacy. 783 samples were collected. Stool samples were analysed by qPCR to determine infection status and intensity. The most prevalent STH species was the hookworm *Necator americanus* (overall prevalence 39.0%). Prevalence increased with age, with the highest prevalence in adults aged 50+ years at 62.2% overall. The cure rate for *N. americanus* with was 64.9% (range 58.5%-76.5% across different age groups). A 91.7% reduction in intensity of *N. americanus* infection was observed after treatment from an average of 11,203 to 520 EPG. The majority of infections were cured or had an intensity reduction of at least 80%. Use of qPCR allowed calculation of both cure rate and egg reduction rate. The efficacy of Zentel used in the main CoDe-STH trial shows comparable efficacy to that reported for other albendazole brands. Chemical analysis showed the tablet composition was comparable with Eskazole.

1244

#### PREVALENCE OF AMERICAN VISCERAL LEISHMANIASIS IN AN INDIGENOUS POPULATION OF THE COLOMBIAN CARIBBEAN COAST

Linda M. Chams, Alberto S. Mestra, Carlos J. Castro

Grupo de Investigaciones Microbiológicas y Biológicas de Cardoba (GIMBIC)-Universidad de Cardoba, Monteria, Colombia

Leishmaniasis is considered a serious zoonosis, caused by a protozoan of the genus *Leishmania*, which can affect humans who come into contact with the parasite's transmission cycle, thus becoming an anthrozoosis. American visceral leishmaniasis (AVL) is caused by a species of the *Leishmania* subgenus, *Leishmania chagasi*. Serological tests were performed on 120 individuals belonging to an indigenous population of the municipality of San Andrés de Sotavento on the Colombian Caribbean Coast, to determine the presence of *L. chagasi* reactors. The sample was taken at random in the towns of Jején, Las Cruces, Bajo Grande, Tuchín, Venecia and Cerro Vidales. A venous blood sample (5 cc) was obtained from each participant, from which the serum that would be used to determine the presence of antibodies against *L. chagasi* was recovered, using the indirect immunofluorescence technique (IFI). The prevalence of antibodies against *L. chagasi* found in the present study was 25.8%, equivalent to 31 samples out of 120 examined. The serological reaction of the positive samples showed titers between 1:8 to 1:16. No reaction was detected for titers greater than or equal to 1:32. The prevalence found by locality corresponded to the following: Jején 13 (10.8%), Las Cruces 3 (2.5%), Bajo Grande 6 (5.0%), Tuchín 1 (0.8%), Venecia 7 (5.8%), and Cerro Vidales 1 (0.8%). The analysis of the results showed a relationship between the seropositivity found and living with canines, since of the 31 seropositive participants, 29 (93.5%) reported living with this animal species. When submitting these data to the statistical analysis of variance, statistical significance was found between the study areas and living with canines ( $p < 0.05$ ). The high prevalence of antibodies against *L. chagasi* (25.8%) found in the present study and its association with having or living with canines highlights an important public health problem in these populations that urgently demands the performance of more studies similar to this one in the canine species to determine its epidemiological importance in the transmission of American visceral leishmaniasis in these communities.

1245

#### EXPERIENCES WITH DIAGNOSIS AND TREATMENT OF CHAGAS' DISEASE AT A COLORADO TEACHING HOSPITAL-CLINICAL FEATURES OF PATIENTS WITH POSITIVE SEROLOGIC TESTING

Peter Hyson, Lilian Vargas Barahona, Jonathan Schultz, Carlos Franco-Paredes, Kellie Hawkins, Andres Henao-Martinez

University of Colorado School of Medicine, Aurora, CO, United States

Chagas' disease (CD), infection by *Trypanosoma cruzi* (TC), is the third most common parasitic infection in the world and can cause cardiac and gastrointestinal complications. While CD is endemic to Latin America, an estimated 300,000 carriers of CD (most born in Latin American) live in the U.S. Diagnosis of chronic CD is established with two different IgG serologies. At University of Colorado Hospital (UCH) positive serologies are confirmed by repeat testing at the CDC. We wanted to describe our institutions experience in diagnosis of CD. The UCH health record was queried for diagnoses of CD and positive TC serologies between 2006 and 2020. All cases with one positive IgG were included. Demographic and clinical data were extracted by manual chart review. 21 cases were included: 20 with a positive IgG serology, 1 with positive histopathology. 4 were confirmed cases of chronic CD, 3 through serology and 1 from histopathology and serology from a heart transplant recipient. 2 chronic CD patients were born in Mexico, 1 in Guatemala, 1 in El Salvador. 2 chronic CD patients were transplant recipients who were diagnosed after transplant had occurred. 3/4 chronic CD patients were treated with benznidazole. Most, (11/20) positive serologies were sent as part

of pretransplant screening but no confirmed cases of CD resulted from these protocols. 60% of positive serologies never had confirmatory testing with 58% of these subjects lost to follow up. We identified a substantial number of patients with positive serologies for TC at a large academic medical center in Colorado. All confirmed cases of CD were among patients born in Latin America. Most of the testing for CD at UCH is part of pre-transplant screening, much of it in patients not from CD endemic countries. In this population, positive results identified during screening are not always confirmed. There is likely underdiagnosis of CD given lack of standardized screening protocols within our institution and other medical centers nationwide. Given the large number of individuals residing in the US with potential latent infection, improved screening efforts are warranted.

1246

### CUTANEOUS LEISHMANIASIS IN KENYA: A STUDY OF KNOWLEDGE, ATTITUDES, AND PRACTICES IN TWO FOCAL SUB-COUNTIES

**Ramadhan Mwatela Kitondo**<sup>1</sup>, Hellen MPH M. Nyakundi<sup>2</sup>, Joseph K. Wang'ombe<sup>3</sup>, Moses M. Atuko<sup>4</sup>, Damaris Matoke<sup>5</sup>, Daniel Masiga<sup>6</sup>, Richard G. Wamai<sup>7</sup>

<sup>1</sup>JKUAT(ITROMID), Nairobi, Kenya, <sup>2</sup>University of Nairobi School of Public Health, Nairobi, Kenya, <sup>3</sup>University of Nairobi School of Public Health., Nairobi, Kenya, <sup>4</sup>County of baringo, Baringo, Kenya, <sup>5</sup>Kenya Medical Research Institute/ICIPE, Nairobi, Kenya, <sup>6</sup>International Centre of Insect Physiology and Ecology, Nairobi, Kenya, <sup>7</sup>Northeastern University, Boston, MA, United States

Cutaneous leishmaniasis (CL), a disfiguring and stigmatizing disease occurs in only two known focal areas in Kenya. Over 3 years (2018-2020), this study sought to determine the behavioral, ecological, and socio-economic characteristics of household members in CL endemic villages in the Gilgil and Kipipiri sub-counties using data on knowledge, attitudes, and practices (KAP). A descriptive research design was used for both qualitative and quantitative data. Through purposive sampling of high-risk CL sites, we used a structured questionnaire to interview 132 respondents in 8 villages. 16 key informants (KIs) were interviewed and 9 FGDs (5 male and 4 female) were conducted. Data analysis was done using STATA and Excel spreadsheets. Respondents were 64% female and 36% male. The majority (62%) had primary education. The mean monthly income for an average 4-member family was Ksh.6, 251 (~\$62). The majority (60%) lived in mud-wall houses with 25.36 meters average distance to animal sheds. CL awareness was high (86%), 24% reported a family member with suspected CL, 21% had been properly diagnosed and 20% received treatment. 63% thought CL was a very serious disease with fear (56%) the first reaction then shame at 16% if they found out they had CL. While 45% knew CL was transmitted by the sandfly, 72% would not recognize it. A small percentage (20%) reported using treated nets and a negligible 2% occasionally sprayed their homes with insecticide. The recurring theme in the FGDs and KIs was fear; fear of the recurring and multiplying nature of the CL lesions, its easy spread, the disfiguring ulcers, stigmatization, and prolonged, painful weekly intralesional injections resulting in many defaulters. The burden of disease is related to social demographics, degree of exposure, knowledge of the disease, and access to treatment. Community sensitization and preventive measures, a short-term effective treatment that is less painful, reconstructive surgery, and psychosocial support for patients with disfiguring scars are recommended.

1247

### CHRONIC CHAGAS CARDIOMYOPATHY MORBIDITY AND MORTALITY BURDEN IN LATIN AMERICA

Henao-Martínez<sup>2</sup>

<sup>1</sup>Alameda Health System - Highland Hospital, Oakland, CA, United States, <sup>2</sup>University of Colorado School of Medicine, Aurora, CO, United States, <sup>3</sup>NRI Medical College, Guntur, India, <sup>4</sup>Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, <sup>5</sup>Anis Rassi Hospital, Goiânia, Brazil

Chagas disease is a largely neglected tropical disease infecting 6-8 million individuals annually in Latin America. Patients with acute or indeterminate infection progress to chronic Chagas cardiomyopathy (CCC) at approximately 5% and 2% yearly. Clinical outcomes vary considerably in CCC and precise estimates of annual mortality rates and its determinants have been challenging to identify. A systematic search was conducted for studies published between January 1946 to October 2018. Inclusion criteria were longitudinal studies of patients diagnosed with CCC that reported data on death. Studies were excluded if they did not state sufficient outcome data. Main outcomes extracted were overall all-cause mortality and specific mortality for cardiovascular, heart failure, sudden death, stroke and noncardiac outcomes. From the initial 10,761 studies identified, 52 studies met the criteria for inclusion. A random-effects meta-analysis using the death rate over the mean follow-up period in years was used to obtain pooled estimated annual mortality rates. The meta-analysis revealed an annual all-cause mortality rate of 7.9% (95% CI: 6.3-10.1; I<sup>2</sup>= 97.74%; T<sup>2</sup>=0.70) among CCC patients. The pooled estimated annual cardiovascular death rate was 6.3% (95% CI: 4.9-8.0; I<sup>2</sup>= 96.32%; T<sup>2</sup>=0.52). Annual heart failure mortality rate was 3.5% (95% CI: 2.4-5.1; I<sup>2</sup>=94.10%; T<sup>2</sup>=0.93), annual sudden cardiac death rate was 2.6% (95% CI: 1.9-3.5; I<sup>2</sup>=89.72%; T<sup>2</sup>=0.53), and annual stroke mortality rate was 0.4% (95% CI: 0.3-0.8; I<sup>2</sup>=63.84%; T<sup>2</sup>=0.49). The annual mortality rate from noncardiac deaths was 1.3% (95% CI: 0.9-1.9; I<sup>2</sup>= 75.06%; T<sup>2</sup>=0.45). Meta regression showed that low left ventricular ejection fraction (coefficient = -0.04; 95% CI: -0.07, -0.02; P= 0.001) was associated with an increase in mortality risk. Subgroup analysis based on AHA classification revealed pooled estimate rates of 4.8%, 8.7%, 13.9%, and 22.4% (P< 0.001) for B1/B2, B2/C, C, and C/D stages of cardiomyopathy, respectively. Findings from this study highlight the substantial mortality risk in CCC, particularly from cardiac causes in endemic regions.

### END-GAME STRATEGIES AGAINST GAMBIENSE HUMAN AFRICAN TRYPANOSOMIASIS IN THE MANDOUL FOCUS OF CHAD: A MATHEMATICAL AND ECONOMIC MODELING STUDY

**Marina Antillon**<sup>1</sup>, Ronald E. Crump<sup>2</sup>, Ching-I Huang<sup>2</sup>, Paul R. Bessell<sup>3</sup>, Alex Shaw<sup>3</sup>, Xia Wang-Steverding<sup>2</sup>, Iñaki Tirados<sup>3</sup>, Philippe Solano<sup>4</sup>, Steve J. Torr<sup>3</sup>, Albert Picado<sup>5</sup>, Joseph Ndung'u<sup>5</sup>, Mallaye Peka<sup>6</sup>, Severin Mbainda<sup>6</sup>, Fabrizio Tediosi<sup>1</sup>, Kat S. Rock<sup>2</sup>

<sup>1</sup>Swiss TPH, Basel, Switzerland, <sup>2</sup>University of Warwick, Coventry, United Kingdom, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>4</sup>Institute of Research for Development, Marseille, France, <sup>5</sup>FIND, Geneva, Switzerland, <sup>6</sup>PNLTHA Chad, Moundou, Chad

Human African trypanosomiasis, caused by the *gambiense* strain of *Trypanosoma brucei* (gHAT), is a deadly parasitic disease transmitted by tsetse. The Chadian government, along with partners from around the world have stepped up efforts to eliminate the disease, in particular in the formerly high-prevalence focus of Mandoul. In this study, we re-evaluate past assessments of the epidemiological status of gHAT using a sophisticated transmission model and up-to-date fitting methodology. We then re-evaluate the efficiency of intensified strategies aimed at

interrupting transmission that were put in place in 2014, and we make recommendations on the best way forward based on both epidemiological projections and economic efficiency. In our analysis we use a transmission dynamic model fit to epidemiological data from Mandoul to evaluate the cost-effectiveness of combinations of active screening, "enhanced" passive screening (expanding the number of health posts capable of screening for gHAT), and vector control activities employing Tiny Targets. For cost-effectiveness analysis, our primary outcome is disease burden, denominated in disability-adjusted life-years (DALYs) and costs, denominated in 2020 US\$. Although new strategies for active and passive screening have paved the way for better evaluation and more rapid and accessible treatment, interventions that include vector control provided a good value-for-money (at less than \$750/DALY averted) and substantially increased the probability of reaching the elimination target. Our transmission modelling and economic evaluations suggest that it may be cost-effective to already halt active screening and vector control as long as passive screening remains robust, as it appears that resurgence of infection in the focus is very unlikely. However, it is critical to factor in data requirements for elimination of transmission to be verified and to protect against possible importation of infection from neighbouring endemic foci.

### **SURVEILLANCE OF TRYPANOSOMA CRUZI INFECTION IN TRIATOMINE VECTORS, FERAL DOGS AND CATS, AND WILD ANIMALS IN AND AROUND EL PASO COUNTY, TEXAS AND NEW MEXICO**

**Felipe Rodriguez**, Rosa Maldonado

*University of Texas at El Paso, El Paso, TX, United States*

The causative agent of Chagas disease, *Trypanosoma cruzi*, is transmitted by triatomine vectors. The insect is endemic in the Americas, including the United States, where epidemiological studies are limited, particularly in the Southwestern region. Here, we have determined the prevalence of *T. cruzi* in triatomines, feral cats and dogs, and wild animals, the infecting parasite genotypes and the mammalian host bloodmeal sources of the triatomines at four different geographical sites in the U.S.-Mexico border, including El Paso County, Texas, and nearby cities in New Mexico. Using qualitative polymerase chain reaction to detect *T. cruzi* infections, we found 66.4% (n = 225) of triatomines, 45.3% (n = 95) of feral dogs, 39.2% (n = 24) of feral cats, and 71.4% (n = 7) of wild animals positive for *T. cruzi*. Over 95% of *T. cruzi* genotypes or discrete typing units (DTUs) identified were TcI and some TcIV. Furthermore, *Triatoma rubida* was the triatomine species most frequently (98.2%) collected in all samples analyzed. These findings suggest a high prevalence of *T. cruzi* infections among triatomines, and feral and wild animals in the studied sites. Therefore, our results underscore the urgent need for implementation of a systematic epidemiological surveillance program for *T. cruzi* infections in insect vectors, and feral and wild animals, and Chagas disease in the human population in the southwestern region of the United States.

Sri Lanka is now considered endemic for leishmaniasis; yet the community knowledge on the disease and its spread remains poor. This study was conducted to assess the public awareness on the disease and its transmission among individuals through a nation-wide study. The survey was done in selected sites covering all 9 provinces of Sri Lanka and included 301 confirmed cutaneous leishmaniasis patients and 2791 healthy individuals as controls (1:10 case: control ratio) from same areas. A validated questionnaire was used. Only 2.1% of the patients knew the disease by its name and the figures were even lower in the controls (1.4%). Majority of both cases and controls (89.7% and 78.7% respectively) referred to the disease as a fly induced skin disease. More than 90% of the cases correctly identified the disease symptoms (skin lesions) but the percentage of controls (79.6%) who knew correct symptoms were significantly low. Percentage of patients who knew that the disease is curable (91.7%) and who correctly named the vector (68.8%) were significantly high when compared to the control group (74.6% and 46.0% respectively). A very low percentage acknowledged that they could identify a sandfly (1.7% cases, 0.9% controls) and were aware of the breeding places of vector (1.7% cases, 1.1% controls). Over 90% of both cases and controls did not know the bite times of vector, but the percentage of cases who knew the details of bite time (3.3%) were significantly high when compared to the controls (1.2%). Knowledge regarding control of vector in the study population is poor with over 90% of cases and controls being unaware of any control methods. Majority of the patients (52.2%) said the source of information on the disease is from hospitals, healthcare workers, while the major source of information for the controls were friends, neighbors or coworkers. The awareness of the disease/ vector among the general community is low when compared to the patients who seems to gather the relevant knowledge through healthcare systems. Increasing the public awareness of the disease will be beneficial in prevention and elimination strategies.

1251

### **THE ROLE OF DIHYDROLIPOYL DEHYDROGENASE IN THE IMMUNOPATHOGENESIS OF LEISHMANIA MAJOR INFECTION: THE ROLE OF DIHYDROLIPOYL DEHYDROGENASE IN THE IMMUNOPATHOGENESIS OF LEISHMANIA MAJOR INFECTION..**

**Somtochukwu Stella Onwah**, Zhirong Mou, Ping Jia, Jude E. Uzonna

*University of Manitoba, Winnipeg, MB, Canada*

Cutaneous leishmaniasis caused by *Leishmania major* is a major public health problem and causes a range of diseases from self-healing infections to chronic disfiguring disease. Currently, there is no vaccine for human leishmaniasis, which is due to poor understanding of key immunodominant antigens and correlates of protective immunity in infected animals. We previously demonstrated that a naturally processed peptide fragment DLD63-79 derived from *Leishmania* dihydrolipoil dehydrogenase (DLD) protein-induced strong protective IFN- $\gamma$ -producing CD4<sup>+</sup> T cell response following *L. major* infection. The role and contribution of DLD in parasite virulence and pathogenesis of leishmaniasis is currently not known. We hypothesize that DLD is a virulence factor and its deficiency in *L. major* will result in an attenuated disease pathology and altered host immune response. Using the protein analysis software (Uniprot, entry Q4Q4U1) we observed more than 90% amino acid homology among DLD from pathogenic *Leishmania* species suggesting that targeting the DLD gene product will be a viable vaccination strategy against all forms of leishmaniasis. We generated DLD deficient (KO) *L. major* using the CRISPR-Cas9 gene-editing technology. We confirmed the deletion of the gene in the null mutant by PCR and Western blot. We assessed this deficiency on parasite proliferation in axenic culture and bone marrow-derived macrophages *in vitro*. Growth kinetics in axenic culture and macrophages, which are the primary target cells infected by

*Leishmania* parasites, show that deficiency of *DLD* gene products results in reduced proliferation in comparison to wild-type (WT) parasites. These findings indicate that *DLD* is an important metabolic enzyme of *Leishmania* and its deficiency results in impaired parasite proliferation in axenic culture and infected macrophages. Further *in vivo* studies will assess the disease pathology and impact on host immune response in infected mice.

### IN VITRO EFFICACY OF SELECTED ANTIMALARIALS AND OTHER ANTIPARASITIC COMPOUNDS AGAINST CIRCULATING SARS-COV-2 VIRUS IN PANAMA

Mario Quijada<sup>1</sup>, Yaneth Pitti<sup>1</sup>, Yamilka Diaz<sup>1</sup>, Marlene Castillo<sup>1</sup>, Carolina de la Guardia<sup>2</sup>, Sandra Lopez<sup>1</sup>, Ariel Magallón<sup>1</sup>, **Nicanor Obaldia<sup>1</sup>**

<sup>1</sup>Instituto Conmemorativo Gorgas de Estudios de la Salud, Panama, Panama, <sup>2</sup>Indicasat-AIP, Panama, Panama

There is an urgent need for antivirals to treat COVID-19 a respiratory disease caused by the SARS-CoV2 virus that has caused millions of deaths around the globe. Even though at present several chemotherapeutic agents had been screened for activity against SARS-CoV2, the only one that had been approved by the FDA is remdesivir. Studies conducted in China early in the pandemic, demonstrated that chloroquine (CQ) and hydroxychloroquine, inhibit SARS-CoV-2 replication *in vitro* in African green monkey kidney cells (Vero-E6). Since then, thousands of compounds have been screened using various cell lines including Vero-E6 and human lung cancer (Calu-3) cells, the former that requires proteolytic cleavage of the S protein for viral entry through the action of an acid-dependent endosomal protease and in which CQ is active, or in the latter by a pH-independent extracellular plasma membrane-associated serine protease, in which CQ is inactive. In this study, we aim to compare the *in vitro* efficacy of a series of selected antimalarials and other antiparasitic compounds against SARS-CoV-2 variants circulating in Panama using these two different cell systems. For this purpose, we first screened twenty-three compounds for cytotoxicity in both cell lines using the methyl thiazolyl tetrazolium (MTT) assay to determine their 50% cytotoxic concentration (CC50). Then, to screen the compounds for their antiviral activity, cell monolayers grown in 48 well plates were infected with the A1-Panama and P1-Brazil SARS-CoV-2 variants and treated with ten-fold serial dilutions of the active compounds to determine their median effective concentration (EC50) and percent inhibition using qPCR and a plaque reduction assay as quantification methods. A sigmoidal concentration-response function was fit to the data using nonlinear regression to plot CC50 and EC50 of the compounds. We expect that the results of this ongoing study will provide evidence of *in vitro* activity of a series of selected antimalarials and other antiparasitic compounds against SARS-CoV-2 variants circulating in Panama.

### TRANSCRIPTOMIC ANALYSIS TO IDENTIFY CANDIDATE GENES ASSOCIATED TO PYRAZINAMIDE RESISTANCE IN MYCOBACTERIUM TUBERCULOSIS

**Fernando Mamani<sup>1</sup>**, Ana Paula Vargas<sup>1</sup>, Eduardo Gushiken<sup>1</sup>, Roberto Alcantara<sup>2</sup>, Robert H. Gilman<sup>3</sup>, Mirko Zimic<sup>1</sup>, Patricia Sheen<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Peruana de Ciencias Aplicadas, Lima, Peru, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Multidrug-resistant tuberculosis (MDR-TB) threatens the progress towards the Global TB Program goals. New treatment schemes have been proposed against MDR-TB, including re-purposed or new drugs. Pyrazinamide (PZA), is a first-line drug used in resistant TB treatments due to its ability to eliminate semi-latent mycobacteria. However, its mechanism of action is not understood. Most PZA resistance is caused by mutations that hinder the pyrazinamidase activity, which is required to convert PZA into its active form. However, PZA resistant strains with a wild-type PZase have been

reported, indicating the involvement of other mechanisms. Identifying such non-canonical agents may require taking a holistic approach such as transcriptomics analysis. Our study sought to identify genes involved in PZA resistance by evaluating changes in the transcriptome of *M. tuberculosis* (MTB) in different stress states, dictated by pH (6.3 and 7.0) and PZA concentrations (0 and 50 µg/mL). Bacterial suspension were incubated at 37°C for 4 weeks, after which RNA was extracted and purified. Paired-end cDNA libraries were prepared and sequenced in Illumina's NextSeq 550 using 5 million read depth. Reads were aligned to the reference genome and abundances were quantified using Salmon. Differential expression analysis was done with the edgeR package, while GOseq was used to perform a gene enrichment analysis. Differentially expressed (DE) genes across conditions were identified using a  $|\log_{2}FC| > 2$  and  $p$ -value  $< 0.05$  threshold. A total of 3979 MTB genes were observed. Drug concentration and pH comparison was done to identify up- and down-regulated genes. We found 13 DE genes of interest, which are involved in regulation of immune system processes, organic substance transport, macromolecule localization, organic compound biosynthesis, and other similar molecular pathways. We also found genes coding for PE/PPE proteins, which we believe could be of interest due to their pivotal role in bacteria survival under stress conditions, such as those generated by PZA intracellular activity.

### RESPIRATORY PATHOGEN DETECTION AMONG FEBRILE INPATIENTS IN NORTHERN TANZANIA, 2016-2019

Yan Zhuang<sup>1</sup>, Marina Zahari<sup>2</sup>, Marcus Mah<sup>1</sup>, Yihui Chen<sup>1</sup>, John Crump<sup>3</sup>, Manuela Carugati<sup>3</sup>, Michael Maze<sup>4</sup>, John Bonnewell<sup>3</sup>, Deng Madut<sup>3</sup>, Bingileki Lwezaula<sup>5</sup>, Blandina Mmbaga<sup>6</sup>, Venance Maro<sup>6</sup>, Gavin Smith<sup>1</sup>, Martin Linster<sup>1</sup>, **Matthew P. Rubach<sup>3</sup>**

<sup>1</sup>Duke-NUS Medical School, Singapore, Singapore, <sup>2</sup>National University of Singapore, Singapore, Singapore, <sup>3</sup>Duke University, Durham, NC, United States, <sup>4</sup>University of Otago, Christchurch, New Zealand, <sup>5</sup>Mawenzi Regional Referral Hospital, Moshi, United Republic of Tanzania, <sup>6</sup>Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania

Febrile illness is a common reason for hospital admission in sub-Saharan Africa, yet the etiology of illness often remains unknown. Incorporation of respiratory pathogen testing, including viral pathogens, could contribute to filling knowledge gaps on etiologies and informing rational antimicrobial utilization among febrile patients with respiratory symptoms. From September 2016 through May 2019, we enrolled a prospective cohort of febrile pediatric and adult inpatients within 24 hours of admission to hospital. We sampled the nasopharynx and oropharynx (NP/OP) at enrollment using Dacron flocculated swabs and placed these swabs in universal transport media. Total nucleic acids were extracted (QIAGEN, QIAmp Virus) and subjected to multiplex polymerase chain reaction using the Luminex NxTAG Respiratory Pathogen Panel (RPP) for detection of 21 pathogens. The cohort included 930 enrolled participants—432 (46.5%) were female, median (interquartile range) age was 22.3 (2.1-44.0) years, 378 (40.7%) met World Health Organization criteria for severe acute respiratory infection (SARI) and 331 (35.6%) had a non-SARI respiratory illness. A pathogen was detected by RPP in 359 (38.6%) of 930: 225 (59.5%) of 378 SARI, 97 (29.3%) of 331 of non-SARI respiratory illness, and 37 (16.7%) of 221 participants without respiratory symptoms. Among SARI, the most common pathogens were influenza A/B virus (n=71, 18.8%), rhinovirus/enterovirus (RV/EV, n=66, 17.5%), respiratory syncytial virus (n=37, 9.8%). Among non-SARI respiratory illness, the most common pathogens were RV/EV (n=39, 11.8%), adenovirus (n=18, 5.4%), and influenza A/B virus (n=17, 5.1%). Among 38 in-hospital deaths, 6 had a pathogen detected by RPP—RV/EV (n=3), and one each adenovirus, coronavirus OC43, and coronavirus 229E. These results demonstrate that RV/EV detection is associated with SARI and other febrile respiratory illnesses requiring hospital admission in northern Tanzania. The findings have implications for vaccine development and vaccine policy efforts aimed at decreasing morbidity and mortality from respiratory infections in low- and middle-income countries.

1255

### SARS-COV-2 ANTIBODY PROFILES IN CONVALESCENT COVID-19 PATIENTS TESTING POSITIVE BY PCR AT POINT G TEACHING HOSPITAL, BAMAKO, MALI: A SURVEY PERFORMED FROM OCTOBER 2020 TO JANUARY 2021

**M' Bouye Doucoure**<sup>1</sup>, Amatigüe Zeguime<sup>1</sup>, John Woodford<sup>2</sup>, David Cook<sup>2</sup>, Souleymane Traore<sup>1</sup>, Moussa L Traore<sup>1</sup>, Sintry Sanogo<sup>1</sup>, Moussa B Kanoute<sup>1</sup>, Sidiki Perou<sup>1</sup>, Adama Ouattara<sup>1</sup>, Mamady Kone<sup>1</sup>, Sibiri Sissoko<sup>1</sup>, Intimbeye Tembène<sup>1</sup>, Abdoulaye Katile<sup>1</sup>, Bourama Kamate<sup>1</sup>, Mahamadou Assadou<sup>1</sup>, Kourane Sissoko<sup>1</sup>, Jennifer Hume<sup>2</sup>, Irfan Zaidi<sup>2</sup>, Justin Doritchamou<sup>2</sup>, Sara Healy<sup>2</sup>, Jennifer Kwan<sup>3</sup>, Jordyn Manucci<sup>4</sup>, Mahamadou S Sissoko<sup>1</sup>, Boubacar Traore<sup>1</sup>, Abdoulaye Djimde<sup>1</sup>, Alassane Dicko<sup>1</sup>, Patrick Duffy<sup>2</sup>, Issaka Sagara<sup>1</sup>

<sup>1</sup>MRTC/USTTB, Bamako, Mali, <sup>2</sup>LMIV/NIAID/NIH, Bethesda, MD, United States, <sup>3</sup>LCIV/NIAID/NIH, Bethesda, MD, United States, <sup>4</sup>DIR/NIAID/NIH, Rockville, MD, United States

To understand antibody responses following SARS-CoV-2 infection in Mali, serum samples were collected between October 2020 to January 2021 from 23 convalescent individuals with previous COVID-19 confirmed by RT-PCR after completion of hospital quarantine. Samples were tested for IgG antibodies to SARS-CoV-2 spike protein and receptor binding domain (RBD) by enzyme-linked immunosorbent assay (ELISA). This study was performed as a positive control cohort as part of a public health surveillance activity in Mali to develop serological tools for use in Mali. Participants were aged from 7 to 74 years and 74% (17/23) were male. The time between RT-PCR diagnosis and collection of samples for ELISA ranged from 27 to 270 days. Disease severity ranged from asymptomatic (17% (4/23)) to critical (13% (3/23)) according to WHO stratification criteria. A single symptom was reported by 26% (6/23) of cases and 2 or more symptoms in 57% (13/23) of cases. This combination of low-acuity illnesses and variable time since infection is likely to be reflective of a community serosurveillance sample. SARS-CoV-2 spike protein and RBD reactivity were strongly correlated ( $r=0.72$ ). Assay absorbance values were higher to spike protein compared to RBD (optical density  $2.43 \pm 1.27$  vs  $1.72 \pm 1.23$ ,  $p=0.004$ ). For both antigens, reactivity was moderately correlated with time since diagnosis (spike  $r=0.56$ , RBD  $r=0.49$ ) and weak to negligibly correlated with disease severity (spike  $r=0.17$ , RBD  $r=0.31$  respectively). Using two-antigen assay cutoffs developed in the United States, 78.3% (18/23) of convalescent cases were considered seropositive. Using assay cutoffs developed for optimized performance in Mali, 73.9% (17/23) were considered seropositive. This study provides preliminary results on SARS-CoV-2 antibody responses in Malian convalescent volunteers, which will be critical to develop a reference ELISA for use in population serosurveillance.

1256

### INCIDENCE AND HOUSEHOLD TRANSMISSION OF SARS-COV-2 IN A COMMUNITY COHORT IN PONCE, PUERTO RICO

**Chelsea G. Major**<sup>1</sup>, Dania M. Rodríguez<sup>1</sup>, Liliana Sánchez-González<sup>1</sup>, Kinda Zureick<sup>2</sup>, Vanessa Rodríguez-Estrada<sup>3</sup>, Tatiana Morales-Ortiz<sup>3</sup>, Carolina Torres<sup>1</sup>, Kasey Kinzel<sup>1</sup>, Nicole M. Pérez-Rodríguez<sup>1</sup>, Nicole Medina-Lopes<sup>1</sup>, Kyle Ryff<sup>1</sup>, Rafael Tosado-Acevedo<sup>1</sup>, Jorge Muñoz-Jordan<sup>1</sup>, Laura E. Adams<sup>1</sup>, Vanessa Rivera-Amill<sup>3</sup>, Melissa A. Rolfes<sup>2</sup>, Gabriela Paz-Bailey<sup>1</sup>

<sup>1</sup>Division of Vector Borne Diseases, Centers for Disease Control and Prevention, San Juan, PR, United States, <sup>2</sup>Centers for Disease Control and Prevention COVID-19 Emergency Response Team, Atlanta, GA, United States, <sup>3</sup>Ponce Health Sciences University and Saint Luke's Episcopal Hospital Consortium, Ponce, PR, United States

Most data on the COVID-19 epidemic in Puerto Rico (PR) and globally come from surveillance and clinical studies and do not capture the full disease spectrum and infection rates of SARS-CoV-2. To inform public health strategies for effective control of COVID-19, cohort studies are needed to investigate SARS-CoV-2 transmission at a community and

household level. In June 2020, we implemented a cohort study for COVID-19 within the Communities Organized to Prevent Arboviruses (COPA) project platform among residents of 18 communities in Ponce, PR. Cohort participants provide weekly self-collected nasal swabs for SARS-CoV-2 polymerase chain reaction testing at an external facility and questionnaires to report acute symptoms and personal protective behaviors. Cohort enrollment began in July 2020 and was completed in February 2021 with 1,008 participants, of which 53% are female with median age 35 years (range 1–95). Among 373 households with one or more participants, 77% of all household members were enrolled. During 14,005 person-weeks of follow-up, enumerated through January 2021, we identified incident SARS-CoV-2 infections in 19 participants from 10 households for a community incidence rate of 1.4 per 1,000 person-weeks. Of these 19 participants, 58% were male, median age was 24 years (range 10–56), 10 (63%) sought medical care, and 16 (84%) had symptomatic infections, of which 81% reported cough, 81% loss of taste or smell, and 50% throat pain. All SARS-CoV-2 infections among participants of the same household were identified within 2 weeks of each other, and no re-infections were identified during follow-up. The estimated household attack rate was 33% among potentially susceptible household members. No secondary infections were detected in participating household members of the three asymptotically infected participants. Preliminary study results showed moderate incidence of SARS-CoV-2 in the community with mostly symptomatic infections and that about one in three exposed household members of index cases were infected with SARS-CoV-2. Results will be updated and expanded as follow-up for the cohort continues through February 2022.

1257

### REASONS FOR CONSENTING TO PARTICIPATE IN COMMUNITY RESEARCH AIMED TO PREVENT TUBERCULOSIS

**Luz Quevedo Cruz**<sup>1</sup>, Maria del Rosario Montoya Villanueva<sup>1</sup>, Adelina Herlinda Lozano Chavez<sup>1</sup>, Jessica Liria Franco Gutierrez<sup>1</sup>, Wilber Enrique Flores Saavedra<sup>1</sup>, Carolina Felicita Tovar Perez<sup>1</sup>, Segundo Carlos Pozo Correa<sup>1</sup>, Pilar Raquel Tapia Mamani<sup>1</sup>, Maria Cecilia Haro Berrospi<sup>1</sup>, Rosario Sosa Ccanto<sup>1</sup>, Eric Steve Ramos Maguñá<sup>1</sup>, Lenin Ceferino Bernaola Silva<sup>1</sup>, Nataly Aracely Bailon Gonzales<sup>1</sup>, Keren Soledad Alvarado Torres<sup>1</sup>, Teresa Rocio Valencia Norabuena<sup>1</sup>, Aurora Maribel Rivero Moron<sup>1</sup>, Jonathan Michael Gomez Suarez<sup>1</sup>, Paula Patricia Carballo Jimenez<sup>2</sup>, Matthew J Saunders<sup>2</sup>, Carlton Anthony Evans<sup>2</sup>, Sumona Datta<sup>3</sup>

<sup>1</sup>Asociación Benéfica Prisma, Lima, Peru, <sup>2</sup>Infectious Diseases & Immunity, Wellcome Trust Imperial College Centre for Global Health Research, London, United Kingdom, <sup>3</sup>Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The World Health Organization's (WHO) End TB strategy is focussed on intensifying research. However, evidence generated by research is influenced by those who agree to participate and can lead to consent bias. The objective of this study was to evaluate the reasons for providing consent or not in community research aimed to prevent TB. All patients starting TB treatment in 32 community health centres in Callao, Peru were approached in the clinic and invited to participate in the PREVENT TB study between July 2016 until November 2018 (N=2821). Callao state has one of the highest rates of TB and drug resistance in Peru (a WHO-defined TB high burden country). The study offered GeneXpert processing of sputum to all participants, and provided half of them with socioeconomic support within a community cluster randomised trial. Using a semi-qualitative questionnaire, the decision and reasons of patients with TB to participate in community research was recorded. There were 42 patients who were ineligible and 3 died before invitation, leaving 2775 eligible patients. In this population, 91% (2536/2775) of patients consented to the study, with significant heterogeneity between health centres (range 80–100%,  $p<0.001$ ). The most frequently stated reason for participation was the GeneXpert PCR test (43%, 1088/2536), which was only available to this community through this research collaboration. The second most frequently stated reason for participation was the ability to help others affected by TB (17%, 418/2536). Within the 8.6% (239/2775)

eligible patients who did not consent, the most frequently stated reasons were: not having time (22%, 52/239,) or not wanting to give their personal information (21%, 49/239). In conclusion, to have equitable and representative samples in research we must understand the motivation and barriers to participation, mitigating the latter. In this setting, high frequency of participation was attributed to incentivisation and altruism, whereas reasons for declining participation were more diverse.

1258

### IMPACT OF SARS-COV-2 IN PERIPHERAL BLOOD ON IMMUNE RESPONSES AND DISEASE SEVERITY IN HOSPITALIZED PATIENTS WITH COVID-19

**Amber Castillo<sup>1</sup>**, Ivy Hurwitz<sup>1</sup>, Qiuying Cheng<sup>1</sup>, Alexandra V. Yingling<sup>1</sup>, Janae Martinez<sup>1</sup>, Clinton O. SARS-CoV-2 is a novel coronavirus which causes COVID-19, a disease ranging from asymptomatic to life-threatening. Production of a hyperinflammatory response, Cytokine Release Syndrome (CRS), is central to acute respiratory distress, heart and renal failure, liver damage, shock, and multiorgan failure in COVID-19 patients. Detection of SARS-CoV-2 in peripheral blood (viremia) is associated with increased disease severity. To identify molecular pathways for targeting by immunotherapy, we are conducting a prospective observational study (15 May 2020 to date) in hospitalized COVID-19 patients (n=336): intensive care unit (ICU) and non-ICU. Clinical and laboratory measures are obtained daily. Peripheral blood is collected on days 0, 1, 2, 3, 6, 9, and 14 to determine viral load dynamics and perform transcriptomics by next-generation sequencing. Results presented here examined the relationship between SARS-CoV-2 viremia and transcriptional profiles in a subset of patients (n=31). Correlation trend tests were used to determine the association between SARS-CoV-2 viral load at each timepoint (n=129) and gene expression levels. Enrichment analysis was performed using MetaCore™ with the threshold set at a correlation trend  $P < 0.05$  and signal intensity input as the correlation trend  $R (-1$  to  $+1)$ . Viremia was associated with elevated expression of Furin, ACE2, and Angiotensin II, a combination of events known to increase adverse reactions in the lungs, heart, kidneys, and blood vessels. Viremia was also associated with impaired antigen processing, as indicated by downregulation of TCR $\alpha/\beta$ , CD8, CD3, and CD4, along with MHC class II (e.g., decreased expression of 9 HLA). Presence of SARS-CoV-2 in blood was further associated with elevated transcript levels of inflammatory mediators that promote CRS in COVID-19 (i.e., IL1RN, IL-10, IP10, MIG, CCL7, and GRO-2). Results presented here

provide novel information about the impact of SARS-CoV-2 in peripheral blood on the immune response and illustrate potential causes for the relationship between viremia and enhanced disease severity in patients with COVID-19.

### SEVERE ACUTE RESPIRATORY SYNDROME - COVID-19: CLINICAL AND EPIDEMIOLOGICAL CHARACTERISTICS IN THE TWO EPIDEMIC WAVES, INSTITUTO DE INFECTOLOGIA EMÍLIO RIBAS-IIER, SÃO PAULO, BRAZIL, 2020 AND 2021

**Ana Freitas Ribeiro<sup>1</sup>**, Roberta Figueiredo Cavalin<sup>2</sup>, Tamara Nassar da Silva<sup>1</sup>, Giulia Soler Bianchi<sup>1</sup>, Victoria Spínola Duarte de Oliveira<sup>1</sup>, Giap Passos F. Pereira Gomes<sup>1</sup>, Ana Angélica B. Portela Lindoso<sup>1</sup>, Jamal Muhamad A.H. Suleiman<sup>1</sup>, Marileide Januaria de Vasconcelos<sup>1</sup>

<sup>1</sup>Instituto de Infectologia Emílio Ribas, São Paulo, Brazil, <sup>2</sup>Instituto de Infectologia Emílio Ribas, São Paulo, Brazil

In December 2019, cluster of pneumonia cases in Wuhan-China was reported to the World Health Organization-WHO. Etiologic agent was identified as a new coronavirus, SARS-CoV-2. On March 11, WHO declared the pandemic of COVID-19 and since then, the disease spread worldwide, with a major impact on morbimortality. Social distance measures to reduce community transmission, although effective, also impact the economy. In the World, 140,332,386 cases of COVID-19 and 3,004,088 deaths were reported, data until April 18, 2021. COVID-19 is a mandatory reportable disease in Brazil within 24 hours after suspicion. We developed a prospective study of notified cases of severe acute respiratory syndrome-SARS, based on the epidemiological investigation form, collected in the routine of epidemiological investigation of the suspected cases of COVID-19 hospitalized in IIER. The information was entered into the database of the Ministry of Health, SIVEP-Gripe. From February 18 to December 30, 2020, 1712 suspected cases of SARS were reported, with 928 (54.2%) laboratory confirmed, 96.5% by RT-PCR in nasopharyngeal secretion. Regarding confirmed cases, 58.6% concentrated in the male gender and 66.3% in the white race. The age group from 15 to 60 years old corresponded to 51.6% of the cases and 60 years old or more to 48.3%. 50.1% of the cases were attended in the ICU and 34.7% with the use of mechanical ventilation. Hospital lethality was 26.3%, with 16.3% in the 15 to 60 age group and 36.9% in the elderly aged 60 or over. Until March 22, 2021, 275 suspected cases were reported, with 178 (64.7%) laboratory confirmed, 98.7% by RT-PCR in nasopharyngeal secretion. Regarding confirmed cases, 60% concentrated in the male gender and 66.1% in the white race. The age group from 15 to 60 years corresponded to 53.8% and 46.2% in over 60 years of age. 55.2% of the cases were attended in the ICU and 30.1% with use of mechanical ventilation. Hospital lethality was 25.1%, with 22.9% in the 15 to 60 age group and 27.8% in the elderly aged 60 or over. Comparing the two epidemic waves there was a statistical difference in the lethality of age groups (15 to 60 and  $\geq 60$  years),  $p = 0.05$  and  $0.048$ , respectively.

### LATE SURGES IN COVID-19 CASES AND VARYING TRANSMISSION POTENTIAL DUE TO PUBLIC HEALTH POLICY CHANGES IN FIVE MIDWEST STATES, MARCH 10, 2020-JANUARY 10, 2021

**Xinyi Hua<sup>1</sup>**, Aubrey D. Kehoe<sup>1</sup>, Joana Tome<sup>1</sup>, Mina Motaghi<sup>1</sup>, Sylvia K. Ofori<sup>1</sup>, Po-Ying Lai<sup>2</sup>, Sheikh Taslim Ali<sup>3</sup>, Gerardo Chowell<sup>4</sup>, Anne C. Spaulding<sup>5</sup>, Isaac Chun-Hai Fung<sup>1</sup>

<sup>1</sup>Georgia Southern University, Statesboro, GA, United States, <sup>2</sup>Boston University, Boston, MA, United States, <sup>3</sup>The University of Hong Kong, Hong Kong, China, <sup>4</sup>Georgia State University, Atlanta, GA, United States, <sup>5</sup>Emory University, Atlanta, GA, United States

North Dakota, South Dakota, Montana, Wyoming, and Idaho experienced low transmission early in the COVID-19 pandemic. This study aims to estimate the area's SARS-CoV-2 transmission potential from March 2020

through January 2021. SARS-CoV-2 time-varying reproduction numbers,  $R_t$ , of a 7-day-sliding-window and of non-overlapping-windows between policy change were estimated using the instantaneous reproduction number method developed by Cori et al. and daily number of new cases. The power-law relationship was evaluated with linear regression between the  $\log_{10}$ -transformed cumulative case number and  $\log_{10}$ -transformed population size. The median  $R_t$  estimates for 7-day-sliding-window across this region were between 1-1.25 during September through November. Between November 13<sup>th</sup> and 18<sup>th</sup> North Dakota had a reduction of  $R_t$  estimates by 14.71% ( $\bar{x} = -0.1396$ , CI [-0.1454, -0.1338]) following a mask mandate, Idaho saw a 1.93% ( $\bar{x} = 0.0729$ , CI [0.0501, 0.0956]) reduction and Montana saw a 9.63% ( $\bar{x} = -0.0868$ , CI [-0.1015, -0.0720]) reduction of  $R_t$  estimates following the tightening of restrictions. Neither Wyoming nor South Dakota implemented any policies or restrictions; however, Wyoming saw an average of 12.12% ( $\bar{x} = -0.0086$ , CI [-0.0310, 0.0137]) reduction, and South Dakota saw an average of 5.02% ( $\bar{x} = 0.0394$ , CI [0.0135, 0.0653]) increase in  $R_t$  estimates. Evidence suggests that high-population counties had higher cumulative case number per-capita in North Dakota at four time points ( $m=0.2758, 0.2171, 0.0729, 0.0986$ ;  $p=0.0034, 0.0018, 0.046, 0.0024$ ; respectively).  $R_t$  decrease after facemask mandate during the region's case count spike suggests a greater reduction in community transmission of SARS-CoV-2.

<sup>1</sup>Laboratorio de Investigación en Enfermedades Infecciosas, LID, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Division of Inflammation and Infection, Linköping University, Linköping, Sweden, <sup>3</sup>Department of Virology, Tohoku University Graduate School of Medicine, Sendai 980-8575, Japan, <sup>4</sup>Department of International Health, Johns Hopkins School of Public Health, Baltimore, MD, United States

Tuberculosis is an infectious disease caused by *Mycobacterium tuberculosis* (MTB) and continues to remain a serious health issue worldwide. Timely diagnosis of tuberculosis is a major problem therefore, it is necessary to find new approaches which also contribute to understand the course of MTB infection. In the present pilot study, we have compared the DNA methylation profiles of peripheral blood mononuclear cells (PBMCs) isolated from five healthy individuals, five patients with latent infection (LTBI), and ten with active tuberculosis (ATB) from Lima, Peru. We utilized the DNA methylation profiles in order to identify potential epigenetic signatures that can serve as diagnostic tools among no infection, latent and active tuberculosis. PBMCs were cryopreserved in liquid nitrogen, thawed and DNA extracted using a commercial kit. Genome-wide DNA methylation analysis of the PBMC samples was performed using Illumina Infinium Methylation EPIC 850K array. We identified differentially methylated CpGs (DMCs), with FDR adjusted p-value of 0.05 and a delta beta value > 0.2. A total of 939 DMCs were identified in our 20 samples from LTBI, ATB, and healthy controls. In addition, combining the identified differentially methylated genes (DMGs) from the PBMCs in a Venn analysis, we discovered one common DMG which could serve as a potential biomarker. Pathway enrichment analyses using the KEGG, Reactome, and Panther databases showed Wnt signaling, TGF-beta signaling among the top pathways in ATB and healthy controls enriched genes, we also observed statistically significant pathways related to the nervous system in LTBI and ATB samples. Further analysis of DMCs and DMGs and their notable involvement in specific pathways can open a new horizon in the diagnosis and prevention of tuberculosis disease.

### SARS-COV-2 SEROASSAY OPTIMIZATION AND PERFORMANCE IN A POPULATION WITH HIGH BACKGROUND REACTIVITY IN MALI

Amatigue Zegjume<sup>1</sup>, M'Bouye Doucoure<sup>1</sup>, John Woodford<sup>2</sup>, David Cook<sup>2</sup>, Souleymane Traore<sup>1</sup>, Moussa L Traore<sup>1</sup>, Sintro Sonogo<sup>1</sup>, Moussa B Kanoute<sup>1</sup>, Sidiki Perou<sup>1</sup>, Adama Ouattara<sup>1</sup>, Mamady Kone<sup>1</sup>, Sibiri Sissoko<sup>1</sup>, Intimbeye Tembène<sup>1</sup>, Abdoulaye Katile<sup>1</sup>, Bourama Kamate<sup>1</sup>, Mahamadou Hamady Assadou<sup>1</sup>, kourane Sissoko<sup>1</sup>, Irfan Zaidi<sup>2</sup>, Justin Doritchamou<sup>2</sup>, Sara Healy<sup>2</sup>, Jennifer Kwan<sup>3</sup>, Jennifer Hume<sup>2</sup>, Mahamadou S Sissoko<sup>1</sup>, Boubacar Traore<sup>1</sup>, Boubacar Traore<sup>1</sup>, Jordyn Manucci<sup>4</sup>, Abdoulaye Djimde<sup>1</sup>, Abdoulaye Djimde<sup>1</sup>, Alassane Dicko<sup>1</sup>, Patrick Duffy<sup>2</sup>, Issaka Sagara<sup>1</sup>

<sup>1</sup>MRTC/USTTB, Bamako, Mali, <sup>2</sup>LMIV/NIAID, Bethesda, MD, United States, <sup>3</sup>LCIM/NIAID, Bethesda, MD, United States, <sup>4</sup>DIR/NIAID, Rockville, MD, United States

In Mali the first case of SARS-CoV-2 infection was identified in March 2020. Due to a limited access to gold-standard molecular diagnostics, qualified serological assays are urgently needed to conduct serosurveys to understand population exposure to the virus, the antibody response to infection, and help direct Public Health interventions. However, poor assay performance may hinder the utility of these tests, including high rates of false-positivity previously reported in sub-Saharan Africa. From 312 Malian samples collected prior to 2020, we measured antibodies to the commonly tested SARS-CoV-2 antigens and four other betacoronaviruses by ELISA, and assessed functional cross-reactivity in a subset using a SARS-CoV-2 pseudovirus neutralization assay. We then evaluated the performance of a two-antigen ELISA developed in the US, using SARS-CoV-2 spike protein and receptor-binding domain. To optimize test performance, we compared single and two-antigen approaches using existing assay cutoffs and population-specific cutoffs for Malian control samples (positive and negative). Background reactivity to SARS-CoV-2 antigens was common in pre-pandemic samples compared to US controls. SARS-CoV-2 reactivity correlated weakly with other betacoronavirus reactivity, varied between Malian communities, and increased with age. No pre-pandemic samples demonstrated functional activity. Regardless of the cutoffs applied, specificity improved using a two-antigen approach. Test performance was optimal using a two-antigen assay with population-specific cutoffs derived from ROC curve analysis [Sensitivity: 73.9% (51.6-89.8), Specificity: 99.4% (97.7-99.9)]. In the setting of high background reactivity such as sub-Saharan Africa, SARS-CoV-2 serological assays need careful qualification to characterize the epidemiology of disease, prevent unnecessary harm, and allocate resources for targeted control measures. This optimization has allowed testing of almost 8000 samples at two time points for use in Public Health serosurveillance in collaboration with the Malian MoH.

### COMPARISON OF THE URINE POINT-OF-CARE CIRCULATING CATHODIC ANTIGEN ASSAY TO THE STANDARD KATO KATZ STOOL TEST IN A SCHISTOSOMIASIS CONTROL PROGRAM IN WESTERN KENYA

Anne Straily<sup>1</sup>, Emmy A. Kavere<sup>2</sup>, Dollycate Wanja<sup>2</sup>, Ryan E. Wiegand<sup>1</sup>, Susan P. Montgomery<sup>1</sup>, Alex Mwaki<sup>2</sup>, Alie Eleveld<sup>2</sup>, W. Evan Secor<sup>1</sup>, Maurice R. Odiere<sup>3</sup>

<sup>1</sup>Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, <sup>2</sup>Safe Water and AIDS Project, Kisumu, Kenya, <sup>3</sup>Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya

Schistosomiasis control program guidelines for evaluation and monitoring are based on the Kato Katz (KK) fecal exam method, but sensitivity may suffer in low prevalence settings. The point of care urine circulating cathodic antigen assay (POC-CCA) has been used as an alternative test to map schistosomiasis prevalence but has not been evaluated for use in monitoring and evaluating control programs. This repeated cross-sectional study sought to determine how guidance based on KK can be translated to POC-CCA and its performance in different prevalence settings. Urine

and stool specimens were collected from public primary school students in western Kenya prior to MDA at baseline and annually thereafter for up to 3 years. Prevalence and infection intensity were determined by KK and POC-CCA; changes were compared within strata of schools grouped according to baseline KK prevalence ("low" 0-10%, "medium" >10-20%, "high" >20%) using negative binomial models. Prevalence by POC-CCA was higher than by KK at all time points for all strata. Prevalence by KK decreased significantly for all strata from baseline to year 2 (low: prevalence ratio [PR]=0.58 (95% confidence interval 0.39, 0.87)  $p < 0.01$ ; medium: PR=0.32 (0.18, 0.58)  $p < 0.01$ ; high: PR=0.53 (0.37, 0.75)  $p < 0.01$ ) and year 3 (low: PR=0.59 (0.36, 0.97)  $p < 0.05$ ; medium: PR=0.2 (0.12, 0.33),  $p < 0.01$ ; high: PR=0.33 (0.25, 0.44)  $p < 0.01$ ) as did infection intensity at years 2 and 3 for medium (arithmetic mean ratio [AMR]=0.18 (0.1, 0.34)  $p < 0.01$ ; AMR=0.34 (95% CI 0.15, 0.79)  $p = 0.01$ , respectively) and high (AMR=0.56 (0.41, 0.77)  $p < 0.01$ , AMR=0.11 (0.08, 0.15)  $p < 0.01$ , respectively) prevalence strata schools. A corresponding decrease by POC-CCA was not always replicated for any of the strata and even increased in some years. Concordance between the two tests was poor; 2.8% (n=356) of POC-CCA results were false negative compared to KK and the highest rate of false negatives occurred among high prevalence schools. The POC-CCA did not perform as expected which raises questions concerning the POC-CCA's usefulness for monitoring schistosomiasis control programs in its current format and/or quality control management.

1264

#### ASSOCIATION OF FEMALE GENITAL SCHISTOSOMIASIS WITH THE CERVICOVAGINAL MICROBIOTA AND SEXUALLY TRANSMITTED INFECTIONS IN ZAMBIAN WOMEN

**Amy S. Sturt**<sup>1</sup>, Emily L. Webb<sup>1</sup>, Lisa Himschoot<sup>2</sup>, Comfort R. Phiri<sup>3</sup>, Joyce Mapani<sup>4</sup>, Maina Mudenda<sup>4</sup>, Eyrun F. Kjetland<sup>5</sup>, Tobias Mweene<sup>3</sup>, Bruno Levecke<sup>2</sup>, Govert J. van Dam<sup>6</sup>, Paul L. Corstjens<sup>6</sup>, Helen Ayles<sup>3</sup>, Richard J. Hayes<sup>1</sup>, Lisette van Lieshout<sup>6</sup>, Isaiah Hansingo<sup>4</sup>, Suzanna C. Francis<sup>1</sup>, Piet Cools<sup>2</sup>, Amaya L. Bustinduy<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>University of Ghent, Ghent, Belgium, <sup>3</sup>Zambart, Lusaka, Zambia, <sup>4</sup>Livingstone Central Hospital, Livingstone, Zambia, <sup>5</sup>Oslo University Hospital, Oslo, Norway, <sup>6</sup>Leiden University Medical Center, Leiden, Netherlands

Female genital schistosomiasis (FGS), caused when eggs from the waterborne parasite *S. haematobium* are entrapped in genital tissue, is prevalent in sub-Saharan Africa and has been associated with adverse reproductive outcomes, including ectopic pregnancy, infertility, and prevalent HIV-1. Non-optimal cervicovaginal microbiota, characterized by a shift from lactic acid producing microbiota (e.g. *Lactobacillus* species) to an increase in anaerobic species can likewise have negative sexual and reproductive health consequences. The cervicovaginal microbiota, including sexually transmitted infections (STI), have not been well-described in PCR-defined female genital schistosomiasis (FGS). Women who were aged 18-31, sexually active, and not pregnant were invited to participate at the final follow-up of the HPTN 071 (PopART) Population Cohort in two communities in Zambia from January - August 2018. We measured key species of the cervicovaginal microbiota (*Lactobacillus crispatus*, *L. iners*, *Gardnerella vaginalis*, *Atopobium vaginae* and *Candida* spp.) and STI (*Chlamydia trachomatis*, *Neisseria gonorrhoeae*, *Trichomonas vaginalis* and *Mycoplasma genitalium*) using PCR. We evaluated associations between the presence and concentration of microbiota and STI and FGS (PCR-detected *Schistosoma* DNA in any of three genital specimens). The presence and concentration of key cervicovaginal species did not differ between participants with (n=30) or without (n=158) PCR-defined FGS. A higher proportion of participants with FGS had *T. vaginalis* compared to FGS negative women ( $p = 0.08$ ), with further analysis showing that *T. vaginalis* was more prevalent among women with  $\geq 2$  *Schistosoma* PCR positive genital specimens (50.0%, 8/16) than among FGS negative women (21.5% 34/158,  $p = 0.01$ ). In conclusion, we found weak evidence of an association between *T. vaginalis* presence and FGS, with a stronger

association in women with a higher burden FGS infection. Additional research is needed on potential between-parasite interactions, especially regarding HIV-1 vulnerability.

1265

#### FEMALE GENITAL SCHISTOSOMIASIS AND HIV-1 INCIDENCE IN ZAMBIAN WOMEN: A RETROSPECTIVE COHORT STUDY

**Amy S. Sturt**<sup>1</sup>, Emily L. Webb<sup>1</sup>, Comfort R. Phiri<sup>2</sup>, Maina Mudena<sup>3</sup>, Joyce Mapani<sup>4</sup>, Barry Kosloff<sup>2</sup>, Maina Cheeba<sup>2</sup>, Kwame Shanaube<sup>2</sup>, Justin Bwiyala<sup>5</sup>, Eyrun F. Kjetland<sup>6</sup>, Suzanna C. Francis<sup>1</sup>, Paul L. Corstjens<sup>7</sup>, Govert J. van Dam<sup>7</sup>, Lisette van Lieshout<sup>7</sup>, Isaiah Hansingo<sup>4</sup>, Helen Ayles<sup>2</sup>, Richard J. Hayes<sup>1</sup>, Amaya L. Bustinduy<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Zambart, Lusaka, Zambia, <sup>3</sup>Livingstone Central Hospital, Lusaka, Zambia, <sup>4</sup>Livingstone Central Hospital, Livingstone, Zambia, <sup>5</sup>Zambart, Livingstone, Zambia, <sup>6</sup>Oslo University Hospital, Oslo, Norway, <sup>7</sup>Leiden University Medical Center, Leiden, Netherlands

In sub-Saharan Africa, there has been a geographical association between areas of high *S. haematobium* prevalence and HIV-1 infection. Female genital schistosomiasis (FGS) has been associated with prevalent HIV-1, though data both support and refute this association. While *S. haematobium* seropositivity has been associated with HIV-1 acquisition, the association of FGS with incident HIV-1 has not yet been described. In this study, we estimated the incidence of HIV-1 infection in Zambian women with and without FGS. Women who were aged 18-31, sexually active and not pregnant were invited to participate in this study at the final follow-up of the HPTN 071 (PopART) Population Cohort in two communities in Zambia from January – August 2018. HIV-1 negative participants at enrolment (n=492) were included in this analysis with testing to confirm incident HIV-1 performed in HPTN 071 (PopART). Association of incident HIV-1 infection with FGS (*Schistosoma* DNA detected by PCR in any genital specimen) was assessed with exact Poisson regression. Incident HIV-1 infections were observed in 4.1% (20/492) participants. Women with FGS were twice as likely to seroconvert as women without FGS but with no statistical evidence for a difference (aRR 2.16, 95% CI [0.21–12.30],  $p = 0.33$ ). Exploratory analysis suggested an association with HIV-1 acquisition among women with  $\geq 2$  positive genital PCR specimens (RR 6.02, [0.58–34.96]),  $p = 0.13$ ). Despite higher HIV-1 seroconversion rates in women with FGS, there was no statistical evidence of association, possibly due to low power. Large prospective studies in areas of higher *S. haematobium* endemicity are needed to evaluate associations with HIV-1 incidence in women.

1266

#### IMPLICATIONS OF OVERCOMING EXISTING CHALLENGES IN MAPPING SCHISTOSOMIASIS: THE EXPERIENCE OF RWANDA

**Eugene Ruberanziza**<sup>1</sup>, Jean Bosco Mbonigaba<sup>1</sup>, Michee Kabera<sup>1</sup>, Alphonse Mutabazi<sup>1</sup>, Elias Nyandwi<sup>2</sup>, Aimable Mbituyumuremyi<sup>1</sup>, Jamie Tallant<sup>3</sup>

<sup>1</sup>Rwanda Biomedical Centre/Ministry of Health, Kigali, Rwanda, <sup>2</sup>University of Rwanda, Kigali, Rwanda, <sup>3</sup>END Fund, New York, NY, United States

Schistosomiasis is a focal neglected tropical disease (NTD) where endemic communities are those surrounding water bodies and wetlands. It is among NTDs targeted for elimination as a public health problem. Most endemic countries have mapped it and implemented several rounds of preventive chemotherapy to control associated morbidity and aim for elimination following the WHO roadmap on NTDs 2021-2030. The latter recognizes the need for innovative mapping methods and tools to get a granular view of schistosomiasis epidemiology to focus interventions at the right risk areas. Rwanda's NTD program aimed to fill the actual global gap using a novel locally designed sampling methodology. In 2020, the Rwanda national NTD program used an innovative sampling methodology, using a rigorous scientific and collaborative design defining communities presumed at risk as ones adjacent to water bodies and wetlands delineated using GIS tools, further ranked taking into account

available epidemiological and socio-economic data and local knowledge. The community-based mapping involved all age groups from children aged 1 to adults. Kato-Katz and Point-Of-Care Circulating Cathodic Antigen tests were used. The present mapping data indicate endemicity levels requiring regular mass treatment in 1013 administrative cells (current implementation units below the sub-districts), distributed in 307 sub-districts and all 30 districts of the country, with a total of 4.6 million school age children and adults estimated to be at risk. The experience of schistosomiasis mapping in Rwanda shows the benefits of an improved sampling design to identify all communities at risk of schistosomiasis to know where control and elimination efforts need to be focused. In the previous mapping, which used different sampling designs, endemicity was only found in 127 sub-districts of 22 districts. Since the disease transmission remains focalized and very dynamic in space and time, technical and financial resources must be considered along with other priorities set in the new WHO roadmap to obtain accurate data to help plan elimination.

1267

### BEHAVIORAL RESPONSES TO A SEASONAL ENVIRONMENT REDUCE FREQUENCY BUT INCREASE EXTENT OF WATER CONTACT IN A SCHISTOSOMIASIS-ENDEMIC REGION OF WEST AFRICA

**Andrea Lund**<sup>1</sup>, M. Moustapha Sam<sup>2</sup>, Alioune Sy<sup>3</sup>, Omar Sow<sup>4</sup>, Susanne Sokolow<sup>5</sup>, Sylvia Bereknayi Merrell<sup>6</sup>, Janine Bruce<sup>6</sup>, Nicolas Jouanard<sup>7</sup>, Simon Senghor<sup>8</sup>, Gilles Riveau<sup>9</sup>, Giulio De Leo<sup>10</sup>, David Lopez-Carr<sup>11</sup>

A variety of seasonal processes govern infectious disease transmission, ranging from fluctuations in pathogen density in the environment to seasonal changes in human behavior. In seasonal climates, snail ecology is an important driver of seasonality in schistosomiasis transmission dynamics. Seasonal fluctuations in temperature, rainfall and water levels also influence the water contact behaviors that expose people to schistosomes. Yet, the extent to which seasonal changes in water contact behavior overlap with seasonal peaks in snail and parasite densities is poorly understood. Along the Senegal River, schistosomiasis has become endemic in a highly seasonal Sahelian environment. We report qualitative data from focus group discussions (n = 12) with adult men, adult women and youth in four villages in this setting, examining how perceptions of the local environment and its seasonality affect how people interact with freshwater resources. Focus group participants (n = 76) associated the risk for schistosomiasis with seasonal changes in temperature and water quality and reported reducing certain water contact behaviors during the rainy season, when they perceived water quality to be low. Participants similarly noted that rainy season increases in water levels affects farmers' ability to cultivate land near shore while others reported that the combination of reduced water quality and high water levels increased the depth to which it was necessary to wade to collect water clear enough for household use. These competing behavioral responses to seasonal changes in the environment make it difficult to discern the net impact of seasonality on human water contact. During the rainy season, when schistosome transmission peaks, people reduce their frequency of occupational and hygienic water contact but also increase the extent of contact necessary to meet household needs. Focus group data revealed

broad patterns in the seasonality of human water contact behavior, how it intersects with seasonality in snail and schistosome ecology and where opportunities exist to ameliorate the tension between livelihoods and health in this setting.

### LONGITUDINAL ANALYSIS OF OCCUPATIONAL EXPOSURE TO SCHISTOSOMA JAPONICUM THROUGH IRRIGATED AGRICULTURE IN A SITE OF REEMERGENT AND PERSISTENT TRANSMISSION IN SICHUAN, CHINA

**Andrea Lund**<sup>1</sup>, Elise Grover<sup>1</sup>, Yang Liu<sup>2</sup>, Ding Lu<sup>2</sup>, Elizabeth J. Carlton<sup>1</sup>

<sup>1</sup>Colorado School of Public Health, Aurora, CO, United States, <sup>2</sup>Sichuan Centers for Disease Control, Chengdu, China

Schistosomiasis reemerged in Sichuan Province, China in 2004 after decades of multifaceted control efforts. In hilly regions of the province, irrigated agriculture is commonly practiced. The cultivation of rice and corn dominate crops grown during the summer months, though vegetables and peanuts are also grown. Because the cultivation of rice involves flooding fields and labor that is often performed barefoot, we hypothesized that the rice planting season may be a key window of exposure. Using longitudinal infection and household survey data collected in seven villages at three points (2007, 2010 and 2016) since the time since reemergence of *S. japonicum* was detected in 2006, we examine the relationship between irrigated agriculture reported at the household level as a predictor of *Schistosoma japonicum* infection status. In this time, the socio-economic conditions in these villages have improved substantially but agriculture has remained an important economic activity. Controlling for age, sex, socio-economic status, number of hatch tests performed and random intercepts accounting for clustered observations by village, we fit generalized linear mixed models of infection status as a function of binary, categorical and continuous indicators of household rice cultivation for each year of observation. We found that among individuals in households cultivating any amount rice were more likely to be infected in 2007 (OR = 1.94, 95% CI 1.05, 3.57) but not in later years. Similarly, the odds of infection were greater among individuals in households that were cultivating small (0-1 mu; OR = 3.11, 95% CI 1.25, 7.79) and large (2+ mu; OR = 2.80, 95% CI 1.03, 8.59) areas of rice in 2007 compared to individuals in households that were not cultivating any rice. This association was not detected in 2010 or 2016. In 2016, the area of rice was associated with a 52% reduction in the odds of infection (OR = 0.48, 95% CI 0.25, 0.91). Our findings suggest that occupational exposure to *S. japonicum* through agricultural activity has decreased since re-emergence, and may be the result of improved socio-economic conditions and the diversification of livelihoods in the region.

### MALARIA AND HELMINTH COINFECTIONS AMONG CHILDREN LIVING IN LOW AND MIDDLE INCOME COUNTRIES: A SYSTEMATIC REVIEW WITH META-ANALYSIS

**Muhammed O. Afolabi**<sup>1</sup>, Boni M. Ale<sup>2</sup>, Edgard D. Dabira<sup>3</sup>, Schadrac C. Agbla<sup>4</sup>, Amaya L. Bustinduy<sup>1</sup>, Jean-Louis A. Ndiaye<sup>5</sup>, Brian Greenwood<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Holo Healthcare Limited, Nairobi, Kenya, <sup>3</sup>Medical Research Council at London School of Hygiene & Tropical Medicine, Banjul, Gambia, <sup>4</sup>University of Liverpool, Liverpool, United Kingdom, <sup>5</sup>University of Thies, Thies, Senegal

Current knowledge on the burden of, and interactions between malaria and helminth co-infections, as well as the impact of the dual infections on anaemia, remains inconclusive. We conducted a systematic review with meta-analysis to update current knowledge as a first step towards developing and deploying coordinated approaches to the control of malaria-helminth co-infections among children living in LMIC. Using PRISMA guidelines, two reviewers independently searched Medline,

Embase, Global Health and Web of Science from database inception until 16 March 2020 for peer-reviewed articles. No language restriction was applied. We used the summary odds ratio and 95% CI as a measure of association (random-effects model), performed Chi-square heterogeneity test and evaluated the severity of heterogeneity using  $I^2$  statistics. The included studies were examined for publication bias using a funnel plot and Egger's test. Fifty-five of the 3,507 citations screened were eligible, 28 of which had sufficient data for meta-analysis. The 28 studies enrolled 22,114 children in 13 countries across SSA, Southeast Asia and South America. Overall, the pooled estimates showed a prevalence of *Plasmodium*-helminth co-infections of 17.7% (95% CI 12.7-23.2%). Fourteen studies showed a lower odds of *P. falciparum* infection in children co-infected with *Schistosoma* spp (OR: 0.65; 95%CI: 0.37-1.16), while 24 studies showed similar lower odds of *P. falciparum* in children co-infected with STH (OR: 0.42; 95%CI: 0.28-0.64). Sixteen studies showed that the odds of anaemia were higher in children co-infected with *Plasmodium* and STH than in children with *Plasmodium* infection alone (OR= 1.20; 95% CI: 0.59-2.45), and were almost equal in children co-infected with *Plasmodium-Schistosoma* spp or *Plasmodium* infection alone (OR= 0.97, 95% CI: 0.30-3.14). This review suggests that the prevalence of malaria-helminth co-infection is very high and vary widely in children living in LMIC. Geo-spatial tools may be needed to generate better understanding of the burden of the co-infection, which is fundamental to the development of appropriate interventions for integrated control.

## 1270

### FACTORS ASSOCIATED WITH KNOWLEDGE OF SCHISTOSOMIASIS IN CHILDREN AND ADULTS IN THE KALABANCORO HEALTH DISTRICT IN 2020

<sup>1</sup>Department of Teaching and Research in Public Health and Specialties, Faculty of Medicine and Odontostomatology of Bamako; Health District of Kalabancoro, Koulikoro, Mali, Bamako, Mali, <sup>2</sup>Department of Teaching and Research in Public Health and Specialties, Faculty of Medicine and Odontostomatology of Bamako; Filarisis Unit, International Center of Excellence in Research, Bamako, Mali, Bamako, Mali, <sup>3</sup>University Clinical Research Center, Point G, Bamako, Mali, Bamako, Mali, <sup>4</sup>Hellen Keller International of Mali, Bamako, Bamako, Mali, <sup>5</sup>Filarisis Unit, International Center of Excellence in Research, Bamako, Mali, Bamako, Mali, <sup>6</sup>Health District of Kalabancoro, Koulikoro, Mali, Bamako, Mali, <sup>7</sup>National Schistosomiasis and Soil-transmitted Control Program, General Directorate of Health and Public Hygiene, Bamako, Mali, Bamako, Mali, <sup>8</sup>Hospital of Dermatology of Bamako, Bamako, Mali, Bamako, Mali, <sup>9</sup>Faculty of Medicine and Odontostomatology, Bamako, Bamako, Mali, <sup>10</sup>Department of Teaching and Research in Public Health and Specialties, Faculty of Medicine and Odontostomatology of Bamako; Filarisis Unit, International Center of Excellence in Research, Bamako, Mali; Hospital of Dermatology of Bamako, Bamako, Mali, Bamako, Mali

Schistosomiasis continues to be a public health problem in many parts of the world, particularly in Africa. In terms of morbidity, it is the most devastating parasitic disease after malaria. It is still endemic in 74 countries and affects 261 million people worldwide with nearly 800 million people at risk. It is estimated that more than 90% of these cases come from sub-Saharan Africa. In Mali in 2019, the overall prevalence rate was 30%. In Kalabancoro, during 2017 assessments, the National Schistosomiasis and Geo-Helminthiasis Control Program reported a urinary schistosomiasis prevalence of 10.83% and an intestinal schistosomiasis prevalence of 50.83%. This district recorded the highest rate for intestinal schistosomiasis among the 46 districts evaluated. To better understand this high prevalence, this study was initiated. To study the knowledge of children and adults about schistosomiasis in the health district of Kalabancoro. A cross-sectional study was conducted from May to November 2020. A two-level cluster sampling (villages and households)

was conducted. Thirty villages were randomly selected from the 117 villages in the district and 947 willing participants were surveyed using a questionnaire. Univariate analysis and binary logistic regression were performed using the Statistical Package for Social Sciences. During the study, 76.1% of participants claimed to know about schistosomiasis; among them, 85.6% did not know the mode of contamination ( $p=0.001$ ), 66.3% knew the traditional treatment ( $p=0.004$ ), and 70% reported knowing how to avoid the disease ( $p<0.01$ ). Variables such as gender (3.47 [2.48-4.85]), age (2.72 [1.94-3.82]), and household near a water reservoir (2.15 [1.49-3.11]) were statistically associated with knowledge of schistosomiasis. The majority of respondents claimed to know about schistosomiasis. However, details about the cause, prevention and treatment of schistosomiasis were not well known. It is important to educate communities about the mode of transmission, prevention and treatment of schistosomiasis and to implement interventions that can reduce the level of transmission.

## 1271

### THE MEASURING OF TREATMENT COVERAGE FOR SCHISTOSOMIASIS WITH PREVENTIVE CHEMOTHERAPY IN BONG, LOFA AND NIMBA COUNTIES IN 2018 IN LIBERIA

Anthony Kerkula Bettee

Ministry of Health, Congo Town, Monrovia, Liberia

Schistosomiasis or Bilharzia is a parasitic disease caused by infection with the trematode blood-flukes schistosomes. In sub-Saharan Africa, two major forms of human schistosomiasis occur intestinal, schistosomiasis caused by mainly *Schistosoma mansoni* infection and urinary schistosomiasis due to *Schistosoma haematobium* infection. Schistosomiasis is among the neglected tropical diseases (NTDs), which remain serious public health problems, posing unacceptable threats to human health. The World Health Assembly resolution 54.19 urges all member states to regularly treat at least 75% of all school-aged children are at risk of morbidity from schistosomiasis with Praziquantel (PZQ). To determine if these global goals are being reached, each national program routinely reports drug coverage. This metric is calculated using the number of treatments distributed during a round of Preventive Chemotherapy (PC) recorded in treatment registers and/or tally sheets for the numerator, and population figures (often obtained from routine census figures) as the denominator. In order to monitor and support NTD program performance, independent drug coverage surveys are recommended by the World Health Organization. These coverage surveys should be carried out across all areas given PC, particularly at crucial time points during the programs i.e. in the first year of the program, in cases where coverage might be suspiciously high or low, to ensure any corrective actions where needed. The result of the survey assists in the identification of recommended actions to improve program delivery. The aim of the coverage survey was to evaluate the effectiveness of PC in reaching the target population in endemic counties. The SCH categories of each county are based on the data collected in the 2012 baseline survey, which was carried out prior to the first MDA in Liberia which shows that schistosomiasis is prevalent in 13 counties with the exception of Rivercess and Grand Kru. During the survey number of interviewed children was low. 651 children/ 1023 adults. The survey contains 14 villages per county (42 in total), 15 Households. PZQ coverage for adults and SAC was 75%.

1272

### DIFFERENTIAL SUSCEPTIBILITY OF BOVINES TO SCHISTOSOMA JAPONICUM IN A CHALLENGE INFECTION MODEL

Mario Jiz<sup>1</sup>, John Ezra dela Cruz<sup>1</sup>, Joseph Valencia<sup>1</sup>, Daria Manalo<sup>1</sup>, Sarah Li<sup>2</sup>, Hannah Wu<sup>3</sup>, Jonathan D. Kurtis<sup>3</sup>

<sup>1</sup>Research Institute of Tropical Medicine, Metro Manila, Philippines, <sup>2</sup>NIH-NIAID Schistosomiasis Resource Center, Biomedical Research Institute, Rockville, MD, United States, <sup>3</sup>Center for International Health Research, Brown University Medical School, Providence, RI, United States

Schistosomiasis japonica is an endemic, zoonotic parasitic disease. In the Philippines, water buffalo (carabao, *Bubalus bubalis*) is a primary transmission source. To identify the optimal vaccination-challenge protocol for the schistosomiasis japonica vaccine, we evaluated factors that may affect worm recovery rate by perfusion. Factors included host species (*Bubalus bubalis* versus *Bos indicus*), age, pretreatment with praziquantel, trickle vs. bolus exposure to cercariae, and the timing of perfusion. Eighteen carabao and three cattle were purchased (groups A to G, n=3) from an *Schistosoma japonicum* non-endemic region and maintained on non-endemic pasture during the four-month study (Oct, 2020 to Jan, 2021). Bovine health was monitored daily by veterinary technicians and weekly with a complete physical exam by a veterinarian. Six groups of carabao and one group of cattle were assigned to different infection-perfusion conditions to identify the optimal infection protocol. All animals were verified as uninfected with *S. japonicum* by PCR at the start of the study. Surprisingly, a majority of animals showed high antibody levels to schistosome specific crude antigens, including ES, SEA, and SWAP, and recombinant full-length paramyosin (rSj97), likely due to prior Fasciola infection. Among the study groups, we found marked heterogeneity in worm recovery rates. Specifically, worm recovery rates were highest in groups C (trickled infection, total dose 3,000 cercariae), F (juvenile 1-1.5yr carabao, 1000 cercariae), and G (Cattle, 500 cercariae). Notably, a worm recovery rate of ~10% is sufficient for vaccine efficacy evaluation, and this level was achieved in three out of the seven groups. We concluded that juvenile carabao with the trickled dose of cercariae infection is the optimal vaccination-challenge model for vaccine trials with carabao in the Philippines and have initiated a trial of rSj97 and rSj6-8 using this protocol.

1273

### GLOBAL BURDEN OF SCHISTOSOMIASIS 1990-2020: A MODELLING ANALYSIS FOR THE GLOBAL BURDEN OF DISEASE STUDY 2020, RELEASE 1

Ewerton Cousin, Cathleen Keller, Stephanie R. Zimsen, Taren Gorman, Martina Vargas, Emily Hilton, Trent Yarosevich, Jonathan Mosser

Institute for Health Metrics and Evaluation, Seattle, WA, United States

Schistosomiasis is one of the most common parasitic diseases in the world. The World Health Organization set a goal to eliminate schistosomiasis as a public health problem by 2025. We aim to describe the burden of schistosomiasis in the world from 1990 to 2020. We estimated the burden of schistosomiasis with data from 5 species (*S. mansoni*, *S. haematobium*, *S. japonicum*, *S. mekongi*, *S. intercalatum*). To estimate deaths, we used a negative binomial regression model of country-year-age-sex-specific deaths, using vital registration and verbal autopsy as sources. To model non-fatal outcomes, we ran a DisMod MR 2.1 model to estimate prevalence among the population at risk, which was then further adjusted to account for total population. We present preliminary results here. Results for GBD 2020, release 1 will be finalized in summer 2021. We estimated 12,500 (95%UI: 10,900-14,000) deaths globally in 2020. The age-standardized death rate in 2020 was 0.15 (95%UI: 0.13 - 0.17) per 100,000, 64% lower than in 1990. In 2020, it also was 25% higher in males than females. Countries in sub-Saharan Africa showed the highest mortality, Central African Republic (6.2 [95%UI: 4.4 - 8.7] deaths per 100,000) and Somalia (5.5 [95%UI: 3.9 - 7.2] deaths per 100,000) had the highest age-standardized mortality rates. Globally, we estimated

155 (95%UI: 118 - 199) million prevalent cases of schistosomiasis in 2020. The age-standardized prevalence rate was 1,989 (95%UI: 1,511 - 2,523) per 100,000 in 2020, 19% lower than in 1990. In terms of DALYs, we estimated a 39% decrease in the age-standardized rate, from 35.2 (95%UI: 24.6 - 54.7) per 100,000 in 1990 to 21.4 (95%UI: 12.7 - 37.8) in 2020. Mauritius, Central African Republic, and Nigeria had the highest age-standardized DALYs rates: 289.1 (95%UI: 126 - 593), 284.2(95%UI: 126 - 594), and 214.6 (95%UI: 119 - 393) DALYs per 100,000, respectively. These findings show progress made in the burden of schistosomiasis over the past 30 years. However, progress in mortality was much greater than in morbidity. The GBD estimates for schistosomiasis can serve as a resource for policymakers to track progress and identify priorities for interventions.

1274

### THE PERSISTENCE OF SCHISTOSOMIASIS IN A LARGE METROPOLITAN AREA OF BRAZIL. RESPONSE OF SCHISTOSOMA MANSONI POPULATION STRUCTURE TO A CHANGING URBAN ENVIRONMENT

Fernanda M. Cedraz<sup>1</sup>, Luciano K. Silva<sup>1</sup>, Mitermayer G. Reis<sup>1</sup>, Ronald E. Blanton<sup>2</sup>, Lucio M. Barbosa<sup>1</sup>

<sup>1</sup>Oswaldo Cruz Foundation Bahia, Salvador, Brazil, <sup>2</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States

Saramandaia, a poor urban neighborhood in Salvador, Brazil is marked by a series of streams and large, semi-commercial vegetable gardens. Most of these gardens have recently been removed for new construction and housing. We evaluated *Schistosoma mansoni* population structure and persistence before (2018) and after (2019) these interventions coupled with praziquantel treatment. In 2018 and 2019, we conducted sociodemographic and parasitological surveys and collected up to 3 stool samples on different days. Positive individuals by Kato-Katz were treated with praziquantel and reexamined four weeks later. Egg DNA from stools was genotyped for 10 microsatellites. Allele frequencies for infrapopulations and component populations were used to measure differentiation and effective population size ( $N_e$ ). Between 2018 and 2019 prevalence reduced from 5.7% to 2.8% ( $p=0.001$ ). Intensity of infection remained constant at 64.0 epg in 2018 and 74.2 epg in 2019. Risk factors for infection were male sex ( $OR=2.5$ ;  $p<0.001$ ), occupational contact with surface water ( $OR=1.7$ ;  $p=0.046$ ), and use/access to water at 2 specific points in the community ( $OR=2.2$ ;  $p=0.005$ ). In 2018,  $D_i$  (mean pairwise differentiation of infrapopulations) was high (0.228) and higher in 2019 (0.297, Cohen's  $D=0.462$ ). Similar results were seen evaluating sex, age, and access/contact with the 3 water contact points in the community.  $D_c$  (mean differentiation of the whole population 2018 vs 2019) was moderate between the 2 years (0.077). However, incident cases and newly enrolled individuals were highly differentiated from the starting population of 2018 (0.220 and 0.261, respectively).  $N_e$  in 2018 was 3,052 and decreased by 30% in 2019. One round of praziquantel treatment coupled with structural intervention was relatively effective in reducing prevalence, however, little effect was seen on parasite's population structure. This may be due in part to only being able to treat ~10% of the population and the continuous nature of housing in urban areas. Treatment and sanitation of a much wider population will be necessary to significantly impact the biological potential of *S. mansoni* in this locality.

## RESULTS FROM A HYBRID IMPLEMENTATION AND EFFECTIVENESS PILOT STUDY TO ASSESS THE FEASIBILITY, ACCEPTABILITY AND PROTECTIVE EFFECT OF SEASONAL MALARIA CHEMOPREVENTION IN NAMPULA PROVINCE, MOZAMBIQUE

**Baltazar Candrinho**<sup>1</sup>, Kevin Baker<sup>2</sup>, Maria Rodrigues<sup>3</sup>, Sol Richardson<sup>2</sup>, Craig Bonnington<sup>2</sup>, Alexandra Wharton-Smith<sup>2</sup>, Mercia Sítio<sup>3</sup>, Christian Rassi<sup>2</sup>, Maddy Marasciulo<sup>2</sup>, Sonia Enosse<sup>4</sup>, Francisco Saute<sup>5</sup>, Pedro Aide<sup>6</sup>, Arantxa Roca-Feltrer<sup>2</sup>

<sup>1</sup>National Malaria Control Programme, Maputo, Mozambique, <sup>2</sup>Malaria Consortium, London, United Kingdom, <sup>3</sup>Malaria Consortium, Maputo, Mozambique, <sup>4</sup>National Institute of Health (Instituto Nacional de Saúde), Maputo, Mozambique, <sup>5</sup>Centro de Investigação em Saúde de Manhiça (CISM), Manhica, Mozambique, <sup>6</sup>Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique

Malaria is a significant cause of morbidity and mortality in children under five in Mozambique. The World Health Organization recommends seasonal malaria chemoprevention (SMC): the administration of monthly courses of sulfadoxine-pyrimethamine (SP) and amodiaquine (AQ) (SPAQ) to children aged 3-59 months during the peak transmission season. Due to widespread prevalence of markers associated with SP resistance in East and Southern Africa, the implementation of SMC has so far been well documented across the Sahel zone of West and Central Africa. During November 2020 to February 2021, Ministry of Health National Malaria Control Programme in collaboration with Malaria Consortium, for the first time, implemented SMC in two districts in Nampula province, Mozambique. We conducted a hybrid implementation and effectiveness study where 2 districts received the intervention and one district acted as the control to understand the: 1) adaption of SMC to the Mozambique context; 2) acceptability and feasibility of the intervention based on interviews and focus group discussions; 3) coverage and quality of SPAQ delivery using a cross sectional end-of-round survey; 4) baseline prevalence of SP and AQ resistance associated genotypes (including Pfdhps, Pfdhfr, Pfcr and Pfmdr1 mutants) and subsequent follow up to determine if selection pressure alters these prevalence measures; and finally 5) reduction in odds of clinically-significant malaria outcomes associated with receipt of SPAQ based on a non-randomised controlled trial with 400 eligible children each in the two intervention districts and a third control district. In brief, initial results showed that SMC was successfully adapted and accepted by stakeholders. Coverage among eligible children in terms of administration of Day 1 SPAQ was 84.0% (95% CI: 82.1-85.8). Of the children recruited to the trial, 64 developed clinical malaria in the intervention period versus 191 in the control arm; we estimated a protective effect of around 80%. The session will describe the complete findings from these studies on the acceptability, feasibility and protective effect of SMC implementation in this context.

## BUILDING DATA INTEGRATION AND VISUALIZATION PLATFORMS TO HELP EMERGENCY OPERATION CENTERS MONITOR MALARIA DURING PUBLIC HEALTH EMERGENCIES - EXPERIENCE FROM THE DEMOCRATIC REPUBLIC OF THE CONGO

**Garyn de Bondt**<sup>1</sup>, Hornel Lama<sup>2</sup>, Jicko Bondole<sup>1</sup>, Marie-Julie Lambert<sup>2</sup>, Jimmy Anzolo<sup>1</sup>, Thomas Warichet<sup>2</sup>, Romain Olekhnovitch<sup>2</sup>, Henry Nkutu<sup>1</sup>, Grégoire Lurton<sup>3</sup>, Trad Hatton<sup>1</sup>, Kammerle Schneider<sup>4</sup>, Nicolas de Borman<sup>2</sup>, Hana Bilak<sup>5</sup>, Hyacinthe Kaseya<sup>6</sup>, Gisèle Mbuyi<sup>7</sup>, Erick Katanga<sup>8</sup>, Eric S. Mukomena<sup>6</sup>, Aron Aruna<sup>7</sup>

<sup>1</sup>PATH, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Bluesquare, Brussels, Belgium, <sup>3</sup>Bluesquare, Brussels, Democratic Republic of the Congo, <sup>4</sup>PATH, Seattle, WA, United States, <sup>5</sup>PATH, Geneva, Switzerland, <sup>6</sup>National Malaria Control Programme, Kinshasa, Democratic Republic of the Congo, <sup>7</sup>Epidemiological Surveillance Department, Ministry of Health, Kinshasa,

*Democratic Republic of the Congo, <sup>8</sup>Health Management Information Systems Department, Ministry of Health, Kinshasa, Democratic Republic of the Congo*

The potential impact of COVID-19 on malaria morbidity and mortality highlighted the need to track malaria trends in near real time and design integrated sustainable interoperable data systems to improve malaria surveillance. Emergency Operations Centers (EOCs) are often geared towards fast response to emerging crises, but the long-term monitoring of a multiplicity of concurrent public health challenges is harder to maintain. Creating platforms for data integration and visualization systems for malaria surveillance, as well as for the coordination, planning, and monitoring of malaria campaigns represents a unique opportunity to reinforce EOC capacity and provide a model for their sustainability. We engaged with the Ministry of Health in the DRC to support its EOC's engagement to respond to COVID-19, all the while strengthening malaria burden reduction efforts and increasing the EOC's efficiency in responding to other emergencies. To support DRC's COVID-19 response, DHIS2-based digital tools to collect and integrate data streams into a single warehouse for COVID-19 data management were adopted. DHIS2 modules were created to enable health workers to track and investigate COVID-19 cases and health service usage; operational and epidemiological dashboards to follow the epidemic and inform the response were created. In collaboration with the National Malaria Control Program, we carried out an assessment of existing malaria data sources and gaps. Malaria dashboards to monitor key indicators, as well as service accessibility and malaria logistic indicators were developed and are now available and used by the National Malaria Control Program. A separate dashboard to track morbidity and mortality data for 21 diseases with epidemic potential, including COVID and malaria, was developed to reinforce the EOC's capacity to monitor multiple diseases. We are now supporting the optimization of outbreak detection algorithms and developed a training curriculum for technical focal points and decision-makers, as well as an online training platform to build capacity and reinforce data use for decision-making.

## EFFECTIVENESS OF A NATIONAL MASS DISTRIBUTION CAMPAIGN OF LONG-LASTING INSECTICIDE-TREATED NETS AND INDOOR RESIDUAL SPRAYING ON CLINICAL MALARIA IN MALAWI, 2018-2020

**Hillary M. Topazian**<sup>1</sup>, Austin Gumbo<sup>2</sup>, Jessie K. Edwards<sup>1</sup>, Katerina Brandt<sup>1</sup>, Varun Goel<sup>1</sup>, Michael Kayange<sup>3</sup>, Tisungane Mvalo<sup>3</sup>, Michael Emch<sup>1</sup>, Audrey Pettifor<sup>1</sup>, Jennifer S. Smith<sup>1</sup>, Jonathan J. Juliano<sup>1</sup>, Irving F. Hoffman<sup>1</sup>

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>National Malaria Control Programme, Malawi Ministry of Health, Lilongwe, Malawi, <sup>3</sup>University of North Carolina Project-Malawi, Lilongwe, Malawi

Malawi's malaria burden is primarily assessed via cross-sectional national household surveys. However, malaria is spatially and temporally heterogenous and no analyses have been performed at a sub-district level throughout the course of a year. The World Health Organization recommends mass distribution of long-lasting insecticide-treated bed nets (LLINs) every three years, but a national longitudinal evaluation has never been conducted in Malawi to determine LLIN effectiveness lifespans. Using District Health Information Software 2 (DHIS2) health facility data, available from January 2018 to June 2020, we assessed malaria risk before and after a mass distribution campaign, stratifying by age group and comparing risk differences by LLIN type or annual application of indoor residual spraying (IRS). 711 health facilities contributed 20,962 facility reports over 30 months. After national distribution of 10.7 million LLINs and IRS in limited settings, malaria risk decreased from 25.6 to 16.7 cases per 100 people from 2018 to 2019 high transmission seasons, and rebounded to 23.2 in 2020, resulting in significant risk differences of -8.9 in 2019 and -2.4 in 2020 as compared to 2018. Piperonyl butoxide-treated (PBO) LLINs were more effective than pyrethroid-treated LLINs, with adjusted risk differences

of -2.3 (95% CI: -2.7 to -1.9) and -1.5 (95% CI: -2.0 to -1.0) comparing 2019 and 2020 high transmission seasons to 2018. Use of IRS sustained protection with adjusted risk differences of -1.4 (95% CI: -2.0 to -0.9) and -2.8% (95% CI: -3.5 to -2.2) relative to pyrethroid-treated LLINs. Overall, 12 of 28 districts (42.9%) experienced increases in malaria risk in from 2018 to 2020. LLINs in Malawi have a limited effectiveness lifespan and IRS and PBO-treated LLINs perform better than pyrethroid-treated LLINs, perhaps due to net repurposing and insecticide-resistance. DHIS2 provides a compelling framework in which to examine localized malaria trends and evaluate ongoing interventions.

### IMPROVING THE QUALITY AND USE OF MALARIA SURVEILLANCE DATA: RESULTS FROM EVALUATING THE EFFECTIVENESS AND ACCEPTABILITY OF A NEW INTEGRATED MALARIA INFORMATION STORAGE SYSTEM IN SELECTED DISTRICTS IN MOZAMBIQUE

**Ann-Sophie Stratil<sup>1</sup>**, Maria Rodrigues<sup>2</sup>, Kevin Baker<sup>1</sup>, Neide Canana<sup>2</sup>, Sarmiento Armando<sup>2</sup>, Sergio Gomane<sup>2</sup>, Edson Zandamela<sup>2</sup>, Arantxa Roca-Feltrer<sup>1</sup>, Baltazar Candrinho<sup>3</sup>

<sup>1</sup>*Malaria Consortium, London, United Kingdom*, <sup>2</sup>*Malaria Consortium, Maputo, Mozambique*, <sup>3</sup>*National Malaria Control Programme, Ministry of Health, Maputo, Mozambique*

Mozambique has the fourth highest burden of malaria in the world. Assessments carried out in 2016 and later in 2018 identified critical challenges to the malaria surveillance system in Mozambique, including poor data quality and integration and lack of automated analysis mechanisms. In response to these findings, the development of an integrated malaria information storage system (iMISS) was initiated. iMISS aligns to the high burden high impact (HBHI) data repositories recommendations and stores malaria data across thematic program areas including case surveillance, vector control and commodity management and includes automated data outputs for users at all levels. It also allows health facilities to directly submit their monthly malaria data reports digitally with the aim of improving data quality replacing the need for an additional intermediary step of paper-based reporting. The primary goal of iMISS is to enable malaria staff at all levels of the health system to monitor key indicators and to provide quality evidence to plan and implement responses. The nation-wide roll-out of iMISS and introduction of the direct digital reporting component in seven selected districts started in February/March 2021. In collaboration with the National Malaria Control Programme, a structured evaluation will be carried out from April to September 2021 with the aim of evaluating the effectiveness of the new system and its acceptability among key users. The design of the evaluation is based on the established RE-AIM framework focusing on the five dimensions: reach, effectiveness, adoption, implementation and maintenance of the new system. The primary objective focuses on assessing the data quality of health facility data reported in iMISS and use of iMISS data for decision-making at all levels of the health system. Results of the evaluation will be presented in this session, along with evidence for improvements in data quality and data use as a result of the new system and document lessons learned, key challenges and possible mitigation actions during the first months of implementation.

### SUB-HEALTH CENTER MALARIA SURVEILLANCE: SETUP AND COMMUNITY USE CASES OF A MOBILE SURVEILLANCE APPLICATION

**Japhet M. Matoba<sup>1</sup>**, Anton Kvit<sup>2</sup>, Mukuma J. Lubinda<sup>1</sup>, Caison Sing'anga<sup>1</sup>, Phil Thuma<sup>3</sup>, Andre Hackerman<sup>2</sup>, Edgar Simulundu<sup>1</sup>, Tamaki Kobayashi<sup>2</sup>, William J. Moss<sup>2</sup>

<sup>1</sup>*Macha Research Trust, Choma, Zambia*, <sup>2</sup>*Johns Hopkins University Bloomberg School Of Public Health, Baltimore, MD, United States*, <sup>3</sup>*Macha Research Trust/Johns Hopkins University Bloomberg School Of Public Health, Choma, Zambia*

In its Malaria Elimination Strategic Plan, the Zambian government identified the health facility catchment (HFC) as the unit of elimination and of intervention for implementation. However, existing surveillance tools focus on implementation at the provincial or district level and are rarely tailored for use and response at the HFC. We examined the use case scenarios generated from providing community based malaria mobile application at the sub-HFC level in a rural pre-elimination setting of southern Zambia. An RShiny based mobile application was developed and piloted at Mapanza Rural Health Centre (RHC) located in Choma district in the Southern Province Zambia that is earmarked for malaria elimination. The app provided malaria surveillance data to health center workers and Community Health Workers (CHW) at the HFC. Sub-health center and RHC catchment maps were created using a combination of satellite imagery, ArcGIS software and physical verification by CHWs and RHC staff. The app was piloted in 2020 and additional iterations made after feedback by the end users. Questionnaires were administered to community level end users on experiences around the ease of use, potential use case scenarios and desired outputs from the mobile application. Inventory of the available surveillance platforms and catchment maps was also conducted. The community-based surveillance malaria app provided timely visibility on emergent and incident malaria cases, as well as opportunities for community targeted passive and reactive strategies. Sub-HFC maps were generated and comparisons made with geometrically estimated models. Although, Mapanza RHC catchment had a higher number of malaria cases in the area when compared to the other RHCs in the Macha hospital catchment, the RSHINY app was able to show that malaria incidences at the Mapanza sub-HFC level was not homogeneous and better inform intervention targeting. RHC staff reported not having any other surveillance platforms targeted for response at the HFC. Community based malaria surveillance apps can be leveraged to target sub-HFC of malaria transmission and thus guide community led interventions.

1280

### MALARIA FRONTLINE PROJECT IMPLEMENTATION: LESSONS LEARNT FROM ZAMFARA AND KANO STATES, NIGERIA, 2016-2019

**Adefisoye Oluwaseun Adewole**, NdadiInasiya Waziri, Saheed Gidado, Amina Umar, Usaini Bala, Simple Edwin, Gideon Ugbenyo, Adam Attahiru, Isaac Igbaver, Patrick Nguku  
*African Field Epidemiology Network, Abuja, Nigeria*

Poor data quality is a problem for Nigeria's health information system. The United States of America's Centers for Disease Control and Prevention (CDC) collaborated with the Nigeria National Malaria Elimination Program of Nigeria (NMEP) to establish the Malaria Frontline Project (MFP) to improve malaria program surveillance and ensure quality malaria data for decision making in Zamfara and Kano states. Every month Local Government Area (LGA) supervisory team analyzed testing rate, clinical diagnosis and directly observed intermittent preventive treatment (IPTp) of facilities from DHIS2. A facility was visited at least once every quarter, but low performing facilities based on the analysis were visited more frequently. During visit on-the-job training and mentoring of healthcare workers (HCWs) was conducted. Visits ranged between 3-7 per facility per year with mean visits of 5. We analyzed health facility (HF) support visits reports for 2017, 2018 and 2019, respectively. Results for the three years

showed HF testing rates increased: [(Kano: 92.2%, 97.6% and 98.3%; Zamfara: 90.8%, 95% and 97.7%)]. Clinical diagnosis decreased [(Kano: 2.6%, 1.5% and 1.1%); Zamfara: 1.9%, 0.5% and 0.5%]. Proportion of HF practicing the recommended directly observed IPTp increased [(Kano: 83.3%, 97.9% and 97.3%; Zamfara: 83.5%, 88.1% and 88.6%)]. According to the visit reports, HF that analyzed the selected indicators from their malaria monitoring chart and used the results to make program decision increased: [Kano: 93.0%, 95.0% and 99%; Zamfara: 88.7%, 90.4% and 90.1%] respectively. Use of DHIS2 data analysis with supportive visits helped HCWs at HF and LGA levels to improve malaria program performance. HF support visits driven by DHIS-2 data reviews and HCW mentoring should be encouraged to improve public health program performance especially at HF and LGA levels as well as HF itself analyzing key indicators and use it to make program decision. The lessons learnt can be adopted by other public health programs in the country.

## 1281

### A PHASE IIIB COMPARATIVE TRIAL OF SEASONAL VACCINATION WITH THE MALARIA VACCINE RTS,S/AS01, SEASONAL MALARIA CHEMOPREVENTION AND OF THE TWO INTERVENTIONS COMBINED

Daniel Chandramohan<sup>1</sup>, Issaka Zongo<sup>2</sup>, Issaka Sagara<sup>3</sup>, Matthew Cairns<sup>1</sup>, Serge Yerbanga<sup>2</sup>, Modibo Diarra<sup>3</sup>, Frederic Nikiema<sup>2</sup>, Amadou Tapily<sup>3</sup>, Frederic Sompougou<sup>2</sup>, Djibrilla Issiaka<sup>3</sup>, Charles Zoungrana<sup>2</sup>, Koualy Sanogo<sup>3</sup>, Alassane Haro<sup>2</sup>, Mahamadou Kaya<sup>3</sup>, Abdoul Aziz Sienou<sup>2</sup>, Seydou Traore<sup>3</sup>, Almahamadou Mahamar<sup>3</sup>, Ismaila Thera<sup>3</sup>, Kalifa Diarra<sup>3</sup>, Amagana Dolo<sup>3</sup>, Irene Kuepfer<sup>1</sup>, Paul Snell<sup>1</sup>, Paul Milligan<sup>1</sup>, Christian Ockenhouse<sup>4</sup>, Opokua Ofori-Anyinam<sup>5</sup>, Halidou Tinto<sup>2</sup>, Abdoulaye Djimde<sup>3</sup>, Jean-Bosco Ouedraogo<sup>2</sup>, Alassane Dicko<sup>3</sup>, **Brian Greenwood<sup>1</sup>**

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, <sup>3</sup>Malaria Research & Training Centre, Bamako, Mali, <sup>4</sup>PATH, Seattle, WA, United States, <sup>5</sup>GSK Vaccines, Rixensart, Belgium

We conducted an individually randomised, double blind placebo controlled trial in Mali and Burkina Faso, to determine whether seasonal vaccination with RTS,S/AS01<sub>E</sub> could provide a similar level of protection to Seasonal malaria chemoprevention (SMC) with sulphadoxine-pyrimethamine plus amodiaquine (SP+AQ), and whether a combination of the two interventions would provide greater protection than SMC alone. Children aged 5-17 months were randomized in April 2017 to receive SMC alone, RTS,S/AS01<sub>E</sub> alone or both interventions (n=5920); 1965, 1988 and 1967 children in these groups respectively were followed over a three-year period. Children in the SMC alone group received three doses of rabies vaccine in year one and a dose of hepatitis A vaccine in years 2 and 3, together with four cycles of SMC each year. Children in the RTSS alone group received three priming doses of RTS,S/AS01<sub>E</sub> vaccine in year one and a booster dose in years 2 and 3 together with four cycles of SMC placebo each year. Children in the combined group received RTS,S/AS01<sub>E</sub> vaccine and SMC each year. The incidence of the primary endpoint, uncomplicated clinical malaria (fever with a parasite density of  $\geq 5000$  per  $\mu$ l) in the SMC alone, RTS,S alone and the combined groups was 305, 278 and 113 per 1000 person-years at risk respectively. The hazard ratio (HR) comparing RTS,S alone to SMC was 0.92, (95% confidence interval (CI): 0.84, 1.01), excluding the pre-specified non-inferiority margin of 1.20. Episodes of , hospital admissions with severe malaria and deaths from malaria were reduced by 70.5% (95% CI: 41.9, 85.0) and 72.9% (95% CI: 2.91, 92.4) in the combined group compared to the SMC alone group and reduced by 70.6% (95% CI: 42.3, 85.0) and 75.3% (95% CI: 12.5, 93.0) in the combined group compared to the RTS,S alone group. Five children given RTS,S/AS01<sub>E</sub> developed febrile convulsion the day after vaccination but recovered without sequelae. Seasonally-targeted RTS,S/AS01<sub>E</sub> vaccine was safe and non-inferior to SMC in preventing uncomplicated malaria. The combination of these interventions was superior to either alone in preventing uncomplicated malaria, severe malaria and death from malaria.

## 1282

### EFFECTS OF SCHISTOSOMA MANSONI AND PRAZIQUANTEL TREATMENT ON THE GASTROINTESTINAL MUCOSA: A COHORT STUDY IN RURAL TANZANIA

Khanh Pham<sup>1</sup>, Gideon Mtalitinya<sup>2</sup>, Christine Aristide<sup>3</sup>, Efeose A. Airewale<sup>3</sup>, Deborah Nyakaru<sup>3</sup>, Paige McMahon<sup>3</sup>, Paul L.A.M. Corstjens<sup>4</sup>, Claudia de Dood<sup>4</sup>, Govert J. van Dam<sup>5</sup>, John M. Changalucha<sup>6</sup>, Humphrey D. Mazigo<sup>7</sup>, Hyasinta Jaka<sup>7</sup>, Jennifer A. Downs<sup>3</sup>

<sup>1</sup>New York-Presbyterian/Weill Cornell Medical Center, New York, NY, United States, <sup>2</sup>Ghana Family Polyclinic, Mwanza, United Republic of Tanzania, <sup>3</sup>Center for Global Health, Weill Cornell Medicine, New York, NY, United States, <sup>4</sup>Department of Cell and Chemical Biology, Leiden University Medical Center, Leiden, Netherlands, <sup>5</sup>Department of Parasitology, Leiden University Medical Center, Leiden, Netherlands, <sup>6</sup>Mwanza Intervention Trials Unit, Mwanza, United Republic of Tanzania, <sup>7</sup>Bugando Medical Centre, Mwanza, United Republic of Tanzania

We conducted a prospective cohort study among women and men living in a Tanzanian fishing village to compare the clinical findings on sigmoidoscopy and laboratory values (hematologic, renal, liver function tests, and erythrocyte sedimentation rate (ESR)) in adults with and without *Schistosoma mansoni* infection at baseline and 6 months after praziquantel treatment. Two groups were enrolled in a 2:1 ratio: an *S. mansoni*-infected group that was positive for both serum schistosome circulating anodic antigen (CAA) and stool ova, and a schistosome-uninfected group. Each participant underwent a baseline sigmoidoscopy and provided peripheral blood for laboratory testing. Schistosome testing was repeated at two-month intervals and treatment with standard-dose praziquantel provided when indicated. Sigmoidoscopies and laboratory testing were repeated at 6 months. Grading of the endoscopic findings was done using the Mayo Scoring System for Assessment of Ulcerative Colitis Activity. In total, 48 individuals were enrolled: 16 infected women, 16 infected men, 10 uninfected women, and 6 uninfected men. *S. mansoni*-infected women had a higher Mayo Score on sigmoidoscopy than uninfected women at baseline (2 versus 0.5,  $p=0.0008$ ). Men with *S. mansoni* infection at baseline had no sigmoidoscopic differences but did have higher eosinophils, aspartate aminotransferase, and ESR and lower body mass index and platelets than uninfected men (all  $p<0.05$ ). At 6 months, 28 individuals completed repeat sigmoidoscopy and blood tests. Of these, 16 had either cleared their baseline infection ( $n=7$ ), or achieved a greater than 5-fold decrease in serum CAA ( $n=9$ ). Among these 16 individuals, women experienced significant improvements in Mayo Score, eosinophils, creatinine, ALT, and ESR. In men, platelets increased after successful treatment. *S. mansoni* infection was associated with mild to moderate sigmoidoscopic abnormalities in women, and hematologic abnormalities in men, which improved after praziquantel treatment. Larger studies are warranted to investigate gastrointestinal mucosal effects of *S. mansoni* infection and potential differences by sex.

## 1283

### HOST TISSUE PROTEOMICS REVEAL INSIGHTS INTO THE MOLECULAR BASIS OF SCHISTOSOMA HAEMATOBIIUM-INDUCED BLADDER PATHOLOGY

Derick N. Osakunor, Kenji Ishida, Olivia Lamanna, Aswini Panigrahi, Michael Hsieh

Children's National Medical Center, Washington, DC, United States

Schistosomiasis remains a major public health concern worldwide. In the case of urogenital schistosomiasis (caused by *Schistosoma haematobium*), adult worms produce eggs in the bladder tissue, which are excreted in the urine and is the major cause of pathology. Disease manifestations include inflammatory fibrosis of the bladder, bladder carcinogenesis, and obstructive renal failure, with death rates of  $>150,000$ /year. While there are enormous opportunities to influence health through specifically designed interventions, limited mechanistic studies imply that the molecular mechanisms underlying pathology have not been

well defined. Based on a mouse bladder wall injection model for urogenital schistosomiasis, proteome profiling of schistosome-infected and uninfected mice bladder tissue was carried out to elucidate the pathways involved in pathology from urogenital schistosomiasis. Purified *S. haematobium* eggs (3,000 eggs/50 µl PBS) or uninfected hamster liver/intestinal extracts (controls) were microinjected into the bladder wall of mice. Mice were sacrificed 7 days post-injection, and bladders were lysed and processed for proteome profiling using mass spectrometry. Multivariate analyses in combination with protein-protein interactions and functional analysis showed that oxidative stress, cell adhesion/aggregation, coagulation, smooth muscle proliferation, and tissue regeneration proteins were more highly represented in egg-injected mice. Proteins involved in immunity/defence responses, including leukocyte migration/aggregation, inflammation, and response to interleukins were more prevalent in egg-injected mice. These findings highlight the host responses induced by active *S. haematobium* infection, characterised by several inflammatory and characteristic bladder tissue changes that lead to pathology, host and parasite survival. This study provides an in-depth analysis of potential host protein indicators and provide new insights into the pathophysiology of urogenital schistosomiasis, and will be relevant for development of improved interventions for disease control.

1284

### HOST METABOLIC ALTERATIONS FROM EARLY SCHISTOSOMA HAEMATOBIIUM INFECTION IN PRESCHOOL-AGED CHILDREN

**Derick N. Osakunor**<sup>1</sup>, Takafira Mduluzi<sup>2</sup>, Douglas Osei-Hyiaman<sup>3</sup>, Karl Burgess<sup>4</sup>, Mark Woolhouse<sup>4</sup>, Francisca Mutapi<sup>4</sup>

<sup>1</sup>Children's National Medical Center, Washington, DC, United States, <sup>2</sup>University of Zimbabwe, Mount Pleasant, Harare, Zimbabwe, <sup>3</sup>National Institutes of Health, Bethesda, MD, United States, <sup>4</sup>University of Edinburgh, Edinburgh, United Kingdom

The worldwide disease burden from schistosomiasis remains significant. Studies in animal models suggest that the pathological consequences from infection are due in part, to parasite-induced changes in host metabolic pathways. There are limited human studies on the impact of infection on host metabolism, none relating to *S. haematobium*, and none describing the changes that occur early in infection. Here, we analysed the changes in host metabolic profiles, in response to the first *S. haematobium* infection and treatment in Zimbabwean children. A cohort of 83 schistosome-negative children (2–5 years old) as determined by parasitological examination, guardian interviews and examination of medical records, was recruited at baseline. Children were followed up after 3 months for parasitological diagnosis of their first *S. haematobium* infection (urine egg count). Children positive for infection were treated with praziquantel, and treatment efficacy checked 3 months after treatment. Blood samples were taken at each time point, and capillary electrophoresis mass spectrometry in conjunction with multivariate analysis were used to compare the change in serum metabolite profiles in schistosome-infected vs. uninfected children. Following baseline at the 3-month follow up, 11 children had become infected with *S. haematobium* (incidence=13.3%). Our results showed that early infection with *S. haematobium* was associated with significant increases (>2-fold) in discriminatory metabolites, linked primarily with energy (G6P, 3-PG, AMP, ADP) and purine (AMP, ADP) metabolism. These observed changes were commensurate with infection intensity, and were resolved within 3 months, following curative treatment. Taken together, these changes are consistent with parasite-related clinical manifestations of malnutrition, poor growth and poor physical and cognitive performance observed in schistosome-infected children. This study provides further understanding into the early host metabolic responses to the infection, the need for early treatment, and development of appropriate interventions aimed at reducing disease consequences.

1285

### IN UTERO METABOLIC RESPONSES TO MATERNAL SCHISTOSOMA JAPONICUM OCCUR IN A SEX-DEPENDENT MANNER

**Emily McDonald**<sup>1</sup>, Zorimel Vargas<sup>1</sup>, Palmera Baltazar<sup>2</sup>, Veronica Tallo<sup>2</sup>, Jennifer Friedman<sup>1</sup>

<sup>1</sup>Rhode Island Hospital, Providence, RI, United States, <sup>2</sup>Research Institute of Tropical Medicine, Manila, Philippines

Metabolic hormones are critical mediators of fetal growth and are known to be impacted by inflammation experienced during pregnancy. We have previously reported maternal *Schistosoma japonicum* to be associated with increased production of pro-inflammatory cytokines by the placenta. In addition, the placental responses to insults *in utero* have been shown to occur in a sex divergent manner, with male fetuses more sensitive than females. IGF binding proteins, particularly IGFBP1, is thought to inhibit IGF availability by binding IGFs in circulation and altering their interaction with receptors on target cells. Accordingly, IGFBP1 is negatively associated with fetal growth. In this study, we evaluated the metabolic hormones adiponectin, leptin, insulin-like growth factor (IGF)-1 and -2, and the mediators IGF binding protein (IGFBP)-1, -3 and -5 in a cohort of pregnant women in Leyte, the Philippines. *S. japonicum* infection was determined via Kato-Katz. All infected women refused treatment with praziquantel. Logistic regression models included maternal education and gestational age for all analyses. Cord blood hormones were not different based on maternal infection. Interestingly, cord blood IGFBP1 levels were lower in females and higher in males ( $P=0.02$ ) born to infected mothers, compared to uninfected counterparts of the same sex. There was no significant difference in the hormones measured in maternal serum based on infection status, although IGFBP3 was significantly lower ( $P=0.03$ ) in circulation of infected mothers carrying female fetuses. Males born to women who experienced *S. japonicum* during pregnancy tended to be born lighter than males born to uninfected mothers ( $P=.06$ ). Our study substantiates this premise, while also displaying a potential sex discordant mechanism by which female fetuses display lower IGFBP1, thereby increasing bioavailability of IGFs and protecting growth *in utero*. Given the relative low prevalence and majority of infections of low intensity in our study (11% and 93%, respectively) these data remain preliminary, however represent an intriguing potential mechanism by which growth may be protected.

1286

### THE ROLE OF MICROBIAL TRANSLOCATION IN THE PATHOGENESIS OF SCHISTOSOMA MANSONI ASSOCIATED MORBIDITY

**Jacqueline Araújo Fiuza**<sup>1</sup>, Susannah Colt<sup>2</sup>, Jonathan Kurtis<sup>2</sup>, Leticia Gambogi de Ornellas<sup>1</sup>, Leonardo Matoso<sup>3</sup>, Gisele Andrade<sup>3</sup>, Andréa Gazzinelli<sup>3</sup>, Jennifer Friedman<sup>2</sup>, Rodrigo Corrêa-Oliveira<sup>1</sup>

<sup>1</sup>René Rachou Institute/FIOCRUZ, Belo Horizonte, Brazil, <sup>2</sup>Lifespan Center for International Health Research, Providence, RI, United States, <sup>3</sup>Escola de Enfermagem, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil

Children with intestinal schistosomiasis are at risk for undernutrition, linear growth stunting, and impaired cognitive development. The mechanisms by which the infection results in these morbidities are understudied. There is evidence that environmental enteric dysfunction (EED) contributes by decreasing gut absorptive capacity and integrity that can result in translocation of luminal microbes and components into the bloodstream with subsequent systemic immune activation. We examined the longitudinal impact of praziquantel (PZQ) treatment on EED biomarkers and a key driver of childhood linear growth, insulin growth factor I (IGF-1). 290 infected children, age 6-15 years, were enrolled from sites in Minas Gerais State/Brazil. Participants were treated with PZQ at baseline. EED biomarkers lipopolysaccharide (LPS), intestinal fatty acid binding protein (I-FABP) were measured, as well as IGF-1 at baseline, 6 and 12-month. Multivariate regression analysis was applied to assess associations between EED biomarkers and both baseline *Schistosoma mansoni* intensity and

changes in biomarkers post treatment after controlling for potential confounding variables (age, sex, weight-for-age z-score, socioeconomic status, and hookworm infection status). At baseline, *S. mansoni* infection intensities were 27.2% low, 46.9% moderate, and 25.9% high. LPS concentrations were significantly reduced at the 12-month when compared to baseline ( $p = 0.0002$ ). No differences were observed for I-FABP or IGF-1 after treatment. At 6-month, I-FABP concentration was significantly higher in high vs low intensity infection at baseline ( $p = 0.0017$ ). IGF-1 concentrations were significantly lower in the moderate and high infection categories when compared to low intensity in all three study visits. We report that PZQ treatment for *S. mansoni* infection resulted in delayed changes in EED biomarkers, suggesting a requisite period needed for gut healing. These findings provide further evidence for the relationship between schistosomiasis and EED and suggests a mechanistic role for EED in schistosomiasis-related morbidities, particularly linear growth.

1287

### INTRANASAL ADMINISTRATION OF AN ADENOVIRUS-VECTOR EXPRESSING CATHEPSIN B PROTECTS FROM SCHISTOSOMIASIS INFECTION IN A PRE-CLINICAL MODEL

Dilhan J. Perera<sup>1</sup>, Adam S. Hassan<sup>1</sup>, Mehdy Elahi<sup>2</sup>, Christine Gadoury<sup>2</sup>, Risini Weeratna<sup>3</sup>, Renald Gilbert<sup>2</sup>, Momar Ndao<sup>1</sup>

<sup>1</sup>Research Institute McGill University Health Center, Montreal, QC, Canada, <sup>2</sup>National Research Council Canada; Human Health Therapeutics Research Center, Montreal, QC, Canada, <sup>3</sup>National Research Council Canada; Human Health Therapeutics Research Center, Ottawa, QC, Canada

Schistosomiasis, caused by the parasite *Schistosoma spp.*, is one of the most prevalent parasitic diseases worldwide. With over 700 million people at risk of infection, this parasite causes debilitating illnesses lasting more than 30 years. This project tested the protective ability of *Schistosoma mansoni* cathepsin B when delivered by a recombinant Adenovirus (AdV-SmCB) as a novel vaccine vector. Previous work consisted of AdV-SmCB delivered intramuscularly followed by two boosts of recombinant antigen. Upon immunization with our vaccine, we observed robust cell-mediated and humoral immune responses, giving significant protection. As *Schistosoma* larva travel through the lung, we sought to harness the capability of our Adenovirus vector to stimulate a mucosal response. Single-dose intranasal administration of our recombinant Adenovirus (AdV-SmCB-IN) was able to elicit robust humoral responses, producing antigen-specific serum IgG, and local IgA production in the lung. More importantly our AdV-SmCB-IN reduced parasite burden by 79% in adult worms and more modestly, 55% and 56% in hepatic and intestinal eggs. Not only does our recombinant Adenovirus vaccine result in higher parasite burden reduction levels than the World Health Organization standard of 40%, but also offers versatility as a needle-free vaccine. An effective vaccine for schistosomiasis would benefit populations in endemic regions aiding the interruption of disease transmission as well as international travelers visiting tropical regions.

1288

### DIMINISHING CROSS-REACTIVITY IN SCHISTOSOMIASIS SEROLOGY BY APPLYING A SINGLE GLYCAN TARGET APPROACH

Anna O. Kildemoes<sup>1</sup>, Tom Veldhuizen<sup>1</sup>, Mio Tanaka<sup>2</sup>, Lisette van Lieshout<sup>1</sup>, Daniel Camprubi-Ferrer<sup>3</sup>, Jose Munoz<sup>3</sup>, Jan Clerinx<sup>4</sup>, Leo Visser<sup>1</sup>, Shinjiro Hamano<sup>2</sup>, Sammy M. Njenga<sup>5</sup>, Meta Roestenberg<sup>1</sup>, Angela van Diepen<sup>1</sup>, Cornelis H. Hokke<sup>1</sup>

<sup>1</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>2</sup>Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan, <sup>3</sup>Barcelona Institute for Global Health, Universitat de Barcelona, Barcelona, Spain, <sup>4</sup>Institute of Tropical Medicine, Antwerpen, Belgium, <sup>5</sup>Kenya Medical Research Institute, Nairobi, Kenya

Many current serological schistosomiasis assays are based on crude soluble egg, cercarial or worm antigen preparations. This poses an inherent liability

for assay specificity as a large proportion of antibodies binding to such crude antigen preparations are recognising a subset of glycan elements present in the parasite's glycoprotein and glycolipid repertoire, that is also present in other helminths, other invertebrates, food stuff of plant origin or the mammalian host. However, extensive glycomics work has shown that schistosomes in addition contain several unique and potentially species specific glycan elements. Therefore, glycan driven cross-reactivity can be overcome by identification of single or a combination of few defined glycan antigens for development of future sensitive and specific serological tools. In order to identify such antigens, we applied an iterative target selection process based on custom-made glycan microarrays combined with well-characterised sample sets. We have assessed the specificity and sensitivity of candidate antigens by analysing schistosome non-endemic area samples from a controlled human schistosome infection model, from Dutch, Belgian and Spanish primary infection traveller samples as well as samples from an Indonesian soil-transmitted helminth endemic area. Furthermore, samples from schistosomiasis endemic areas in Kenya were investigated. Through this process a candidate target with promising accuracy for primary schistosomiasis infection has been found. Development of a highly sensitive and specific antibody detection assay would be a beneficial addition to the existing diagnostic tool repertoire for schistosomiasis. An accurate antibody detection tool would have particular impact and use in traveller diagnostics as well as in very low endemic, near- and post-elimination settings for transmission monitoring purposes.

1289

### A PHASE 1 OPEN-LABEL TRIAL WITH DENGUE-1-VIRUS LIVE VIRUS HUMAN CHALLENGE ASSESSMENT OF HEALTHY U.S. ADULTS PREVIOUSLY PRIMED WITH TETRAVALENT DENGUE VIRUS PURIFIED INACTIVATED VACCINE AND BOOSTED WITH TETRAVALENT DENGUE VIRUS LIVE ATTENUATED VACCINE FORMULATION

Kirsten E. Lyke<sup>1</sup>, Joel V. Chua<sup>2</sup>, Monica McArthur<sup>1</sup>, Faith Pa'ahana-Brown<sup>1</sup>, Kathy A. Strauss<sup>1</sup>, Gregory D. Gromowski<sup>3</sup>, Rafael A. De La Barrera<sup>4</sup>, Jeffrey W. Froude<sup>4</sup>, Simon Pollett<sup>3</sup>, Richard G. Jarmen<sup>5</sup>, Robert Edelman<sup>6</sup>, Michael A. Koren<sup>3</sup>

<sup>1</sup>University of Maryland, Center for Vaccine Development, Baltimore, MD, United States, <sup>2</sup>University of Maryland, Institute for Human Virology, Baltimore, MD, United States, <sup>3</sup>Viral Diseases Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>4</sup>Pilot Bioproduction Facility, Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>Strategic Planning Office, Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>6</sup>University of Maryland, Center for Vaccine Development, Baltimore, MD, United States

Dengue Human Infection Models (DHIM) are critically needed to down-select tetravalent dengue virus (TDEN) vaccine candidates before advanced clinical trials. An attenuated DENV-1 DHIM was previously dose-optimized and was safe, well-tolerated and induced symptomatic, mild dengue illness. As part of a heterologous prime-boost strategy, volunteers received TDEN Purified Inactivated Vaccine (PIV) prime followed by a TDEN Live Attenuated Vaccine (LAV) boost at 90 or 180 days in 2018. Vaccinated volunteers ( $n = 6$ ) aged 18-50 years, with detectable pre-DHIM TDEN antibody titers and flavivirus-naïve control volunteers ( $n = 4$ ) were challenged with DENV-1 strain 45AZ5 in Jan 2021. Volunteers were followed daily from Days 4-16 with quantitative PCR used for detection, and DENV-1 solicited adverse events assessed. A novel Illness Index, incorporating dengue signs and symptoms as well as laboratory abnormalities was employed to score illness. Nine of 10 volunteers developed detectable viremia (5/6 vaccinees and all 4 controls). The mean viremia onset in vaccinees was day 5 (range 5-6) versus day 8 (range 7-10) for controls,  $P = 0.007$ . The viremia duration was 8.2 days (range 7-10 days) in vaccinees vs. 9.75 (range 9-11) in controls,  $P = 0.088$ . There was no difference in viremia area under the curve (vaccinees  $3.35 \times 10^7$  vs. controls  $2.66 \times 10^7$ ,  $P = 0.895$ ). Despite earlier onset and shorter duration, the vaccinee Illness Index scored at 17.5 vs controls' 15.1,  $P = 0.55$ . The most common symptoms were headache, myalgia, and rash. Mild to moderate leukopenia and transaminitis were commonly observed. Grade

3 adverse events were detected in vaccinees only: fever >102.1°F (n = 3) and headache (n = 1), with one transient Grade 4 AST/ALT (393/124). Immunogenicity assays, including microneutralization and *in vitro* antibody dependent enhancement tests, are underway. We conclude that TDEN-PIV primed, TDEN-LAV boosted volunteers were unprotected against DENV-1 with a trend towards more severe symptoms than flavivirus-naïve controls. These findings highlight the importance of utilizing DHIM before advanced Phase I/II clinical trials of dengue vaccine candidates.

1290

### CUMULATIVE SAFETY ASSESSMENT OF THE TAKEDA TETRAVALENT DENGUE VACCINE CANDIDATE IN PARTICIPANTS 4 TO 60 YEARS OLD

Sanjay S. Patel<sup>1</sup>, Martina Rauscher<sup>1</sup>, Hang Peng<sup>2</sup>

<sup>1</sup>Takeda Pharmaceuticals, Glattpark-Opfikon (Zurich), Switzerland, <sup>2</sup>Takeda Pharmaceuticals International Inc., Cambridge, MA, United States

Takeda's tetravalent live-attenuated dengue vaccine candidate, TAK-003 (TDV), has been assessed in 13 phase 2 and 3 clinical trials with >25,000 participants 4-60 years old. Safety assessment of TDV includes >2 years of data accumulated from >20,000 4-16 year-olds (TDV:placebo [PBO], 2:1) living in dengue-endemic areas from the ongoing phase 3 trial (ClinicalTrials.gov NCT02747927). An integrated safety data analysis was conducted for all 5 placebo-controlled trials (14,627 TDV and 7,167 PBO recipients) in which ≥98% of participants received 2 doses of vaccine 3 months apart. Demographic and baseline characteristics were well-balanced between TDV and PBO groups; 30.6% TDV vs 28.8% PBO recipients were baseline dengue seronegative. Data from a subset of ~5000 participants showed solicited reactogenicity was generally less frequent after the second vaccine dose; local adverse events (AEs) within 7 days (43.4% TDV vs 25.7% PBO) were mostly mild and transient injection site pain, and resolved within 1-3 days, while systemic AEs within 14 days (43.8% TDV vs. 37.1% PBO) were mostly mild or moderate in severity, most frequently headache and myalgia, and generally resolved within 3-4 days. Evaluation of unsolicited AEs, AEs leading to vaccine and/or trial discontinuation, medically attended AEs, and serious AEs (SAEs) revealed no important safety risks. Unsolicited AEs (21.3% TDV vs 22.8% PBO) within 28 days after each vaccination comprised mainly medical conditions normally observed in the evaluated age groups; ≤3% were assessed as related to vaccination. SAEs, mostly infections or infestations, occurred in <0.4% of participants within 30 days of vaccine or PBO. Fewer SAEs occurred for TDV than for PBO (2.84 vs 3.26 per 100 person-years) mainly owing to fewer dengue-related SAEs in the TDV group. SAEs in 5 study participants were study vaccine related (1 TDV vs 4 PBO). There were 9 deaths in PBO-controlled trials (6 TDV vs 3 PBO): all were considered unrelated. The integrated analysis, including up to 4 years' safety data, has identified no important risks; TDV was well-tolerated in 4- to 60-year-olds irrespective of prior dengue exposure.

The development of safe and effective dengue antivirals would bring significant benefits to public health. A novel dengue-specific antiviral small molecule, JNJ-1802, inhibited dengue virus (DENV) infection of Vero cells with laboratory-adapted and clinical strains of all four serotypes at pico- to nanomolar range. JNJ-1802 prevents the interaction between DENV proteins NS3 and NS4B. When immunocompromised AG129 mice were non-lethally challenged with DENV-2 (10<sup>2</sup> PFU), prophylactic once daily (q.d.) administration of JNJ-1802 at 1 mg/kg resulted in undetectable viral RNA. Twenty-five days after lethal infection with DENV-2 (10<sup>6</sup> PFU), survival in AG129 mice dosed with 0.3 to 10 mg/kg JNJ-1802 twice daily (b.i.d.) was significantly increased (≥80%) versus vehicle-treated mice (0%). Additionally, JNJ-1802 offered significant protection in mice after lethal infection with DENV-1, -3 and -4, demonstrating pan-serotype coverage in this *in vivo* mouse model. Next, protective efficacy of JNJ-1802 against DENV infection was assessed in rhesus macaque (*Macaca mulatta*) models. In macaques dosed prophylactically with JNJ-1802 and challenged with DENV-2 (10<sup>2</sup> TCID<sub>50</sub>), a potent and dose-dependent efficacy was observed. No viral RNA and no IgG seroconversion were detected (until day 28 post-inoculation) after q.d. oral dosing (from 1 day pre- to 10 days post-challenge) with either 0.93 or 3 mg/kg, while vehicle-treated animals had a mean peak viral load of 5.64 log<sub>10</sub> copies/ml and developed IgG seroconversion. Similarly, when challenged with DENV-1 (0.6x10<sup>5</sup> PFU), no viral RNA and no IgG seroconversion were observed (until day 29 post-inoculation) in macaques dosed orally with JNJ-1802 at 6 mg/kg q.d. (from 3 days pre- to 10 days post-challenge) versus vehicle (mean peak viral load of 5.17 log<sub>10</sub> copies/ml and IgG seroconversion). These preclinical

data support a pan-serotype protective role for JNJ-1802 against DENV infection. This work is the first to demonstrate *in vivo* efficacy of a dengue antiviral small molecule in non-human primates. The first-in-human study of JNJ-1802 has been completed and it is moving further into clinical development.

### EFFECTIVENESS OF A TETRAVALENT DENGUE VACCINE, BRAZIL, 2016 - 2019

**Expedito J. Luna**<sup>1</sup>, Irina Riediger<sup>2</sup>, Fernanda Crosewski<sup>3</sup>, Denise Garrett<sup>4</sup>, Jose C. Moraes<sup>5</sup>

<sup>1</sup>Universidade de Sao Paulo, Sao Paulo, Brazil, <sup>2</sup>Laboratório Central do Estado do Parana, Sao Jose dos Pinhais, Brazil, <sup>3</sup>Secretaria de Estado da Saude do Parana, Curitiba, Brazil, <sup>4</sup>Sabin Vaccine Institute, Washington DC, MD, United States, <sup>5</sup>Faculdade de Ciencias Medicas da Santa Casa de Sao Paulo, Sao Paulo, Brazil

The Brazilian state of Paraná conducted a mass vaccination campaign against dengue with the tetravalent attenuated vaccine CYD-TDV. The campaign targeted 30 endemic municipalities. The objective of this study was to assess the effectiveness of CYD-TDV in preventing symptomatic virologically confirmed dengue cases according to specific age groups in five of the 30 municipalities. A case-control study was carried out in the five most populous municipalities targeted by the vaccination. Vaccine uptake with the full schedule (3 doses) in these municipalities was 25%. Symptomatic dengue cases in the age groups targeted by the campaign were notified by the municipal health departments. The age groups targeted were 15-18 and 19-27 in all municipalities and 9-14 and 28-44 in one municipality. All cases were confirmed by real time reverse transcription quantitative polymerase chain reaction (RT-qPCR). For each case, two controls were selected: a neighborhood control and a workplace or school/college control, matched by age group. Vaccine status was ascertained by the participants' vaccine cards and by the State's electronic vaccine registry. A conditional logistic regression model was used to determine the odds ratio for vaccination and the vaccine effectiveness. Study participants included 618 RT-qPCR-confirmed dengue cases and 1,236 matched controls (with a non-reactive dengue IgM serologic test). Vaccine effectiveness against dengue due to any serotype was 11.1% (95% CI: -19.0%; 33.6%). Effectiveness against DENV-1 was 33.3% (95% CI: -5.0%; 57.6%) and against DENV-2 was -56.7% (95% CI: -142.2%; -1.5%). No DENV-3 cases were detected in these municipalities. The vaccine was significantly effective in the prevention of DENV-4 cases (VE = 93.3%; 95% CI: 47.7%; 99.2%). CYD-TDV was effective in the prevention of symptomatic cases due to DENV-4, but not due to any serotype. The low dengue sero-prevalence in the target population could possibly be related to these results.

1293

### STRUCTURE-GUIDED STABILIZED DENV2 ENVELOPE SUBUNIT VACCINE ELICITS DENV2 NEUTRALIZING ANTIBODY IN VIVO.

The four dengue virus (DENV) serotypes are mosquito-borne flaviviruses that infect several hundred million people living in tropical regions of the world. Vaccines have great potential for protecting people from flavivirus infections. Several live attenuated dengue virus vaccines are currently being evaluated in human clinical trials. Investigators have also evaluated the use of recombinant envelope (E) proteins from DENVs as subunit vaccines with limited success. Potent neutralizing human antibodies against DENVs target quaternary structure epitopes that are presented by the E dimers on the virion. However, wild-type DENV2 E protein, when expressed as secreted antigen (WT rE), is predominantly monomeric and

does not display these quaternary structure epitopes. Here we report on studies to test if recombinant DENV2 E dimers are better vaccine antigens than monomers. Using molecular modeling, Rosetta, we have identified mutations that greatly increase the stability of DENV2 E dimers (RD) under physiological conditions of vaccination. Unlike WT rE, RD was recognized by quaternary epitope-targeting human neutralizing antibodies. Mice were immunized with WT rE and RD to compare the binding and functional properties of antibodies induced by each antigen. RD vaccinated mice sera had more dimer-specific antibodies and neutralized DENV2 significantly better than WT-vaccinated mice. Our data suggest that the oligomeric state of DENV rE is crucial in eliciting DENV neutralizing antibodies, and that structure-guided antigen design is a viable option to develop a successful dengue subunit vaccine.

1294

### IMMUNE PROFILING OF HOST RESPONSE TO TRIVALENT AND TETRAVALENT DENGUE CANDIDATE VACCINE AND DENGUE CHALLENGE

**Ruixue Hou**<sup>1</sup>, Lewis E. Tomalin<sup>1</sup>, Seunghee Kim-Schuzle<sup>1</sup>, Ana Fernandez-Sesma<sup>1</sup>, Anna P. Durbin<sup>2</sup>, Mayte Suárez-Fariñas<sup>1</sup>

Safe and effective vaccines are needed for dengue prevention. Understanding the immune response to dengue is essential for developing a vaccine that is protective against all four dengue serotypes without disease enhancement. Here, we used samples from two randomized, placebo-controlled clinical trials; one in which participants received the live attenuated tetravalent dengue vaccine TV005 (N=18) or placebo (N=18) [CIR-299], and another in which participants received a live attenuated trivalent vaccine (rDEN1Δ30, rDEN3Δ30/31, rDEN4Δ30) (N=15) or placebo (N=6) [CIR-300]. All participants in both trials were challenged with DEN2Δ30 (Tonga/74) on day 180 after enrollment. Here we evaluate the immune response post-vaccination and post-challenge for both dengue vaccines. Longitudinal Luminex-based immune profiles for 41 cytokines were obtained from samples collected at 0, 8 and 21 days post-vaccination and post-challenge. Significant increases in IP-10 expression were observed following receipt of either the trivalent or tetravalent vaccine. Following receipt of the challenge virus, a large increase in IP-10 expression was observed in the placebo (FCH = 4.5) and trivalent groups (FCH = 2.3) but not in the tetravalent group (FCH = 1.1). MCP-1, IL-1RA, and MIP-1β exhibit a similar pattern as IP-10. These results illustrate the protective effects of trivalent and tetravalent vaccines against dengue virus, and suggest a better protective effect with the tetravalent than the trivalent vaccine. Since epidemiology studies have found that the non-Black race is a risk factor for more severe dengue, we explored the differences between African Americans (N=26) and Caucasian subjects (N=26). The vaccination and challenge IP-10 responses observed in the placebo and trivalent group were specific to Caucasians, with African Americans showing an attenuated response. These results indicated racial differences in the immune response to vaccination and infection post-vaccination and may explain why Caucasians may have a more vigorous dengue virus immune response than African Americans.

### MONOMERIC IGA1 ANTAGONIZES IGG1-MEDIATED ENHANCEMENT OF DENV-3 INFECTION IN VITRO

**Adam Wegman**<sup>1</sup>, HengSheng Fang<sup>1</sup>, Heather Friberg<sup>2</sup>, Gregory Gromowski<sup>2</sup>, Jeffrey Currier<sup>2</sup>, Alan Rothman<sup>3</sup>, Stephen Thomas<sup>1</sup>, Timothy Endy<sup>1</sup>, Adam Waickman<sup>1</sup>

<sup>1</sup>SUNY Upstate Medical University, Syracuse, NY, United States, <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>3</sup>University of Rhode Island, Kingston, RI, United States

Dengue virus (DENV) is a prevalent human pathogen, infecting approximately 400 million individuals per year and causing symptomatic

disease in approximately 100 million. A distinct clinical feature of dengue is the increased risk for severe disease in some individuals with a preexisting DENV-specific immunity. One proposed mechanism for this phenomenon is antibody-dependent enhancement (ADE), in which poorly-neutralizing IgG isotype antibodies from a prior infection opsonize DENV to infect  $F_c$  gamma receptor-bearing cells, increasing the infection burden and consequent immunopathology. While IgM and IgG are the most readily observed DENV-reactive antibody isotypes induced after DENV infection, our group and others have described induction of a DENV-specific serum IgA antibody response during dengue. This IgA fraction is induced between IgM and IgG seroconversion, peaks near convalescence, and wanes more rapidly than the other isotypes. Notably, though detectable in both primary and secondary dengue cases, the IgA fraction appears to achieve a higher titer during primary infection. Despite being the second most abundant isotype in circulation, the role of IgA in dengue is not well characterized. We hypothesized that monomeric IgA would be able to neutralize DENV virions without the possibility of ADE, given its lack of an  $F_c$ -gamma domain. To test this, we synthesized IgG1 and IgA1 versions of two different DENV-reactive monoclonal antibodies. We demonstrate that isotype-switching does not impact the antigen binding and neutralization properties of the two mAbs. However, we show that DENV-reactive IgG, but not IgA, mediates ADE in an  $F_c$  gamma receptor-bearing cell line, and that introducing a fraction of IgA into an infection-enhancing IgG solution can potentially antagonize ADE. These results suggest an unappreciated role for DENV-reactive IgA during the humoral response to DENV infection and raise the potential that IgA is a regulator of disease severity and inflammation.

Cholera caused by *Vibrio cholerae* O139 could re-emerge, and proactive development of an effective O139 vaccine would be prudent. To define immunoreactive and potentially immunogenic carbohydrate targets of *Vibrio cholerae* O139, we assessed immunoreactivity of various OSP-related polysaccharides with plasma from humans hospitalized with cholera caused by O139, comparing responses to those induced in recipients of a commercial oral whole cell killed bivalent (O1, O139) cholera vaccine (WC-O1/O139). We also assessed conjugate vaccines containing selected subsets of these saccharides for their ability to induce protective immunity using a mouse model of cholera. We found that patients with wild type O139 cholera develop IgM, IgA, and IgG immune responses against O139 OSP and many of its fragments, but we were only able to detect a moderate IgM response to purified O139 OSP-core, and none to its fragments in immunologically-naive recipients of WC-O1/O139. We found that immunoreactivity of O139-specific polysaccharides with wild type infection-elicited antibodies markedly increased when saccharides contain colitose and phosphate residues, that a synthetic terminal tetrasaccharide fragment of OSP is more immunoreactive and protectively immunogenic than complete OSP, that native OSP-core is a better protective immunogen than the synthetic OSP lacking core, and

that functional vibriocidal activity of antibodies predicts *in vivo* protection in our model, but depends on capsule thickness. Our results suggest that O139 OSP-specific responses are not prominent following vaccination with a currently available oral cholera vaccine in immunologically naive humans, and that vaccines targeting *V. cholerae* O139 should be based on native OSP-core or terminal tetrasaccharide.

1297

#### EFFECTIVENESS OF TYPHOID CONJUGATE VACCINE AGAINST CULTURE-CONFIRMED TYPHOID IN A PERI-URBAN SETTING IN KARACHI: A CASE-CONTROL STUDY

Rabab Batool<sup>1</sup>, Mohammad Tahir Yousafzai<sup>1</sup>, Sonia Qureshi<sup>1</sup>, Miqdad Ali<sup>1</sup>, Tahira Sadaf<sup>1</sup>, Junaid Mehmood<sup>1</sup>, Per Ashorn<sup>2</sup>, Farah Naz Qamar<sup>1</sup>

<sup>1</sup>Aga Khan University Hospital, Karachi, Pakistan, <sup>2</sup>Tampere University of Applied Sciences, Tampere, Finland

Enteric fever, caused by *Salmonella* Typhi and *S. Paratyphi*, is a cause of high morbidity and mortality among children in South Asia. Rising antimicrobial resistance presents an additional challenge. Typhoid Conjugate Vaccine (TCV) is recommended by the World Health Organization for use among people 6 months to 45 years old living in endemic settings. This study aimed to assess the effectiveness of TCV against culture-confirmed *S. Typhi* in Lyari Town, Karachi, Pakistan. This peri-urban town was one of the worst affected by the outbreak of extensively drug-resistant (XDR) typhoid that started in November 2016. A matched case-control study was conducted following a mass immunization campaign with TCV at Kharadar General Hospital, Lyari General Hospital and Jan Bai Aga Khan Secondary care Hospital from August 2019 through December 2019 in Lyari Town Karachi, Pakistan. Children aged 6 months to 15 years presenting with culture-confirmed *S. Typhi* were enrolled as cases. Controls were afebrile children at least seven months of age and born within  $\pm$  six months of the date of birth of a case 6-36 months old or born within  $\pm$  three years of the date of birth of a case 3-15 years old, visiting the same hospitals as case or living in the neighborhood of the case. For each case, at least one age-matched hospital control and two age-matched community controls were enrolled. Of 82 typhoid fever patients enrolled, 8 (9.8%) had received the vaccine for typhoid. Of the 164 community controls and 82 hospital controls enrolled, 38 (23.2%) community controls and 27 (32.9%) hospital controls were vaccinated for typhoid. The age and sex-adjusted vaccine effectiveness was found to be 72% (95% confidence interval: 34% - 88%). Using multivariate conditional logistic regression, the consumption of meals prepared outside the home more than once per month (adjusted odds ratio: 3.72, 95% CI: 1.55- 8.94; p-value: 0.003) was significantly associated with culture-confirmed typhoid. A single dose of TCV is effective against culture-confirmed typhoid among children aged 6 months to 15 years old in an XDR typhoid outbreak setting of a peri-urban community in Karachi, Pakistan.

1298

#### ANTIMICROBIAL RESISTANT TYPHOID AS A CAUSE OF ACUTE FEBRILE ILLNESS IN BANGLADESH

Pritimoy Das<sup>1</sup>, M Ziaur Rahman<sup>1</sup>, Sayera Banu<sup>1</sup>, Mahmudur Rahman<sup>1</sup>, Daniel W. Martin<sup>2</sup>, Mahabub Ul Anwar<sup>2</sup>, Adam L. Cohen<sup>2</sup>, Michael Friedman<sup>2</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh (icddr), Dhaka, Bangladesh, <sup>2</sup>Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States

Typhoid is a major cause of acute febrile illness (AFI) in Bangladesh, with a reported incidence of 200 episodes per 100,000 person-years. We report the clinical manifestations and antimicrobial resistance patterns of patients with *Salmonella* Typhi in selected Bangladeshi hospitals. During May 2019-March 2020, study physicians screened patients aged >2 years presenting to outpatient departments of 4 public hospitals in different regions. We randomly enrolled patients who had measured fever

( $\geq 100.4^{\circ}\text{F}$ ) during assessment with onset within the past 14 days but did not take any antibiotics in the past 24 hours. We collected and transported their blood to the icddr,b laboratory within 24 hours for bacterial culture. Grown blood cultures were subjected to bacterial identification and antibiotic susceptibility testing in a fully automated VITEK 2 system. Among 690 AFI patients enrolled, 67 (9.7%) were culture-positive for *Salmonella* Typhi. Typhoid was more common among males (52, 78%) and urban residents (59, 88%). The proportion of typhoid cases sharply increased after 10 years of age; 67% of all typhoid cases were  $\geq 15$  years old. Typhoid was found to be more likely in patients with high temperature  $>103^{\circ}\text{F}$  than lower (adjusted odds ratio, AOR 3.1, 95% CI 1.3-7.7), among students than non-students (AOR 2.6, 95% CI 1.4-4.8), among males than females (AOR 2.1, 95% CI 1.2-3.9), in medicine than pediatrics (AOR 2.4, 95% CI 1.3-4.6), in Rajshahi (AOR 4.0, 95% CI 1.4-12) and Dhaka (AOR 3.5, 95% CI 1.2-10.6) than Sylhet. *Salmonella* Typhi isolate antimicrobial sensitivities were as follows: ceftriaxone (61/61, 100%), amoxicillin-clavulanic acid (56/64, 88%), azithromycin (25/30, 83%), cotrimoxazole (43/63, 68%), ampicillin (37/66, 56%), and ciprofloxacin (7/25, 11%). After enrollment, patients were treated with azithromycin (38%), ceftriaxone (33%), ciprofloxacin (16%), cefixime (13%), and cefuroxime (8%) stated by the patients who could mention the antibiotic names ( $n=24$ ). No hospitalizations or deaths were reported. Preventive measures such as typhoid vaccination and appropriate antimicrobial use could reduce the typhoid burden in Bangladesh.

1299

#### ANTIBIOTICS IMPROVE GROWTH IN TANZANIAN CHILDREN WITH SMALL INTESTINE BACTERIAL OVERGROWTH

Jeffrey Donowitz<sup>1</sup>, Samuel Huang<sup>2</sup>, Sarah E. Elwood<sup>3</sup>, Anne W. Wanjuhi<sup>3</sup>, Jean Gratz<sup>3</sup>, Samwel Jatosh<sup>4</sup>, Siphael Katengu<sup>4</sup>, Paschal Mdoe<sup>4</sup>, Eric R. Houghton<sup>3</sup>, James Platts-Mills<sup>3</sup>, Elizabeth Rogawski McQuade<sup>3</sup>, Estomih Mduma<sup>4</sup>, Mark D. DeBoer<sup>3</sup>

<sup>1</sup>Children's Hospital of Richmond at Virginia Commonwealth University, Richmond, VA, United States, <sup>2</sup>Virginia Commonwealth University, Richmond, VA, United States, <sup>3</sup>University of Virginia, Charlottesville, VA, United States, <sup>4</sup>Haydom Lutheran Hospital, Haydom, United Republic of Tanzania

Small intestine bacterial overgrowth (SIBO) is common in children living in low-income countries. SIBO has been associated with environmental enteric dysfunction and poor linear growth. We conducted a 2x2 factorial designed randomized interventional trial of antimicrobials (azithromycin + nitazoxanide), nicotinamide, antimicrobials + nicotinamide, or a placebo to determine these intervention's effect on linear growth. Children were enrolled at birth and followed through 18 months of age. Nicotinamide was administered daily. Azithromycin was given as a single dose at months 6, 9, 12, and 15 and nitazoxanide was given as a 3-day course at months 12 and 15. A subset of children enrolled in this trial were tested for SIBO with the hypothesis that children with SIBO would respond to antimicrobials with improved growth. SIBO was measured by glucose-hydrogen breath test at 6, 12, and 18 months. A  $>12\text{ppm}$  increase in breath hydrogen over baseline was considered SIBO positive. We stratified children by those who received the antimicrobial intervention and those that did not and created separate linear regression models for each group to predict the change in Length-for-Age Z score (delta LAZ) between birth and 18 months of age. 400 children were enrolled in the SIBO testing subset. 202 received antimicrobials while 198 did not. 316 children were SIBO tested at 6 months of age with 4% positivity. 227 were tested at 12 months of age with 19% positive. 353 children were tested at 18 months of age with 16% positivity. 359 children had at least 2 SIBO tests. The average LAZ at enrollment was  $-0.8$  SD and by 18 months of age the average LAZ had dropped to  $-1.9$  SD. For the children who received antimicrobials, the number of positive SIBO tests was not a significant predictor of growth (parameter estimate 0.15 SD [95% CI  $-0.15$  to  $0.47$  SD,  $p = 0.31$ ]). However, for the children that did not receive the antimicrobial intervention, for each positive SIBO test the delta LAZ from

0 to 18 months decreased by 0.43 SD (95% CI  $-0.74$  to  $-0.13$ ,  $p = 0.005$ ). These results suggest that antimicrobials can abrogate the negative effects of SIBO on longitudinal growth.

1300

#### EXPANDING THE VACCINE VALUE PROPOSITION BY QUANTIFYING THE BURDEN OF ANTIBIOTIC USE THAT CAN BE ATTRIBUTED TO SHIGELLA AND IS POTENTIALLY AVERTABLE BY VACCINES

Elizabeth Tacket Rogawski McQuade<sup>1</sup>, Stephanie Brennhofner<sup>1</sup>, Joseph A. Lewnard<sup>2</sup>, James A. Platts-Mills<sup>1</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>University of California, Berkeley, Berkeley, CA, United States

Vaccines for *Shigella* may reduce selection for antimicrobial resistance (AMR) by preventing diarrhea that prompts antibiotic treatment. To quantify these benefits, we estimated the burden of antibiotic use attributable to *Shigella* in the MAL-ED birth cohort study. We analyzed 9392 diarrhea episodes, 38085 stools, and 15697 antibiotic courses in 1715 children. We estimated attributable fractions and incidence rates of overall and diarrhea-specific antibiotic use attributable to *Shigella*. We estimated associations with antibiotic treatment, adjusting for age, sex, site, and socioeconomic status. Finally, we estimated the incidence and proportion of antibiotic exposure to other enteropathogens that was attributed to treatment of *Shigella* diarrhea. *Shigella* was a leading cause of antibiotic use, responsible for 14.8 antibiotic courses per 100-child years, including 11.7% of antibiotic courses for diarrhea and 3.2% of all antibiotic courses. *Shigella* was responsible for a larger proportion of all fluoroquinolone (12.2%) and macrolide (5.5%) use, drug classes that are appropriate for diarrhea treatment and of concern for AMR. *Shigella*-attributable diarrhea was 47% more likely to be treated compared to other etiologies (RR:1.47; CI:1.34, 1.61), and 26% of this association was mediated by either higher diarrhea severity or dysentery. However, less than one-fifth (18.7%) of all antibiotic treatments attributable to *Shigella* were for dysentery episodes. Additionally, treatment of *Shigella* diarrhea resulted in frequent antibiotic exposures to other pathogens that were carried asymptotically at the time of treatment, including 5.6 antibiotic exposures per 100-child years to *Campylobacter*, and 11.1 per 100-child years to diarrheagenic *Escherichia coli*. *Shigella* was disproportionately responsible for antibiotic use due to its high burden and severity, which strengthens the value proposition for *Shigella* vaccines. A *Shigella* vaccine could further reduce the risk of AMR by preventing a substantial proportion of antibiotic exposures to other pathogens commonly carried among children in low-resource settings.

#### A CLINICAL PREDICTION RULE TO GUIDE DIAGNOSTIC TESTING IN CHILDREN UNDER-FIVE PRESENTING WITH DIARRHEA IN LOW AND MIDDLE INCOME COUNTRIES

Sharia M. Ahmed<sup>1</sup>, Benjamin Brintz<sup>1</sup>, Patricia Pavlinac<sup>2</sup>, James A. Platts-Mills<sup>3</sup>, Karen L. Kotloff<sup>4</sup>, Daniel T. Leung<sup>1</sup>

<sup>1</sup>University of Utah, Salt Lake City, UT, United States, <sup>2</sup>University of Washington, Seattle, WA, United States, <sup>3</sup>University of Virginia, Charlottesville, VA, United States, <sup>4</sup>University of Maryland, Baltimore, MD, United States

Diarrheal diseases are a leading cause of death for children under-5 worldwide, and identification of etiology helps guide pathogen-specific therapy. However, the availability of diagnostic testing is often limited in low and middle income countries (LMICs), where the majority of diarrhea morbidity and mortality occurs. We developed a clinical prediction tool to guide clinicians in identifying when to use a hypothetical point-of-care diagnostic for making diarrhea treatment decisions. We used clinical and demographic data from the Global Enteric Multicenter Study (GEMS) study to build predictive models to identify pediatric diarrhea patients that could potentially benefit from antibacterial therapy (*Shigella*/EIEC or *Vibrio cholerae* attributable fraction  $\geq 0.5$ ) in children  $\leq 59$  months presenting

with moderate-to-severe diarrhea (MSD) in Africa and Asia. We screened variables using random forests, and assessed predictive performance with random forest regression and logistic regression using 5-fold cross-validation. Of the 5304 cases with etiology, 1524 (29%) had an etiology that would benefit from antibiotic therapy. Our ability to predict which diarrhea patients would potentially benefit from antibiotic therapy was high, with an AUC=0.79 (95% CI: 0.78, 0.80) for a model including only the top two predictive variables, age and presence of bloody diarrhea. We show that by using our CPR to triage who receives diagnostic testing, 39% more children would receive necessary antibiotics and 33% fewer children would receive unnecessary antibiotics compared to using bloody diarrhea (dysentery) as the only criteria for antibiotic use, with only 41% of children targeted for the point-of-care test. We demonstrate how a clinical prediction rule can be used to guide use of a point-of-care diagnostic test for diarrhea management in LMICs. Using our CPR, available diagnostic capacity can be optimized to improve appropriate antibiotic use.

1302

### DEVELOPMENT AND VALIDATION OF A CLINICAL PREDICTION MODEL FOR ACUTE VIRAL DIARRHEA IN BANGLADESH

**Stephanie C. Garbern**<sup>1</sup>, Md. Taufiqul Islam<sup>2</sup>, Kamrul Islam<sup>2</sup>, Ashraf I. Khan<sup>2</sup>, Mami Taniuchi<sup>3</sup>, James A. Platts-Mills<sup>3</sup>, Firdausi Qadri<sup>2</sup>, Daniel T. Leung<sup>4</sup>

<sup>1</sup>Alpert Medical School of Brown University, Providence, RI, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>University of Virginia, Charlottesville, VA, United States, <sup>4</sup>University of Utah, Salt Lake City, UT, United States

Diarrhea remains a major cause of morbidity and mortality in low- and middle-income countries (LMICs) where antibiotics are commonly used for viral causes of illness. Our aim was to develop a clinical prediction model to estimate risk of viral-only diarrhea in patients of all ages in Bangladesh to improve clinical decision-making. This retrospective analysis used data from a collaborative nationwide diarrhea surveillance network (2,516 patients) of the International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b) and Bangladesh's Institute of Epidemiology Disease Control and Research (IEDCR) and icddr,b routine clinical surveillance data (3,000 patients) from 2014-2018. The datasets included historical, clinical, and microbiological data from patients with acute diarrhea. Microbiological testing was performed using TaqMan Array Cards (TAC) PCR for 23 enteric pathogens. A multivariable logistic regression model was derived using all clinically relevant candidate predictors available from the nationwide dataset for the primary outcome of viral only pathogen(s) using TAC PCR cycle threshold (CT) of <30. The model was then externally validated using the icddr,b surveillance dataset. Viral diarrhea was most common in children under 5 with 67% having viral-only pathogens. Predictors included in the model were: age, sex, diarrhea duration, presence of abdominal pain, stool frequency, vomiting, dehydration status. Multivariable logistic regression showed that younger age, longer diarrhea duration, lack of abdominal pain, non-bloody stool were significantly associated with viral only etiology. The clinical prediction model's AUC was 0.82 with internally validated AUC of 0.80. In external validation, discrimination of the model was still robust with an AUC of 0.75 with calibration slope 0.75. This model is now being planned to be developed into a mobile health tool for clinical implementation to identify patients with viral diarrhea who do not warrant antibiotics and can be managed with rehydration alone. This may help to support rational use of antibiotics and reduce concerns of antibiotic resistance in LMICs.

1303

### POPULATION SYNCHRONY AS AN ARBOVIRUS RISK METRIC IN CONNECTICUT, USA

**Joseph McMillan**, Philip Armstrong

*The Connecticut Agricultural Experiment Station, New Haven, CT, United States*

Synchrony is the degree of co-variance of disparate populations in space and time, and measures of synchrony are associated with species' persistence and stability. Whether synchrony can inform public health risk by providing indices of similarity among arbovirus surveillance sites has not been previously explored. We used multiple functions in the R packages *vegan* and *synchrony* to define synchrony among 19 mosquito and 7 arbovirus species at 87 long-term surveillance sites in Connecticut, US from 2001 - 2020; we then used machine learning approaches to determine the influence of distance, habitat, and climate on metrics of synchrony among the 19 species. We concluded our analyses by examining spatial patterns of synchrony among the disease vector species *Culiseta melanura* and *Culex pipiens* to develop risk maps for specific regions of CT. Mosquito communities were highly synchronous among sites, and 77% of sites displayed significant patterns of community synchrony (avg.  $S = 0.35$ ,  $p < 0.05$ ). 84% of species displayed significant patterns of synchrony among sites (avg  $S = 0.26$ ,  $p < 0.05$ ), and three flood-water nuisance (*Aedes trivittatus*, *Aedes vexans*, and *Psorophora ferox*) and two disease vector (*Cs. melanura* and *Cx. pipiens*) species had the highest indices of synchrony. Among the arboviruses, synchrony was considered significant for Cache Valley, eastern equine encephalitis, and Potosi virus isolates. Similarity in collections decayed with distance across all species and viruses, yet habitat and climate similarity scores were more informative of synchrony. In our species-specific analyses, *Cs. melanura* collections among sites were positively and significantly correlated up to 20km while *Cx. pipiens* collections were positively and significantly correlated up to 25km then negatively correlated near the extremes of the data set (> 100 km). These metrics provide useful and easy-to-interpret information for local public health departments regarding arboviral risk based on information obtained outside of a specific department's jurisdiction.

1304

### NATURAL AEDES-BORNE VIRUS INFECTION IN AEDES AEGYPTI WITH IMPLICATIONS FOR ESTIMATES OF TRANSMISSION RISK

**Oscar D. Kirstein**<sup>1</sup>, Guadalupe Ayora Talavera<sup>2</sup>, Karina J. Ciau-Carrillo<sup>2</sup>, Ester Rodríguez-Martin<sup>2</sup>, Zhuoran Wei<sup>1</sup>, Azael Che Mendoza<sup>2</sup>, Anne L. Piantadosi<sup>4</sup>, Pablo Manrique-Saide<sup>3</sup>, Gonzalo Vazquez-Prokopec<sup>1</sup>

<sup>1</sup>Department of Environmental Sciences, Emory University, Atlanta, GA, United States, <sup>2</sup>Laboratorio de Virología, Centro de Investigaciones Regionales "Dr. Hideyo Noguchi", Universidad Autónoma de Yucatán, Mérida, Yucatán, Mexico, <sup>3</sup>Unidad Colaborativa de Bioensayos Entomológicos, Universidad Autónoma de Yucatán, Mérida, Yucatán, Mexico, <sup>4</sup>Emory University, Atlanta, GA, United States

Emerging *Aedes*-borne viruses (ABVs) such as chikungunya (CHIKV), Dengue (DENV) and Zika (ZIKV) contribute significantly to the global burden of infectious diseases, usually affecting low income areas. In this study we describe the natural infection rate of CHIKV, DENV, and ZIKV in individually tested field-caught mosquitoes in Merida, Yucatan, Mexico. We used indoor *Aedes aegypti* sequential sampling with Prokopack aspirators to collect all mosquitoes inside houses with suspected active ABV transmission to quantify the arbovirus infection rate of captured females *Aedes aegypti* mosquitoes and males (a proxy of transovarial transmission), we tested all collected specimens by RT-PCR followed by SANGER sequencing analysis for final confirmation. We tested 2,161 females (62.8% of the collection) and 1,278 males (37.2% of the collection). From these, a total of 250 (7.3%) mosquitoes were positive for an ABV coming from 52 of the 200 (29.0%) houses tested. The majority of ABV-positive mosquitoes were positive for CHIKV (203, 81.2%),

followed by 31 (12.4%) mosquitoes positive for DENV and 16 (6.4%) mosquitoes positive for ZIKV. The distribution of infected *Aedes aegypti* for both sexes was overdispersed, the maximum number of positive mosquitoes detected per house was 32 specimens, 25 females and 11 males. We also found a positive association between infected females and male mosquitoes. Remarkably we found a large number of ABV-positive male mosquitoes from a natural urban setting (CHIKV= 74; DENV= 12, ZIKV= 1). These findings suggested vertical transmission and its possible role to viral maintenance in endemic settings contributing to periodic re-emergence among humans.

## 1305

### SKIN IMMUNE SIGNATURES AFTER Aedes Aegypti MOSQUITO BITE IN CAMBODIAN VOLUNTEERS IS CONSISTENT WITH AN ANTI-INFLAMMATORY PROFILE

David Guerrero<sup>1</sup>, Hoa Vo<sup>1</sup>, Jennifer Bohl<sup>2</sup>, Sreynik Nhik<sup>3</sup>, Sophana Chea<sup>3</sup>, Somnang Man<sup>3</sup>, Sokunthea Sreng<sup>4</sup>, Sokna Ly<sup>4</sup>, Rekol Huy<sup>4</sup>, Rithea Leang<sup>4</sup>, Jesus G. Valenzuela<sup>2</sup>, Chanthap Lon<sup>5</sup>, Dorothee Misse<sup>6</sup>, Fabiano Oliveira<sup>2</sup>, Jessica Manning<sup>2</sup>, Tineke Cantaert<sup>1</sup>

<sup>1</sup>Institute Pasteur du Cambodge, Phnom Penh, Cambodia, <sup>2</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, <sup>3</sup>International Center of Excellence in Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Phnom Penh, Cambodia, Phnom Penh, Cambodia, <sup>4</sup>International Center of Excellence in Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Phnom Penh, Cambodia, <sup>5</sup>International Center of Excellence in Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Phnom Penh, Cambodia, <sup>6</sup>Institut de Recherche pour le Développement, Université de Montpellier, Montpellier, France

Vector-host-pathogen interactions in the skin microenvironment influence host innate and adaptive immune responses. In order to determine the immune signatures against *Aedes aegypti* mosquito saliva in the skin, we enrolled 10 healthy Cambodian participants to undergo a controlled *Aedes aegypti* uninfected mosquito feed. Three millimeter punch biopsies were taken from unbiten skin and from bitten (control) skin at 30 minutes, 4 hours and 48 hours after the mosquitoes fed on participants' forearms. After tissue dissociation, skin immune cells from the biopsies were stained and analyzed by flow cytometry on a FACS Aria. Whereas at 30 minutes post-feeding minimal changes in innate and adaptive immune populations were observed, at four hours post-feeding, we found an increased frequency of Langerhans cells (CD207<sup>+</sup>, p<0.001) and activated dermal dendritic cells compared to normal skin (NSK) (CD1c<sup>+</sup>CD69<sup>+</sup>, p<0.05). In addition, the frequency of M2 type macrophages (CD163<sup>+</sup>CD14<sup>+</sup>, p<0.001) and their activation status (CD16<sup>+</sup>, p<0.01 and CD69<sup>+</sup>, p<0.05) increased whereas the frequency of degranulating cells decreased (CD56<sup>+</sup>CD107a<sup>+</sup>, p<0.001). At 48 hours post-feeding, frequencies of activated CD8<sup>+</sup> T cells expressing PD1 exhaustion marker were increased (p<0.01) compared to NSK. Within the CD4 compartment, compared to NSK the frequencies of Th1 cells decreased (p<0.01) while frequencies of Th2 cells increased (p<0.05). After *in vitro* re-stimulation with salivary gland extract, mostly CD8<sup>+</sup> T cells upregulated co-stimulatory molecules and produced TNF- $\alpha$  (p<0.01) 48h post mosquito bite. Via a novel clinical design utilizing uninfected mosquito-bitten skin from endemic participants, these data demonstrate that the early innate skin immune response to mosquito saliva is anti-inflammatory. The T-cell response, primarily observed at 48h, is Th2-skewed and driven by CD8<sup>+</sup> T cells confirming data generated from animal models. Identification of key cell populations that mediate the response to mosquito saliva in human skin is a fundamental step towards understanding arboviral infections transmitted by *Aedes aegypti* mosquitos.

## 1306

### UNDERSTANDING RESPONSES TO A CHANGING CLIMATE USING COMMON GARDEN AND SELECTION EXPERIMENTS ON Aedes MOSQUITOES

Nina L. Dennington<sup>1</sup>, Matthew Thomas<sup>2</sup>

<sup>1</sup>The Pennsylvania State University, University Park, PA, United States, <sup>2</sup>York Environmental Sustainability Institute, York, United Kingdom

The dynamics and distribution of mosquitoes and the diseases they transmit are strongly influenced by environmental temperature. Given the predicted increase in temperature with climate change, there is concern over the possible shift in populations of vectors such as *Aedes aegypti*, and associated viruses such as dengue, Zika and Chikungunya. Many mechanistic models that explore the effects of temperature on transmission assume 'average' thermal performance curves that are representative for a species. However, thermal adaptation to a local environment could lead to population-level differences in thermal performance. In this study, we used common garden experiments and experimental evolution to assess evidence for local thermal adaptation of *Ae. aegypti*. We examined thermal tolerance using a physiological knockdown assay previously shown to be able to differentiate between local populations of *Drosophila*. This assay was used to explore whether there were population level differences in five field populations of *Ae. aegypti* from Mexico, together with a standard laboratory strain. The assay revealed differences in knockdown between populations, with an indication that populations from locations with higher/more variable temperatures had higher thermal tolerance. To confirm whether local temperature could indeed select for differences in knockdown we established 6 replicate lines from one of the field populations and maintained half of them at a standard insectary temperature of 27°C and the other half at an elevated temperature of 31°C. After 10 generations we found the high-temperature selected lines to exhibit an increase in thermal tolerance in our knockdown assay. Our results indicate that differences in environmental temperature can lead to differences in thermal performance between vector populations, suggesting that average, species-level thermal performance curve might be insufficient for predicting the effects of climate and climate change on vector-borne disease transmission at a local level.

## 1307

### REEMERGENCE OF YELLOW FEVER VIRUS IN SOUTHEASTERN BRAZIL, 2017-2018: WHAT SPARKED THE SPREAD?

Joelle Rosser<sup>1</sup>, Karin Nielsen-Saines<sup>2</sup>, Trevon Fuller<sup>3</sup>

<sup>1</sup>Stanford University, Stanford, CA, United States, <sup>2</sup>David Geffen UCLA School of Medicine, Los Angeles, CA, United States, <sup>3</sup>University of California, Los Angeles, Institute of the Environmental and Sustainability, Los Angeles, CA, United States

The 2017-2018 yellow fever virus (YFV) epidemic in southeastern Brazil marked a reemergence of YFV in urban states that had been YFV free for nearly a century. Unlike earlier urban YFV transmission, this epidemic was also driven by forest mosquitos. The objective of this study was to evaluate environmental drivers of this epidemic. Using surveillance data from the Brazilian Ministry of Health of human and non-human primate (NHP) cases of yellow fever, we traced the spatiotemporal progression of the epidemic. We then assessed the epidemic timing in relation to drought using a monthly Standardized Precipitation Evapotranspiration Index. Lastly, we evaluated demographic risk factors for rural or outdoor exposure amongst YFV cases. Both human and NHP cases were first identified in a hot, dry, rural area in northern Minas Gerais before spreading southeast into the more cool, wet urban states of Espírito Santo, São Paulo, and Rio de Janeiro. Outbreaks also coincided with drought in all four southeastern states of Brazil. Confirmed YFV cases had an increased odds of being male (OR 2.58; 95% CI 2.28-2.92), being of working age (OR: 2.03; 95% CI: 1.76-2.35), and having recent travel from an urban to a rural area (OR: 5.02; 95% CI: 3.76-6.69). The 2017-2018 YFV epidemic in Brazil originated in hot, dry rural areas of Minas Gerais before expanding south

into urban centers. An unusually severe drought in this region may have created environmental pressures that sparked the reemergence of YFV in Brazil's southeastern cities.

1308

### MOSQUITOES ARE EXCITO-REPELLED UPON CONTACT WITH TOPICAL REPELLENTS: A 3D VIDEO TRACKING ANALYSIS OF MOSQUITOES EXPOSED TO COMMON TOPICAL REPELLENTS IN THE STANDARD ARM-IN-CAGE TEST

Mathurin Baptiste Fatou<sup>1</sup>, Steven Nicholas Fry<sup>2</sup>, Pie Muller<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland,

<sup>2</sup>Tasstalstrasse 88, Winterthur, Switzerland

Topical repellents may provide personal protection against mosquito bites and their efficacy is usually assessed in the arm-in-cage test. In this assay, study participants expose their repellent-treated forearm into a cage containing host-seeking mosquitoes. This procedure is then repeated at regular intervals (e.g. every hour) until the study participants are bitten, which provides an estimate for the formulation's complete protection time. However, the endpoint says little about how mosquitoes would interact with the repellent under a real world scenario since in the arm-in-cage test the mosquitoes are confined to a very small volume, while in nature they would approach humans over much longer distances, integrating an array of different distance-dependent stimuli. Therefore, understanding of how mosquitoes interact with topical repellents is essential to assess the validity of the arm-in-cage test. Here, we measured the behaviour of host seeking mosquitoes in the arm-in-cage test using a 3D infrared video camera system. We tracked mosquito flight paths of *Aedes aegypti* and *Anopheles stephensi* at a rate of 50 positional data per second and in real time as the mosquitoes interacted with a repellent-treated forearm in the arm-in-cage test. The applied repellents included 20% ethanolic solutions of N,N-diethyl-meta-toluamide, p-menthane-3,8-diol, icaridin and ethyl butylacetylaminopropionate. All four repellents reduced the number of bites while simultaneously increasing the number of contacts the mosquitoes made with the arm. The mosquito behaviour was primarily characterised by gustatory excito-repellency upon contact with the arm rather than being repelled by volatile chemicals. Our observations cast doubts on the validity of the arm-in-cage test as the only basis for making label claim recommendations for the complete protection times of topical repellents.

1309

### FIRST REPORT OF HIGH SURVIVAL AND FECUNDITY RATES OF MALARIA VECTOR MOSQUITOES IN IRRIGATED AREAS OF ETHIOPIA

Dawit Hawaria Logita<sup>1</sup>, Solomon Kibret<sup>2</sup>, Delenasaw Yewhalaw<sup>3</sup>, Guiyun Yan<sup>2</sup>

<sup>1</sup>Yirgalem Hospital Medical College, Hawasa, Ethiopia, <sup>2</sup>University of California, California, CA, United States, <sup>3</sup>Jimma University, Jimma, Ethiopia

Irrigated agriculture is key to increase crop productivity and ensure food security in Africa. However, unintended negative public health impacts such as malaria have been a challenge around such developmental projects. This study aimed at assessing the effects of irrigation practices on malaria vector mosquito development and survivorship in Ethiopia. The study was conducted in two agroecosystems, irrigated and non-irrigated areas, in western Ethiopia. Monthly larval surveys were conducted between 2017 and 2020. Life-table experiment was done to examine the effect of environmental modification on survivorship and development of both immature and adults *Anopheles arabiensis*. Habitat diversity, larval abundance, pupation rate, development time of immatures and adult longevity and fecundity were compared between the two agroecosystems. The number of anopheline positive habitats was two-fold higher in irrigated than non-irrigated areas. Anopheline larval abundance in the irrigated area was 16.6 % higher than the non-irrigated area. Irrigated agroecosystem was significantly associated with larval anopheline occurrence. The estimated mean survival time of female *An. arabiensis* in

the irrigated and non-irrigated areas was 37.9 and 31.3 days, respectively. The study found that fecundity of *An. arabiensis*, was 96.2% higher in the irrigated agroecosystem than in the non-irrigated area. The findings of this study underscore that irrigation in semi-arid areas of Ethiopia increase the survival and fecundity of the major malaria vector, *An. arabiensis*. Integrated Vector Management that incorporates environmental management is critical to control mosquito breeding around irrigation schemes.

1310

### MICROFILARIAE-INDUCED EOSINOPHIL EXTRACELLULAR DNA TRAPS ARE INDUCED VIA THE DECTIN-1 RECEPTOR, NADPH OXIDASE AND THE INFLAMMASOME

Alexandra Ehrens<sup>1</sup>, Benjamin Lenz<sup>1</sup>, Anna-Lena Neumann<sup>1</sup>, Wiebke Strutz<sup>1</sup>, Coralie Martin<sup>2</sup>, Daniel Kulke<sup>3</sup>, Achim Hoerauf<sup>1</sup>, Marc P. Hübner<sup>1</sup>

<sup>1</sup>University Hospital Bonn, Bonn, Germany, <sup>2</sup>Museum National d'Histoire Naturelle, Paris, France, <sup>3</sup>Iowa State University College of Veterinary Medicine, Ames, IA, United States

Eosinophils and their cytotoxic granules play an important part in the protective immunity against filariae. The release of those granules can be mediated through different mechanisms including the extracellular DNA trap cell death (ETosis), a form of cell death where intracellular DNA is explosively released, entrapping pathogens and supporting their killing. The results of the present study demonstrate that microfilariae (MF) of the filarial nematode *Litomosoides sigmodontis* trigger DNA release by bone marrow-derived eosinophils. *In vitro*, these eosinophil DNA traps (EETosis), consisting of nuclear and mitochondrial DNA, inhibit MF motility in a DNA- and cell contact-dependent manner. Dectin-1 was identified as the pattern-recognition receptor involved in triggering the MF-induced EETosis. Moreover, EETosis in response to MF is dependent on NADPH oxidase since eosinophils derived from *Cybb*<sup>-/-</sup> mice, which lack NADPH oxidase, are not able to release extracellular DNA traps. Furthermore, caspase-1 is activated during MF-induced EETosis and inhibition of caspase-1 in wild-type eosinophils and caspase-1-deficient eosinophils do not undergo EETosis. This suggests that the inflammasome pathway is involved during filarial-induced EETosis. *In vivo* studies reveal an increase in local DNA concentration upon *L. sigmodontis* infection in mice. Intraleural MF injection raises local DNA concentrations, which is partly mediated by eosinophils, indicating a potential role of EETosis as an *in vivo* effector mechanism as well. Furthermore, MF covered by DNA traps and injected into naïve mice are removed faster from the peripheral circulation than MF that are not covered by extracellular traps suggesting a potential role of EETosis in MF clearance. In summary, these results identify eosinophil EETosis as an important mechanism in protective immunity against MF and reveal the underlying signaling mechanism during eosinophil DNA release.

1311

### ADOPTIVE TRANSFER OF IMMUNE CELLS INTO RAG1L-2RG-DEFICIENT MICE: A NOVEL APPROACH TO INVESTIGATE IMMUNITY AGAINST HUMAN AND RODENT FILARIAE

Anna Filz<sup>1</sup>, Laura Layland<sup>1</sup>, Kathrin Arndts<sup>1</sup>, Lisa Wadephul<sup>1</sup>, Ruth Tamadaho<sup>1</sup>, Dennis Borrero-Wolff<sup>1</sup>, Valerine Chunda<sup>2</sup>, Achim Hoerauf<sup>1</sup>, Samuel Wanji<sup>2</sup>, Manuel Ritter<sup>1</sup>

<sup>1</sup>Institute for Medical Microbiology, Immunology and Parasitology (IMMIP), University Hospital Bonn (UKB), Bonn, Germany, <sup>2</sup>Parasite and Vector Biology Research Unit, Department of Microbiology and Parasitology, Faculty of Science, University of Buea, Buea, Cameroon

Besides severe clinical symptoms, the majority of filarial infections are asymptomatic due to the filariae-driven modulation of host immunity. A major obstacle for research on human filariae has been the inability to obtain adult worms and the insufficient possibility to analyse infection kinetics and immune signalling. Thus, the *Litomosoides sigmodontis* filarial mouse model is well-established and serves to study host-parasite interactions. Research revealed several important factors, molecules and

immune cells that are crucial for immune responses against the rodent filarial nematode. Nevertheless, the complex immunological mechanisms associated with filarial control and disease progression remain unclear and translation to human infections is difficult, especially since human filarial infections in rodent models are limited. To overcome these obstacles, we performed adoptive transfer experiments into RAG2IL-2Ry-deficient C57BL/6 mice. These mice have no T, B and natural killer cells, develop full patency upon 72 days post-infection (p.i.), despite the fact that C57BL/6 mice normally clear the infection upon 40 days p.i., and have been shown to be susceptible for infection with the human filaria *Loa loa*. Using this mouse model in combination with the adoptive transfer cell transfer, we revealed that CD4<sup>+</sup> T cells from *L. sigmodontis*-infected C57BL/6 donor mice significantly reduce worm burden, length and fertility, dampen tissue inflammation at the site of infection and moreover block microfilariae (offspring of the filaria) release. These findings were accompanied with an increased Th17 CD4<sup>+</sup> T cell response, distinct cytokine and chemokine secretion patterns and altered innate cell composition. In summary, this study shows for the first time that CD4<sup>+</sup> T cells and their immune responses are central for the immunity against *L. sigmodontis* in C57BL/6 mice. Moreover, adoptive transfer of immune subsets in RAG2IL-2Ry-deficient C57BL/6 mice will provide an optimal platform to decipher cell populations, cytokines, chemokines and receptors that control worm survival and patency of rodent and human filarial infections.

1312

#### RNASEQ-BASED ANALYSES OF THE EFFECT OF BRUGIA MALAYI MICROFILARIAL-DERIVED EXTRACELLULAR VESICLES ON HUMAN MONOCYTES AND DENDRITIC CELLS

**Alessandra Ricciardi**, Gayatri Sanku, Neelam Redekar, Justin Lack, Thomas Nutman

*National Institute of Health, Bethesda, MD, United States*

Live microfilariae (mf) and mf-derived extracellular vesicles (EVs) have been shown to modulate human antigen presenting cell (APC) function, most notably by suppressing the induction of IL-12 (and other pro-inflammatory cytokines) following activation with LPS and interferon- $\gamma$ . Moreover, live mf and mf-derived EVs have been shown to suppress mTOR phosphorylation to the same degree as did rapamycin. To explore further how EVs alter human APC function, we studied the effect of mf and EVs on human elutriated monocytes and monocyte-derived DCs following exposure to Mf, mf-derived excretory/secretory (E/S) products, E/S depleted of EVs through ultracentrifugation and purified EVs. After demonstrating that almost all of the measurable responses (cytokines, mTOR phosphorylation) induced by live mf could be recapitulated by EVs and EV-containing E/S, we next performed RNAseq analysis of human DC and human monocytes following exposure to live mf, EVs, E/S, or EV-depleted E/S. In preliminary analyses of the data for the DC, using a false discovery rate (FDR)<0.05, EV-exposed DCs had induced the expression of 212 differentially expressed genes (DEGs) when compared to unexposed DC and 157 when compared to ES-depleted EVs. These genes were enriched in GO biological processes associated with neutrophil degranulation and 15 DEGs associated with KEGG Lysosome pathways. IPA analysis point to immune dysregulation. We are further analyzing the DEGs of human monocytes. Common pathways modulated by EVs in both DC and monocytes are being explored specifically in directed experiments to understand the intracellular processes altered by EVs and the effect these have on effector T cells. Taken together, our data suggest a modulatory role of EVs on APC function that likely leads to defects in T cell effector function.

1313

#### IL-11 REGULATES INNATE MUCOSAL IMMUNITY IN ACUTE HELMINTH INFECTION

**Jonah Kupritz**<sup>1</sup>, Kimberly Zaldana<sup>1</sup>, Erik Karmele<sup>2</sup>, Fabricio Oliveira<sup>3</sup>, Olena Kamenyeva<sup>4</sup>, Thomas B. Nutman<sup>1</sup>, Pedro H. Gazzinelli-Guimaraes<sup>1</sup>

<sup>1</sup>Laboratory of Parasitic Diseases, NIAID, National Institutes of Health, Bethesda, Maryland, MD, United States, <sup>2</sup>Laboratory of Molecular Immunology, NIAID, National Institutes of Health, Bethesda, Maryland, MD, United States, <sup>3</sup>Laboratory of Immunology and Genomics of Parasites, Department of Parasitology, ICB, UFMG, Belo Horizonte, Brazil, <sup>4</sup>Biological Imaging Section, Research Technology Branch, NIAID, National Institutes of Health, Bethesda, Maryland, MD, United States

Interleukin (IL)-11, a pleiotropic IL-6 family-member cytokine, appears to play a role in both innate and adaptive immune responses and tissue inflammation. Little is known, however, about its function in helminth infection. Having shown that IL-11 gene expression is upregulated in the lungs of *Ascaris*-infected mice at 8 days post-infection (dpi), we sought to understand the role played by IL-11 at lung barrier surfaces following infection with *Ascaris*. Compared to uninfected mice, IL-11 levels were significantly elevated in the lung tissue of *Ascaris*-infected mice (2,825 pg/mL vs 894 pg/mL, P<0.0001 at 8 dpi). Using both flow cytometry and confocal microscopy, we found that bronchial epithelial cells and subepithelial fibroblasts were the primary IL-11-producing populations following *Ascaris* infection. To assess the function of IL-11 in *Ascaris* infection, we administered anti-IL-11 antibody intranasally during *Ascaris* infection. This IL-11 neutralization impaired the influx of macrophages and neutrophils to the lungs; moreover, there was induction of CXCL5, a chemokine known to inhibit neutrophil trafficking. Intranasal administration of recombinant IL-11, conversely, induced G-CSF and CXCL1, increased neutrophil influx, and reduced airway inflammation and worm burden (40% decrease, P<0.01) in the *Ascaris*-infected mice when compared with PBS-treated, infected mice, suggesting an immune-mediated regulatory effect of IL-11 in helminth infection; similar effects have been reported in bacterial pneumonia and inflammatory bowel disorders. To model the interaction between *Ascaris* and lung epithelial cells, we used an *in vitro* system whereby a human bronchial epithelial cell line grown in a monolayer on an extracellular gel matrix was shown to produce markedly increased (55% above baseline) amounts of IL-11 following exposure to *Ascaris* larvae. These data suggest that IL-11 acts as an alarmin released by bronchial epithelial cells in response to *Ascaris* larvae (or larval products) that may in turn regulate the neutrophil-dominated inflammation seen during acute helminth infections.

#### COMPARING IMMUNE RESPONSES TO PRIMARY INFECTION WITH DENGUE, CHIKUNGUNYA AND ZIKA VIRUSES

**Lewis E. Tomalin**<sup>1</sup>, Sandra Bos<sup>2</sup>, Adeeb H. Rahman<sup>1</sup>, Yitong Chen<sup>1</sup>, Daniela Michlmayr<sup>2</sup>, Magelda Montoya<sup>3</sup>, Guillermina Kuan<sup>4</sup>, Angel Balmaseda<sup>5</sup>, Eva Harris<sup>2</sup>, Mayte Suarez-Farinas<sup>1</sup>

<sup>1</sup>Icahn School of Medicine at Mount Sinai, New York, NY, United States, <sup>2</sup>University of California Berkeley, Berkeley, CA, United States, <sup>3</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>4</sup>Sustainable Sciences Institute, Centro de Salud Socrates Flores Vivas, Ministry of Health, Managua, Nicaragua, <sup>5</sup>Sustainable Sciences Institute, Laboratorio Nacional de Virologia, Centro Nacional de Diagnostico y Referencia, Ministry of Health, Managua, Nicaragua

Dengue virus (DENV), Zika virus (ZIKV) and chikungunya virus (CHIKV) are mosquito-borne arboviruses with similar epidemiology and transmission cycles, collectively causing >50 million cases each year, with a resurgence in recent decades. Although clinical symptoms are similar and can be mild, all 3 viruses can lead to severe and life-threatening complications that differ among the viruses. To characterize immune responses to these 3 viruses, we measured and compared immune cell profiles by CyTOF in children naturally infected with DENV1, DENV3, ZIKV or CHIKV

in two longitudinal studies in Managua, Nicaragua. Abundance of 28 cell populations were measured in children following primary infection with CHIKV (n=42), DENV1/DENV3 (n=28) or ZIKV (n=87), during acute infection (~1-3 days post-onset of symptoms) and convalescence (~14-21 days). Linear mixed-effects models were used to compare changes in the log<sub>10</sub> frequency of immune cell populations in acute infection vs. convalescent infection, as well as to compare profiles between virus types. In total, 26 cell types showed a significant frequency difference (FDR < 0.05) in acute samples vs. convalescence for at least one virus type. Acute infection with CHIKV was characterized by a higher proportion of CD14+ monocytes, while acute ZIKV infection showed higher proportions of CD4+ naïve T cells and CD8+ central memory T cells. Immune cell profiles following acute DENV1/DENV3 infection shared similarities with both ZIKV and CHIKV infection. Convalescence after infection with any of the 3 viruses was characterized by a higher proportion memory B cells, CD27- B cells, and CD1c+ Type-2 dendritic cells. In this study, we have identified changes in immune cell subtypes that are characteristic of the infection responses to three major arboviruses. More research is needed to understand how the infection mechanisms of each virus influence immune responses, and how specific immune cell types determine disease progression and the potential for severe complications. More broadly, this work demonstrates the utility of mass cytometry for studying immune responses to natural arbovirus infection.

### PEPTIDE-BASED SEROLOGIC PLATFORMS CAPABLE TO DIFFERENTIALLY IDENTIFY DENGUE AND ZIKA INFECTIONS IN AN ENDEMIC REGION

**Alice Freitas Versiani<sup>1</sup>**, Irene Bosch<sup>2</sup>, Leonardo A. Trigo<sup>1</sup>, Matheus H. Avila<sup>1</sup>, Andreia F. Reis<sup>1</sup>, Andresa L. Santos<sup>1</sup>, Fernanda S. Dourado<sup>1</sup>, Beatriz C. Marques<sup>1</sup>, Nathalia Zini<sup>1</sup>, Cassia F. Estofolete<sup>1</sup>, Flavio G. Da Fonseca<sup>3</sup>, Lee Gehrke<sup>2</sup>, Nikos Vasilakis<sup>4</sup>, Mauricio L. Nogueira<sup>1</sup>

<sup>1</sup>School of Medicine of Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil, <sup>2</sup>Massachusetts Institute of Technology, Cambridge, MA, United States, <sup>3</sup>Federal University of Minas Gerais, Belo Horizonte, Brazil, <sup>4</sup>University of Texas Medical Branch, Galveston, TX, United States

Dengue is one of the most important infectious diseases nowadays, and early diagnosis is a determining factor for disease outcomes. Co-circulation of viruses with serological cross-reactivity with Dengue virus (DV), such as Zika virus (ZV), further complicates diagnosis. One approach towards creating diagnostic tests able to differentiate between such viruses is to determine peptides that would lack immune response cross-reactivity. However, the immobilization of small proteins or peptides on surfaces has been a barrier to the development of tests. This work aims to identify specific peptides in the non-structural protein 1 (NS1) of DV and ZV and evaluate their use in serological diagnostic platforms. For this, we screened DV and ZV peptide libraries with NS1 monoclonal DV1-4 and ZV antibodies (NS1 mAbs). Three peptides were identified with specific binding: one that is ZV-specific and two that are DV-specific. We tested our peptide ELISA assay with 170 human samples from patients who had known a prior diagnosis of DV and/or ZV infection validated by plaque neutralization assay (PRNT). The pepELISA DV-specific showed a sensitivity of 97% and a specificity of 96,3%. The pepELISA ZV-specific showed a sensitivity of 77,9% and a specificity of 97,7%. After that, 1365 samples from an endemic area were tested, where 60,4% was seroprevalent for DV and 15,6% for ZV – with 13% of this population positive for both infections. With the success of pepELISA, we evaluated a lateral flow-based assay using gold nanoparticles (GNP) in two immobilization variations. For the first, biotinylated peptides were conjugated with streptavidin and spotted onto a nitrocellulose membrane, and GNP conjugated with anti-human IgG was tested with the human samples. For the second test, peptides synthesized covalently linked to lipoic acid were conjugated to the surface of GNP. Both strategies were able to differentiate ZV and DV mAbs and patient samples. These techniques presented here are effective, fast, and inexpensive tests and would allow in the near future the rapid assessment of the exposure - essential in a vaccine campaign of both viruses.

The four Dengue virus serotypes (DENV1-4) infect several hundred million people per year. Primary DENV infections stimulate serotype-specific (TS) neutralizing antibodies (NAbs) that are correlated with protection against homologous but not heterologous serotypes. A secondary infection with a new serotype stimulates both TS NAbs as well as serotype-cross reactive (CR) NAbs that are associated with long lasting immunity to all serotypes. We currently have a poor understanding of the epitopes targeted by NAbs in people exposed to DENV3 infections or vaccines. The DENV envelope (E) protein with three distinct domains (EDI, EDII and EDIII) is the main target of NAbs. To study individual variation in humoral immune responses after DENV3 infection or vaccination, we created a panel of recombinant chimeric DENVs in which the DENV3 EDI, EDII or EDIII domains of the E protein were individually transplanted into a DENV1 backbone. Monoclonals (mAbs) binding to known epitopes on the E-protein were run against DENV1/3 EDI, EDII & EDIII chimeras to assess that each virus retained domain-specific DENV antibody epitopes. Using these chimeric viruses, we also mapped three new DENV3 neutralizing mAbs to EDII, bringing the total number of known EDII-directed DENV3 TS neutralizing mAbs to 5. Two of the 5 EDII-directed mAbs neutralized DENV3 genotype 3 (GIII) but not genotype 4 (GIV). The critical residues in these epitopes were mapped using DENV3/3 genotype chimeras with select residues or "clusters" from DENV3 GIII transplanted into the DENV3 GIV backbone. Additionally, important structural targets of natural & vaccine-induced polyclonal TS 1° immunity to DENV3 were identified with the DENV1/3 (EDI-III) chimeric panel. Together, the DENV1/3 EDI-III chimeric virus panel has revealed major antigenic sites on E protein targeted by NAbs in people exposed to primary DENV3 infections. In the future, full-domain transplant chimeric reagents can be used as a tool to assess antibody quality after natural infection or vaccination & to learn about structural targets of immunity for other DENV serotypes.

<sup>1</sup>National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>3</sup>University of Florida, Gainesville, FL, United States, <sup>4</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>University of Florida, Florida, FL, United States, <sup>6</sup>GlaxoSmithKline (GSK) Vaccines, Singapore, Singapore, <sup>7</sup>Institut Pasteur in Cambodia, Phnom Penh, Cambodia, <sup>8</sup>University of Cambridge, Cambridge, United Kingdom

Antigenic relationships among the four dengue virus serotypes (DENV1-4) are important determinants of dengue disease risk. Whether the DENV serotypes change antigenically in response to one another remains uncertain. We tracked the antigenic dynamics of DENV1-4 selected from 1,944 sequenced viruses isolated in Bangkok, Thailand between 1994-

2014 (n=348) in comparison to regional and global DENV antigenic diversity (n=64 strains). DENV1-4 circulating in Thailand oscillated in antigenic distance relative to one another but overall became more antigenically dissimilar over the observational period. For DENV1, DENV2, and DENV4, greater antigenic relatedness to other serotypes correlated with antigenic movement away from the same serotype and with larger epidemics. For DENV3, antigenic similarity to other serotypes co-occurred with low DENV3 transmission and a genotype replacement, at which point newer DENV3 strains antigenically moved away from older DENV3 strains and other serotypes simultaneously. We observe that the four DENV serotypes circulating in one geographic area evolve antigenically over time in relation to one another and epidemic magnitude, providing insights into theorized tradeoffs for DENV evolution.

Immune status to dengue virus (DENV) currently represents the greatest risk factor for hospitalization after a bite from a DENV-infected mosquito. However, additional susceptibility factors exist, as <5% of patients with pre-existing anti-DENV IgGs develop severe disease. While anti-viral antibodies generally confer protective functions, antibodies against DENV are associated with enhanced disease susceptibility. Antibodies can mediate DENV infection of leukocytes via Fcγ receptors, likely contributing to dengue disease pathogenesis. Severe dengue patients are characterized by increased abundance of afucosylated IgG1 glycoforms, which exhibit higher affinity for the activating FcγR11a. Whether afucosylated anti-DENV IgG is the result of secondary DENV infection, or their increased abundance truly represents a prognostic factor for susceptibility to severe dengue disease remains unknown. We examined Fab and Fc structures from a Cambodian pediatric cohort pre- and post-infection (n=18) and from individuals who were inapparent infected (n= 23) or hospitalized (n=48) and classified according to WHO1997 criteria. Neither antibody titers nor neutralizing activity correlated with disease severity in DENV-infected populations. Afucosylation is associated with dengue disease susceptibility as secondary inapparent infected individuals had lower levels of DENV-specific and total afucosylated IgG1 compared to hospitalized cases. Moreover, IgG1 afucosylation is associated with dengue disease severity and correlates with biological features of severe disease. Afucosylation is increased during secondary infection compared to primary infection. Analyzing plasma samples from individuals before and after infection revealed that afucosylation increases after infection and during convalescence. Moreover, IgG1 afucosylation was specifically modulated by DENV infection, as we did not observe any changes after West Nile or Zika virus infection. Thus, the IgG1 fucosylation status represents a robust prognostic tool for dengue disease and highlights the key role of the Fc glycan structure in dengue pathogenesis.

Dengue cases are known to exhibit focal clustering in space and time at the level of the household and neighborhood, driven by local mosquito population dynamics, human population immunity, and fine scale human and mosquito movement. We examined how the spatiotemporal clustering of dengue cases was disrupted by introduction of the arbovirus-blocking bacterium *Wolbachia* (wMel-strain) into the *Aedes aegypti* population in a randomized controlled efficacy trial in Yogyakarta, Indonesia. We analysed 318 serotyped dengue cases and 5,921 test-negative controls with geolocated residence enrolled over 27 months following randomized wMel deployments. The odds that a pair of individuals within a given space-time window are homotypic dengue cases, versus heterotypic cases or test-negative controls, serves as a measure of local transmission. A lack of homotypic clustering is therefore supportive of limited or absent local transmission. We find evidence of significant spatial dependence up to 300m among the 265 dengue cases detected in the untreated arm of the trial. Spatial dependence is strongest within 50m, with a 4.68-fold increase (compared to 95% permutation null range: 0.13, 1.22) in the odds that a pair of individuals enrolled within 30 days and 50m of each other are homotypic dengue cases – and therefore potentially transmission-related – compared to pairs occurring at any distance. In contrast, we find no evidence of spatial dependence among the 53 dengue cases detected in the wMel-treated arm. Strikingly, in 6 of the 12 wMel-treated areas not a single pair of homotypic dengue cases occurred in any 30-day window. This provides compelling evidence that introgression of wMel *Wolbachia* into *Aedes aegypti* mosquito populations interrupts local dengue virus transmission, leading to reduced case incidence.

### LAND USE, INFRASTRUCTURE, AND THE HETEROGENEOUS BURDEN OF DENGUE VIRUS INFECTION WITHIN A HIGHLY-ENDEMIC COMMUNITY

**Kathryn B. Anderson**<sup>1</sup>, Darunee Buddhari<sup>2</sup>, Sopon Iamsirithaworn<sup>3</sup>, Henrik Salje<sup>4</sup>, Derek A. Cummings<sup>5</sup>, Anon Srikiatkachorn<sup>6</sup>, Taweewun Hunsawong<sup>2</sup>, Direk Khampaen<sup>7</sup>, Rotjana Khontong<sup>8</sup>, Stefan Fernandez<sup>2</sup>, Stephen J. Thomas<sup>1</sup>, Alan L. Rothman<sup>6</sup>, Timothy P. Endy<sup>1</sup>

<sup>1</sup>SUNY Upstate Medical University, Syracuse, NY, United States, <sup>2</sup>Armed Forces Research Institute for Medical Sciences, Bangkok, Thailand, <sup>3</sup>Department of Disease Control, Thai Ministry of Public Health, Bangkok, Thailand, <sup>4</sup>University of Cambridge, Cambridge, United Kingdom, <sup>5</sup>University of Florida, Gainesville, FL, United States, <sup>6</sup>University of Rhode Island, Providence, RI, United States, <sup>7</sup>Office of Disease Prevention and Control 3, Nakhonsawan, Thailand, <sup>8</sup>Kamphaeng Phet Provincial Hospital, Kamphaeng Phet, Thailand

Dengue is described as an urban disease, yet the burden in rural areas can be high. Across the urban-rural gradient, hot spots of transmission are observed. We hypothesized that risk of DENV is spatially associated with land use, and modified by infrastructural factors such as water and waste management. Data derive from an ongoing study for DENV infection among families in an agricultural Thai province. Blood and data regarding demographics and household features are collected on enrollment. Using satellite imagery and supervised classification, land cover was defined as developed, cropland, and water. The proportions of each within a 500-meter buffer around each house's coordinates were computed. Clusters of development (towns/villages) were identified using k-means clustering. Seropositivity was defined as hemagglutination inhibition titer  $\geq 20$  for any DENV serotype. Predictors of seropositivity were evaluated using mixed models, controlling for age and clustering by household. Between 2015-2019, 2872 individuals in 470 families were enrolled, with a median age of 21 years (range: 0-93 years). 87.0% were seropositive on enrollment. 22.5% of the study area was classified as developed and 76.9% as cropland. 58.8% of households were within 2.5km of a town/village ('non-rural'). Many previously-identified risk

factors for DENV (lack of screens, presence of water containers, housing materials promoting mosquito entry) were more common in rural homes. Despite this, residence in or near a town/village was associated with DENV seropositivity (OR=1.65), as were residing in a house on poles (OR=3.6) and a 10-container increase in water containers on premises (OR=1.20) ( $p<0.05$  for all). There was a strong interaction between rurality and the requirement to transport trash to the dump in predicting seropositivity (OR=5.2 in non-rural versus OR=1.7 in rural areas,  $p<0.05$ ). We describe high transmission across this largely-agricultural study area, with highest risk in and around areas of development. We report modifiable infrastructural factors such as trash management and water supply / storage that underlie these differences in risk.

1321

### WAIT AND WATCH: A POTENTIAL TRACHOMA SURVEILLANCE STRATEGY FROM AMHARA, ETHIOPIA

<sup>1</sup>The Carter Center, Addis Ababa, Ethiopia, <sup>2</sup>The Carter Center, Atlanta, GA, United States, <sup>3</sup>Amhara Public Health Institute, Research and Technology Transfer Directorate, Bahir Dar, Ethiopia, <sup>4</sup>Amhara Regional Health Bureau, Health Promotion and Disease Prevention, Bahir Dar, Ethiopia, <sup>5</sup>Federal Ministry of Health, Disease Prevention and Control Directorate, Addis Ababa, Ethiopia

Recrudescence of trachoma after the elimination as a public health problem threshold has been reached is a serious concern for global trachoma control. Currently, many district-level surveillance surveys (conducted  $\geq 2$  years since elimination threshold has been reached) are resulting in a trachomatous inflammation-follicular (TF) among children ages 1 to 9 years above the elimination threshold ( $\geq 5\%$ ). This problem is particularly acute in Ethiopia, where 50% of surveillance surveys have had results above threshold. Once a district returns to TF  $\geq 5\%$ , a program typically restarts costly mass drug administration (MDA) campaigns. In Amhara region, Ethiopia, most surveillance surveys which result in a TF prevalence  $\geq 5\%$  have a prevalence close to 5%, making it difficult to determine whether the result is due to true recrudescence or to statistical variability. This study's aim was to monitor recrudescence within Amhara by waiting to restart MDA within 2 districts with a TF prevalence  $\geq 5\%$  at surveillance survey; the districts would be resurveyed 1 year later using traditional and alternative trachoma indicators, such as measures of infection and serology (a "wait and watch" approach). Surveys were multi-stage cluster surveys whereby certified graders assessed TF. For the post-surveillance surveys, children ages 1 to 9 years also provided a dried blood spot, and children 1 to 5 years provided an ocular swab. In 2017 both Metema and Woreta town districts reached the 5% threshold for the first time. During the 2019 surveillance surveys both Metema (5.2%) and Woreta town (5.1%) had a TF prevalence just greater than the threshold. No MDA occurred in these districts during the 2020 MDA in Amhara, and they were surveyed again in 2021. The TF prevalence in Metema and Woreta town was 3.6% (95% Confidence Interval (CI): 1.4-6.4) and 2.5% (95% CI: 0.8-4.5), respectively. Infection and serology data will help characterize and confirm this low trachoma burden. Based on these results, the Program should not restart MDA in these 2 districts and should consider the wait and watch approach for other districts above the elimination threshold at surveillance survey.

1322

### STATE AND LOCAL GOVERNMENT AREA ESTIMATES FOR TRACHOMA SEROPREVALENCE IN 1 TO 9-YEAR-OLDS IN NIGERIA USING MULTIPLEX BEAD ASSAY

**Nishanth Parameswaran<sup>1</sup>**, Ndidi Agala<sup>2</sup>, Andrew N. Thomas<sup>2</sup>, Chimaoghe Achugbu<sup>3</sup>, Ado G. Abubakar<sup>2</sup>, Stacie M. Greby<sup>4</sup>, Nnaemeka C. Iriemenam<sup>4</sup>, Gretchen M. Cooley<sup>5</sup>, Sarah E. Gwyn<sup>5</sup>, Ryan E. Wiegand<sup>5</sup>, Sarah A. Guagliardo<sup>5</sup>, Diana L. Martin<sup>5</sup>

<sup>1</sup>CDC Foundation, Atlanta, GA, United States, <sup>2</sup>IHVN, Abuja, Nigeria, <sup>3</sup>Nigeria Centre for Disease Control, Abuja, Nigeria, <sup>4</sup>Centers for Disease Control and Prevention, Abuja, Nigeria, <sup>5</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Trachoma is the leading infectious cause of blindness, resulting from repeated infections of the conjunctivae by *Chlamydia trachomatis* (Ct). The clinical sign trachomatous inflammation—follicular (TF) is used to assess transmission of ocular Ct in 1–9-year-olds during population-based, two-stage cluster surveys generally conducted at district level (population sizes of 100,000–250,000). Testing for antibodies may be useful for surveillance for Ct transmission after elimination of trachoma as a public health problem by leveraging samples collected in serosurveys for other infectious diseases. In Nigeria, where trachoma is endemic in certain local government areas (LGA, similar to districts), dried blood spots (DBS) were collected during the 2018 Nigeria HIV/AIDS Indicator and Impact Survey (NAIIS), a national household HIV survey conducted in all 36 states and the Federal Capital Territory. DBS from 20,695 children age 1–9 years were tested using a multiplex bead assay (MBA) for antibodies against 35 antigens for various infectious and vaccine-preventable diseases, including Ct Pgp3. State-level seroprevalence estimates ranged from 0.6% (95% CI: 0.1–1.9) in Abia State to 31.3% (95% CI: 25.9–37.0) in Yobe State. Three states with the highest seroprevalence estimates (Yobe, Jigawa, and Borno) are in the Northeast; their LGA-level seroprevalence estimates ranged from 5% to 100%. Of the 741 LGAs surveyed, 289 (39%) had seropositive children; 14 of the 15 LGAs with the highest seroprevalence estimates were in Yobe, Jigawa, and Borno. Further analyses will assess for clustering in LGAs using spatial methods and geolocation data from the survey. Because trachoma is a highly focal disease, nationally representative surveys such as NAIIS may undersample and miss foci of transmission. Data from this survey, where the number of children sampled per LGA (median 24, range 1–127) is approximately a log-fold lower than in trachoma-focused surveys (approximately 1000 children per LGA), will help us understand the utility and limits using specimens from other disease-specific surveys as an alternative method for trachoma surveillance.

1323

### PREDICTING FUTURE COMMUNITY-LEVEL OCULAR CHLAMYDIA TRACHOMATIS INFECTION PREVALENCE USING SEROLOGICAL, CLINICAL, MOLECULAR AND GEOSPATIAL DATA

**Christine Tedijanto<sup>1</sup>**, Solomon Aragie<sup>2</sup>, Zerihun Tadesse<sup>2</sup>, Mahteme Haile<sup>3</sup>, Taye Zeru<sup>3</sup>, Scott D. Nash<sup>4</sup>, Dionna M. Wittberg<sup>1</sup>, Hugh J. Sturrock<sup>5</sup>, Thomas M. Lietman<sup>1</sup>, Jeremy D. Keenan<sup>1</sup>, Benjamin F. Arnold<sup>1</sup>

<sup>1</sup>Francis I. Proctor Foundation, University of California San Francisco, San Francisco, CA, United States, <sup>2</sup>The Carter Center Ethiopia, Addis Ababa, Ethiopia, <sup>3</sup>Amhara Public Health Institute, Bahir Dar, Ethiopia, <sup>4</sup>The Carter Center, Atlanta, GA, United States, <sup>5</sup>Locational, Poole, United Kingdom

Trachoma is targeted for elimination as a public health problem by 2030. Models to predict future community-level infections could help direct control programs. We hypothesized that (1) communities with high levels of infection would be geographically clustered in stable foci of transmission ("hotspots") and (2) models using trachoma indicators (clinical grading, ocular *C. trachomatis* (Ct) infections, and IgG responses to Ct antigens) and remotely sensed geospatial data would accurately predict future community-level Ct infections. We tested our hypotheses using measurements from a randomized controlled trial designed to

assess improved water, sanitation and hygiene in the absence of mass drug administration among 40 communities in Amhara, Ethiopia. Median Ct infection prevalence among children 0-5 years old (0-5y) increased from 7% at enrollment to 29% by month 36. We found no evidence for high degrees of global clustering in trachoma indicators over the study area. At baseline, correlation between community-level seroprevalence and Ct infection was stronger among children 0-5y ( $p = 0.76$ , 95% CI = 0.56-0.88) than children 6-9y ( $p = 0.48$ , 95% CI = 0.23-0.68), and stronger than the correlation between clinical trachoma and Ct infection (0-5y  $p = 0.56$ , 95% CI = 0.28-0.75; 6-9y  $p = 0.40$ , 95% CI = 0.10-0.67). Seroprevalence was the strongest concurrent predictor of community-level infections at month 36 among children 0-5y (cross-validated  $R^2 = 0.76$ , 95% CI = 0.59-0.85). In longitudinal analyses, seroprevalence among children 0-5y from 12 months prior was a weak predictor of infection prevalence at month 36 ( $cvR^2 = 0.33$ ), and performance further declined for seroprevalence from 24 and 36 months prior ( $cvR^2 = -0.02$  and  $-0.03$ , respectively). Geospatial layers, a spatial Gaussian process, and stacked ensemble machine learning did not meaningfully improve predictions. Serological markers among children 0-5y may be well-suited for community-level monitoring given their objectivity and strong correlation with concurrent Ct infection prevalence, but accurate, future prediction in the context of unstable transmission remains an open problem.

In 2015, among 5.9 million child (<5 years) deaths globally, 45% were in the neonatal period with sepsis the third most common cause in neonates. The Child Health and Mortality Prevention Surveillance (CHAMPS) network aims to determine causes of stillbirths and under-5 mortality in sub-Saharan Africa and South Asia. Post-mortem tissue specimens were collected using minimally invasive tissue sampling (MITS). The project used multiple laboratory diagnostic platforms, including microbial culture,

TaqMan Array Card-based real time PCR, histopathology of MITS, coupled with demographic and clinical data and verbal autopsy to determine the cause of each death. Cause of death was adjudicated by a multi-disciplinary panel (DeCoDe panel) using all available data. From January 2017 to December 2019, 675 neonatal deaths were adjudicated by DeCoDe panels in 7 CHAMPS sites. Due to infection 19% of neonates died <24 hours following birth, 44% in the early neonatal (1-6 days) and 37% in the late neonatal (7-28 days) period. In 320 (47% of 675) cases, invasive infectious disease was identified in the causal chain leading to death. Country specific apportionment of infection in the causal chain was 26% in Bangladesh (20/76), 75% in Ethiopia (12/16), 31% in Kenya (31/100), 39% Mali (25/64), 25% in Mozambique (18/72), 61% in Sierra Leone (22/36) and 62% in South Africa (192/311). Over 65% (311/462) of causal pathogens were identified as Gram-negative bacteria, including 118 (38%) *Klebsiella* spp, 113 (36%) *Acinetobacter* spp and 39 (13%) *E. coli*. Gram-positive organisms were determined to be in the causal pathway in 23% (105/462) of cases, including 30 (29%) *Streptococcus agalactiae*. Other non-bacterial organisms included *Candida* spp in 5% (25/462), and viruses in 4% (20/462). Neonatal deaths were attributed to polymicrobial infections in 110 (37/ 320) cases. Our analysis showed that Gram negative bacterial infection still plays a significant role in neonatal death. Deciphering the route of these infections in early days of life and development of appropriate preventive and therapeutic measures will reduce neonatal death in low- and middle-income countries.

#### INITIAL VALIDATION OF A NOVEL RECOMBINASE POLYMERASE AMPLIFICATION-LATERAL FLOW ASSAY FOR DIAGNOSIS OF HUMAN BRUCELLOSIS

Clark H. Cunningham<sup>1</sup>, Osahon Iyamu<sup>2</sup>, Elise King<sup>2</sup>, Ross M. Boyce<sup>1</sup>, Jonathan J. Juliano<sup>1</sup>, Emily J. Ciccone<sup>1</sup>

<sup>1</sup>University of North Carolina School of Medicine, Chapel Hill, NC, United States, <sup>2</sup>University of North Carolina, Chapel Hill, NC, United States

Brucellosis is a common zoonotic disease that is endemic in most parts of the world and disproportionately affects rural and resource-limited settings. *Brucella* spp. are highly contagious and can be transmitted to humans through contact with fluids from infected animals, inhalation of aerosolized particles, or consumption of unpasteurized milk and cheese. The diagnosis of human brucellosis is usually made by serologic tests, which are often qualitative, do not differentiate between acute and chronic infection, and can cross react with other bacteria, causing false positives. These issues lead to both over and under-diagnosis of brucellosis and, in turn, inappropriate or inadequate antibiotic treatment. To address the need for new diagnostic tools that can be used at peripheral health facilities in resource-constrained settings, we developed a real-time Recombinase Polymerase Amplification (RPA)-based diagnostic assay for brucellosis that is performed isothermally at 37°C in under 30 minutes and adapted it to a lateral-flow (LF) detection platform. We selected *bcspp31* as the gene target, which encodes for a surface membrane protein that is conserved across *Brucella* spp. The RPA-LF assay detected genomic DNA (BEI Resources, Manassas, VA) from the following *Brucella* spp: *Brucella suis* biovar 1, *Brucella suis* biovar 2, *Brucella abortus* biotype 4, *Brucella abortus* biotype 9, *Brucella abortus* RB51, and *Brucella melitensis* biotype 1. We also performed serial dilutions of *Brucella abortus* biovar 4, and the assay demonstrated high sensitivity with an estimated lower limit of detection of 1.37 genomes by probit analysis. The assay did not detect bacteria known to at times cross-react with existing serologic assays (*Escherichia coli*, *Ehrlichia chaffeensis*, *Yersinia enterocolitica*, and *Francisella tularensis*). In conclusion, preliminary experiments indicate that an RPA-LF assay targeting the *bcspp31* gene is sensitive and specific for detection of genomic DNA from *Brucella* spp. in a laboratory setting. Further evaluation with clinical specimens in real-world contexts is planned.

1326

### HIGH RESOLUTION METABOLOMICS HIGHLIGHTS DIFFERENCES IN LIPID AND NUTRITIONAL METABOLISM ACROSS THE LEPROSY SPECTRUM PROVIDING AVENUES FOR ADVANCES IN LEPROSY HOST-PATHOGEN RESEARCH

Jessica K. Fairley<sup>1</sup>, José A. Ferreira<sup>2</sup>, Thomas R. Ziegler<sup>1</sup>, Dean P. Jones<sup>1</sup>, Lucia A. Fraga<sup>3</sup>, ViLinh T. Ly<sup>1</sup>, Sandra Lyon<sup>2</sup>, Jeffrey M. Collins<sup>1</sup>

<sup>1</sup>Emory University School of Medicine, Atlanta, GA, United States, <sup>2</sup>Faculdade da Saúde e Ecologia Humana, Vespasiano, Brazil, <sup>3</sup>Universidade Federal de Juiz de Fora-Campus GV, Governador Valadares, Brazil

High resolution metabolomics (HRM) has led to better understanding of host-pathogen interactions of various infectious diseases but has rarely been used in leprosy research. Thousands of small molecules from endogenous metabolism, diet, the environment, medications, the microbiome and from infectious pathogens themselves can be detected through HRM and advanced data extraction. Our objectives were to identify unique metabolic signatures related to leprosy and to increase our understanding of associated nutrient metabolism. Between June 2018 and December 2019, adults newly diagnosed with leprosy and healthy controls were recruited from leprosy referral clinics in Minas Gerais, Brazil. Plasma samples were drawn, frozen, and shipped to the Clinical Biomarker Laboratory at Emory University. Metabolites were detected using an established HRM platform and characterized by accurate mass *m/z* and retention time. The Mummichog informatics package was used to compare metabolic pathway activity between groups. Additionally, select individual metabolites were quantified and compared between groups. All analyses controlled for age and sex. Sixty-seven individuals with leprosy were enrolled of which 26 (62% of cases) were multibacillary (MB), 16 were paucibacillary (PB), and 25 were controls (including 16 household contacts). Exploratory analysis of metabolic pathways showed several statistically significant differences between groups: arachidonic acid metabolism between cases vs controls ( $p = 0.01$ ); vitamin E ( $p=0.007$ ) and retinol metabolism ( $p=0.04$ ) between cases and controls; and vitamin D3 metabolism between MB and PB ( $p=0.004$ ). In addition, plasma tryptophan concentrations were lower in MB vs PB, consistent with an increase in catabolism by indoleamine-2,3-dioxygenase. These metabolic signatures provide insight into leprosy host-pathogen interactions that will improve our understanding of the pathophysiology of infection that could lead to improved diagnostics and therapeutics. HRM is, thus, an innovative tool for a neglected pathogen and these preliminary data provide a foundation for a wide range of future studies.

### METAPROTEOMIC ANALYSIS OF HUMAN BRONCHOALVEOLAR LAVAGE FLUID REVEALS MICROBIOMES ASSOCIATED WITH SUSCEPTIBILITY AND PROTECTION AGAINST TB INFECTION

Javan Ochieng Okendo, Clemens Hermann, Nicola Mulder, Jonathan Blackburn

University of Cape Town, Cape Town, South Africa

The human lung metaproteomic profile has been extensively studied in individuals having pulmonary TB, and the main biospecimen that is widely used is the human sputum. The sputum microbiota composition does not reflect the microbiota composition in the lower respiratory tract, which the human BALF can reveal. To the best of our understanding, no study has investigated the metaproteomic profile of individuals with a broad spectrum of TB infection following the lung challenge with the live BCG and PPD antigens. The individuals were divided into two cohorts: protective phenotypes (LTB,  $n=75$  & SIM,  $n=33$ ) and susceptible phenotypes (RTB,  $n=33$ , & PTB,  $n=69$ ). BALF samples were analyzed using Q-Exactive tandem mass spectrometry. The bioinformatics workflow involved the construction of the samples specific database using the MetaLab version 2.0 pipeline. MSFregger version 3.1.1 was used for the target-decoy sequence database search. The identified peptides were

analyzed using UniPept for taxonomic classifications. The human BALF's microbiota composition following lung challenge with the live BCG and PPD was mainly composed of the Phylum, *Firmicutes*, *Bacteroidetes*, *proteobacteria*, *Actinobacteria*, *Fusobacteria*, *Spirochaetes*, and *Synergistetes*. RTB cohort has a less diverse phylum composition, and the LTB cohort had a diverse phylum composition. There was a significant reduction in the short-chain fatty acid (SCFA) producers in the RTB cohort compared with the PTB, LTB, and SIM at the genera level. The bacteria composition of the SIM and LTB were characterized by the high abundance of the SCFA producers. This research shows that the protection of TB depends on the abundance of SCFA producers in the human lungs. These findings will help the vaccine developers as it emerges that the commensal bacteria's function should be considered when developing the vaccines. It also increases our understanding of the Correlation of protection and susceptibility to TB infection in humans.

### PROSTAGLANDIN E2 SIGNALING REGULATES OENOCTOYD IMMUNE FUNCTION THAT IS ESSENTIAL FOR ESTABLISHING ANOPHELES GAMBIAE INNATE IMMUNITY

Hyeogsun Kwon, David R. Hall, Ryan C. Smith

Iowa State University, Ames, IA, United States

Bioactive fatty acids such as prostaglandin E2 (PGE2) and its cognate prostaglandin receptors play pivotal roles in mediating immune and inflammatory processes across species. While prostaglandin signaling has previously been implicated in mosquito anti-*Plasmodium* and anti-viral immunity, the receptor(s) responsible for mosquito prostaglandin signaling have not been characterized. Here, we identify a PGE2 receptor (*AgPGE2R*) in *Anopheles gambiae* and demonstrate that its expression is most abundant in specialized mosquito immune cell populations known as oenocytoids. Through the administration of PGE2 and *AgPGE2R*-silencing, we demonstrate that prostaglandin signaling regulates a subset of prophenoloxidasases (PPOs) and antimicrobial peptides (AMPs) that significantly limit bacterial replication and *Plasmodium* oocyst survival. Additional experiments demonstrate that PGE2 signaling is essential to the late-phase immune response through the regulation of *PPO1* and *PPO3* expression to promote oocyst killing. We also provide evidence that PGE2 signaling induces oenocytoid cell rupture at high PGE2 concentrations and demonstrate that oenocytoid cell lysis prior to *Plasmodium* infection negates the antagonistic effects of PGE2 signaling on parasite survival. Together, these results provide new mechanistic insights into the influence of prostaglandin signaling on oenocytoid function that promotes pathogen killing in the mosquito host.

### INVESTIGATING THE ENERGETIC COSTS OF INSECTICIDE-RESISTANCE IN CALIFORNIA Aedes Aegypti

Erin Taylor Kelly, Geoffrey M. Attardo

UC Davis, Davis, CA, United States

We collected 12 pools of 10 adult female *Aedes aegypti* from two colonies to investigate differences in the physiology of a laboratory strain (ROCK) and a colony derived from the Central Valley of California (CLOVIS) with high-throughput metabolomics. This technique offers a snapshot of the insects metabolome, and can reveal different levels of metabolic activity and demands on metabolic pathways. Samples were processed by the UC Davis Metabolomics center which provided data on the abundance of primary metabolites, lipids, and biogenic amines. We analyzed the data in Metaboanalyst, and observed these two groups had markedly different metabolomes. The CLOVIS metabolome had evidence of significantly elevated glucose metabolism, elevated pentose phosphate pathway activity, and lower amounts of storage lipids. This led us to speculate some of these differences may be attributable, in part, to the energetic costs of maintaining metabolic mechanisms of pyrethroid insecticide resistance. The ROCK group is fully susceptible to commonly used pyrethroid insecticides, while CLOVIS has both target site and metabolic

mechanisms of resistance to pyrethroid insecticides. These findings imply that the maintenance of metabolic mechanisms of resistance are costly, and may come at the expense of energy storage, which may help explain observations of reduced lifespan, fecundity, and adult body size in pyrethroid resistant insects. We predict these features may leave these resistant insects more susceptible to inhibitors that interact with pathways experiencing increased demand, and plan to evaluate inhibitors which interact with the pentose phosphate pathway and insect lipid metabolism as novel products for mosquito control.

### CHARACTERIZATION OF ANOPHELES CHAPERONIN COMPLEX PREFOLDIN: A POTENTIAL BROAD-SPECTRUM PLASMODIUM BLOCKING TARGET IN ANOPHELINE MOSQUITOES

**Yuemei Dong**, Seokyoung Kang, Simone Sandiford, Purnima Ravisankar, Shengzhang Dong, Andrew Pike, George Dimopoulos

*Johns Hopkins School of Public Health, Malaria Research Institute, Baltimore, MD, United States*

*Plasmodium* relies on numerous mosquito-derived host factors, when engaging its intimate interactions with the vector's midgut, hemolymph, and salivary glands. We have identified prefoldin subunit 6 (PFDN6) as a potent agonist host factor for *Plasmodium* infection. The evolutionarily conserved eukaryotic prefoldin (PFD) is a chaperone protein that acts as a heterohexameric complex and aids in the assembly of microtubules and microfilaments. Through CRISPR/Cas9-mediated gene editing we have confirmed the essential biological function of PFDN6; especially in the absence of PFDN6, mosquitoes have shown pre-adult (embryonic and larval stages) lethality due to the lack of properly assembled actin. RNAi-mediated gene silencing of *Pfdn6* (as well as any of the other five subunit genes (*Pfdn1-5*) silenced individually or in combinations) suggests PFD works as a heteromultimeric protein complex, in association with its known partner CCT/TRiC, when fulfilling its agonist function for *Plasmodium*; furthermore the same function of PFDN6 was validated through CRISPR/Cas9-based conditional knockout of *Pfdn6* in the midgut. An interactome study based on co-immunoprecipitation has identified several interacting partners with PFDN6, including Tep15, LRIM 26, Enolase, and several cytoskeletal proteins. Enolase has shown similar function as PFD through RNAi- and CRISPR/Cas9- based studies. Interestingly, different species of anopheline mosquitoes (*A. gambiae*, *A. stephensi*, and *A. dirus*) co-fed with the polyclonal PFDN6 antibodies and *P. falciparum* or *P. vivax* gametocytes infected blood resulted in significant lower parasites loads in the mosquito midguts and salivary glands, suggesting its broad-spectrum *Plasmodium* agonist function in a variety of mosquito vectors. A preliminary transmission-blocking vaccine (TBV) assay based on a mouse model system showed the same phenotypes, further suggesting PFD as a powerful candidate for the development of TBV targeting various malaria parasites in the major vectors. Finally, through several approaches we have elucidated a potential mechanism of the PFD's role as a host factor.

1331

### THE ROLE OF MOSQUITO SALIVA IN THE ACTIVATION OF FIBRINOLYSIS

**Zarna Rajeshkumar Pala**, Thiago L. Alves E Silva, Paola Carolina Valenzuela Leon, Ines Martin-Martin, Eric Calvo, Joel Vega-Rodriguez

*National Institutes of Health, Rockville, MD, United States*

Malaria parasites undergo two severe bottlenecks during the sexual reproduction in the mosquito midgut and during sporozoite infection of the human. To overcome these bottlenecks *Plasmodium* parasites can co-opt host proteins to enhance infectivity. Our laboratory has shown that malaria parasites hijack the fibrinolytic system to facilitate infection of both, the mosquito vector and the vertebrate host. Plasminogen, the key

molecule of the fibrinolytic system, is activated into the serine protease plasmin by tissue-type (t-PA) and urokinase-type (u-PA) plasminogen activator. It has been shown that mosquito saliva injected in the dermis of a human or ingested by the mosquito during blood feeding, can alter hemostatic responses. To determine how mosquito saliva plays a role in the activation of the fibrinolytic system, we established a fluorescence-based biochemical assay to detect Plasminogen and t-PA activation by saliva or salivary gland (SG) extracts. We detect activation of t-PA in the presence of mosquito SG extract or saliva when compared to the control (SG extract or saliva without t-PA). Plasminogen was not activated when incubated with saliva. Activation of t-PA was lost when the saliva was pre-incubated at 65 °C or 100 °C, and Western blot analysis shows that saliva induces cleavage of inactive single-chain t-PA into the active two-chain form, pointing that the t-PA activator is a protease. To identify the saliva t-PA activator, we fractionated SG extracts by size-exclusion chromatography and identified a fraction which activated t-PA. Mass-spectrometry analysis of the active fraction identified eight proteins as potential t-PA activators. We are currently characterizing the identified SG proteins for activation of t-PA. Studying the interaction between the mosquito saliva, the mammalian fibrinolytic system and the malaria parasite could lay the foundation for the development of new malaria intervention strategies.

1332

### MOSQUITO LIPOGENIC AND LIPOLYTIC PATHWAYS ARE CRITICAL METABOLIC CHECKPOINTS FOR ANOPHELES REPRODUCTION AND PLASMODIUM TRANSMISSION

**Maurice A. Itoe**<sup>1</sup>, Kristine Werling<sup>2</sup>, Robert W. Shaw<sup>1</sup>, Amy Deik<sup>3</sup>, Clary Clish<sup>3</sup>, Flaminia Catteruccia<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States,

<sup>2</sup>Pennsylvania State University, State College, PA, United States, <sup>3</sup>Broad Institute of Harvard and MIT, Cambridge, MA, United States

Female *Anopheles* mosquitoes require several blood meals during their life span to initiate multiple cycles of egg development, and these obligatory steps are exploited by *Plasmodium* parasites for their own transmission. Blood feeding is therefore a critical step for both mosquito reproduction and parasite transmission that could be exploited to impact malaria dynamics in endemic areas. Here, we elucidated the specific role of blood meal-derived lipids (and/or of lipids synthesized *de novo* after a blood meal) in *Anopheles gambiae* reproduction and *Plasmodium falciparum* development in mosquito stages. Initial targeted lipidomic analyses revealed a coordinated accumulation and depletion of major lipid classes across key mosquito tissues during blood meal digestion, reflective of an engagement of lipogenic and lipolytic pathways. RNA interference (RNAi) against triglyceride (TAG) lipase 2 (TL2) and associated proteins, involved in lipolytic breakdown of TAGs to yield free fatty acids and diacylglycerol (DAG), significantly impairs egg development and abolishes fertility. TL2-depleted females have impaired lipid mobilization from midgut and fat body, possibly responsible for the increase in *P. falciparum* growth rates observed in these conditions. Additionally, RNAi inhibition of fatty acid synthase (FAS), the rate limiting enzyme in *de novo* fatty acid synthesis, completely abrogates egg development and *P. falciparum* infection. Altogether, this study identifies both mosquito lipogenic and lipolytic pathways as critical metabolic checkpoints for mosquito reproduction and parasite development, providing new targets for the control of malaria transmission.

1333

### CTL4 CONTROLS TEP1-INDEPENDENT MELANIZATION OF HUMAN MALARIA PARASITES

**Maria L Simoes**, Yuemei Dong, Godfree Mlambo, George Dimopoulos

*Johns Hopkins University, Baltimore, MD, United States*

Melanization is one of the most effective innate defense mechanisms in mosquito vectors. Numerous studies have shown that the *Anopheles* TEP1-controlled complement-like system is essential for melanization of

the rodent model malaria parasite *Plasmodium berghei*, which evades this defense by recruiting C-type lectins. But the role of TEP1 has not been sufficiently addressed in the context of malaria infection with the clinically relevant human malaria parasite, *Plasmodium falciparum*. Using CRISPR/Cas9 genome editing, we show that the melanization of *P. falciparum* is independent of the TEP1-controlled complement-like system, and a small proportion of *P. falciparum* ookinetes are capable of evading this defense mechanism in the midgut tissue of CTL4<sup>null</sup> mosquitoes, in contrast to the complete melanization of rodent *P. berghei*. Furthermore, we discovered that the major anti-*Plasmodium* pathway Imd does not influence *Plasmodium* melanization. Our study proves CTL4 as one of the most potent malaria transmission-blocking targets.

1334

### A LABRUM-INTERACTING PROTEIN CONTROLS PROBING IN AEDES MOSQUITOES

Irene Arnoldi<sup>1</sup>, Giulia Mancini<sup>2</sup>, Marco Fumagalli<sup>2</sup>, Luigi Scietti<sup>2</sup>, Federico Forneris<sup>2</sup>, **Paolo Gabrieli**<sup>3</sup>

<sup>1</sup>IUSS, Pavia, Italy, <sup>2</sup>University of Pavia, Pavia, Italy, <sup>3</sup>University of Milan, Milan, Italy

We demonstrate that the Labrum-Interacting Protein-2 (LIPS-2) from the saliva of *Aedes albopictus* females binds a cuticular protein located at the tip of the labrum, regulating the probing phase during the piercing of a vertebrate skin. LIPS-2 is a protein with orthologs found only in species belonging to the subfamily Culicinae and we show that it is characterized by a novel folding topology. Contrary to most mosquito saliva proteins characterized so far, the experimentally-determined structural model of the protein suggests that it lacks any evident enzymatic activity or pockets for small molecule binding. Knocking down the expression of this gene via RNA interference prolongs probing time, while the purified recombinant protein stimulates female mosquitoes to display probing movements. The fluorescently-labeled protein binds to the tip of the labrum at the stylet fascicle forming the food channel. Pre-treatment of the labrum with trypsin causes a remarkable loss of fluorescent signal, suggesting the presence of a protein interactor. Searching for possible interacting proteins, we used a yeast-two-hybrid approach. We built the screening library using mRNA extracted from labra formed mostly within 8 hours from pupation, as highlighted by X-ray tomography analysis of labrum development. From the screening, we identified a cuticular protein as a possible interactor of LIPS-2. Immunofluorescence assays using specific antibodies localized this cuticular protein at the tip of female mosquito proboscis. We further confirmed the interaction between LIPS-2 and its interactor using biochemical and molecular assays. Taken together, our results widen our understanding of the molecular interactions occurring at the site of a mosquito bite, paving the way for the development of strategies to block or to inhibit it. This has major implication considering that the mosquito-borne pathogens are transferred to the vertebrate host together with the insect saliva.

1335

### EVALUATION OF SAFETY AND EFFICACY OF NEW WORLD LEISHMANIA MEXICANA CENTRIN GENE DELETED (LMEXCEN-/-) LIVE ATTENUATED PARASITES AS A PROPHYLACTIC VACCINE AGAINST VISCERAL LEISHMANIASIS

Subir Karmakar<sup>1</sup>, Nevien Ismail<sup>1</sup>, Wenwei Zhang<sup>2</sup>, Oliveira Fabiano<sup>3</sup>, Greta Volpedo<sup>4</sup>, Shinjiro Hamano<sup>5</sup>, Greg Matlashewski<sup>6</sup>, Shaden Kamhawi<sup>3</sup>, Jesus Valenzuela<sup>3</sup>, Abhay Satoskar<sup>4</sup>, **Ranadhir Dey**<sup>1</sup>, Hira Nakhasi<sup>1</sup>

<sup>1</sup>CBER/FDA, Silver Spring, MD, United States, <sup>2</sup>McGill University, Montreal, QC, Canada, <sup>3</sup>NIAID/NIH, Twinbrook, MD, United States, <sup>4</sup>Ohio State University, Columbus, OH, United States, <sup>5</sup>Nagasaki University, Nagasaki, Japan, <sup>6</sup>McGill University, Montreal, QC, Canada

Leishmaniasis is a vector-borne parasitic disease afflicting millions of peoples worldwide. To date there is no licensed vaccine available

against human leishmaniasis. It has been shown that infection with a low dose of dermatropic wild type *Leishmania major* confers protection against cutaneous leishmaniasis (CL) and cross-protects against visceral leishmaniasis (VL). However, such a method of immunization is not practical because of a greater risk of complications in a naïve population. Therefore, genetically modified live attenuated parasites that are non-pathogenic might induce the same protective immunity as leishmanization. Previously, we have demonstrated that immunization with Old World *Leishmania major* lacking the centrin gene can protect against CL and VL. In this study we have explored whether deleting the centrin gene using CRISPR-Cas methodology in *Leishmania mexicana* (*LmexCen-/-*), a new world *Leishmania* sp., is safe, immunogenic as well as efficacious against heterologous challenge with *L. donovani* in the hamster model. Intradermal immunization of hamsters with *LmexCen-/-* did not produce detectable lesions, while wild type *L. mexicana* parasites induced severe pathology. Upon immunization, *LmexCen-/-* induced proinflammatory IFN- $\gamma$  as measured by RTPCR in splenocytes. Seven weeks post-immunization hamsters were infected with *L. donovani* by either needle injection or by infected sand flies. In both cases, ten months post-challenge, non-immunized hamsters developed severe hepatosplenomegaly of VL, while immunized hamsters survived and showed no signs of VL pathology. Additionally, immunized hamsters had a significantly lower parasite burden in the liver and spleen compared to non-immunized animals. Our studies demonstrate that the *LmexCen-/-* mutant parasite is safe and has a potential to be an effective vaccine against VL.

1336

### IN SILICO IDENTIFICATION OF PEPTIDES THAT INTERACT WITH HLA-DRB1 ALLELES ASSOCIATED WITH CHAGAS DISEASE CARDIOMYOPATHY

**Thaiany Goulart Silva**<sup>1</sup>, Guilherme Ferreira Evangelista<sup>2</sup>, Kenneth John Gollob<sup>2</sup>, Walderez Ornelas Dutra<sup>1</sup>

<sup>1</sup>Federal University of Minas Gerais, Belo Horizonte, Brazil, <sup>2</sup>AC Camargo Cancer Center, Sao Paulo, Brazil

Our group has shown that more than 60% of Chagas heart disease patients present at least one HLA-DRB1 allele (\*0103, \*0402, \*1301 and \*1302) expressing the DERAA epitope, which may be associated with susceptibility to Chagas disease cardiomyopathy. The objective of this work was to identify peptides from the parasite and from the human host that may be recognized by the \*0103, \*0402, \*1301 and \*1302 alleles of HLA-DRB1. Immune Epitope Database tool was used to identify potential antigens that bind to these HLA-DRB1 alleles, while NetMHCIIpan 2.3 was used to determine potential epitopes and to predict peptide-HLA binding affinity. The HPEPDOCK server and Pymol software were used for peptide-HLA-II docking. Our initial analysis showed that no peptide from the parasite was recognized by these HLA-DRB1 alleles. However, we found that antigens from the host immune system such as immunoglobulins and antigens from the HLA system were recognized by these alleles. In addition, peptides from vimentin, enolase, cathepsin S, collagen and myelin basic protein were potentially recognizable by these alleles. Interestingly, all immunoglobulin-derived putative peptides showed homology with parasite proteins related to escape mechanisms, and proteins crucial for the maintenance and replication of *T. cruzi*. In general, these antigens had a higher binding affinity to the HLA-DRB1 \*13 gene. In addition, using a database of cardiac tissue transcripts from patients with Chagas cardiomyopathy, we observed that mRNA for vimentin, cathepsin S, HLA-DRA and COL2A1 were up-regulated in heart from Chagas cardiomyopathy patients, but not in idiopathic heart disease, which suggests that these changes are intrinsic to Chagas disease. Determine the nature of the parasite antigen, especially those with high homology to self-antigens with the potential to induce cross-reactivity, and determine the nature of the HLA-DRB1 molecule that selects a dominant motif, can assist in monitoring patients at potential risk of developing Chagas heart disease, as well as identify potential targets for alternative immunotherapy for human Chagas disease.

### REVEALING THE LOCATION AND CONFIRMING THE PRESENCE OF Tc24 IN DIFFERENT PARASITIC LIFE STAGES OF TRYPANOSOMA CRUZI

Leroy Versteeg<sup>1</sup>, Rakesh Adhikari<sup>1</sup>, Cristina Poveda<sup>1</sup>, Maria Jose Villar-Dragon<sup>1</sup>, Kathryn Jones<sup>1</sup>, Peter Hotez<sup>1</sup>, Maria Elena Bottazzi<sup>1</sup>, Edwin Tijhaar<sup>2</sup>, Jeroen Pollet<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Wageningen University, Wageningen, Netherlands

Different studies have shown that Tc24-C4, a recombinant version of the flagellar calcium-binding protein of *T. cruzi*, has excellent potential as a therapeutic vaccine candidate to prevent Chagas Disease, showing reduced parasitemia and cardiac inflammation in animal models. Here, we report new findings made with the novel monoclonal antibody (mAb) Tc24-C4/884 raised against Tc24-C4. The antibody, which recognizes recombinant Tc24-C4, wild type Tc24 (Tc24-WT) and native Tc24 from *T. cruzi*, appeared to be very well suited to localize native Tc24 in *Trypanosoma cruzi* by different imaging techniques. Surprisingly, when using fluorescent confocal microscopy to detect binding of Tc24-C4/884 to native Tc24 in *T. cruzi* trypomastigotes, we observed that Tc24 is mostly intracellular, which contradicts the hypothesis made by previous studies that stated that Tc24 is a surface-exposed antigen. Consequently, antibody-mediated immune responses against Tc24 cannot opsonize the parasites or induce antibody-mediated lysis of *T. cruzi*. Further research using imaging flow cytometry showed that the expression of Tc24 decreases significantly when *T. cruzi* trypomastigotes enter host cells and transform into amastigotes. As part of the flagellum, Tc24 will likely be one of the proteins discarded by the parasite upon host cell internalization, then processed and presented on the MHC-I of infected cells. The cellular response against Tc24 may therefore be a more important part of the mechanism of Tc24-C4 as a vaccine candidate.

### COMPARISON OF FUNCTIONAL CHARACTERISTICS OF CD4+ AND CD8+ T-CELLS IN CHAGAS DISEASES CARDIOMYOPATHY AND IDIOPATHIC HEART DISEASES AND THEIR ASSOCIATION WITH PATHOLOGY

Eula Graciele Amorim Neves, Carolina Cattoni Koh, Ana Carolina Carvalho Silva, Thaiany Goulart de Souza Silva, Teresiamia Velikkakam, Maria do Carmo Pereira Nunes, Walderez Ornelas Dutra

Federal University of Minas Gerais, Belo Horizonte-Minas Gerais, Brazil

Chronic Chagas cardiomyopathy (CCC) is the most severe form of Chagas disease, caused by infection with *Trypanosoma cruzi*. While T cells are critical in mediating cardiac pathology in CCC, whether the mechanisms underlying CCC pathology are exclusive of Chagas disease or play a role in other heart diseases is not defined. We sought to study the involvement of potentially cytotoxic CD4+ and CD8+ T cells in CCC or in idiopathic cardiopathies (ID). We evaluated the expression of cytokines and their receptors, cytotoxic molecules, and those associated with cellular recruitment to the heart in circulating CD4+ and CD8+ cells from CCC and ID patients using multiparameter flow cytometry, combined with conventional and unsupervised machine-learning strategies. We also used an *in-silico* approach to evaluate the expression of genes that code for key molecules related to CD4 and CD8 function in CCC and ID. Our data demonstrated an increased frequency of expression of IFN- $\gamma$ , TNFR1, IL-17, IL-10 by CD8+ T cells in CCC as compared to ID. Analysis of TNFR1/IL10R ratio suggested a predominantly inflammatory profile in CD8+ T cells from CCC. These cells expressed higher frequency of CCR5 and c-MET in CCC, which have been associated with cardiotropism. *In silico* analysis of gene transcripts in the cardiac tissue demonstrated up-regulation of CD8+, IFN- $\gamma$ , perforin, granzyme A, CCR5, and its ligands CCL3, CCL4 and CCL5 in CCC. There was an increased frequency of TNFR1 in circulating CD4+ T cells from ID, than CCC. These cells expressed CCR4 and CXCR3, and the frequency of CD4+IFN- $\gamma$  cells was positively correlated with

CD4+CXCR3+CCR4+ cells in ID. Our data shows that circulating CD8+ T cells from CCC display inflammatory and cytotoxic potential and that the molecules that define those functions are also upregulated in the heart of CCC, suggesting that CD8+ T cells mediate the continuous inflammatory response in CCC. In contrast, CD4+ T cells seem to be the principal agents involved with pathology in ID. These data show the involvement of distinct T cell populations and their functions in CCC and ID, which may contribute to identify specific immunotherapeutic targets.

### TOLL LIKE RECEPTOR-9 (TLR-9) SIGNALING PLAYS AN IMPORTANT ROLE IN LIVE ATTENUATED LEISHMANIA VACCINE INDUCED PROTECTIVE IMMUNITY

Parna Bhattacharya, Nevien Ismail, Sreenivas Gannavaram, Ranadhir Dey, Hira L. Nakhasi

FDA, Silver Spring, MD, United States

Visceral leishmaniasis (VL), is a vector-borne zoonotic disease with no available vaccine. Recently, we have demonstrated the protective role of live attenuated centrin gene-deleted *Leishmania donovani* (*LdCen*<sup>-/-</sup>) parasite vaccine by induction of strong innate immunity in animal models. Innate responses during VL contribute in parasite control and help in the development of efficient adaptive responses. Amongst those, Toll-like receptors (TLRs), present mainly on the surface of the innate cells, play a crucial role in the initial steps of *Leishmania* infection. Although several studies have shown the importance of TLRs, the role of TLRs in the development of a specific response to a live attenuated *Leishmania* vaccine is not known. Hence, we analyzed the role of TLRs during *LdCen*<sup>-/-</sup> infection and compared with wild type *L. donovani* (*LdWT*) infection both *in vitro* and *in vivo*. We found that *LdCen*<sup>-/-</sup> infection significantly upregulates TLR-9 expression on dendritic cells (DCs), along with concomitant downregulation of TLR-2 expression, compared to *LdWT* infection both *in vitro* and *in vivo*. Additionally, we found that *LdCen*<sup>-/-</sup> infection activates TLR-9 mediated downstream signaling in DCs, facilitating active nuclear translocation of nuclear factor  $\kappa$ B. These events culminated in up-regulation of the DC's proinflammatory response, activation and DC mediated CD4+T cell proliferation which was abrogated by treatment with TLR9-specific small interfering RNA. Importantly, TLR-9 silencing in *LdCen*<sup>-/-</sup> infected DCs significantly increased the expression of TLR-2 and the frequency of IL-10 associated disease promoting nTreg and Tr1 cells. This study demonstrates that TLR9 mediated antagonistic regulation of TLR-2 pathway, and concomitant induction of DC activation, plays a crucial role in shaping the *LdCen*<sup>-/-</sup> vaccine induced host protective immune response.

### ENDOGENOUS NEUTROPHIL ACTIVATION IN SUBCLINICAL LEISHMANIA BRAZILIENSIS INFECTION

Jacilara Conceicao<sup>1</sup>, Pedro Carneiro<sup>2</sup>, Andreza Dórea<sup>2</sup>, Walker Nonato<sup>2</sup>, Aline Muniz<sup>2</sup>, Ednaldo Lago<sup>2</sup>, Edgar Carvalho<sup>3</sup>, Mary Wilson<sup>1</sup>, Olívia Bacellar<sup>2</sup>

<sup>1</sup>University of Iowa, Iowa City, IA, United States, <sup>2</sup>Immunology Service, Federal University of Bahia, Salvador, Brazil, <sup>3</sup>Gonçalo Moniz Research Center - Fiocruz Bahia, Salvador, Brazil

Individuals with subclinical (SC) *L. braziliensis* infection in Corte de Pedra, Brazil, are characterized by positive leishmania skin test and/or high production of IFN- $\gamma$  specific to leishmania antigen, in the absence of clinical symptoms. We previously demonstrated that innate immune response contributes to protective immunity in SC. We also showed that neutrophils cooperate to the immunopathogenesis of CL and this phenotype is altered after treatment and cure. We hypothesized that neutrophils from SC individuals display a distinct profile and contribute to immune protection against CL. Neutrophils were isolated from peripheral blood of SC and CL individuals, infected with *L. braziliensis*, stained and evaluated by light microscopy. Additionally, whole blood samples from both groups were stained with antibodies to CD15, CD62L, CD66b, TLR2,

TLR4 and HLA, and assessed by flow cytometry. The oxidative capacity of infected neutrophils was also measured by flow cytometry with CM-H2DCFDA usage. Our results show that the percentage of neutrophils infected, and the total numbers of parasites phagocytosed were lower in neutrophils from SC compared to CL patients. Despite generating greater amounts of ROS, the percentage of infection and parasite burden in CL neutrophils increased over time. SC neutrophils displayed lower amounts of CD62L and trended toward higher expression of CD66b, TLR2 and TLR4 in comparison to CL neutrophils, consistent with a more activated state. In contrast, CL neutrophils showed higher expression of HLA. In summary, neutrophils from SC individuals had a more activated phenotype than CL patients and were less permissive to infection with *L. braziliensis*. Unexpectedly, there was a dissociation between ROS production and parasite killing by CL neutrophils. The expression of HLA on CL neutrophils raises the possibility that cells of the DC-neutrophil hybrid phenotype might play a role in the immunopathogenesis of CL. Whether the observed neutrophil diversity correlates with or drives the outcome of *L. braziliensis* infection is of prime importance in understanding the host protective versus exacerbating response in CL.

### CROSSTALK BETWEEN MYELOID CELLS AND CD4 AND CD8 T CELLS IN THE CONTEXT OF IMMUNE EXHAUSTION

**Diogo Valadares**

*University of Iowa, Iowa City, IA, United States*

Leishmaniasis is a chronic disease of reticuloendothelial organs that is usually controlled by TH1-type CD4 T cells. Anti-microbicidal responses are ineffective during disease progression, and it is reported that T cells in humans and dogs with visceral leishmaniasis (VL) express markers of cell exhaustion. We hypothesized that myeloid cells provide counter-receptors for inhibitory receptors on T cells at the local sites of *Leishmania infantum* infection, inhibiting T cell effector functions. In a BL6 mice model of *L. infantum* infection, DCs (CD11b+CD11c+Ly6G<sup>low</sup>Ly6GC+MHCII+) from infected mice demonstrated an exhausted profile with increased surface expression of inhibitory receptors (IRs) as PDL1, Gal 9, increased secretion of IL-10 and lower surface expression CCR7. Those cells also revealed a dysfunctional state with lower antigen processing and phagocytosis ability, comparing with cells from health animals. Sorted and *L. infantum* mCherry transfectants infected DCs, presented similar dysfunctional phenotype of DCs from infected mice. Antigen experienced (CD49+ CD11a+) CD4 and CD8 T cells presented a Tex like profile with increased surface expression of IRs, such as PD1, TIM3 and a shift for secretion of IL-10. Surprisingly naïve (CD49- CD11a-) and low activated (CD49+ CD11a<sup>low</sup>) CD4 and CD8 T cells also revealed markers of Tex phenotype in infected animals. Disruption of pro-exhaustion interaction between DCs and Tex using blocking antibodies (@PDL1, @TIM3 or @Galelectin 9) ameliorated balance between IL-12 and IL-10 secretion by DCs, but also increased T cell expansion, induced a cytokine profile to a resistant pattern with increased IFN-g and reduced IL-10. In treated cultures, blockade strategies cited above also increased surface markers of memory like cells (CD49d, CD11a, CD45RO). In vertical transmitted dogs with canine leishmaniasis, clinical score correlates with number of CD14+PDL1+ cells in several tissues as liver, spleen and bone marrow. Data suggests that *L. infantum* parasites may benefit from pro-exhaustion crosstalk between myeloid cells and T cells to evade immune mechanisms of infection control.

### NUTRITIONAL SUPPLEMENTATION COST-EFFECTIVELY DECREASES TUBERCULOSIS INCIDENCE AND MORTALITY IN INDIA: THE RATION OPTIMIZATION TO IMPEDE TUBERCULOSIS MODEL

**Pranay Sinha**<sup>1</sup>, Subitha L. Lakshminaryanan<sup>2</sup>, Chelsie Cintron<sup>1</sup>, Prakash B. Narasimhan<sup>2</sup>, Lindsey M. Locks<sup>3</sup>, Nalin Kulatilaka<sup>4</sup>, Kimberly Maloomian<sup>5</sup>, Senbagavalli P. Babu<sup>2</sup>, Madeline E. Carwile<sup>1</sup>, Anne F. Liu<sup>6</sup>, C. <sup>1</sup>*Boston Medical Center, Boston, MA, United States*, <sup>2</sup>*Jawaharlal Institute for Postgraduate Medical Education and Research, Puducherry, India*, <sup>3</sup>*Boston University College of Health & Rehabilitation Sciences, Boston, MA, United States*, <sup>4</sup>*Boston University Questrom School of Business, Boston, MA, United States*, <sup>5</sup>*Kimba's Kitchen, West Palm Beach, FL, United States*, <sup>6</sup>*Brigham and Women's Hospital, Boston, MA, United States*, <sup>7</sup>*Boston University School of Public Health, Boston, MA, United States*

Undernutrition is the leading risk factor for tuberculosis (TB) in India and is associated with increased TB incidence, severity, and mortality. Through mathematical modeling, we wanted to explore if nutritional interventions could be used cost-effectively to end India's TB epidemic. Using available cost and epidemiologic data, we developed a cohort model which simulated TB disease progression and mortality among undernourished individuals. We simulated an augmented rations intervention wherein undernourished Indian adults would receive 2600Kcal/d diet until they attained a BMI of 20kg/m<sup>2</sup> from the existing government ration system and compared it to a continuation of current subsidies. The model calculated costs and outcomes including TB cases, TB deaths, attainment of BMI >20kg/m<sup>2</sup>, and quality-adjusted life years (QALYs). Over 5 years, augmented rations could avert 78% of TB cases, prevent 88% of TB deaths among undernourished Indians, and yield a ten-fold higher resolution of undernutrition compared to the status quo. Additionally, we found that augmented rations would be highly cost-effective, as compared to usual rations, with an estimated incremental cost-effectiveness ratio of \$460 which is considerably lower than the per-capita GDP of India (\$2104). Most of the cost-effectiveness was driven by the collateral benefit of reducing undernutrition. Our findings were robust to deterministic and probabilistic sensitivity analyses. We conclude that a robust nutritional intervention would be highly cost-effective in reducing TB incidence and mortality while reducing widespread undernutrition in India.

### DIETARY INTAKE AND PNEUMOCOCCAL VACCINE RESPONSE AMONG CHILDREN (5-7 YEARS) IN MSAMBWENI DIVISION, KWALE COUNTY, KENYA

**Eleonora Migliore**<sup>1</sup>, Vivian K. Amaita<sup>2</sup>, Francis M. Mutuku<sup>3</sup>, Indu Malhotra<sup>4</sup>, Dunstan Mukoko<sup>4</sup>, Anika Sharma<sup>1</sup>, Prathik Kalva<sup>1</sup>, Amrik S. Kang<sup>1</sup>, Charles H. King<sup>5</sup>, A. Desiree LaBeaud<sup>1</sup>

<sup>1</sup>*Stanford University School of Medicine, Department of Pediatrics, Division of Infectious Diseases, Stanford, CA, United States*, <sup>2</sup>*Kenyatta University, Department of Community Health, Nairobi, Kenya*, <sup>3</sup>*Technical University of Mombasa, Department of Environment and Health Sciences, Mombasa, Kenya*, <sup>4</sup>*Ministry of Health, Vector Borne Disease Control Unit, Nairobi, Kenya*, <sup>5</sup>*Case Western Reserve University, Center for Global Health and Diseases, Cleveland, OH, United States*

Vaccine and sufficient food availability are key factors for reducing pneumonia outbreaks in sub-Saharan Africa. In this study, the 10-valent pneumococcal conjugate vaccine (Synflorix® or PCV10) was administered to a child cohort (5-7 years old, n=230) in Msambweni division, Kenya, to determine relationships between dietary intake, nutritional/socioeconomic status of mothers/caregivers, and vaccine response. 7-day food frequency questionnaire (FFQ), dietary diversity score (DDS) and single 24-h dietary recall were used to address participants' dietary assessment and nutritional status. Individual food varieties were recorded and divided into 9 food groups as recommended by Food and Agriculture

Organization. Anthropometric measurements, nasopharyngeal swabs and vaccine administration were performed at the initial visit. Participants were followed after 4-8 weeks with a blood draw for pneumococcal IgG titers assessed by Luminex assay. Chronic malnutrition was prevalent in the cohort (15% stunting, 16% underweight). Unbalanced dietary intake was observed, with mean energy intake 14% below Recommended Dietary Allowances (1822Kcal) for 5-7 years age range. 72% of the daily energy derived from carbohydrates, 18% from fats and only 10% from proteins. Poor anthropometric status (stunting/underweight) was associated with low socioeconomic/educational status and mothers/caregivers young age ( $p < 0.001$ ). Lack of essential micronutrients (vitamins A, E, K) and minerals (calcium, potassium) due to poor consumption of fresh fruits, vegetables and animal source foods (dairy, meat) was observed and correlated with poor vaccine response ( $p < 0.001$ ). In contrast, children who consumed higher amounts of dietary fiber, vitamin B1, zinc, iron, and magnesium had adequate vaccine response ( $p < 0.05$ ). Correlation between higher dietary diversity score (DDS), higher Vitamin E, K, Zinc intake and adequate vaccine response was also observed ( $p < 0.03$ ). Overall, this study highlights ongoing food scarcity and malnutrition in Kenya and demonstrates the links between adequate socioeconomic conditions, nutrition status and vaccine efficacy

<sup>2</sup>Fundacion para la Salud Integral de los Guatemaltecos, Retalhuleu, Guatemala, <sup>3</sup>Colorado School of Public Health, Aurora, CO, United States,

<sup>4</sup>University of Virginia School of Medicine, Charlottesville, VA, United States,

<sup>5</sup>University of Colorado - Denver, Denver, CO, United States,

<sup>6</sup>Vanderbilt University School of Medicine, Nashville, TN, United States

The Agricultural Workers and Respiratory Illness (AGRI) study aims to evaluate the clinical and socioeconomic impacts of respiratory illness (influenza, RSV, and COVID-19) among Guatemalan agricultural workers and the potential benefits of work-based vaccination. In the study, a continuously enrolled prospective cohort of banana plantation workers undergoes influenza-like illness (ILI) surveillance using 3 strategies: 1) self-reporting to study personnel at weekly site visits or by phone, 2) sentinel surveillance at worker-health posts, and 3) active screening of workers with absenteeism. Workers with ILI have influenza and RSV RT-PCR (Roche cobas<sup>®</sup> Liat) and SARS-CoV-2 antigen testing (SD Biosensor<sup>®</sup>). Workers with ILI and randomly selected asymptomatic controls complete clinical (Flu-iiQ<sup>®</sup> inventory, outcomes) and economic (direct/indirect costs, household expenditures) surveys at the time of illness and at 7- and 28-day follow up. The study also collects company-reported absenteeism and productivity data (units of production, wages) and collects annual and ILI-related blood samples for serology. Beginning in June 2020, 1,431 workers were enrolled (80.8%); the cohort is mostly male (84.1%) and young (31.3 years, SD=8.7); 69.2% work in the fields and mean monthly income is \$355.7 (SD=\$128.0). Obesity (10.6%) and kidney disease (3.4%) are the most common self-reported comorbidities. The first 30 workers with ILI (7 SARS-CoV-2, 1 RSV, 0 influenza) had greater Flu-iiQ severity scores at day 7 (2.15 vs 0.44,  $p=0.02$ ) and 28 (2.28 vs 0.45,  $p=0.07$ ) than controls ( $n=236$ ). The first 7 workers with COVID-19 had higher Flu-iiQ severity scores compared to SARS-CoV-2-negative ILI (O-ILI) at day 0 (28.0 vs 12.95,  $p=0.02$ ), day 7 (3.67 vs 1.31,  $p=0.15$ ), and day 28 (4.0 vs 0.76,  $p=0.27$ ). COVID-19 cases had more work absenteeism ( $p=0.0002$ ) and lost income (\$177.8 vs \$16.4,  $p=0.02$ ) than O-ILI at day 7. Per self-report, the worker was usually the index ILI case within their household (93.1%) but site of acquisition (workplace or other) could not be determined.

In summary, our preliminary data suggest ILI and COVID-19 placed a significant clinical and economic burden on Guatemalan agricultural workers.

### "COUGHING? IT MIGHT BE TB": ADDRESSING COUGH-RELATED STIGMA IN THE TIME OF COVID-19 THROUGH SOCIAL AND BEHAVIOR CHANGE IN NIGERIA

**Bolatito Aiyenigba**<sup>1</sup>, Joseph Edor<sup>1</sup>, Justin DeNormandie<sup>1</sup>, Charles Ugwuanyi<sup>1</sup>, Jennifer Orkisz<sup>2</sup>, Linda Osaji<sup>1</sup>, Debby Nongo<sup>3</sup>, Temitayo Odusote<sup>3</sup>, Itohowo Uko<sup>4</sup>

<sup>1</sup>Breakthrough ACTION - Nigeria, Abuja, Nigeria, <sup>2</sup>Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, <sup>3</sup>United States Agency for International Development, Abuja, Nigeria, <sup>4</sup>National Tuberculosis and Leprosy Control Programme Federal Ministry of Health, Abuja, Nigeria

Nigeria experienced a noticeable decline in uptake of Tuberculosis (TB) services at the start of the COVID-19 pandemic. Lockdown measures restricted clients' ability to go to health facilities for testing and treatment, similarity in TB and COVID-19 symptoms delayed access to care as patients were screened for COVID-19 before considering TB, and cough-related stigma deterred health-seeking behavior. To mitigate the effects of COVID-19, the USAID-funded Breakthrough ACTION-Nigeria (BA-N) project, the National TB and Leprosy Control Program and TB stakeholders collaborated to develop a national "Check Am O!" social and behavior change (SBC) campaign to address TB in the context of COVID-19. The campaign targeted anyone with any form of cough lasting more than 2 weeks. The main objectives were to increase knowledge of the difference between TB and COVID-19 symptoms, and testing for TB if presenting with symptoms suggestive of TB. Strategic communication approaches included radio spots, animated videos on television and social media, posters, stickers, brochures and a provider job aid. All materials encouraged the audience to call the toll-free national TB hotline for more information. The campaign went on air in December 2020, and formally launched for World TB Day in March 2021. BA-N aired 13,614 radio spots and 2,944 television spots between December 7, 2020 and March 31, 2021. Preliminary data from the April 2021 omnibus survey showed that 71% of adult men and women had been exposed to the campaign. The National TB Hotline received 22,028 calls in the October to December 2020 quarter and 209,125 calls in the January to March 2021 quarter, suggesting the campaign was effective in increasing calls to the hotline, a proxy indicator for behavior change. Additional data on associated knowledge, attitudes and practices and national TB service delivery statistics before and after campaign implementation will be shared in the final presentation. This was the first national SBC campaign to address TB in the context of COVID-19. The campaign's success suggests that this approach may be useful for adaptation in other countries.

### IT'S A FAMILY AFFAIR: HIGH RATES OF INTRA-HOUSEHOLD TRANSMISSION OF SARS-COV-2 IN A HYBRID CLUSTER - COHORT STUDY IN CENTRAL NEW YORK

**Michael Conroy**, Harry Taylor, Anjee Panjwani, Andrea Shaw, Natalia DeMaria, Julia Cramer, Megan Harris, Daniel Lichtenstein, Stephen Thomas, Frank Middleton, Kathryn Anderson  
*SUNY Upstate, Syracuse, NY, United States*

Transmission of SARS-CoV-2 within households is a major driver of the global pandemic. In order to assess risk of infection of household associates, we are conducting a community-based cluster study of households in central New York, which began in June 2020. Recently confirmed SARS-CoV-2 infections were identified from Upstate University Hospital medical records. Eligible households were briefed and consented by phone. Enrolled 'initiating' cases and their household 'associates' underwent phone interview, PCR testing at enrollment, and collection of serum at enrollment and roughly 6 weeks later. SARS-CoV-2 infection

status was determined by PCR, IgM positivity, IgG seroconversion, or self-report of a positive test within two weeks of enrollment. Mixed effects logistic regression, accounting for clustering by household, was conducted to analyze risk factors of infection among associates. Through March 2021, we enrolled 70 symptomatic initiating cases and 113 household associates (1-4 associates per initiating case). The median age of participants was 34 years (1-78 years). 55.1% identified as female, 69.9% as non-LatinX white, and 40.0% as essential workers. At enrollment, 48 (42.5%) associates were confirmed to have recent SARS-CoV-2 infection. By week 6, an additional 5 (7.7%) associates were found positive by IgG seroconversion. Among associates infected at enrollment, 14 (29.2%) had an asymptomatic infection, and 11 (22.9%) reported CDC 'warning signs' of shortness of breath, chest pain, or confusion. The odds of infection in adults was 2.56 times that of children. Essential workers (OR=5.54) and individuals of LatinX ethnicity (OR=2.32) were also more likely to be infected. In a multivariate analysis controlling for age, race, presence of comorbid medical conditions, and essential worker status, essential workers remained more likely to be infected (OR = 5.12). We found a very high risk for SARS-CoV-2 infection among household associates with numerous cases captured by serologic testing alone. Essential workers are at particularly high risk and should practice extreme caution if working during the quarantine period.

### INCREASED COVID-19 DISEASE SEVERITY IN HOSPITALIZED AMERICAN INDIAN/ALASKA NATIVE PATIENTS

**Alexandra V. Yingling<sup>1</sup>**, Janae Martinez<sup>1</sup>, Amber Castillo<sup>1</sup>, Qiuying Cheng<sup>1</sup>, Michelle Harkins<sup>2</sup>, J. Pedro Teixeira<sup>2</sup>, Christophe Lambert<sup>1</sup>, Anthony Worsham<sup>3</sup>, Phillip Seidenberg<sup>4</sup>, Kristan Schneider<sup>5</sup>, Jens Langsjoen<sup>3</sup>, Ivy Hurwitz<sup>1</sup>, Douglas J. Perkins<sup>1</sup>

<sup>1</sup>Center for Global Health, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>2</sup>Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>3</sup>Division of Hospital Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>4</sup>Department of Emergency Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>5</sup>Department of MNI, University of Applied Sciences Mittweida, Mittweida, Germany

In the US, the American Indian/Alaska Native (AI/AN) population has been disproportionately affected by coronavirus disease 2019 (COVID-19) cases, hospitalizations, and deaths. However, there have been limited reports describing relationships between patient risk factors and the COVID-19 disease course in the AI/AN population. The identification of attributes contributing to disease severity is key for improving clinical outcomes. In this study, hospitalized COVID-19 patients (n=332) admitted between 23 April 2020 and 2 February 2021 were recruited from the University of New Mexico Hospital. Patient medical histories and hospital course information were obtained via medical chart reviews and interviews with the patient or legally authorized representative. Data analysis was conducted using Fisher's Exact Test for proportional data and one-way ANOVA for mean data. Patients were stratified by self-reported ancestry: AI/AN (n=121), Hispanic (n=135), non-Hispanic White (n=63), and Other (n=13; not included in statistical analyses due to sample size). On average, the patients were symptomatic for 6.2±5.2 days prior to hospitalization, with no significant difference between groups. AI/ANs were more likely to present at hospital with cough (P=0.004) and increased oxygen requirements (P=1.7x10<sup>-4</sup>). Established risk factors for COVID-19 severity (e.g., age, BMI, respiratory disease) were either comparable or less prevalent in the AI/AN patients. During the hospital course, AI/ANs had a higher proportion of ICU admissions/deaths (P=0.036), increased oxygen requirements (P=0.022), and longer hospitalization times (P=0.001). These findings suggest that despite the lack of underlying conditions and a similar symptomatic time period prior to hospitalization, the AI/AN group had more severe disease outcomes than the Hispanic and non-Hispanic

White groups. Further research should investigate other potential factors contributing to disease severity and the development of specialized care options to alleviate the escalated disease burden on the AI/AN population.

1348

### CROSS-REACTIVITY OF PRE-COVID-19 PANDEMIC SERA FROM A MALARIA-ENDEMIC AREA ON TWO SARS-COV-2 SEROLOGICAL ASSAYS

**Laura C. Steinhardt<sup>1</sup>**, Fehintola Ige<sup>2</sup>, Nnaemeka Iriemenam<sup>3</sup>, Stacie Greby<sup>3</sup>, Yohhei Hamada<sup>4</sup>, Mabel Uwandu<sup>2</sup>, Maureen Aniedobe<sup>2</sup>, Kristen Stafford<sup>5</sup>, Alash'le Abimiku<sup>6</sup>, Nwando Mba<sup>7</sup>, Ndidi Agala<sup>6</sup>, Olumide Okunoye<sup>3</sup>, Augustine Mpamugo<sup>8</sup>, Mahesh Swaminathan<sup>3</sup>, Edewede Onokevbagbe<sup>8</sup>, Temitope Olaleye<sup>6</sup>, Ifeanyichukwu Odoh<sup>6</sup>, Barbara Marston<sup>1</sup>, McPaul Okoye<sup>3</sup>, Ibrahim Abubakar<sup>4</sup>, Molebogeng Rangaka<sup>4</sup>, Eric Rogier<sup>1</sup>, Rosemary Audu<sup>2</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Nigerian Institute of Medical Research, Lagos, Nigeria, <sup>3</sup>Centers for Disease Control and Prevention, Abuja, Nigeria, <sup>4</sup>University College of London, London, United Kingdom, <sup>5</sup>UMB, Baltimore, MD, United States, <sup>6</sup>IHVN, Abuja, Nigeria, <sup>7</sup>Nigeria Centre for Disease Control, Abuja, Nigeria, <sup>8</sup>UMB, Abuja, Nigeria

Accurate SARS-CoV-2 serological assays are critical for COVID-19 serosurveillance. However, prior studies have indicated possible cross-reactivity of some assays, including in malaria-endemic areas. We tested 213 pre-pandemic samples from Nigeria using two SARS-CoV-2 serological assays: the Abbott Architect IgG and the Euroimmun NCP IgG assay, both targeting the SARS-CoV-2 nucleocapsid protein (NCP). Pre-pandemic samples from 2018 were previously tested for malaria antigens and antibodies to malaria and other endemic pathogens using a Luminex bead-based multiplex assay. To assess antibody binding strength, an avidity assay was performed on these samples and on plasma from 32 SARS-CoV-2 RT-PCR-positive persons. Thirteen (6.1%) of 212 samples run on Abbott and 38 (17.8%) of 213 run on Euroimmun were seropositive for SARS-CoV-2. Anti-*Plasmodium* IgG levels were significantly higher among -false-positives for both Abbott and Euroimmun for five of nine malaria antibodies: PfCSP, pmmSP1, pomSP-1, glurp (Euroimmun only), and Pfama1 (Euroimmun only), but not for pfmsp1, pvmsp1, hrp2 or lsa1. No association was found with active *P. falciparum* infection. An avidity assay at various concentrations of urea wash in the Euroimmun assay reduced loosely-bound IgG: of 37 positive/borderline pre-pandemic samples, 46%, 86%, 89%, and 97% became negative using 2M, 4M, 5M, and 8M urea washes, respectively. The wash reduced antibody avidity in samples from SARS-CoV-2 patients taken ≤28 days of RT-PCR confirmation; thereafter, avidity increased for all urea concentrations except 8M, which decreased avidity on SARS-CoV-2-positive samples to <30%. This validation found moderate cross-reactivity on two SARS-CoV-2 NCP-based serological assays in samples from a malaria-endemic setting. A single urea wash appeared to alleviate cross-reactivity but needs further validation and assessment of optimal concentration. SARS-CoV-2 serological assays targeting NCP should be interpreted with caution in malaria-endemic settings; use of a urea wash, multi-assay testing algorithms, or multi-antigen-target assays should be considered in such settings.

## REVIEWING THE EVIDENCE FOR AND AGAINST SELECTION OF SPECIFIC PYRETHROIDS FOR PROGRAMMATIC PURPOSES

**Rosemary Susan Lees**<sup>1</sup>, Natalie Lissenden<sup>1</sup>, Thomas Churcher<sup>2</sup>, Penelope Hancock<sup>3</sup>, Hanafy Ismail<sup>1</sup>, Mara Kont<sup>2</sup>, Ben Lambert<sup>3</sup>, Audrey Lenhart<sup>4</sup>, Philip McCall<sup>1</sup>, Catherine Moyes<sup>3</sup>, Mark Paine<sup>1</sup>, Giorgio Praulins<sup>1</sup>, David Weetman<sup>1</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Imperial College London, London, United Kingdom, <sup>3</sup>University of Oxford, Oxford, United Kingdom, <sup>4</sup>Centres for Disease Control, Atlanta, GA, United States

Pyrethroids are present in all WHO prequalified insecticide treated nets (ITNs) and are still used for indoor residual spraying (IRS). Pyrethroid resistance is widespread in malaria vectors, and differential mortality in discriminating dose assays to different pyrethroids is often observed during susceptibility monitoring in the lab and field. However, there is uncertainty about whether the monitoring methods can reliably identify differential resistance phenotypes. Therefore, when differential mortality is observed, it is unclear if this should be interpreted as an indication of differential levels of susceptibility within the pyrethroid class, or if this should be interpreted in another way (e.g. inherent variability in mortality results; differently calibrated discriminating doses). Considering this, when 'differential susceptibility' is observed there is a question over whether countries can target or preferentially use specific pyrethroid insecticides as an effective resistance management strategy. We reviewed evidence from (i) molecular information, insecticide resistance patterns and testing results (ii) in laboratory colonies and (iii) from field data, and (iv) lessons learned from behavioural assays, to address these questions. Where one pyrethroid is seen to be consistently more effective in resistance screening, preferably coupled with additional, more direct evidence of superior performance, the pyrethroid with the greater killing capacity should probably be deployed, if costs and other considerations, most notably formulation or delivery method (e.g. net type), are comparable. However, the evidence suggests that in areas where pyrethroid resistance exists, different results in insecticide susceptibility assays are not necessarily indicative of a true or operationally relevant difference in potential performance of the specific pyrethroids currently in common use (deltamethrin, permethrin,  $\alpha$ -cypermethrin and  $\lambda$ -cyhalothrin). It is not advisable to use rotation between these pyrethroids as an insecticide resistance management strategy.

## EFFICACY OF A SPATIAL REPELLENT FOR CONTROL OF Aedes-borne virus transmission: A CLUSTER RANDOMIZED TRIAL IN IQUITOS, PERU

<sup>1</sup>Department of Pathology, Microbiology, and Immunology, School of Veterinary Medicine, University of California, Davis, CA, United States, <sup>2</sup>Department of Health Metrics Sciences, University of Washington, Seattle, WA, United States, <sup>3</sup>Department of Entomology and Nematology, University of California, Davis, CA, United States, <sup>4</sup>Department of Virology and Emerging Infectious Diseases, U.S. Naval Medical Research Unit No. 6, Lima, Peru, <sup>5</sup>Dirección General de Saneamiento Ambiental (DIGESA), Iquitos, Peru, <sup>6</sup>Department of Entomology, U.S. Naval Medical Research Unit No. 6, Lima, Peru, <sup>7</sup>Genomics Laboratory, Pontificia Universidad Católica del Perú, Lima, Peru, <sup>8</sup>Department of Global Community Health and Behavioral Sciences, Tulane School of Public Health and Tropical

Medicine, New Orleans, LA, United States, <sup>9</sup>Department of Biological Sciences, Eck Institute for Global Health, University of Notre Dame, Notre Dame, IN, United States

Over half the world's population is at risk for viruses transmitted by *Aedes* mosquitoes, such as, dengue and Zika. The primary vector, *Aedes aegypti*, thrives in urban environments. Despite decades of effort, cases and the geographic range of *Aedes*-borne viruses (ABV) continue to expand. To date, there are no rigorously proven vector control interventions that prevent ABV diseases. Spatial repellents, a new option, are designed to decrease human exposure to ABV by releasing active ingredients into the air that disrupt mosquito-human contact. A parallel, cluster-randomized controlled trial was conducted in Iquitos, Peru to quantify the impact of a transfluthrin-based spatial repellent on ABV infection. From 2,907 households across 26 clusters (13 per arm), 1,578 participants were assessed for seroconversion (primary endpoint) by survival analysis. Incidence of acute disease was calculated among 16,683 participants (secondary endpoint). Bi-monthly adult mosquito collections were conducted to compare *Ae. aegypti* abundance, blood-fed capture rate and parity status through mixed effect difference-in-difference analyses. The spatial repellent significantly reduced ABV infection by 34.1% (95% CI 6.9%,  $\infty$ );  $p = 0.0236$ ,  $z = 1.98$ ). *Aedes aegypti* abundance and blood-fed capture rates were significantly reduced by 28.6% (95% CI 24.1%,  $\infty$ );  $z = -9.11$  and 12.4% (95% CI 4.2%,  $\infty$ );  $z = -2.43$ ), respectively. Our trial provides the first conclusive evidence of significant protective efficacy by any chemical vector control intervention, in this case a spatial repellent, to reduce the risk of ABV transmission. Results support vector control as a beneficial component to ABV disease prevention.

## INVESTIGATING BIRD-DELIVERED IVERMECTIN AS A NOVEL URBAN WEST NILE VIRUS CONTROL STRATEGY

**Karen Holcomb**<sup>1</sup>, Chilingh Nguyen<sup>2</sup>, Nicholas Komar<sup>3</sup>, Nicholas Panella<sup>3</sup>, Brian D. Foy<sup>2</sup>, Christopher M. Barker<sup>1</sup>

<sup>1</sup>Davis Arbovirus Research and Training Lab, University of California Davis, Davis, CA, United States, <sup>2</sup>Arthropod-borne and Infectious Diseases Laboratory, Colorado State University, Fort Collins, CO, United States, <sup>3</sup>Centers for Disease Control and Prevention, Division of Vector-Borne Infectious Diseases, Fort Collins, CO, United States

Current mosquito control strategies have limited ability to target *Culex* mosquitoes involved in transmission of West Nile virus (WNV) without disseminating insecticides over large areas. The endectocide ivermectin (IVM) offers a potential alternative, due to its recently described mosquitocidal properties and ability to deliver it via birds that are frequently bitten by WNV vectors. We hypothesized that treating birds that are common bloodmeal sources for *Culex* mosquitoes with IVM will reduce WNV transmission because few mosquitoes will survive long enough to take a subsequent bloodmeal. To assess the efficacy and feasibility of this strategy, we conducted a randomized field trial in backyard chickens and then developed a mathematical model informed by birdfeeder usage and nocturnal roosting habits of common backyard birds. First, we placed 48 chickens into 4 treated and 4 untreated control flocks in backyard coops across Davis, California, administering IVM daily in feed to treated flocks (Jul-Sep 2019). We assessed entomological indices weekly around each coop, monitored serum IVM levels, and tested for WNV antibodies in all chickens. WNV seroconversions were reduced in treated vs. untreated flocks, indicating reduced WNV transmission intensity at treated coops. We also observed a reduction in parous mosquitoes near treated flocks, paired with increased mortality of wild *Culex* following a bloodmeal on a treated vs. untreated chicken, suggesting a change in population structure, and subsequently viral dynamics, due to IVM. To estimate the potential for IVM-based control in wild birds, we developed a spatially-implicit mathematical model of WNV transmission in a neighborhood with IVM-treated birdfeeders. Parameters for bird movement were based on our telemetry of 27 birds in Fort Collins, Colorado (Aug-Sep 2020). Using the model, we estimated up to 84% reduction in infectious mosquito-days and 61% fewer bird infections with IVM-treated feeders. Future work is

needed to refine estimated IVM-induced mortality in wild mosquitoes. Our work provides the foundation for designing future lab and field studies of IVM for local WNV control.

### GENE EXPRESSION TEMPORAL ANALYSIS OF PYRETHROID RESPONSE IN CALIFORNIAN Aedes AEGYPTI

Lindsey Kay Mack, Geoffrey M. Attardo

University of California Davis, Davis, CA, United States

*Aedes aegypti*, the vector of Zika and dengue, first established in California in 2013 and have since spread to 22 counties across the state. These mosquitoes arrived with established resistance to pyrethroids, the primary class of insecticides used for public health applications. Pyrethroids act on the insect voltage gated sodium channels causing prolonged depolarization and death, and resistance can be developed through mutations at the target site or through over-expression of detoxifying enzymes like cytochrome P450s and glutathione-S-transferases (GSTs). However, there are over 100 genes coding for P450 enzymes alone in *Ae. aegypti*. To identify putative resistance mediating enzymes as well as the overall genetic response to insecticide exposure, mosquitoes were exposed to permethrin for 1 hour via CDC Bottle Bioassay. They were then placed in a cage and collected 6, 10, and 24 hours post exposure. The transcriptional profiling of the response to pyrethroid exposure identified 20 cytochrome P450s and 6 GSTs that demonstrated significant increases in transcript abundance suggesting their involvement in reducing the toxic effects of pyrethroid exposure. Enzymes associated with oxidation-reduction reactions are overrepresented across time points suggesting the response to insecticidal challenge results in a significant amount of oxidative stress. Another significant feature identified in this analysis revealed upregulation of genes coding for enzymes required for fundamental metabolic activities including glycolysis, the pentose phosphate shunt as well as lipid metabolism. Overall, these findings reveal that this strain of mosquitoes have a strong genetic response to insecticide exposure. In addition, this response appears to require activation of other fundamental metabolic pathways to reduce the associated oxidative stress and to maintain the demand for energy generated by these activities. These results provide evidence of metabolic resistance in this population, new enzymatic targets for investigation, and generates new questions to pursue as to the resistance profile of these invasive Californian populations.

### MAPPING THE FREQUENCY OF GENETIC MUTATIONS CONFERRING INSECTICIDE TARGET SITE RESISTANCE IN AFRICAN MALARIA VECTOR SPECIES

Penelope A. Hancock<sup>1</sup>, Catherine L. Moyes<sup>2</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>University of Oxford, Oxford, United Kingdom

Resistance in malaria vectors to pyrethroid insecticides, the most widely used class of insecticides for malaria vector control, is a concerning threat to the efficacy of vector control tools including long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS). Target site resistance is an important genetic mechanism of resistance to pyrethroids that is caused by mutations in the *Vgsc* gene that regulates the voltage-gated sodium channel, the target site of pyrethroid insecticides in mosquitoes. Understanding the geographic distribution of target site resistance mechanisms, and how this is changing over time across different malaria vector species, can inform strategic deployment of vector control tools. Further, geospatial analyses can quantify relationships between phenotypic pyrethroid resistance in field malaria vector populations and the prevalence of target site resistance mechanisms. Here we develop a Bayesian statistical spatiotemporal model ensemble to interpret species-specific trends in the frequency of two target site resistance mutations in the *Vgsc* gene, 995S and 995F, in the three vector species *An. gambiae*, *An. coluzzii*, and *An. arabiensis* over the period 2005-2017. The models are

informed by 2418 observations of the frequency of each mutation in field sampled mosquitoes collected from 27 countries spanning western and eastern regions of Africa. For nine selected countries, we develop annual predictive maps which reveal geographically structured patterns of spread of each mutation at regional and continental scales. The results show associations, as well as stark differences, in spread trajectories of the two mutations across the three vector species. We also find that our mapped *Vgsc* allele frequencies are a significant partial predictor of the prevalence of phenotypic resistance to the pyrethroid deltamethrin in *An. gambiae* complex mosquito populations. The results demonstrate how patterns of phenotypic resistance seen in field vector populations are linked to both vector species composition and target site resistance mechanisms.

### INSECTICIDE SUSCEPTIBILITY OF ANOPHELES GAMBIAE S.L. POPULATION IN HEALTH DISTRICTS AFTER DEPLOYMENT OF NEW GENERATION NETS IN BURKINA FASO

Antoine Sanou<sup>1</sup>, Joe Wagman<sup>2</sup>, Madou Tapsoba<sup>1</sup>, Soumanaba Zongo<sup>1</sup>, Nfale Sagnon<sup>1</sup>, Christelle Gogue<sup>2</sup>, Gauthier Tougri<sup>3</sup>, Adama Gansane<sup>1</sup>, Geraldine M. Foster<sup>4</sup>, W. Moussa Guelbéogo<sup>1</sup>, Robertson Molly<sup>2</sup>, Hilary Ranson<sup>4</sup>

<sup>1</sup>Centre National de Recherche et de Formation sur le Paludisme (CNRFP), Ouagadougou, Burkina Faso, <sup>2</sup>PATH, Washington, WA, United States, <sup>3</sup>National Malaria Control Programme, Ouagadougou, Burkina Faso, <sup>4</sup>Liverpool School of Tropical medicine, Liverpool, United Kingdom

Long-Lasting Insecticide-treated Nets and Indoor Residual Spraying are the common tools used in vector control that have contributed to reducing malaria transmission in Sub-Saharan Africa. However, the rise and spread of insecticide resistance is a threat to the continued success of these tools. With the advent of new generation insecticide-treated nets (ITN), Burkina Faso has deployed multiple ITN types since 2019, including PBO-pyrethroid, Interceptor G2, and standard pyrethroid-only nets, guided by local resistance patterns and malaria burden. The current study aimed at monitoring the insecticide resistance intensity and mechanisms in the net deployment areas after the 2019 mass distribution campaign. Here, we are undertaking three-years (2019 - 2021) of insecticide resistance monitoring in seven villages from four distinct deployment areas which received a different type of ITN. Thus, experimental hut trials (EHT) at two villages known for high insecticide resistance level and different vector species composition) and World Health Organization (WHO) bioassay tube tests (using deltamethrin and alphacypermethrin) are performed. Screening for the variation in the expression of putative metabolic resistance genes and frequency of target site mutation are underway. No variation in mortality was observed considering the result from the WHO standard tube test results between the two years. *Anopheles gambiae* complex member's overall mortality rate was ~18% after exposure to the diagnostic dose (DD) and ~76% after exposure to 10 times the DD of both insecticides. Preexposure to the synergist PBO showed 10 - 72% increase in the mortality, varying by study villages, indicating an involvement of cytochrome P450 and esterase in the resistance among other mechanisms. However, the preliminary results indicated 18 -50% decrease in the mortality rate of the local vector to all type of tested nets (standard and new generation) in the EHT between 2019 and 2020. Results indicate variation in the mortality rate between sites and decrease in susceptibility of the local vector to all types of nets tested including new generation net in huts trials.

### VECTRON™ T500 (BROFLANILIDE), A NEW INSECTICIDE FOR INDOOR RESIDUAL SPRAYING PROVIDES IMPROVED AND PROLONGED CONTROL OF PYRETHROID-RESISTANT MALARIA VECTORS IN BENIN

Renaud Govoetchan<sup>1</sup>, Augustin Fongnikin<sup>2</sup>, Martial Gbegbo<sup>2</sup>, Corine Ngufor<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>Centre de Recherche Entomologique de Cotonou, Cotonou, Benin

The rotational use of insecticides with different modes of action for indoor residual spraying (IRS) is recommended for improving malaria vector control and managing insecticide resistance. Insecticides with new chemistries are urgently needed and broflaniilide is a newly discovered insecticide with a novel mode of action. We investigated the efficacy of a wettable powder (WP) formulation of broflaniilide (50%) for IRS on mud and cement wall substrates in experimental hut against pyrethroid-resistant malaria vectors in Benin, in comparison with pirimiphos-methyl CS (Actellic 300CS). There was no evidence of cross-resistance to pyrethroids in CDC bottle bioassays. At application rate of 100 mg/m<sup>2</sup> of VECTRON™ T500 in experimental huts in Cote, Benin, the mortality of wild pyrethroid-resistant *An. gambiae* s.l. entering the huts over 12 months was 53% to 63%, which was mostly similar to pirimiphos-methyl CS (53%), regardless of wall substrates. Initial experimental hut mortality rates with VECTRON™ T500 were steady over 11 months. Monthly, *in situ* wall cone bioassay mortality of susceptible and pyrethroid resistant mosquitoes remained >80% for 16 months with VECTRON™ T500, irrespective of the substrate and for 7-8 months with Actellic CS. The results of this hut study show that VECTRON T500 is non-inferior to Actellic 300CS against pyrethroid-resistant mosquito vectors and could thus be a crucial addition to the current portfolio of IRS insecticides.

### SAFETY OF SINGLE DOSE MOXIDECTIN COMBINATION THERAPY FOR BANCROFTIAN FILARIASIS

Catherine M. Bjerum<sup>1</sup>, Benjamin Koudou<sup>2</sup>, Allassane Ouattara<sup>2</sup>, Toki Pascal Gabo<sup>3</sup>, Peter U. Fischer<sup>4</sup>, Gary J. Weil<sup>4</sup>, Christopher L. King<sup>1</sup>, Philip Budge<sup>4</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Swiss Center for Scientific Research, Abidjan, Côte D'Ivoire, <sup>3</sup>Agboville Regional Hospital, Agboville, Côte D'Ivoire, <sup>4</sup>Washington University in St. Louis, St. Louis, MO, United States

In sub-Saharan Africa, the World Health Organization (WHO) recommends 5-7 years of mass drug administration (MDA) for elimination of lymphatic filariasis (LF) with a combination of ivermectin (IVM) and albendazole (ALB), and a combination of IVM plus ALB plus diethylcarbamazine (DEC; IDA) in areas of the world without onchocerciasis or loiasis. Moxidectin (Mox) has recently been approved for treatment of onchocerciasis in people 12 years and older. We are now conducting the first clinical trial of moxidectin for LF. This Phase III, randomized, open-label, masked-observer superiority trial in Côte d'Ivoire compares Mox+ALB (MoxA) with IVM+ALB (IA) and Mox+DEC+ALB (MoxDA) with IDA for treating LF. In a separate abstract we have described the preliminary efficacy results. Here we describe its safety and tolerability. We enrolled 141 non-pregnant, non-breast feeding adults 18-70 years old with no chronic medical problems, 99 with *Wuchereria bancrofti* microfilariae (Mf) levels >40Mf/mL and 42 with Mf levels <40Mf/mL. The first 73 participants were treated and monitored closely in an inpatient setting with active adverse event (AE) monitoring, including daily tests of liver and kidney function for 72 hours post-treatment, and again at day 7. The subsequent 68 participants were treated in their village and followed for AEs at 24 and 48 hours. There were no serious AEs. Seventy-one percent of participants experienced at least 1 AE; 85% of all AEs were mild (grade I). The most common AEs were creatinine elevations (20%), increased respiratory rate (20%), muscle and joint pain (18%), hypertension (17%), AST elevation (16%) and headache (15%). There was no difference in the rate ( $\chi^2$  p = 0.59) or

severity (Wilcoxon p = 0.21) of AEs across treatment groups, and rates of AEs did not differ between those with higher (>40) vs lower (<40) Mf counts ( $\chi^2$  p = 0.75). These first data suggest that Mox is safe for use in combination with ALB and/or DEC for LF elimination. Given the established safety of Mox and ALB for onchocerciasis, MoxA may also be useful for areas co-endemic for LF and onchocerciasis.

### MOXIDECTIN EFFICACY IN SINGLE DOSE COMBINATION THERAPIES WITH ALBENDAZOLE AND DIETHYLCARBAMAZINE FOR TREATMENT OF LYMPHATIC FILARIASIS IN CÔTE D'IVOIRE: PRELIMINARY RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

Benjamin G. Koudou<sup>1</sup>, Philip Budge<sup>2</sup>, Allassane Ouattara<sup>1</sup>, Toki Pascal Gabo<sup>3</sup>, Peter U. Fischer<sup>2</sup>, Christopher L. King<sup>4</sup>, Gary J. Weil<sup>2</sup>, Catherine Bjerum<sup>4</sup>

<sup>1</sup>Swiss Center for Scientific Research, Abidjan, Côte d'Ivoire, <sup>2</sup>Washington University in St. Louis, St. Louis, MO, United States, <sup>3</sup>Agboville Regional Hospital, Agboville, Côte d'Ivoire, <sup>4</sup>Case Western Reserve University, Cleveland, OH, United States

Lymphatic filariasis (LF) remains endemic in much of Africa despite many years of annual mass drug administration of ivermectin (IVM) and albendazole (ALB). Moxidectin (Mox) is a macrocyclic lactone closely related to IVM but with a much longer half-life and has proven more effective for sustained suppression of onchocerciasis microfilaridemia compared to IVM. To determine whether Mox combination therapy might also be superior for LF, we are conducting a phase III, randomized, open-label superiority trial comparing Mox+ALB (MoxA) against annual IVM+ALB (IA), the current standard mass drug administration (MDA) used in areas of sub-Saharan Africa not coendemic for loiasis. This is the first study to evaluate Mox efficacy against *Wuchereria bancrofti*. We are concurrently comparing Mox + diethylcarbamazine (DEC) + ALB (MoxDA) against IVM+DEC+ALB (IDA), which is used for MDA in areas outside sub-Saharan Africa unlikely to meet 2030 LF elimination goals. The primary study endpoints are Mf clearance at 12 (IA vs. MoxA) or 24 (IDA vs. MoxDA) months post-treatment, as measured by 1ml filtration of night venous blood. Enrolment for the study began in August, 2020, and to date we have 6-month efficacy data for 44 adult participants infected with >40 Mf/ml per mL of blood at baseline (MoxA n=10, MoxDA n=11, IDA n=10 and, IA n=13). To date, none of the participants in the MoxA (baseline Mf range 52 - 549) or MoxDA group (baseline Mf range 83 - 1633) had detectable blood Mf at 6 months post-treatment. In contrast, eight (62%) of the IA recipients (baseline Mf range 73 - 1091) and four (40%) of the IDA recipients (baseline Mf range 61 - 946) were microfilaridemic (Mf ranges 0 - 153 and 0 - 27), at 6 months (p=0.001 Kruskal-Wallis equality of populations rank test). These preliminary data strongly suggest that combination therapies with MoxA and MoxDA are superior to IA and IDA in clearing *W. bancrofti* Mf at 6-months. Study enrolment is ongoing, and 6-month data from additional participants, as well as 12-month data from the participants reported here should be available by August 2021.

### TRANSCRIPTOMIC ANALYSIS REVEALS ACTIVATION OF CONSERVED IMMUNE PATHWAYS IN THE HUMAN SKIN RESPONSE TO THE BITES OF DIVERGENT VECTOR SPECIES OF GLOBAL HEALTH IMPORTANCE

<sup>1</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, Rockville, MD, United States, <sup>2</sup>University of Georgia, Athens, GA, United States, <sup>3</sup>University of Miami Miller School of

Medicine, Miami, FL, United States, <sup>4</sup>LID Clinical Studies Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Arthropod vectors such as mosquitoes and sand flies deliver infectious pathogens into the skin of humans while taking a blood meal. Pathogens are co-delivered with vector saliva containing a complex mixture of immunomodulatory components, including salivary proteins and microbiota. In animal models, vector bites and saliva are critical for establishing infection and exacerbating disease pathogenesis. However, the mechanisms by which vector bites do this in humans remain poorly understood. To address this, we conducted the BITE Study, the first clinical study to perform global profiling of the human skin immune response to vector bites. Healthy human volunteers were exposed to uninfected bites of one of three vectors of global health importance – the mosquitoes *Aedes aegypti* and *Anopheles gambiae*, or the New World sand fly *Lutzomyia longipalpis*. Skin biopsies were collected from bite sites at 4 hrs and 48 hrs after vector exposure. The skin transcriptome from the bite sites was determined by RNA-seq and compared to unbiten skin as a negative control. Despite these vector species being separated by over 200 million years of evolutionary divergence, upstream regulator analysis revealed remarkable conservation of the skin transcriptomic response to vector bites, including prominent activation of TNF $\alpha$ , TLR9, and interferon/STAT1 signaling, even in the absence of pathogens. In agreement with histologic findings, computational deconvolution of the bulk RNA-seq data highlighted a transient early influx of neutrophils and monocytes at 4 hrs post-bite, followed by later recruitment of monocytes, T cells, and dendritic cells to bite sites by 48 hrs. Current work is focused on applying digital spatial profiling to determine the architecture and organization of cutaneous immunity to vector bites. Our discovery of a conserved vector bite response in humans underscores the potential for developing vaccines against vector-borne pathogens by targeting mediators of early immune events in the skin.

<sup>1</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, Maryland, USA, Rockville, MD, United States, <sup>2</sup>National Center of Parasitology, Entomology, and Malaria Control, Phnom Penh, Cambodia, Phnom Penh, Cambodia, <sup>3</sup>Department of Population Health and Disease Prevention, University of California, Irvine, California, USA, California, CA, United States, <sup>4</sup>Clinical Monitoring Research Program Directorate, Frederick National Laboratory for Cancer Research, Frederick, Maryland, USA, Frederick, MD, United States, <sup>5</sup>Biostatistics Branch, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, Maryland, USA, Bethesda, MD, United States, <sup>6</sup>Kampong Speu District Referral Hospital, Chbar Mon, Kampong Speu, Cambodia, Kampong Speu, Cambodia

Defining dengue burden and the *Aedes aegypti* vector determinants that exacerbate transmission and disease outcome are critical for Cambodian public health authorities. Characterization of human immunity to *Aedes* mosquito saliva is required to expand the armamentarium of control measures for sudden and emerging mosquito-borne epidemics. We established the first prospective cohort to understand *Aedes aegypti* saliva-specific humoral immunity in the context of dengue virus infection. Children aged 2 to 9 years old enrolled in a community-based cohort called PAGODAS (Pediatric Assessment Group of Dengue and *Aedes* Saliva) in Cambodia. They were followed semi-annually for antibodies to dengue

virus and *Ae. aegypti* salivary gland homogenate using enzyme-linked immunosorbent assays and dengue-specific neutralization titers. Children presented with fever at any time to undergo dengue rapid testing and confirmatory polymerase chain reaction. From July 13 to August 30, 2018, we enrolled 771 children and follow them to present day. At baseline, 22% (173/770) of children had evidence of neutralizing antibodies to one or more serotypes of dengue. Of the 597 dengue-naïve children in August 2018 to August 2020, 51 children had symptomatic PCR-confirmed dengue while 148 dengue-naïve children had clinically inapparent dengue defined by neutralization assays. Individuals with higher antibodies to *Ae. aegypti* salivary gland homogenate were 1.5x more likely to seroconvert for any dengue serotype on PRNT50 (HR 1.47 95% CI 1.05–2.06; p=0.02), primarily driven by individuals with inapparent dengue (HR 1.64 95% CI 1.12–2.40; p=0.01). High levels of humoral immunity to *Ae. aegypti* saliva are associated with future development of dengue infection, specifically inapparent dengue, in dengue-naïve Cambodian children. This provides the rationale to explore how anti-vector saliva antibodies may influence development of clinical disease in humans.

<sup>1</sup>Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Department of Surgery, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, <sup>4</sup>Biostatistics Research Branch, Division of Clinical Research, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Rockville, MD, United States, <sup>5</sup>Clinical Monitoring Research Program Directorate, Frederick National Laboratory for Cancer Research, Frederick, MD, United States, <sup>6</sup>Imutex Ltd, London, United Kingdom, <sup>7</sup>LID Clinical Studies Unit, Laboratory of Infectious Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Mosquito-borne diseases cause ~360 million cases and >600,000 deaths annually, although the true burden is likely underestimated. A vaccine efficacious against multiple mosquito-borne diseases could significantly impact public health. AGS-v PLUS is a vaccine containing five mosquito salivary peptides, aiming to induce an immune response that blocks mosquito-borne pathogen transmission. A Phase 1 randomized, double-blinded, placebo-controlled clinical trial was conducted to determine safety and immunogenicity of AGS-v PLUS. Five dosing groups received injections on days 1 and 22 as follows: Group 1, two doses non-adjuvanted AGS-v PLUS; Group 2, ISA-51-adjuvanted AGS-v PLUS and saline placebo; Group 3, two doses ISA-51-adjuvanted AGS-v PLUS; Group 4, two doses Alhydrogel-adjuvanted AGS-v PLUS; and Group 5, and two doses saline placebo. Primary objectives were to determine safety and tolerability, and to measure immune responses. 51 participants were enrolled, 11 in Group 3 and 10 in the other groups. No participant experienced any treatment-emergent or serious adverse event. 134 solicited symptoms were reported: 20 local and 35 systemic in 25 (49%) participants after dose 1, and 23 local and 56 systemic in 23 (45%) participants after dose 2. All were considered mild/moderate except for one severe fever that occurred in a placebo recipient. The most common solicited local symptom was pain, occurring in 15 (29%) and 11 (22%) of participants after dose 1 and 2, respectively. The most common solicited systemic symptoms were headache, malaise, and fatigue, occurring in 9 (18%), 5 (10%) and 7 (14%) participants after dose 1, and 9 (18%), 11 (22%) and 11 (22%) participants after dose 2, respectively. Solicited symptoms after placebo injections appear similar to those after vaccine, except that

pain was less common in the placebo group. Compared with placebo, all groups had significantly higher interferon-gamma and IgG responses to AGS-v PLUS pooled peptides. In this first-in-human study, AGS-v PLUS was well-tolerated and generated strong immune responses. Further testing to determine expanded safety, tolerability, and efficacy is warranted.

### RISK-STRATIFYING YELLOW FEVER PATIENTS AT THE TIME OF ADMISSION

**Max A. McClure**<sup>1</sup>, Izabela M. Rezende<sup>2</sup>, Amrik S. Kang<sup>2</sup>, Leonardo S. Pereira<sup>3</sup>, Adriana Cenachi<sup>3</sup>, Pedro A. Alves<sup>4</sup>, Andréa Teixeira-Carvalho<sup>5</sup>, Olindo A. Martins-Filho<sup>5</sup>, Betânia P. Drumond<sup>3</sup>, A. Desiree LaBeaud<sup>2</sup>

<sup>1</sup>Department of Medicine, Stanford University School of Medicine, Palo Alto, CA, United States, <sup>2</sup>Department of Pediatrics, Division of Infectious Diseases, Stanford University School of Medicine, Palo Alto, CA, United States, <sup>3</sup>Laboratório de Vírus, Instituto de Ciências Biológicas, Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, <sup>4</sup>Imunologia de Doenças Virais, Instituto René Rachou, Fundação Oswaldo Cruz/FIOCRUZ, Belo Horizonte, Brazil, <sup>5</sup>Grupo Integrado de Pesquisas em Biomarcadores, Instituto René Rachou, Fundação Oswaldo Cruz/FIOCRUZ, Belo Horizonte, Brazil

The course of yellow fever (YF) is poorly understood. During the 2017-2018 outbreaks in Minas Gerais, Brazil, a cohort of PCR-confirmed YF patients (n=300) was followed longitudinally at Hospital Eduardo de Menezes (HEM), Belo Horizonte with the goal of characterizing the clinical progression of YF and identifying risk factors for mortality in YF inpatients. We analyzed available demographic, clinical, sonographic and laboratory exposure factors predictive of a fatal outcome (n=120) using univariate analysis of relative risk, with continuous variables dichotomized on optimal cutoffs identified on ROC curves. For patients who had sufficient serum studies drawn on admission (n=285), we generated a classifier based on laboratory results using random forests, an ensemble learning method of classification, which we trained on a randomly selected half of the dataset. Older age (p=0.04), prior history of pulmonary disease (RR 2.2 [1.6, 3.1]), clinical signs of acute liver failure including neurologic findings (somnia (RR 1.7 [1.3, 2.3]), coma (2.8 [2.3, 3.3]), confusion (2.0 [1.5, 2.6]), seizures (2.3 [1.9, 3.0]), and asterixis (1.9 [1.0, 3.3])), bleeding diatheses (epistaxis (1.6 [1.1, 2.8]), gingival bleeding (2.2 [1.7, 2.8]), melena (1.8 [1.2, 2.7]), hematemesis (2.1 [1.6, 2.7]), and petechiae (2.0 [1.5, 2.6])), jaundice (1.8 [1.4, 2.4]), dyspnea (1.7 [1.3, 2.2]) or oliguria (2.6 [2.1, 3.2]), and sonographic evidence of hepatomegaly (RR 2.0 [1.2, 3.4]) or loss of renal corticomedullary differentiation (2.5 [1.7, 3.5]) were all predictive of mortality. In our random forests classifier, the three most important variables by structural and classification accuracy measures were international normalized ratio (mean decrease in accuracy 0.051), aspartate aminotransferase (0.028), and creatinine (0.017), which are typical markers of acute liver failure. The resulting classifier distinguished between fatal and nonfatal cases with AUC=0.77. These results suggest that YF patients may be effectively risk-stratified on the basis of data available at the time of admission.

Understanding transmission dynamics of dengue (DENV) outbreaks is critical to mitigation of pathogen spread. In 2019, Cambodia suffered its worst DENV epidemic in recorded history with a significant portion of the burden in peri-urban and rural areas. We collected sera from 105 DENV-positive Cambodian patients, extracted viral RNA, prepared and sequenced cDNA libraries on Illumina platforms. We first used a de novo assembly method within the open-source IDseq platform to identify the closest pre-existing phylogenetic sequence in GenBank and constructed 105 full-length consensus genomes mapping to that reference with Nextflow (51 DENV1 genomes, 52 DENV2 genomes, 3 DENV4 genomes). We compiled resulting sequences into Bayesian phylogenetic time trees via BEAST for each serotype. With Bayesian coalescent methods, we estimated changes in effective population size and reproduction number through time for DENV-1 and DENV-2. The proportion of sequence pairs within the same 'transmission chain' were identified as those with a least common ancestor within the past six months and compared them across geographic distance, age, gender, and infection severity. Our results indicate that both the effective population size and effective reproduction number had correlated increases through time for DENV1, and more substantially for DENV2. DENV1 sequences showed identity on extremely local scales whereas DENV2 transmission was over a greater geographical space. Transmission chains were more tightly associated in those under age 10 years old. Infection severity had a significant effect on sequence affinity with higher fevers (>38.5°C) and lower white blood cell counts generating more tightly-related transmission chains. In conclusion, genetic diversity of peri-urban transmission of DENV is dependent on spatial distance, but over a larger geographic scale than has been previously described in urban environments. More intensely focal transmission resulted from lack of homotypic immunity to the epidemic DENV1 and geographically restricted lifestyles of younger participants as well as those with clinically severe infections.

### FLUOROQUINOLONE RESISTANT ESCHERICHIA COLI RECOVERED AT THE INTERFACE BETWEEN HUMANS, POULTRY AND THEIR SHARED ENVIRONMENT- A POTENTIAL PUBLIC HEALTH RISK

**Mabel Kamweli Aworh**<sup>1</sup>, Jacob K. Kwaga<sup>2</sup>, Rene S. Hendriksen<sup>3</sup>, Emmanuel C. Okolocha<sup>2</sup>, Chikwe Ihekweazu<sup>4</sup>, Siddhartha Thakur<sup>5</sup>

<sup>1</sup>Department of Veterinary & Pest Control Services, Federal Ministry of Agriculture & Rural Dev, Abuja, Nigeria, <sup>2</sup>Department of Veterinary Public Health and Preventive Medicine, Ahmadu Bello University, Zaria, Nigeria, <sup>3</sup>WHO, FAO, EU, Reference Laboratory for Antimicrobial Resistance, National Food Institute, Technical University of Denmark, Kgs. Lyngby, Denmark, Lyngby, Denmark, <sup>4</sup>Nigeria Center for Disease Control, Abuja, Nigeria, <sup>5</sup>Population Health and Pathobiology College of Veterinary Medicine, NC State 1060 William Moore Drive, Raleigh, NC 27609, NC, United States

Commensal *Escherichia coli* residing in the guts of humans and animals are reservoirs of multidrug resistance genes, including quinolone resistance genes. This study aimed to characterize fluoroquinolone resistance in *E. coli* recovered from poultry workers, chickens, and farm/market environments in Abuja, Nigeria. Of 110 *E. coli* isolates, quinolone-resistance phenotypes were observed in 68.2% (n=75) isolates. Plasmid-mediated quinolone resistance (PMQR) genes were detected in 63.6% (n=70) isolates, mainly from chickens 34.3% (24/70). Among PMQR genes, *qnrS1* was the most detected in 80% (56/70) of isolates followed

by qnrB19 in 20% (14/70) of isolates. We detected *aac(6)-Ib-cr* gene responsible for reduction in the activity of ciprofloxacin in two (2.9%) PMQR-positive *E. coli* isolates recovered from chickens. Most (15/22) isolates with ciprofloxacin-resistance and Nalidixic acid-resistance (19/75) showed double mutations in the quinolone-resistance determining regions of *gyrA*, with single or double mutations in *parC*, and single mutation in *parE*. The most prevalent amino-acid substitutions observed were S(83)L+D(87)N in *gyrA* (46.5%, n=20), S(80)I in *parC* (51.2%, n=22) and S(458)A in *parE* (14%, n=6). Plasmid-mediated colistin resistance (PMCR) gene *mcr-1.1* (n=2), and genes encoding extended-spectrum beta lactamase (ESBL) - *bla*CTX-M-15 and *bla*CTX-M-65 (n=2), were detected in PMQR-positive isolates. PMQR genes were prevalent in *E. coli* isolates recovered from healthy humans, chickens and the poultry farm/market environments. PMCR genes (*mcr-1.1*) occurred in PMQR-positive isolates recovered from manure and drinking water originating from poultry farm/market environments. It was found that the gene encoding ESBL coexisted with *qnrS* positive isolates of human and avian origin. Horizontal transfer of PMQR genes among *E. coli* isolates in the human-poultry-environment interface has public health implications for the spread of antimicrobial resistance. Relevant government agencies should enforce regulations to restrict the use of critically important antimicrobials in poultry production.

### SURVEILLANCE FOR ZONOTIC INFLUENZA A VIRUSES IN LIVE BIRD MARKETS, NORTHERN VIETNAM

Robert D. Hontz<sup>1</sup>, Dao Duy Tung<sup>2</sup>, Kristen K. Coleman<sup>3</sup>, Vuong N. Bui<sup>2</sup>, Than The Son<sup>3</sup>, Hung Nguyen-Veit<sup>4</sup>, Emily R. Robie<sup>5</sup>, Jose A. Garcia-Rivera<sup>6</sup>, Pham Duc Phuc<sup>7</sup>, Gregory C. Gray<sup>5</sup>

<sup>1</sup>U.S. Naval Medical Research Unit TWO (NAMRU-2), Singapore, Singapore, <sup>2</sup>National Institute of Veterinary Research, Hanoi, Viet Nam, <sup>3</sup>Duke-NUS Medical School, Singapore, Singapore, <sup>4</sup>International Livestock Research Institute, Hanoi, Viet Nam, <sup>5</sup>Duke University, Durham, NC, United States, <sup>6</sup>U.S. Naval Medical Research Unit TWO (NAMRU-2), Phnom Penh, Cambodia, <sup>7</sup>Hanoi University of Public Health, Hanoi, Viet Nam

Highly pathogenic avian influenza (AI) virus outbreaks pose a serious threat to both poultry and human health. Such outbreaks have the ability to cross over and infect neighboring countries via live bird markets (LBMs) and perhaps become enzootic among local aquatic birds and poultry. We employed a One Health approach to examine live bird markets (LBMs) in northern Vietnam for evidence of zoonotic influenza A viruses. Environmental, animal, and animal worker samples were collected from four LBMs across four provinces (Hanoi, Lang Son, Lao Cai, and Quang Ninh) in northern Vietnam from January 2019 - January 2021. At each sampling visit, up to three NIOSH two-stage aerosol samplers were positioned 0.5 m from the ground on tripods and connected to SKC AirCheck TOUCH pumps run at 3.5 L per min for up to 4 hrs. Up to ten oropharyngeal (OP) and fifteen cage swabs were collected from poultry near the NIOSH samplers. Market poultry workers permitted nasal wash sample collections and completed questionnaires. All samples were screened for influenza A virus using real-time reverse transcription polymerase chain reaction (qRT-PCR). Positive samples were used for egg inoculation to assess the infectivity of the detected viruses. A total of 3,114 LBM samples were collected. Among the 2,896 samples examined by qRT-PCR thus far, 892 (30.8%) tested positive for influenza A virus, including 202 (40.5%) of the bioaerosol samples, 374 (36.3%) of the poultry cage swabs, 288 (41.9%) of the poultry OP swabs, and 28 (4.1%) of the human nasal washes. Among the 2,692 samples examined with egg culture thus far, 527 (19.6%) yielded viable influenza A virus, including 43 (9.1%) of the bioaerosol samples, 260 (26.1%) of the poultry cage swabs, 224 (33.5%) of the poultry OP swabs, and 0 human nasal washes. Poultry cages and bioaerosols at LBMs are environmental sources of infectious influenza A viruses that may pose an occupational risk for zoonotic infection as evidenced by virus-positive human nasal washes. Additionally, bioaerosol sampling appears to be a sufficient influenza virus surveillance tool that could potentially replace more invasive bird swab sampling.

### DETECTION AND MOLECULAR CHARACTERIZATION OF ZONOTIC AND PANDEMIC SWINE INFLUENZA VIRUS IN JOS: IMPLICATION FOR PUBLIC HEALTH

Jeremiah O. Ijomanta<sup>1</sup>, Clement A. Meseko<sup>1</sup>, Emmanuel C. Okolocha<sup>2</sup>, Caleb A. Kudi<sup>2</sup>

<sup>1</sup>National Veterinary Research Institute, Vom, Plateau State, Nigeria., <sup>2</sup>Faulty of Veterinary Medicine, Ahmadu Bello University, Zaria, Nigeria

Pig is a mixing vessel for Influenza A viruses and have been implicated in pandemics. Human and animal influenza are inextricably linked therefore pigs are important for the generation of novel influenza viruses with pandemic potentials. This study aimed to detect, isolate, characterize and determine the phylogeny of Influenza A virus in Jos and its environs in Nigeria. Eighty six nasal / tracheal swabs and 55 oropharyngeal swabs were collected from apparently healthy pigs and pig handlers respectively and were screened by PCR and virus isolation. Six pig samples and four human samples were positive with CT value below 35. Next Generation Sequence of the amplicons from one positive virus was carried out and local alignment tool was used to compare gene sequences obtained with others in the GeneBank. Nucleotide sequence and construction of Phylogenetic trees of the eight influenza gene segments were done using MEGA 7 software and the Neighbour- Joining method with 1,000 bootstrap replicates. The Nigerian A/swine/Nigeria/19RS1081-19/2017\_ H1N1- PA is closely related to human isolate MH637504 A/Baltimore/ P0258/2018(H1N1). The study showed the detection and characterization of pandemic 2009 influenza A H1N1 from pigs and presents the second full genome sequence in Nigeria and the first in Plateau State. Genomic sequence data obtained has been deposited in the GeneBank with accession number MN54844-PB1, MN540843-PA, MN540838-HA, MN540841-NP, MN540841-NA, MN540839-MP, MN540842-NS. Inter specie transmission from human to pigs appears persistent in Nigeria and can be a source of epidemic and pandemic. This further justifies One Health approach in the control of influenza. We therefore advocate regular surveillance, molecular characterization as part of the preparedness to prevent or mitigate the next pandemic.

1366

### PLAGUE INFECTION IN URBAN SMALL MAMMALS AND FLEAS IN MADAGASCAR

Soanandrasana Rahelinirina<sup>1</sup>, Mireille Harimalala<sup>1</sup>, Mamy Gabriel Randriamanantsoa<sup>2</sup>, Romain Girod<sup>1</sup>, Minoarisoa Rajerison<sup>1</sup>

<sup>1</sup>Institut Pasteur de Madagascar, Antananarivo, Madagascar, <sup>2</sup>National Plague Control Program, Ministry of Public Health, Antananarivo, Madagascar

Plague is a zoonotic disease caused by *Yersinia pestis* and usually transmitted to humans via bites from rodent fleas. Madagascar is the most affected country in the world and plague is mainly occurred in rural areas but rarely in urban cities. In 2017, an outbreak of urban pneumonic plague was recorded in Antananarivo and Toamasina with a few cases of bubonic plague. To better understand the situation of plague in the urban areas we conducted surveillance on reservoirs and their fleas to identify human risk exposure to plague and refine plague prevention measures. Between January and May 2019, we captured small mammals using live traps in 22 markets belonged to 5 urban areas of Antananarivo, Antsirabe, Fianarantsoa, Toamasina and Mahajanga. Serum and spleen samples were collected from small mammals captured to detect IgG anti-F1 *Y. pestis* antibodies by ELISA and for testing *Y. pestis* F1 antigen using rapid diagnostic test (RDT). Fleas were collected from small mammals and identified to determine the flea index (FI) as the average number of fleas per host and *Y. pestis* infected fleas. Overall, 652 small mammals belonging to three rodent and one shrew species were trapped. *Yersinia pestis* F1 antigen were detected in 31 (4.8%) small mammals including *R. norvegicus* (n=15, 3.3%), *R. rattus* (n=9, 6%), *S. murinus* (n=6, 17%) and *M. musculus* (n=1, 14.3%). Animals positive were trapped in eight

markets of Mahajanga, Toamasina and Fianarantsoa. *Rattus norvegicus* is the predominant rodent in 4 urban areas except Fianarantsoa where *R. rattus* were found in abundance. No animals were positive for IgG antibodies; this may indicate an early stage of plague infection in the RDT positive individual or an evolution of plague resistance. A total of 1,822 *X. cheopis* fleas were collected from small mammals and no flea were positive to *Y. pestis* infection. The FI ranged from 0.2 to 7.5 and above the threshold risk (1) in 14 markets. Our findings point towards the importance of the urban markets in the maintaining of plague in enzootic cycle among rodent population. Both in Central Highlands and in coastal areas, rodent survey should be conducted regularly to identify plague risk indicators.

1367

### SCOPE AND OPPORTUNITIES FOR A ONE HEALTH APPROACH FOR GUINEA WORM CONTROL

**Matthew R. Boyce**, Ellen P. Carlin, Jordan Schermerhorn, Claire J. Standley

*Georgetown University, Washington, DC, United States*

Guinea worm disease (GWD) is a neglected tropical disease caused by the nematode *Dracunculus medinensis*. The disease was targeted for eradication several decades ago because of its limited geographical distribution, predictable seasonality, straightforward diagnosis, and exclusive infection of humans. A growing body of evidence now suggests that GWD can affect both humans and animal populations, challenging this last attribute. Accordingly, we endeavored to review publicly available epidemiological data that could support the utility of a One Health approach for GWD control in the six countries that have reported human GWD cases since 2015 – Angola, Cameroon, Chad, Ethiopia, Mali, and South Sudan. Our results demonstrate that while human GWD cases have dramatically declined overall, recent years have witnessed a gradual increase in human case counts, a rapidly growing number of reported animal infections, and cases in new geographies. A majority of the documented animal Guinea worm infections have occurred in dogs, but infections have also been reported in cats, baboons, and a donkey. Given that molecular evidence has demonstrated humans and dogs share exposure to the same populations of worms, it has been hypothesized that the observed increase in animal cases may be driving the increase in human GWD cases – or at a minimum, sustaining the risk of human infection. While this shift likely reflects changes in surveillance and not novel transmission patterns in animal species, it underscores the importance of embracing new approaches if the goal of eradicating GWD is to be achieved. There is a compelling case for controlling GWD using a framework grounded in a One Health approach. This framework should find its foundation in improving disease surveillance, pinpointing the dominant routes of infection, and elucidating the disease burden in animals; determining transmission risk factors among animals and from animals to humans; and identifying practical ways to foster horizontal and multidisciplinary approaches to surveillance, diagnosis, and intervention.

1368

### URBANIZATION SHAPES THE ABUNDANCE AND DIVERSITY OF RODENT-BORNE PATHOGENS IN MALAYSIAN BORNEO: IMPLICATIONS FOR ZONOTIC DISEASE RISK

**Cadhla Firth**<sup>1</sup>, Kim R. Blasdel<sup>2</sup>, Ayda Susana Ortiz-Baez<sup>3</sup>, Amy Hahs<sup>4</sup>, Susan GW Laurance<sup>5</sup>, Stephen L. Doggett<sup>6</sup>, Serge Morand<sup>7</sup>, Edward C. Holmes<sup>3</sup>, David Perera<sup>8</sup>

<sup>1</sup>*EcoHealth Alliance, New York, NY, United States*, <sup>2</sup>*The Commonwealth Scientific and Industrial Research Organisation, Geelong, Australia*,

<sup>6</sup>*Westmead Hospital, Sydney, Australia*, <sup>7</sup>*Montpellier University, Montpellier, France*,

<sup>8</sup>*Universiti Malaysia Sarawak, Kota Samarahan, Malaysia*

Urbanization a widespread and significant process of global change that modifies the landscape rapidly, extensively, and often permanently.

Although this process results in the destruction and fragmentation of natural habitats, it also creates new ecological niches and an abundance of resources in cities, allowing some species to thrive. Rodents are amongst the most successful urban mammals, with several species distributed globally in cities and many others persisting locally in urban and suburban areas. However, rodents are also known reservoirs of many significant human diseases, including leptospirosis, Lyme disease, and viruses that cause hemorrhagic fevers. Our work seeks to understand how the ecological and environmental context of cities influences zoonotic disease dynamics and human disease risk, using rodent-borne diseases as a model system. In this study, we use a combination of ecological and evolutionary approaches to explore how the community composition of rodents, their ectoparasites, and their pathogens vary across an urban-rural gradient in Sarawak, Malaysia. We find that although the microbial response to urbanization is heterogeneous overall, there is clear evidence that urbanization promotes the persistence and spread of a subset of zoonotic pathogens and viruses, including globally significant zoonotic diseases like leptospirosis. We hypothesize that differences in the response of pathogens to urbanization may be driven by differences in transmission dynamics and replication strategy, which suggests a potential route through which disease risk can be mitigated in urbanizing regions across the globe. Finally, we explore how features of the urban environment influence human disease risk and discuss how a One Health-based approach to urban pest management can be used to ensure the continued and healthy coexistence of people and rodents in city environments.

1369

### EMERGENCE OF ZONOSSES: WOULD GOLD MINING BE A CONTRIBUTING FACTOR?

**Maylis Douine**<sup>1</sup>, Yann Lambert<sup>1</sup>, Louise Mutricy<sup>1</sup>, Muriel Galindo<sup>1</sup>, Mathieu Picardeau<sup>2</sup>, Mona Saout<sup>3</sup>, Roxane Schaub<sup>1</sup>, Mathieu Nacher<sup>1</sup>, Stephen Vreden<sup>4</sup>, Martha Suarez-Mutis<sup>5</sup>, Loïc Epelboin<sup>6</sup>

<sup>1</sup>*Centre d'Investigation Clinique Antilles-Guyane, Inserm 1424, Cayenne Hospital, Cayenne, French Guiana*, <sup>2</sup>*National reference center for leptospirosis, Institut Pasteur de Paris, Paris, France*, <sup>3</sup>*University Laboratory, Cayenne Hospital, Cayenne, French Guiana*, <sup>4</sup>*Foundation for the Advancement of Scientific Research in Suriname, Paramaribo, Suriname*, <sup>5</sup>*Parasitology Laboratory, Foundation Oswaldo Cruz, Rio de Janeiro, Brazil*, <sup>6</sup>*Infectious diseases department, Cayenne Hospital, Cayenne, French Guiana*

The emergence of pathogens has increased significantly since 1940, particularly of zoonotic origin (60% of emerging diseases), mainly from wildlife (72%). Anthropization and disruption of ecosystems favor the crossing of inter-species barriers, particularly in areas of high biodiversity such as the Amazon. Would people practicing gold mining, especially unregulated, be particularly affected by zoonoses? Capitalizing on a study among malaria on illegal gold mines in French Guiana, a complete clinical examination and a biological sampling were carried out on consenting adults working on these mines. The examination recorded the dermatological signs of leprosy and leishmaniasis and history of vaccination against yellow fever. Biological tests were performed for neutralizing antibodies (Ab) against yellow fever, phase I and II IgG against Q fever, and Microscopic Agglutination Test against leptospirosis. Between October and December 2019, 380 individuals were included. The seroprevalence of leptospirosis was 28.1% (CI95%=23.6-33.0). This high seroprevalence is consistent with a wild cycle of leptospirosis in the Amazon where many mammals are known to be leptospires carriers. The prevalence of Q fever was 2.9% (CI95%=1.2-4.6), which is lower than the prevalence on the coast, which weakens the hypothesis of a deep forest or terrestrial reservoir of *Coxiella burnettii*, a reservoir still unknown in the region. The majority of participants reported being vaccinated against yellow fever (91.8%) and 97.9% had seroneutralizing Ab. The risk of a yellow fever epidemic, as in Brazil in 2016-2019, seems therefore unlikely. Ten percent (0.7-1.3) of the participants had lesions of cutaneous leishmaniasis. Five persons had typical lesions of leprosy thus an estimated prevalence of 78.9/10,000 py. All came from the Brazilian state of Maranhão, where the prevalence in 2019 was 17 times lower

at 4.5/10,000 py. These unique data shed new light on the transmission cycles of zoonoses that are still poorly understood in the region. In the era of One Health, special attention must be paid to these vulnerable populations in direct contact with biodiversity.

1370

### DURABILITY OF SEROPOSITIVITY IN PATIENTS WITH NEUROCYSTICERCOSIS AFTER LEAVING AN ENDEMIC AREA

**Nina Tang**, Theodore Nash, Thomas B. Nutman, Elise Michelle O'Connell

*National Institutes of Health, Bethesda, MD, United States*

Seroepidemiological surveys play an important role in establishing the prevalence of neurocysticercosis (NCC), a leading cause of epilepsy in many developing countries. However, these antibody-based techniques can skew estimations of morbidity due to persisting seropositivity following disease cure. Using a serological assay of recombinant and synthetic *Taenia solium* antigens, we identified the rates of seropositivity following cure in patients with various forms of NCC. In an optimized ELISA format, we measured IgG to the previously described antigens T24H, GP50, and a truncated Ts8 isoform. These assays produced ROC-based signal/noise (S/N) cutoffs with 96.34% sensitivity and 95.92% specificity when tested with 70 NCC positive and 49 NCC negative samples, with GP50 reactivity driving assay performance. In longitudinal analyses of serum collected from 64 patients over a course of up to 10 years following disease cure, patients with extra-parenchymal (intraventricular and basilar subarachnoid/racemose) NCC maintained the highest levels of seroreactivity post-cure compared with parenchymal NCC. At 5 years post-cure, 50% and 84.21% of ventricular and subarachnoid patients, respectively, continued to be seropositive compared to only 30% of patients with parenchymal disease. Notably, 60% of patients cured of subarachnoid NCC continued to exhibit seropositivity even 10 years post-cure. Correlation analysis showed that GP50 S/N and time to/since cure were inversely correlated (R -0.66,  $p < 0.0001$ ), suggesting that degree of seroreactivity is dependent on both burden of disease and duration of cure. In patients with calcified NCC, we found that seropositivity post-cure was correlated with the number of calcifications (R 0.62,  $P = 0.0016$ ), indicating that these calcifications may help maintain seroreactivity. Our findings show that seroreactivity in patients with NCC varies based on disease type and can persist for many years following cure in a population that is not being re-exposed to *T. solium* antigens. These data will be important for designing future seroepidemiology studies to ensure accurate estimations of disease burden.

### CROSS-SECTIONAL STUDY OF POPULATION SCREENING FOR URINARY ANTIGENS TO DETECT SUBARACHNOID NEUROCYSTICERCOSIS IN A COMMUNITY SETTING

**Lauralee J. Fernandez**<sup>1</sup>, Samantha E. Allen<sup>2</sup>, Percy Vilchez<sup>3</sup>, Ricardo Gamboa<sup>3</sup>, Claudio Muro<sup>3</sup>, Yesenia Castillo<sup>3</sup>, Pierre Dorny<sup>4</sup>, Javier Bustos<sup>5</sup>, Hector H. Garcia<sup>5</sup>, Seth E. O'Neal<sup>1</sup>, Cysticercosis Working Group<sup>6</sup>

<sup>1</sup>Oregon Health & Science University – Portland State University, School of Public Health, Portland, OR, United States, <sup>2</sup>School of Medicine, Oregon Health & Science University, Portland, OR, United States, <sup>3</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Tumbes, Peru, <sup>4</sup>Department of Biomedical Sciences, Institute of Tropical Medicine, Antwerp, Belgium, <sup>5</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia & Cysticercosis Unit, National Institute of Neurological Sciences, Lima, Peru, <sup>6</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Peru, Tumbes, Peru

Subarachnoid neurocysticercosis (SANCC) is the most morbid form of *Taenia solium* infection. SANCC is diagnosed usually at late stages when treatment options are limited, and patients experience frequent adverse treatment complications due to advanced disease. We validated population screening to detect cysticercosis antigens (cyst-Ag) in urine

to identify SANCC in earlier asymptomatic stages. Urine collection is practical, non-invasive, and readily accepted in Peru. Our objective was to identify cases of SANCC in a population-based setting using a two-step screening process of urine based antigen tests followed by neuroimaging. We conducted a cross-sectional study in 2018 to screen for SANCC in residents of Tumbes, Peru, (n=8115). We collected first morning urine from participants at their homes and calculated optical density ratios (ODR) for cyst-Ag in these samples using ELISA and monoclonal antibody set B158/B60. We offered all participants with an  $ODR \geq 3$  a non-contrast MRI of the brain to identify intracranial *T. solium* cysts, and a clinical evaluation for neurologic symptoms consistent with neurocysticercosis (NCC). Of 8315 individuals screened, 81 (0.97%) had an  $ODR \geq 3$  and were offered MRI. Seventy-four obtained MRI and 17 had SANCC; 13 (76.4%) reported no symptoms. Another 7 had non-subarachnoid forms of viable NCC. Globally, the prevalence of SANCC was 2 per 1000 persons, but there were significant regional differences with higher prevalence of urinary cyst-Ag and SANCC in regions with greater immigration. In these regions, the positive predictive value (PPV) of the urine screen was 32.5% for SANCC and 42.0% for all NCC. Population urine screening in a *T. solium* endemic region identified cases of asymptomatic SANCC with an acceptable PPV. An ongoing observational cohort and planned clinical trial will help determine whether early medical intervention of asymptomatic SANCC is safe, and whether this approach merits further evaluation of efficacy to improve clinical prognosis.

### CYSTIHUMAN: A MODEL OF HUMAN NEUROCYSTICERCOSIS

**Gabrielle M. Bonnet**<sup>1</sup>, Francesco Pizzitutti<sup>1</sup>, Eloy Gonzales-Gustavson<sup>2</sup>, Sarah Gabriël<sup>3</sup>, William K. Pan<sup>4</sup>, Javier A. Bustos<sup>5</sup>, Hector H. Garcia<sup>6</sup>, Seth E. O'Neal<sup>7</sup>, for the Cysticercosis Group in Peru<sup>8</sup>

<sup>1</sup>Independent consultant with OHSU, Portland, OR, United States, <sup>2</sup>Tropical and Highlands Veterinary Research Institute, University of San Marcos, Huancayo, Peru, <sup>3</sup>Department of Veterinary Public Health and Food Safety, Ghent University, Ghent, Belgium, <sup>4</sup>Nicholas School of Environment and Duke Global Health Institute, Duke University, Durham, NC, United States, <sup>5</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Tumbes, Peru, <sup>6</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia & Cysticercosis Unit, National Institute of Neurological Sciences, Lima, Peru, <sup>7</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Peru & School of Public Health, Oregon Health & Science University and Portland State University, Portland, OR, United States, <sup>8</sup>Universidad Peruana Cayetano Heredia, Lima, Peru

Cysticercosis is a neglected tropical disease that was deemed “eradicable” by the World Health Organization. Neurocysticercosis (NCC) is a major cause of epilepsy in developing countries, also causes intracranial hypertension and hydrocephalus, and can lead to death. Simulation models can help identify interventions likely to bring higher benefit to cost ratios before they are implemented at a large scale and high cost. CystiHuman, the first human NCC model, was developed to allow for cost-effectiveness analyses that focus on the actual impact of the disease rather than using proxies as is the case with transmission models. It also allows the comparison of a broader range of interventions (e.g., treatment of NCC symptoms) than usual models. CystiHuman is an agent-based model that projects NCC and associated pathologies. It uses the output of another model, CystiAgent, which projects the evolution of pig cysticercosis and human taeniasis. It includes a model of human cyst stage and location, and of symptom and treatment likelihood. CystiHuman accounts for delays in the appearance of human symptoms to help make time-dependent predictions of changes in the human disease. RCystiHuman was used so far to model the situation at baseline in three endemic villages in Peru. It gives reasonable results for the disease and its clinical presentation, and reproduces patterns of increase in NCC prevalence with age. Initial simulations suggest that NCC prevalence increases rapidly after a peak in taeniasis but decreases very slowly after this peak has passed. In conclusion, it is possible to develop and calibrate a model of human NCC and obtain reasonable results. Initial outcomes

suggest that short-term interventions may not be well suited to achieve significant changes in human NCC. Further work is needed to validate the model and develop projections of the economic and health benefits/costs of different interventions.

### THE ROLE OF BENZIMIDAZOLE TREATMENT IN THE CLINICAL MANAGEMENT OF ALVEOLAR ECHINOCOCCOSIS IN GERMANY - BENEFITS AND CHALLENGES

**Lynn Peters**, Sanne Burkert, Julian Schmidberger, Andreas Hillenbrand, Tilmann Grater, Benjamin Hagemann, Thomas Barth, Nina Eberhardt, Ambros Beer, Wolfgang Kratzer, Beate Gruner  
*University Hospital Ulm, Ulm, Germany*

Alveolar echinococcosis (AE) is a progressive parasitic disease caused by the larval stage of *Echinococcus multilocularis* (EM). Benzimidazoles are the only approved pharmaceutical treatment options, yet drug intolerance and non-response occur frequently and hamper further clinical management. This retrospective cohort study included 275 patients. Descriptive statistics included demographics, stage of disease, initial symptoms, treatment options, and complications. A regression model revealed risk and protective factors for adverse outcomes. Additionally, a cross-sectional study evaluated the absorption of albendazole depending on nutrition and possible side effects. Median age at diagnosis was 55 years, 55% were female. When diagnosis was established, more than 60% reported no specific symptoms, yet 62% presented in an advanced stage. AE was inoperable in 57% and hence treated with benzimidazoles (BMZ). Within this group, 7% suffered from absolute BMZ intolerance resulting in hepatotoxicity. A total 9% received a structured treatment interruption (STI). A follow-up period of 803 cumulative patient-years was monitored. While 26% of patients were cured, 71% were stable and 3% suffered from progressive disease. Risk factors for adverse outcomes included advanced stage, vascular and biliary complications, BMZ toxicity and relapse after STI. Surgical treatment, high albendazole serum level and a long-term BMZ treatment were identified as protective factors. Using decreasing serum levels of *Echinococcus* antibodies and IgE as surrogate markers for treatment response, BMZ treatment proved to be effective. In contrast to the drug information, the absorption of albendazole does not necessarily require 40g of solid fat. Side-effects often reported included gastrointestinal discomfort and diarrhoea. BMZ allowed for a long-term stable disease, especially if well-tolerated with sufficient serum levels. However, cases with non-response to BMZ or BMZ toxicity resulted in adverse outcomes with complex clinical management. In carefully selected patients, a STI can present a valuable alternative to life-long BMZ treatment.

1374

### NOVEL HUMAN INFECTION WITH AN UNKNOWN SPECIES OF DRACUNCULUS, VIETNAM.

**Sarah G. Sapp**<sup>1</sup>, Pham Thach<sup>2</sup>, H. Rogier Van Doorn<sup>3</sup>, Henry S. Bishop<sup>1</sup>, Mark S. Fox<sup>1</sup>, Vitaliano A. Cama<sup>1</sup>, Le Van Duyet<sup>4</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>National Hospital for Tropical Diseases, Hanoi, Viet Nam, <sup>3</sup>Oxford University Clinical Research Unit, Hanoi, Viet Nam, <sup>4</sup>National Hospital for Tropical Disease, Hanoi, Viet Nam

With the recent detection of *Dracunculus medinensis* (Guinea worm) in Angola, there has been an increased concern that dracunculiasis may be present in countries not previously endemic for Guinea worm. In 2020, a 23-year-old male living in northern Vietnam with no history of foreign travel was hospitalized, and five large nematodes were recovered from abscesses on the arms and legs. These nematodes measured 30–60 cm in length and were grossly consistent with *Dracunculus* sp. A segment of one worm was sent to the reference laboratory at the US Centers for Disease Control and Prevention (CDC), where the species of the worm was evaluated using microscopy and molecular tools. Microscopically, the segment of worm possessed a finely striated cuticle and L1 larvae

measuring an average of 339 µm long were present. The larval measurements excluded *D. medinensis* as the causative species and were instead consistent with a few described species of *Dracunculus* mostly reported from reptile hosts. Sequencing of the entire 18S gene placed this specimen in a clade separate from *D. medinensis* and more closely aligned with *D. lutrae* and *D. insignis*. Species could not be further resolved due to the lack of additional morphologic features and missing sequence data for most members of the genus. The only prior report of *Dracunculus* spp. in Vietnam was *D. houdemeri* collected from checkered keelback snakes (*Fowlea piscator*). While the larvae of *D. houdemeri* are consistent with the measurements in this specimen, no DNA sequence data are available for confirmation. Surveillance for similar cases among animals and humans in the region is warranted to better understand possible transmission routes. Additionally, this study highlights the importance of effective public health surveillance systems demonstrated in this collaborative work between public health authorities from Vietnam, WHO and US-CDC.

1375

### RPACAN3990, A NOVEL, HIGHLY SENSITIVE RECOMBINASE POLYMERASE ASSAY WITH A VISUALIZABLE READOUT

**William Sears**<sup>1</sup>, Yvonne Qvarnstrom<sup>2</sup>, Thomas B. Nutman<sup>1</sup>

<sup>1</sup>NIAID, Bethesda, MD, United States, <sup>2</sup>CDC, Atlanta, GA, United States

*Angiostrongylus cantonensis* (Ac) is one of the leading causes of eosinophilic meningitis worldwide. A field deployable molecular detection method could enhance both environmental surveillance and clinical diagnosis of this emerging pathogen. Accordingly, RPACan3990, a recombinase polymerase assay (RPA) was developed to target a region predicted to be highly repeated in the Ac genome. The assay was then adapted to produce a visually interpretable fluorescent readout using an orange camera lens filter and a blue light. Using Ac genomic DNA, the limit of detection was found to be 1fg/µl by both fluorometer measurement and visually. All clinical samples tested known to be positive for Ac from various areas of the globe were positive by RPACan3990. Clinical samples known to be positive by other etiologies of eosinophilic meningitis (i.e. *Toxocara* sp) were negative in the RPACan3990 assay. The optimal incubation temperature range for the reaction was found to be between 35-40 °C. The assay successfully detected 1fg/µl of Ac genomic DNA after incubation at human body temperature (in a shirt pocket). In conclusion, these data suggest RPACan3990 is potentially a point of contact molecular assay capable of detecting Ac by efficiently producing visually interpretable results with minimal instrumentation.

1376

### EXPLORING THE GENETIC DIFFERENCES AMONG POPULATIONS OF TRICHURIS TRICHIURA FROM LAOS, TANZANIA AND COTE D'IVOIRE WITH DIFFERING RESPONSES TO ALBENDAZOLE-IVERMECTIN COMBINATION TREATMENT

**Abhinaya Venkatesan**<sup>1</sup>, Rebecca Chen<sup>1</sup>, Brenna Reimer<sup>1</sup>, Russell Avramenko<sup>1</sup>, Chandni Patel<sup>1</sup>, Eveline Hürlimann<sup>2</sup>, Sophie Welche<sup>2</sup>, Jennifer Keiser<sup>2</sup>, John Gilleard<sup>1</sup>

<sup>1</sup>University of Calgary, Calgary, AB, Canada, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

*Trichuris trichiura*, one of the most important Soil Transmitted Helminth (STH) species, infects over 500 million people globally with a major socio-economic impact in developing countries. STH Mass Drug Administration (MDA) programs use either albendazole or mebendazole. However, these benzimidazole drugs have very low efficacy against *T. trichiura*, with cure rates and egg reduction rates typically <30% and <50%, respectively. Recent trials of albendazole-ivermectin combination treatments revealed high efficacy at two geographical sites with egg reduction rates above 98% in Pemba, Tanzania and Lao PDR. In contrast, there was much lower efficacy at a third site in Cote d'Ivoire with an egg reduction rate below 70%. To explore whether this difference in efficacy could be due to genetic differences in the parasite populations, we have undertaken Illumina short-read deep amplicon sequencing of multiple loci on 29,

37 and 22 *T. trichiura* PCR positive fecal samples from Pemba, Tanzania, Lao PDR and Cote d'Ivoire, respectively. Phylogenetic analysis of the ITS-2 rDNA locus revealed that the Amplicon Sequence Variants (ASVs) from all samples from Pemba, Tanzania and Lao PDR clustered together whereas those from Cote d'Ivoire clustered separately. Primers targeting the mitochondrial *nad1*, *nad4* and the major  $\beta$ -tubulin gene generated ASVs mapping to the appropriate reference sequences from all samples from Pemba, Tanzania and Lao PDR but not from any samples from Cote d'Ivoire. There were no potential candidate benzimidazole resistance mutations at codons 167, 198 and 200 in the  $\beta$ -tubulin gene in any of the mapped ASVs from Pemba, Tanzania and Lao PDR. Overall, these results suggest that the *T. trichiura* population from Cote d'Ivoire is genetically divergent to those from Pemba, Tanzania and Lao PDR and this has the potential to underlie the differences in ivermectin-albendazole efficacy. Further sequence analysis of additional genetic loci is underway.

1377

### INVESTIGATIONS OF THE ROLE OF DRUG RESISTANCE IN RELAPSING BABESIA MICROTI INFECTIONS

Wesley Rogers<sup>1</sup>, Annie Leung<sup>1</sup>, Pooja Lamda<sup>2</sup>, Sara Krivacsy<sup>2</sup>, Matthew Simon<sup>1</sup>, Luis Marcos Raymundo<sup>2</sup>, Laura Kirkman<sup>1</sup>

<sup>1</sup>Weill Cornell Medicine, New York, NY, United States, <sup>2</sup>Stony Brook Medicine, Stony Brook, NY, United States

Guidelines for the treatment of babesiosis rely on combination therapy, with most patients receiving azithromycin and atovaquone during their treatment course. Atovaquone is the key anti-infective in all recommended treatment regimens for relapsing babesiosis. However, a low barrier to the development of atovaquone resistance is well defined for a variety of pathogens *in vitro* and *in vivo*. Several reports have demonstrated the emergence of mutations in the gene encoding target of atovaquone, *cytb*, in samples of relapsing babesiosis. Our expanded survey of relapsing babesiosis samples has demonstrated additional mutations in *cytb* with several repeatedly mutated sites including amino acid changes near the conserved PEWY region, and amino acid changes at site 134, which was previously identified as key to atovaquone resistance in other organisms and an *in vivo* model of *B. microti* infection. In addition, we have surveyed for mutations in *rpl4*, the gene that encodes that target protein for azithromycin. We repeatedly see amino acid changes at position 86, exclusively in samples of relapsing disease. Of the six relapsing cases tested 100% (6/6) had mutations in *cytb* and 50% (3/6) were found to have *rpl4* mutations. We also surveyed 20 non relapsing cases and found no mutations in these samples. Our data highlights that relapsing disease is often but not exclusively associated with mutations in the targets for atovaquone and azithromycin and we are working to define the role these mutations play in the successful treatment of these complicated babesiosis patients.

### DEVELOPMENT OF A LATERAL FLOW ASSAY FOR NEUROLOGICAL TOXOPLASMOSIS

Hannah E. Steinberg<sup>1</sup>, Amanda Haymond<sup>2</sup>, Andrea Diestra<sup>3</sup>, Catherine Apaza<sup>3</sup>, Marilly Donayre Urquiza<sup>4</sup>, Lilia Cabrera<sup>5</sup>, Freddy Tinajeros<sup>5</sup>, Viviana Pinedo Cancino<sup>4</sup>, Lastenia Ruiz<sup>4</sup>, Cesar Ramal<sup>6</sup>, Weidong Zhou<sup>2</sup>, Paul Russo<sup>2</sup>, Lance Liotta<sup>2</sup>, Nancy E. Freitag<sup>1</sup>, Natalie M. Bowman<sup>7</sup>, Vernon Carruthers<sup>8</sup>, Maritza Calderon<sup>3</sup>, Alessandra Luchini<sup>2</sup>, Robert H. Gilman<sup>9</sup>

<sup>1</sup>University of Illinois, Chicago, Chicago, IL, United States, <sup>2</sup>George Mason University, Fairfax, VA, United States, <sup>3</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>4</sup>Universidad Nacional de la Amazonia Peruana, Iquitos, Peru, <sup>5</sup>AB Prisma, Lima, Peru, <sup>6</sup>Hospital Regional de Loreto, Iquitos, Peru, <sup>7</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>8</sup>University of Michigan, Ann Arbor, MI, United States, <sup>9</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Opportunistic neurological infections in persons living with HIV (PLHIV) are challenging to diagnose. CT and MRIs with a clinical suspicion can guide

treatment, but definitive diagnosis remains elusive for many patients. *Toxoplasma gondii* (*T. gondii*) is known to cause Toxoplasmic Encephalitis in PLHIV. Though difficult to diagnose, it has up to 90% clinical response rate to treatment. Innovations in *T. gondii* diagnostics, such as our team's urine-based diagnostic western blot utilizing hydrogel nanoparticle antigen concentration, require laboratory equipment and skilled personnel, limiting its range. To expand access to the diagnostic assay, we initiated structural and functional studies of the antigen of interest, GRA1, to allow for transition to a lateral flow assay. We have tested 8 antibody clones for their ability to form a sandwich around GRA1, resulting in an antibody pair with detection to 62.5pg/ml of recombinant antigen. Despite this high sensitivity in recombinant antigen, formation of the sandwich is not observed in urine from *T. gondii*-infected patients who are positive for GRA1 via western blot. Immunoprecipitations into mass spectrometry of *T. gondii* identified SAG2, a surface antigen, as a binding partner to GRA1. This interaction has been confirmed by western blotting. Circular dichroism studies suggest that GRA1 has a 96% alpha helical structure that refolds in the presence of calcium or increasing pH. Enzymatic digestion studies suggest that GRA1 undergoes N-linked glycosylation on the 30<sup>th</sup> amino acid. This glycan is estimated to be one third the size of the total GRA1 structure and may be obstructing antibody binding. Despite being a known secretory protein, GRA-1's function and structure is currently unknown; our data sheds light on GRA1's signaling role and structural modifications, which impact design of lateral flow immunodiagnosics. Moving forward, we will use a mass spectrometry based protein-protein interaction identification technique to map the binding sites of the 8 antibody clones as well as SAG2 to GRA1. This data will assess if the antibodies are impeded in their binding by the glycan or binding partners.

1379

### CATALYSIS OF DRUG DISCOVERY RESEARCH AGAINST NEGLECTED TROPICAL DISEASES (NTDS) AT THE UNIVERSITY OF YAOUNDE 1: IMPACT OF THE BIOVENTURE FOR GLOBAL HEALTH

Fabrice Fekam Boyom

University of Yaounde 1, Yaounde, Cameroon

Our vision at the Antimicrobial and Biocontrol Agents Unit (AmBcAU), University of Yaounde 1 is to improve the health and well-being of people burdened by infectious diseases of poverty through research and innovation towards the elimination of specific neglected tropical diseases (NTDs). Within the last 10 years, we have partnered with African and extra-African public and private institutions to pursue our drug discovery research. We have successfully implemented a middle-high throughput drug discovery platform in a conducive research environment to perform routine phenotypic *in vitro/in vivo* screening of natural products and libraries of small molecules against the causative agents of malaria, leishmaniasis, amoebiasis, Human African trypanosomiasis, Buruli ulcer, toxoplasmosis and resistant bacterial infections. Among the major contributors to this achievement, the impact of the Bio-Venture for Global Health (BVGH) through WIPO Re:Search, a global consortium that drives innovative public-private partnerships to address unmet medical needs for neglected infectious diseases and build research and development capacity in low- and middle-income countries is paramount. Indeed, this consortium has initiated and nurtured strong international partnerships between University of Yaounde 1 and institutions such as University of South Florida, FL, USA, that provides support in natural products isolation and structure elucidation; Merck Healthcare KGaA, Germany, Johnson and Johnson's Janssen pharmaceuticals, USA; Eisai Co., Ltd., Japan and Pfizer all providing target-based chemical libraries of inhibitors of critical metabolic pathways in eucaryotic pathogens; and the Guangzhou Institutes of Biomedicine and Health (GIBH), that collaborates on drug discovery against Buruli ulcer. To date, we have achieved significant data on hit inhibitors of the targeted pathogens to support further drug development against the diseases of interest.

### ARGONAUTE MEDIATED GENE SILENCING IN CRYPTOSPORIDIUM INFECTION

Alejandro Castellanos-Gonzalez

University of Texas Medical Branch, Galveston, TX, United States

The World Health Organization reports diarrhea kills around 760,000 children under five every year. *Cryptosporidium* is a leading cause of moderate-to-severe diarrhea in children. Nitazoxanide is the only FDA-approved medication available for cryptosporidiosis treatment, but it has limited efficacy in malnourished children and is ineffective in immunocompromised individuals. Therefore, more effective treatment options are urgently needed. Recently we developed a unique technology to silence genes in this pathogen using antisense RNA-argonaute (Ago) complexes. We have demonstrated that Ago complexes block expression of essential genes involved in *Cryptosporidium* infection. In addition, we treated orally mice with labeled complexes to show the feasibility to deliver RNA-Ago on intestinal cells of infected mice. Overall, our results show the possibility to conduct *In vivo* silencing to study gene function in *Cryptosporidium*. Therefore Ago-RNA complexes could be used to inhibit selected genes and reduce *Cryptosporidium* infection.

### SINGLE ADMINISTRATION OF A BIODEGRADABLE MICRONEEDLE CAN SUBSTITUTE FOR REPEATED APPLICATION OF EYEDROPS IN THE TREATMENT OF ACANTHAMOEBA KERATITIS

Hee Kyoung Kang<sup>1</sup>, SeungHyun Park<sup>2</sup>, KangJu Lee<sup>3</sup>, WonHyoungh Ryu<sup>2</sup>, Hyun Beom Song<sup>1</sup>

<sup>1</sup>Seoul National University College of Medicine, Seoul, Republic of Korea, <sup>2</sup>Yonsei University, Seoul, Republic of Korea, <sup>3</sup>Chonnam National University, Seoul, Republic of Korea

Infectious keratitis (i.e., an infection of the cornea) is one of the main causes of corneal opacities and the 4th cause of blindness globally. *Acanthamoeba* keratitis is one of rare etiologies and is known to be associated with contact lens usage, but, in developing countries, it can account up to 2% of microbiology-proven cases mostly without association with contact lens. The treatment relies on topical antibiotics, biguanides. To achieve and maintain the required therapeutic concentration in the cornea where the tear fluid continuously rinses the surface, the antibiotics must be frequently applied, even while the patient is sleeping. However, the inevitably poor compliance decreases drug bioavailability. In this study, a single microneedle (MN) is injected into the cornea to substitute for the repeated application of eyedrops in the treatment of *Acanthamoeba* keratitis. After comparing the mechanical integrity and drug release profiles of three different drug tips, the drug tip with the "high" drug concentration that releases 12.5 ng drug within 3 days is applied to a cornea to evaluate the transferability and *in vivo* drug release. In the treatment of infectious keratitis with repeated application of eyedrops for six consecutive days, a single MN injection is substituted for the initial 3 days of eyedrop applications. The progression remains similarly attenuated after 3 days without eyedrops, and comparable efficacy is achieved on day 6 when combined with delayed eyedrop treatment from day 3. Thus, the single administration of a biodegradable MN can substitute for the repeated application of eyedrops in the treatment of *Acanthamoeba* keratitis.

### RELATIONSHIP OF GALECTIN-3 BIOMARKER FOR CLINICAL OUTCOMES IN A CHAGAS DISEASE COHORT FROM A BRAZILIAN ENDEMIC REGION

Carlos H. Moreira<sup>1</sup>, Fabio F. Fernandes<sup>2</sup>, Lea C. De Oliveira<sup>1</sup>, Ana L. Bierrenbach<sup>1</sup>, Clareci Cardoso<sup>3</sup>, Claudia Di Lorenzo<sup>4</sup>, Ariela M. Ferreira<sup>5</sup>, Thallyta M. Vieira<sup>6</sup>, Renata F. Damasceno<sup>5</sup>, Desiree S. Haikal<sup>5</sup>, Nayara D. Quintino<sup>3</sup>, Maria do Carmo Nunes<sup>7</sup>, Antonio Luiz Riberio<sup>6</sup>, Ester C. Sabino<sup>1</sup>

<sup>1</sup>Instituto de Medicina Tropical, São Paulo, Brazil, <sup>2</sup>Instituto do Coracao, São Paulo, Brazil, <sup>3</sup>Universidade Federal de Sao Joao Del Rei, Sao Joao Del Rei, Brazil, <sup>4</sup>University of Sao Joao Del Rei, Sao Joao Del Rei, Brazil, <sup>5</sup>Universidade Estadual de Montes Claros, Montes Claros, Brazil, <sup>6</sup>Universidade Federal de Minas Gerais, Belo Horizonte, Brazil, <sup>7</sup>Universidade Federal de Minas Gerais - UFMG, Minas Gerais, Brazil

Chagas cardiomyopathy evolves through inflammation, cardiac remodeling, fibrosis. Represents a leading cause of infectious myocarditis worldwide, with an estimate 12.000 deaths per year, by 2010. Galectin-3 (GAL-3) can translate fibrogenesis potential and stratify who will evolve towards cardiac disease spectrum and earlier death. We evaluated GAL-3 levels are associated with cardiomyopathy onset, progression, or all-cause death among a cohort subset of no benznidazole-experienced patients from a vectorial controlled transmission and highly endemic Brazilian region. We described baseline sociodemographic and clinical data, Gal-3, NT-proBNP, serology titres, ECG minor or major abnormalities, and functional class. The median follow-up time was 2.5 years, and we reassessed changes in: NT-proBNP, ECG, NYHA, and all-cause mortality. We ran multivariate-adjusted Cox regression with Gal-3. We studied 1313 patients, mean age 59.8 (± 12.5) years, mostly female (n=884; 67%), frequent comorbidities (hypertension, 64.5%; dyslipidemia, 41.2%; diabetes, 10.1%); NYHA I-II, 57.2%. ECG abnormalities at baseline were frequent: minor, 23.3%, and major, 60.1%. Overall, Gal-3>25.9 ng/mL was associated with deaths and more disease severity markers. One hundred (8.2%) patients died. Gal-3 was higher among deceased 19.9 (±8.7) ng/mL, survivor's levels, 17.5 (±6.2) ng/mL; p<0.001. For higher Gal-3 stratum, HR 2.07 [CI95%: 1.21-3.52]; for composite higher Gal-3 and major-ECG, HR 6.85 [CI95%: 3.10-15.10]; while for Gal-3>25.9 ng/mL, and abnormal age-adjusted NT-proBNP, HR 7.93 [CI95%: 3.88-16.21]. Worsening ECG, age-adjusted NT-proBNP, NYHA wasn't associated with Gal-3>25.9 ng/mL. Among no benznidazole experienced *T.cruzi* infected patients, Gal-3 >25.9ng/mL depicted higher death rates. When associated with major abnormalities in ECG or abnormal NT-proBNP, even higher HRs weren't related to representing disease evolution.

### ELEVATED PEDIATRIC CHAGAS DISEASE BURDEN COMPLICATED BY CONCOMITANT GASTROINTESTINAL PARASITES AND MALNUTRITION IN EL SALVADOR

Melissa S. Nolan<sup>1</sup>, Kristy O. Murray<sup>2</sup>, Rojelio Mejia<sup>2</sup>, Peter J. Hotez<sup>2</sup>, Maria Jose V. Mondragon<sup>2</sup>, Stanley Rodriguez<sup>3</sup>, Jose Palacios<sup>3</sup>, William E. Contreras<sup>4</sup>, Mary K. Lynn<sup>1</sup>, Myriam Torres<sup>1</sup>, Carlota Monroy<sup>5</sup>

<sup>1</sup>University of South Carolina, Columbia, SC, United States, <sup>2</sup>Baylor College of Medicine, Houston, TX, United States, <sup>3</sup>University of El Salvador, San Salvador, El Salvador, <sup>4</sup>El Salvador Ministry of Health-Western Region (SIBASI), Sonzacate, El Salvador, <sup>5</sup>University of San Carlos, San Carlos, Guatemala

The eradication of *Rhodnius prolixus* from Central America was heralded as a victory for controlling *Trypanosoma cruzi* transmission. While public health officials believed this milestone achievement would effectively stop vector transmission, case reports of acute vector transmission began amassing within a few years. Our investigation employed a cross-sectional serosurvey of children either presenting with fever for clinical care or children living in homes with known triatomine presence in the state of Sonsonate, El Salvador. Over the 2018 calendar year, we identified a 2.3%

Chagas disease seroprevalence among children with hotspot clustering in Nahuizalco. Positive serology was significantly associated with dogs in the home, older participant age, and a higher number of children in the home by multivariate regression. Concomitant gastrointestinal parasitic infection was noted in a subset of studied children; 60% having at least one gastrointestinal parasite and 15% having two or more concomitant infections. Concomitant parasitic infection was statistically associated with an overall higher parasitic load detected by qPCR. Lastly, we identified a four-fold higher burden of stunting in our cohort compared to the national average, with four-fifths of mothers reporting severe food insecurity. Our study highlights that pediatric polyparasitism and malnutrition are common comorbidities in El Salvador, and a systems-based approach is warranted when treating Chagas disease seropositive children.

<sup>1</sup>Center for Global Health, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>2</sup>Division of Epidemiology, Biostatistics and Preventative Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>3</sup>Department of Medical Biochemistry, School of Medicine, Maseno University, Maseno, Kenya, <sup>4</sup>Department of Medical Laboratory Sciences, School of Public Health Biomedical Sciences and Technology, Masinde Muliro University of Science and Technology, Kakamega, Kenya, <sup>5</sup>Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>6</sup>Division of Nephrology, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>7</sup>Division of Hospital Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>8</sup>Department of Emergency Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>9</sup>Department of MNI, University of Applied Sciences Mittweida, Mittweida, Germany

There are limited data describing COVID-19 disease severity in disproportionately affected minority groups, particularly American Indians/Alaska Natives (AI/ANs). This prospective observational study (15 May-20 October 2020) at the University of New Mexico Hospital determined the relationship between SARS-CoV-2 viral burden and clinical outcomes in patients (n=94) of different ancestries. SARS-CoV-2 viral loads in the upper respiratory tract (URT) and peripheral blood (viremia) were quantified on days 0, 1, 2, 3, 6, 9, and 14 in hospitalized COVID-19 patients with non-severe and severe disease. The cohort was stratified into AI/AN and all other races/ethnicities combined (non-AI/AN). Among the 94 patients, 45.7% identified as AI/AN. Baseline characteristics (i.e., comorbidities and laboratory values) at admission were similar between the AI/AN and non-AI/AN groups. Individuals of AI/AN descent had more severe disease (odds ratio [OR]=7.46, [95% CI, 2.20-25.29], P=0.001, adjusted for age, sex, remdesivir, and steroids). Viral loads in the URT were comparable between ancestral groups with non-severe and severe disease. However, viremia was higher in the AI/AN group with severe disease on days 0, 1, 2, and cumulatively across 14 days (P=0.009). AI/AN ancestry was associated with a greater risk of having viremia (OR=4.73, [1.67-13.43], P=0.004, adjusted with identical covariates). SARS-CoV-2 viremia during hospitalization was associated severe disease (OR=9.19, [3.33-25.34], P=1.84x10<sup>-5</sup>, adjusted with identical covariates). In summary, individuals of AI/AN descent had more severe disease, characterized by elevated blood viral loads, despite comparable comorbidities. Viremia during hospitalization was associated with severe disease and was more common in the AI/AN group. These

findings may explain, at least in part, the disproportionate disease burden of COVID-19 witnessed in this population. It will be important to define the biological/molecular basis of these virological findings in future studies to design interventions for improved clinical outcomes.

Pedro Teixeira<sup>2</sup>, Anthony Worsham<sup>3</sup>, Michelle Harkins<sup>2</sup>, Phillip Seidenberg<sup>4</sup>, Jens O. Langsjoen<sup>3</sup>, Kristan Schneider<sup>5</sup>, Christophe G. Lambert<sup>1</sup>, Douglas J. Perkins<sup>1</sup>

<sup>1</sup>Center for Global Health, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>2</sup>Division of Pulmonary, Critical Care, and Sleep Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>3</sup>Division of Hospital Medicine, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>4</sup>Department of Emergency Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States, <sup>5</sup>Department of MNI, University of Applied Sciences Mittweida, Mittweida, Germany

Race and ethnicity data in the US indicate that minority groups suffer disproportionately from COVID-19 cases, hospitalization rates, and mortality. Throughout the pandemic, American Indian/Alaska Native (AI/AN) populations have had the highest hospitalization rates and second highest proportion of cases and mortality. In New Mexico, the AI/AN population has experienced the highest number of COVID-19 cases, hospitalization rates, and deaths. However, the underlying molecular characteristics of COVID-19 pathogenesis in AI/AN remains unresolved. To identify molecular pathways for targeting by immunotherapy, we are conducting a prospective observational study (15 May 2020 to date) in hospitalized COVID-19 patients. Daily clinical and laboratory measures are obtained, along with peripheral blood samples (days 0, 1, 2, 3, 6, 9, and 14). To date, 336 hospitalized patients have been enrolled. Transcriptomics by next-generation sequencing was performed on a subset of temporally collected samples from patients stratified into AI/AN (n=26) and all other races/ethnicities combined (non-AI/AN, n=13). Enrichment analysis was performed using MetaCore™ for significantly (P<0.05) dysregulated genes (log<sub>2</sub>). The AI/AN group had elevated Furin on days 2 and 6 which can facilitate conversion of the SARS-CoV-2 spike protein into S1 for binding to ACE2 and subsequent endocytosis. In addition, antiviral cytokines (IFN-α, IFNL3, and IFNL4) were downregulated early in the infection, whereas IFN-γ was upregulated. Early infection was also characterized by reduced expression of HLA-DMB, HLA-DRB1, and MHC class II which can lead to diminished antigen presentation. An increase of P-selectin expression was observed until day 6, at which time, PAI1 was upregulated. The combination of these two events can enhance platelet-leukocyte adhesion, thrombosis, and acute respiratory distress syndrome in COVID-19. Collectively, these results provide novel insight into the molecular basis of enhanced disease severity in the AI/AN population and identify potential targets for future therapeutics.

### AN ADENO-ASSOCIATED VIRUS (AAV)-BASED GENE DELIVERY FOR IMMEDIATE PROTECTION AGAINST PANDEMIC CORONAVIRUSES

**Longping V. Tse**, Sarah R. Leist, Ande West, Rita M. Meganck, Stephanie Dong, Ralph S. Baric

University of North Carolina, Chapel Hill, NC, United States

The emergence of novel coronaviruses from zoonotic transfer as well as the variants of concern (VOC) from the COVID-19 pandemic continue to pose major challenges for society. Although multiple vaccines against

SARS-CoV-2 have been deployed at a record pace to combat the current pandemic, development times and safety testing for traditional vaccines hinder rapid response to new outbreaks. Passive immunization by adeno-associated virus (AAV) is a plug-and-play system which can provide immediate protection against future pandemics. As a proof of concept, we delivered the potent neutralizing Ab LCA60 via AAV in a humanized mouse challenge model for Middle East Respiratory Syndrome Coronavirus (MERS-CoV). Vaccinated mice showed reduction in lung viral titer and gross lung pathology against MERS-CoV m35c4 challenge one week after AAV administration. In response to COVID-19, we used the same AAV system to deliver REGN10933 and tested efficacy in a mouse adapted SARS-CoV-2 model. Similar protection was seen in vaccinated mice suggesting broad applicability against different CoVs. Currently, we are developing an AAV-based pan-sarbecovirus therapeutic by delivering a broadly neutralizing antibody, ADG2, to mice followed by challenge with SARS-CoV-1 MA15, SARS-CoV-2 MA10 and other pre-pandemic CoVs. Our proof-of concept experiments demonstrate the significant potential for AAV-based passive immunization strategies to provide a quick countermeasure for future pandemic/pre-pandemic viruses, especially for first responders prior to the development of new vaccines.

#### ASSOCIATION BETWEEN HYPERINFLATION (DEFINED BY RIB COUNT) ON CHEST RADIOGRAPHS WITH VIRAL ETIOLOGY AMONG CHILDREN WITH SEVERE PNEUMONIA IN LOW-INCOME AND MIDDLE-INCOME COUNTRIES (LMICS)

Monica A. Lu<sup>1</sup>, Melissa M. Higdon<sup>2</sup>, Christine Prosper<sup>2</sup>, Maria D. Knoll<sup>2</sup>, Nasreen Mahomed<sup>3</sup>, Eric D. McCollum<sup>1</sup>, The PERCH Study Group<sup>4</sup>

<sup>1</sup>Johns Hopkins University School of Medicine, Baltimore, MD, United States, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>University of Witwatersrand, Johannesburg, South Africa

The Pneumonia Etiology Research for Child Health (PERCH) study, a case-control study of severe and very severe pneumonia in children in low-income and middle-income countries (LMICs), used a novel analytic method which incorporated sensitivities and specificities of multiple specimens and laboratory test results to estimate probabilities of viral or bacterial pneumonia etiology. As hyperinflation has been associated with viral infections, using these PERCH probability estimations in combination with rib counts on chest radiographs may be useful for predicting pneumonia etiology. In this study, chest radiographs of HIV-uninfected cases aged 1-23 months enrolled into PERCH in Mali, Zambia, and Gambia with either a high probability of viral (HPrV) etiology ( $\geq 90\%$ ) ( $n=105$ ) or high probability of bacterial (HPrB) etiology ( $\geq 90\%$ ) ( $n=82$ ) were selected for rib counts by a pediatric pulmonologist blinded to etiology results. The number of visible anterior and posterior ribs on both the right and left sides were recorded. Definitions of hyperinflation were created using varying definitions of anterior and posterior rib counts, with odds ratio (OR), sensitivity, specificity, and predictive values for HPrV vs. HPrB cases calculated for each definition. Definition 1 (the presence of  $\geq 6$  anterior or  $\geq 9$  posterior ribs on both the right and left hemithorax) produced the highest odds ratio for HPrV etiology (OR 3.73, 95% CI: 1.53-9.10). For HPrV cases, presence of  $\geq 6$  anterior ribs on both the right and left hemithorax maximized the sum of sensitivity and specificity (84% and 34%, respectively), followed by Definition 1 (sensitivity=91.7%, specificity=25.3%). While hyperinflation has previously been associated with viral etiology, no definition of hyperinflation in this study resulted in both high sensitivity and specificity, nor high positive and negative predictive values for distinguishing probable viral from bacterial infection. Our findings suggest that with further research, rib counts may be a useful research tool for aiding in viral pneumonia identification.

#### FOOD INSECURITY IN INDIA: THE CORRELATION WITH UNDERNUTRITION AND ANTHROPOMETRY AMONG HOUSEHOLD CONTACTS OF TUBERCULOSIS CASES

Chelsie Cintron<sup>1</sup>, Prakash Narasimhan<sup>2</sup>, Jessica Wise<sup>3</sup>, Komal Jain<sup>2</sup>, Lindsey Locks<sup>4</sup>, Nonika Rajkumari<sup>2</sup>, Kimberley Maloomian<sup>5</sup>, Senbagavalli Babu<sup>2</sup>, Pranay Sinha<sup>1</sup>, Jerrold Ellner<sup>6</sup>, Padmini Salgame<sup>6</sup>, Subitha Lakshminarayanan<sup>2</sup>, Natasha Hochberg<sup>1</sup>

<sup>1</sup>Boston Medical Center, Boston, MA, United States, <sup>2</sup>Jawaharlal Institute of Postgraduate Medical Education and Research, Puducherry, India, <sup>3</sup>Boston University School of Public Health, Boston, MA, United States, <sup>4</sup>Boston University, Boston, MA, United States, <sup>5</sup>Miriam Hospital, Providence, RI, United States, <sup>6</sup>Rutgers New Jersey Medical School, New Brunswick, NJ, United States

India accounts for more than one quarter of the world's tuberculosis (TB) cases. Undernutrition is widely prevalent in India and is the leading risk factor for TB; the COVID-19 pandemic and its impact on food security are likely exacerbating this situation. The TB Learning the Impact of Nutrition Study (TB LION) examines how undernutrition and food supplementation alter immune responses to *Mycobacterium tuberculosis* infection and risk of progression to TB disease among household contacts (HHC) of TB cases in Puducherry and Tamil Nadu, India. We assessed the prevalence of food insecurity (based on household food insecurity assessment survey [HFIAS] scores), malnutrition based on body mass index (BMI), triceps skinfold thickness (as a measure of body fat), and their correlation in HHC using Pearson correlation and Chi-square tests. Between July 2019 - April 20, 2021, we enrolled 356 participants; 145 (41%) male and the median age was 35 years (range 18-59). By reporting severe food insecurity conditions in the home and/or reporting insecurity more frequently on HFIAS, 165 (66.8%) participants were categorized as food secure, 38 (15.4%) mildly food insecure, 9 (3.6%) moderately food insecure, and 35 (14.2%) severely food insecure. Overall, 51 (14.3%) were undernourished (BMI  $< 18.5 \text{ kg.m}^2$ ) and 305 (85.7%) well nourished (BMI  $\geq 18.5 \text{ kg.m}^2$ ), and the median triceps skinfold thickness was 20.7 mm (range 4-20.4). We found a significant, negative correlation between HFIAS and BMI ( $r = -0.18$ ,  $p = 0.003$ ), between HFIAS and triceps skinfold ( $r = -0.22$ ,  $p = 0.0004$ ), and a significant, positive correlation between BMI and triceps skinfold ( $r = 0.66$ ,  $p < 0.0001$ ). Although only 14.3% of HHCs were malnourished, rates of food insecurity were far higher and the two are strongly associated. Although anthropometry is typically used to assess nutritional status and associated TB risk, these findings underscore the fragile nature of access to food and the need for a broader assessment of and response to undernutrition. Moreover, sustained mild food insecurity and negative health effects, are likely with the interruption of food access from COVID-19.

1389

#### DEVELOPMENT AND PERFORMANCE OF AN EMERGENCY DEPARTMENT-BASED SYNDROMIC SURVEILLANCE PLATFORM IN PUERTO RICO TO PREDICT INCREASES IN COVID-19 COMMUNITY TRANSMISSION

Hannah R. Volkman<sup>1</sup>, Laura E. Adams<sup>1</sup>, Janice Perez-Padilla<sup>1</sup>, Vanessa Rivera-Amill<sup>2</sup>, Jorge Bertran-Pasarell<sup>3</sup>, Diego Sainz de la Peña<sup>3</sup>, Gabriela Paz-Bailey<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, San Juan, Puerto Rico, <sup>2</sup>Ponce Health Sciences University / Ponce Research Institute, Centro Médico Episcopal San Lucas, Ponce, Puerto Rico, <sup>3</sup>Hospital Auxilio Mutuo, San Juan, Puerto Rico

Syndromic illness surveillance platforms integrating data from multiple emergency departments (EDs) have been utilized to monitor a broad range of health trends, including seasonal respiratory illnesses, and, more recently, indicators of COVID-19. Puerto Rico, other territories, and international settings in which electronic medical record (EMR) technologies are being implemented can benefit from the development of syndromic surveillance platforms to identify emerging issues in real-time.

Due to delays in diagnostic test results and reporting, syndromic indicators may more quickly predict or indicate increases in COVID-19 transmission. We collaborated with two tertiary care hospitals and one community outpatient emergency room in Puerto Rico to extract data on ED visits and monitor syndromic and diagnostic indicators of COVID-19 transmission. Data were obtained for visits starting March 1, 2020 and are updated on an ongoing weekly basis. Demographics, triage, chief complaint, rapid test, and International Classification of Diseases, 10<sup>th</sup> revision (ICD-10) diagnosis code data were used to construct dashboards to visualize trends in respiratory indicators. Our syndromic indicators identified week-to-week increases in COVID-19-like illness, shortness of breath, cough, and rapid test percent positive one to two weeks faster than published data on COVID-19 testing from the territorial health department. Concordance in syndromic and diagnostic trends, once information was complete, indicate this platform is well-calibrated to monitor COVID-19. Due to the breadth of information available and immediacy of ED visit data, syndromic surveillance platforms can not only be used to monitor COVID-19 closer to real-time than other surveillance approaches, but also create resilient infrastructures through which other emerging health issues can be identified and monitored. The COVID-19 trends observed in Puerto Rico have been useful for situational awareness for clinicians at participating institutions, and, more broadly, for informing public health decision making and pandemic response efforts.

1390

### COVID-19 INFLUENCE ON ANTENATAL CARE ATTENDANCE IN NTCHU AND NKHATA BAY DISTRICTS, MALAWI

Alinafe Chibwana<sup>1</sup>, Julie R. Gutman<sup>2</sup>, Jobiba Chinkhumba<sup>1</sup>, John Munthali<sup>3</sup>, Katherine Wright<sup>3</sup>, Ethel Chilema<sup>3</sup>, Don P. Mathanga<sup>1</sup>, Suzanne Powell<sup>2</sup>, Collins Kwizombe<sup>4</sup>, Doreen Ali<sup>5</sup>, Sosten Lankhulani<sup>6</sup>, Michael Kayange<sup>5</sup>, Fannie Kachale<sup>5</sup>, **Shelby Cash<sup>2</sup>**

<sup>1</sup>University of Malawi College of Medicine, Blantyre, Malawi, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Management Sciences for Health, Medford, MA, United States, <sup>4</sup>President's Malaria Initiative, United States Agency for International Development, Lilongwe, Malawi, <sup>5</sup>Ministry of Health, Lilongwe, Malawi, <sup>6</sup>National Malaria Control Programme, Lilongwe, Malawi

While major gains have been made over the last two decades to control malaria, the rapid emergence and spread of COVID-19 created substantial global disruptions impacting routine health services, including antenatal care (ANC) attendance in sub-Saharan Africa. This is a serious threat to the health of pregnant women and their unborn babies, as lack of routine ANC means women will not have access to vital, life-saving services, including malaria prevention. Project data from a study assessing the uptake of preventive health services in pregnant women showed a 14% decline in average monthly ANC attendance at the beginning of the COVID-19 pandemic (April–June 2020) compared to January 2019 – March 2020 in 20 study health facilities (HF) in Ntcheu and Nkhata Bay Districts, Malawi. To examine the extent to which knowledge and perceived risk of COVID-19 infection disrupted the uptake of ANC, in-depth interviews were conducted during July–August 2020 with 68 randomly selected women aged 16–49 years who were pregnant or delivered in the previous 12 months. Data were coded and analyzed using NVivo 12. Most respondents knew at least three symptoms of COVID-19 and were aware of at least two actions to prevent infection; however, COVID-19 was perceived as a greater risk over malaria. Country stay-at-home policies, lack of access to masks, HF closures, poor quality of care, and fear of SARS-CoV-2 infection at HF were cited as barriers to continued ANC attendance. Noted motivations for continued ANC attendance included desire to care for one's own health and unborn child, positive perceptions of HF staff, and access to information on strategies to mitigate COVID-19 infection. This study provides insights on the extent to which COVID-19 risk perception influenced ANC attendance during the early phase of the COVID-19 pandemic. Demand generating activities highlighting HF actions to prevent COVID-19 transmission, reiterating the importance of regular ANC attendance during pregnancy, and

communicating the high risk for poor outcomes due to malaria in absence of preventive care may be considered to promote and maintain ANC attendance.

### EVOLUTION OF PFS47 AND THE ADAPTATION OF ANCESTRAL PLASMODIUM FALCIPARUM TO VECTORS OF HUMAN MALARIA

Alvaro Molina-Cruz<sup>1</sup>, Ankit Dwivedi<sup>2</sup>, Gaspar E. Canepa<sup>1</sup>, Weimin Liu<sup>3</sup>, Nadia Raytselis<sup>1</sup>, Beatrice Hahn<sup>3</sup>, Joana C. Silva<sup>4</sup>, Carolina Barillas-Mury<sup>1</sup>

<sup>1</sup>LMVR / NIAID / NIH, Rockville, MD, United States, <sup>2</sup>Institute for Genome Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>University of Pennsylvania, Philadelphia, PA, United States, <sup>4</sup>Institute for Genome Sciences, Department of Microbiology and Immunology, University of Maryland School of Medicine, Baltimore, MD, United States

Previous studies indicate that *Plasmodium falciparum* originated when *Plasmodium praefalciparum*, a gorilla malaria parasite, was transmitted to humans by sylvan anopheline mosquitoes. Eventually, the parasite adapted to vector species like *An. gambiae* in Africa and *An. dirus* in Asia, allowing it to spread to human populations beyond tropical Africa. We explored the evolutionary genetics of *Pfs47*, to assess whether the mosquito immune system was a barrier for adaptation of ancestral *P. falciparum* to new vectors of human malaria. We have shown that *Pfs47*, a protein on the surface of the parasite, allows *P. falciparum* to evade the mosquito immune system by interacting with compatible *Pfs47*-receptors in the mosquito gut. Analysis of 4,971 *Pfs47* gene sequences from different continents revealed signatures of selection, and a strong geographic population structure between and within continents, consistent with natural selection of *Pfs47* haplotypes by different vector species. Interestingly, we detected more ancestral *Pfs47* haplotypes in Asia/Oceania, suggesting that ancestral *P. falciparum* readily adapted to Asian vectors. Furthermore, transformed *P. falciparum* carrying *Pfs47* orthologues of *P. praefalciparum* or *P. reichenowi*, two ape malaria parasites adapted to African sylvan vectors, were more effective at evading the immune system of *An. dirus* (Asian vector) than of *An. gambiae*. Consistent with these results, phylogenetic analysis showed that the *Pfs47*-receptors of African sylvan malaria vectors, such as *An. moucheti* and *An. marshallii*, are evolutionary more closely related to Asian vectors than to *An. gambiae*. Our results suggest that ancestral *Pfs47* haplotypes had compatibility to Asian vectors and facilitated an early adaptation of *P. falciparum* to that continent, likely occurring prior to adaptation to *An. gambiae*. Thus, we hypothesize that Asian *P. falciparum* may harbor ancestral variants in other genes. In depth genetic analysis of *Pfs47* revealed unexpected aspects of the evolutionary history of *P. falciparum* that appear to be determined by its mosquito vectors.

1392

### ENGINEERING A BIODEGRADABLE TRANSGENE IN THE DENGUE MOSQUITO AEDES AEGYPTI

Keun Chae, Chanell Dawson, Collin Valentin, Kevin M. Myles, Zach N. Adelman

Texas A&M University, College Station, TX, United States

*Aedes aegypti* is a critical vector for transmitting Zika, dengue, chikungunya, and yellow fever viruses to humans. Conventional methods to prevent mosquito-transmitted diseases have been insufficient, and as a consequence promising genetics-based vector control approaches are being developed. Less clear is how such transgenes can be removed from the environment, a concern that is particularly relevant for self-propagating gene drive transgenes that can rapidly spread into a population in a super-Mendelian manner. Here, we lay the groundwork for a transgene removal system based on a eukaryotic DNA repair mechanism called single strand annealing (SSA), which requires two molecular features to remove a target sequence: 1) two parallelly identical sequences, named

direct repeats (DRs) and 2) an intervening sequence where a targeted DNA double strand break (DSB) can be induced. We hypothesized that if a transgene is engineered with flanking DRs, then it can be deleted via SSA-based DNA repair when required. A transgene we refer to as the SSA-based rescuer strain (*kmo*<sup>RG</sup>) was engineered to have DRs in the *Ae. aegypti* *kynurenine 3-monooxygenase* (*kmo*) gene flanking the intervening cargo genes, *DsRED* and *EGFP*. Targeted induction of DSBs in the *DsRED* transgene successfully triggered complete elimination of the entire cargo from the *kmo*<sup>RG</sup> strain and restored the wild-type *kmo* gene and thereby normal eye pigmentation. This work provides the proof-of-principle underlying an SSA-based transgene removal system, which could be leveraged to more efficiently remove transgenic material following field evaluations of genetic control approaches involving vector mosquito populations.

1393

### AN IMPROVED GENOME ASSEMBLY OF THE WEST NILE VIRUS CULEX QUINQUEFASCIATUS REVEALED NEW INSIGHTS INTO CHROMOSOME AND GENOME EVOLUTION IN MOSQUITOES

Sergei S. Ryazansky<sup>1</sup>, Anasasia N. Naumenko<sup>1</sup>, Varvara Lukyanchikova<sup>2</sup>, Reem A. Masri<sup>1</sup>, Ilya I. Brusentsov<sup>3</sup>, Dmitry A. Karagodin<sup>2</sup>, Zhijian Tu<sup>1</sup>, **Maria V. Sharakhova**<sup>1</sup>

<sup>1</sup>Virginia Tech, Blacksburg, VA, United States, <sup>2</sup>Institute of Cytology and Genetics, Novosibirsk, Russian Federation, <sup>3</sup>Institute of Cytology and Genetics, Blacksburg, Russian Federation

Mosquitoes of two subfamilies Anophelinae and Culicinae have different genome sizes and chromosome arrangements. However, the details of these differences are not completely understood. In this study, chromosome and genome evolution in mosquitoes was investigated using highly improved chromosome-scale assemblies for four species from the major branches of the mosquito evolution, including recently reported *Culex quinquefasciatus* genome. The quality of this genome was improved using Oxford Nanopore Technology sequencing, physical and Bio-Nano optical mapping, and Hi-C scaffolding. Phylogenetic analysis, conducted in this study clarified the divergence time between Culicinae and Anophelinae as ~135 Mya while between *Cx. quinquefasciatus* and *Ae. aegypti* ~69 Mya. In addition to the previously detected chromosomal rearrangements, we identified a pericentric inversion in sex-determining homomorphic chromosome 1 between *Cx. quinquefasciatus* and *Ae. aegypti*. Comparison of the rate of the chromosomal evolution in different species indicated that, similarly to the X chromosome in *An. coluzzii*, the sex-determining chromosome 1 has significantly higher rate of evolution in *Cx. quinquefasciatus* but not in *Aedes aegypti*. Our study supports the previous observations that genome evolution in Culicinae mosquitoes is associated with significant expansion of transposable elements in their genome. Concentrated only in the pericentromeric and some internal regions in the genomes of *Anopheles* species, they spread along the arms toward the telomeres in *Cx. quinquefasciatus* and became evenly distributed in the *Ae. aegypti* genome. We hypothesized that overrepresentation of the repeats in the genome of *Ae. aegypti* is related to the low recombination rates during meiosis and a dramatic decrease in the population sizes in this mosquito.

1394

### EFFECTS OF DISRUPTED CIRCADIAN CLOCK ON AEADES AEGYPTI BEHAVIORS

**Vinaya Shetty**<sup>1</sup>, Jacob I. Meyers<sup>1</sup>, Ying Zhang<sup>2</sup>, Christine Merlin<sup>2</sup>, Michel A. Slotman<sup>1</sup>

<sup>1</sup>Department of Entomology, Texas A&M University, College Station, TX, United States, <sup>2</sup>Department of Biology, Texas A&M University, College Station, TX, United States

*Aedes aegypti* displays strong circadian patterns in blood feeding, mating, and endogenous gene expressions. Much of its behavior is believed to be under the control of an endogenous clock, which consists of a series

of transcriptional and translational negative feedback loops. This results in cyclical gene expression and circadian behavioral activity with high activity peaks towards the later part of the light phase. Furthermore, in this species blood-feeding reduces the expression of circadian clock genes. Female mosquitoes stop responding to host cues after blood-feeding, and it has been hypothesized that clock gene suppression is the mechanism through which this is achieved. To examine the connection between the endogenous clock and various *Aedes aegypti* behaviors, we used CRISPR/Cas9 system-mediated gene knockout of *AeCycle* to disable the endogenous circadian clock. We show that *CYCLE* does not form a functional dimer with *CLOCK* and that the endogenous clock is disabled. This reduces hatching rates, adult survival and female response to host odor. Furthermore, mating success (after 1 hour) of both *AeCyc*<sup>-/-</sup> male and female is significantly lower than in the WT. This demonstrates the extent to which these essential behaviors are under endogenous clock control. These data are also consistent with the suggestion that clock gene suppression after blood feeding is one of the mechanisms through which females stop responding to hosts. Surprisingly however, the propensity to blood feed in *AeCyc*<sup>-/-</sup> females is significantly higher than in WT females, indicating that blood feeding itself may not be under endogenous clock control.

1395

### PRINCIPLES OF 3D GENOME ORGANIZATION IN MALARIA MOSQUITOES

**Igor V. Sharakhov**<sup>1</sup>, Varvara Lukyanchikova<sup>1</sup>, Miroslav Nuriddinov<sup>2</sup>, Polina Belokopytova<sup>2</sup>, Alena Taskina<sup>2</sup>, Jiangtao Liang<sup>1</sup>, Maarten J. Reijnders<sup>3</sup>, Livio Ruzzante<sup>3</sup>, Romain Feron<sup>3</sup>, Robert M. Waterhouse<sup>3</sup>, Zhijian Tu<sup>1</sup>, Veniamin Fishman<sup>2</sup>

<sup>1</sup>Virginia Tech, Blacksburg, VA, United States, <sup>2</sup>Institute of Cytology and Genetics SB RAS, Novosibirsk, Russian Federation, <sup>3</sup>University of Lausanne, Lausanne, Switzerland

Chromosomes are hierarchically folded within cell nuclei into territories, domains and subdomains, but the functional importance and evolutionary dynamics of these hierarchies are poorly defined. In disease vectors, nuclear architecture may modulate gene expression underlying epidemiologically relevant traits. Of the malaria triad members (human, *Plasmodium*, *Anopheles*), only mosquitoes are lacking studies of the 3D genome organization. Here, we comprehensively profiled spatial genome organizations of five *Anopheles* mosquito species and showed how different levels of chromatin architecture influence each other. The principles of the 3D chromosome folding were determined using Hi-C - a technology that exploits *in vivo* chromatin proximity information. Patterns observed on Hi-C maps were associated with cytological structures, epigenetic profiles, and gene expression levels. Topologically associated domains (TADs) found in A-compartments correspond to genomic regions with high levels of gene expression, while TADs in B-compartments correspond to regions with low levels of gene expression. Evolutionary analysis revealed conservation of chromatin architecture within syntenic blocks and enrichment of syntenic breakpoints in regions with increased genomic insulation, associated with gene-rich environments. At the level of individual loci, we identified specific, extremely long-ranged looping interactions, conserved for ~100 million years. These long-distance chromatin contacts can span a distance up to 31 Mb. The anchors of the largest loops are not associated with the clustering of active genes and also display low levels of H3K27me3 enrichment, which indicates that they do not correspond to Polycomb-mediated loops. Our data suggest that large loops found in *Anopheles* are formed by other, yet unknown, mechanisms. Overall, our results provide a new framework for understanding of how genomes are organized and function within the nuclear space in disease vectors. An improved understanding of the 3D mosquito genome will inform efforts focused on the control of malaria mosquitoes through genetic approaches.

1396

### USE OF A NOVEL HIGH-THROUGHPUT INVERTEBRATE AUTOMATED PHENOTYPING PLATFORM ASSAY TO SHOW THAT GAL4-UAS MEDIATED OVEREXPRESSION OF SINGLE GENES IN ANOPHELES GAMBIAE LARVAE CAN CONFER RESISTANCE TO MULTIPLE INSECTICIDES

Beth Crawford Poulton<sup>1</sup>, Steven D. Buckingham<sup>2</sup>, Amalia Anthonusi<sup>3</sup>, Fraser Colman<sup>1</sup>, Gareth J. Lycett<sup>1</sup>, David B. Sattelle<sup>4</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Queen Mary University of London, London, United Kingdom, <sup>3</sup>University of Crete, Heraklion, Greece, <sup>4</sup>University College London, London, United Kingdom

Insecticide resistance is a looming threat to malaria and arbovirus control programmes targeting the mosquito vector. Integrated control programmes which include control of larval stages are becoming more important for *Anopheles* control with increasing urbanisation in malaria endemic areas and remains crucial in *Aedes* control. However, the existing WHO recommended mortality-based larval resistance assay is low-throughput and subject to investigator bias. To address these issues, a novel assay was developed using the Invertebrate Automated Phenotyping Platform (INVAPP) and analysis algorithm (Vectorgon) which provides automated quantification of larval motility after insecticide exposure. The INVAPP-Vectorgon assay has been used to: screen large compound libraries for novel compounds; carry out dose response assays; and investigate resistance phenotypes (where a suitable comparator strain is available). Additionally, this assay has been developed into smartphone technology which has many potential field applications. This assay has been demonstrated to work well to predict resistance phenotypes in *Aedes aegypti* and *An. gambiae* wild type and in transgenic *An. gambiae* first instar larvae. These results highlight the potential of this novel assay for use both in the laboratory and in the field.

1397

### AN AMPLICON SEQUENCING PANEL ENABLES LOW-COST POPULATION GENETICS STUDIES IN Aedes Aegypti

I'ah Donovan-Banfield<sup>1</sup>, Andrea Gloria-Soria<sup>2</sup>, Jeffrey R. Powell<sup>2</sup>, Seth N. Redmond<sup>3</sup>

<sup>1</sup>University of Liverpool, Liverpool, United Kingdom, <sup>2</sup>Yale University, New Haven, CT, United States, <sup>3</sup>Monash University, Clayton, Australia

*Aedes aegypti* is the principal vector of dengue virus, a pathogen that is estimated to cause 96m cases of dengue fever a year and 20,000 deaths. Understanding this vector at the population level is a priority for researchers, however in contrast to large scale population genetic studies that have been completed in malaria vectors using whole-genome sequencing, examples of this kind of work in *Ae. aegypti* are smaller in scale. This is in large part due to the size of the genome; 1.3gb genome of *Ae. aegypti* is more than five times the size of *Anopheles gambiae*, and a 10-20X coverage genome will cost ~\$200-300usd per sample. Moreover, 65% of this genome consists of repeats and transposable elements, making it effectively unusable. This renders population genetics projects involving hundreds or thousands of samples beyond the reach of even the largest institutes. Targeted genotyping a panel of loci across the genome will reduce these costs significantly and still provide high quality information on population diversity and relatedness. We have designed an amplicon panel appropriate for genomic studies in this species and tested it on a panel of globally distributed genetic backgrounds. Our panel of neutral, multiallelic markers is well powered to enable studies of genetic relatedness, delineation, and diversity in this species. At a maximum per-sample cost of ~\$12usd, including DNA extraction and sequencing costs, we believe this technology will be transformative to the field.

1398

### HYPERLOPIT ANALYSIS REVEALS CRYPTOSPORIDIUM SECRETORY ORGANELLES

Amandine Nicole Germaine Guerin<sup>1</sup>, Katherine Strelau<sup>1</sup>, Konstantin Baryluk<sup>2</sup>, Bethan Wallbank<sup>2</sup>, Ross F. Waller<sup>2</sup>, Boris Striepen<sup>1</sup>

<sup>1</sup>University of Pennsylvania, Philadelphia, PA, United States, <sup>2</sup>University of Cambridge, Cambridge, United Kingdom

Cryptosporidium infection is a leading cause of child mortality, no vaccine is available and the current drug treatment against this diarrheal pathogen is inefficient. The disease is transmitted through food or water contaminated with oocysts, the chlorine-resistant parasite stage. The parasite infects the epithelial cells of the small intestine in which it replicates intracellularly. Invasion and intracellular development require extensive modifications of the host cell that remain largely unknown at the molecular level. We recently showed that parasite secreted proteins play an important role in this process, however, our knowledge remains limited to a small number of factors from one organelle, the rhoptry. Here we conducted a proteomic experiment, hyperLOPIT, on fractionated *Cryptosporidium* sporozoites. We resolved numerous clusters of proteins based on their subcellular location including the ribosome, proteasome, ER, mitochondria and nucleus. We distinguished multiple clusters enriched in signal peptide containing proteins including the conserved secretory organelles micronemes, rhoptry and dense granules. These assignments were confirmed by epitope tagging candidates followed by localization studies in sporozoites and infected cells. This allowed us to identify the first four *Cryptosporidium* dense granule proteins. Interestingly, our dataset identified other clusters enriched in signal peptide containing proteins corresponding to the oocyst wall and the crystalloid body, as well as a previously unknown secretory cluster. The latter was found to accumulate around the parasite nucleus and its content is secreted upon invasion. Altogether, this list of *Cryptosporidium* secreted proteins will help fill important gaps in our knowledge of the host/parasite interplay.

*P. falciparum* parasites must balance persistence in the current host with transmission to the next. The first requires continuous asexual replication in red blood cells while the second requires sexual differentiation into gametocytes that can infect the mosquito vector. The frequency of this developmental decision is determined based on stochastic activation of a heterochromatin-silenced locus encoding the transcription factor AP2-G. Recent work showed that the frequency of ap2-g de-repression is responsive to the serum levels of phospholipid precursors such as lysophosphatidylcholine, however, the regulatory mechanisms linking these lipid precursors to AP2-G expression remained unknown. Using chemical, metabolomic, and genetic approaches, we found that this response is mediated by competition for the universal methyl donor S-adenosylmethionine (SAM) between de novo phospho-choline synthesis and histone methylation. When phospho-choline precursors are scarce, increased consumption of SAM for de novo synthesis of phospho-choline results in a decrease in the deposition of silencing histone methylation marks at the ap2-g locus. This weakened silencing state increases the probability of reaching AP2-G expression levels sufficient to trigger the transcriptional feedback loop that activates and locks in the sexual differentiation expression program. Our findings demonstrate the first

mechanistic link between metabolite utilization and gene expression in malarial parasites and explains the connection between lipid metabolism and sexual differentiation.

### TUFT CELL-DERIVED ACETYLCHOLINE REGULATES EPITHELIAL FLUID SECRETION DURING HOMEOSTASIS AND TYPE 2 IMMUNITY

**Tyler Billipp**, Jakob Von Moltke

*Department of Immunology, University of Washington, Seattle, WA, United States*

The intestinal epithelium maintains a barrier against microbiota, pathogens, and environmental insults in part through the secretion of fluid and mucus. During the Type 2 immune response to parasitic helminths, IL-13 signaling drives dramatic epithelial remodeling, resulting in goblet cell hyperplasia and increased mucus production that contribute to the “weep and sweep” required for helminth clearance. Tuft cells, rare chemosensory epithelial cells that initiate this Type 2 response upon sensing of helminths and certain microbial metabolites, also express the enzyme ChAT required for synthesis of acetylcholine (ACh). ACh is a potent inducer of epithelial fluid and mucus secretion but is typically thought to be produced by enteric neurons. We find that at homeostasis the microbial metabolite succinate induces rapid fluid secretion in the distal small intestine dependent on tuft cell-derived ACh. Secretion also requires tuft cell chemosensing and is independent of neuronal involvement. Fluid secretion is enhanced during Type 2 inflammation, consistent with the observed increase in ChAT+ tuft cells. Upon infection with the hookworm *Nippostrongylus brasiliensis*, tuft-specific ChAT-deficient mice suffer delayed worm clearance despite robust epithelial remodeling. Our findings suggest that upon sensing of luminal signals produced by helminths and microbes, tuft cells stimulate an epithelium-intrinsic effector unit to rapidly respond with fluid secretion. This response is amplified by epithelial remodeling that occurs during the Type 2 response, contributing to anti-helminth immunity.

### A KINASE THAT COORDINATES NUCLEAR ABSCISSION IN THE MALARIA PARASITE PLASMODIUM FALCIPARUM

**Benjamin Scott Liffner**, S. Absalon

*Indiana University School of Medicine, Indianapolis, IN, United States*

Apicomplexa, a phylum of parasitic unicellular eukaryotes, exhibits extraordinary diversity in their mechanisms of cellular division. *Plasmodium falciparum*, the deadliest cause of malaria in humans, undergoes alternative rounds of DNA replication and nuclear division followed by a single round of cytokinesis. This division strategy, known as schizogony, allows a single parasite to form approximately 30 daughter parasites every 48 hours. Despite the biological and therapeutic attractiveness of this division strategy, little is known about the proteins that coordinate this process. Here, we identify a Tausled-like kinase (TLK) encoded by *P. falciparum* and using super-resolution microscopy we show that TLK has dual localisation, showing both a pericentromeric localisation and localising to the cleavage furrow of dividing nuclei. Inducible knockdown of TLK results in a severe growth defect. Using expansion microscopy, we show that TLK depleted parasites undergo DNA replication but are unable to perform nuclear abscission, resulting in the formation of parasites with multiple genome copies inside a giant conjoined nuclear envelope. Moreover, we show this phenotype is likely caused by perturbations in microtubule formation. These findings begin to uncover molecular detail of the poorly explored biology of apicomplexan cell division and highlight a potential target for therapeutic development.

### IDENTIFICATION OF NEW RHOPTRY SECRETION FACTORS IN TOXOPLASMA USING THE CILIATE TETRAHYMENA

**Daniela Sparvoli**<sup>1</sup>, Jason Delabre<sup>1</sup>, Justine Heckendorn<sup>1</sup>, Lev M. Tsybin<sup>2</sup>, Diana Penarete-Vargas<sup>1</sup>, Marjorie Maynadier<sup>1</sup>, Marta Mendonça Cova<sup>1</sup>, Aaron P. Turkewitz<sup>2</sup>, Maryse Lebrun<sup>1</sup>

*<sup>1</sup>Université de Montpellier, Montpellier, France, <sup>2</sup>University of Chicago, Chicago, IL, United States*

Together with ciliates and dinoflagellates, apicomplexan parasites belong to the Alveolata superphylum. Apicomplexa possess secretory organelles called rhoptries, that undergo regulated exocytosis during invasion. Upon injection into the host cell, rhoptry proteins support invasion, vacuole formation, and subversion of host immune function. Combining decades-old pioneering ultrastructural observations in Apicomplexa with data on regulated secretion from the ciliate *Paramecium tetraurelia*, we recently showed that rhoptry exocytosis involves a “rosette” of 8 particles embedded in the plasma membrane. The rosette is conserved in Ciliata and its formation requires conserved Alveolata “Nd” proteins. These findings point to the existence of an Alveolata-conserved mechanism for organellar membrane fusion events, and provide proof of concept that we can decipher rhoptry exocytosis machinery using a PAN-Alveolata approach. Here we extend our ciliate analogy to uncover new rhoptry secretion factors. We used the transcriptional profiles of Nd genes of the ciliate *Tetrahymena thermophila* to select genes that are co-regulated, and also conserved in Apicomplexa. In this way we identified two uncharacterized *Tetrahymena* proteins that contribute to the exocytosis of secretory organelles. They have similar architecture and show homology with *Plasmodium* Cysteine Repeat Modular Proteins (CRMPs), a family of proteins essential for *Plasmodium* transmission from the mosquito to the host. We will present the functional characterization of the two *Toxoplasma* CRMPs, including their dynamic location during invasion. While they are not required for rosette formation, we show that they are essential for rhoptry secretion, suggesting a function distinct from that of previously characterized exocytic “Nd” factors.

### ACTIN ORGANIZATION AND DYNAMICS IN MOTILE TOXOPLASMA GONDII PARASITES

**Christina Hueschen**<sup>1</sup>, Li-av Segev Zarko<sup>1</sup>, Jian-Hua Chen<sup>2</sup>, Mark LeGros<sup>3</sup>, Carolyn Larabell<sup>3</sup>, John Boothroyd<sup>1</sup>, Rob Phillips<sup>4</sup>, Alexander R. Dunn<sup>1</sup>

*<sup>1</sup>Stanford University, Palo Alto, CA, United States, <sup>2</sup>University of California San Francisco, Palo Alto, CA, United States, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States, <sup>4</sup>California Institute of Technology, Pasadena, CA, United States*

Apicomplexan parasite gliding is powered by a thin layer of filamentous (F)-actin and specialized myosin motors that lie just beneath the parasite plasma membrane. How is this actomyosin network organized to give rise to coherent traction forces and move the cell forward? Using single-molecule imaging, we tracked individual actin filaments and myosin A light chain (MLC1) complexes in living extracellular *Toxoplasma gondii* tachyzoites. These measurements revealed that actin filaments can undergo rapid directional movement while myosin is largely immobile, consistent with anchorage to the inner membrane complex. F-actin transport direction was strikingly heterogeneous, suggestive of a dynamic or self-organized system, rather than uniformly following the fixed polarity of underlying microtubules as previously believed. To understand whether actin polarity and velocity patterns could arise from filament-filament and filament-motor interactions alone, we developed a continuum model for actin self-organization constrained by the geometry of the parasite. In the absence of filament turnover, this model predicted the emergence of actin patches that recirculate up and down the cell, a “cyclosis” that we observed experimentally for drug-stabilized actin bundles in live parasites. The addition of actin turnover and polymerization at the parasite apical end enabled the emergence of a second steady-state mode, in which

actin polarity and transport is largely rearward. These results suggest that polarized actin dynamics govern the transition between experimentally observed bidirectional (patch or pendulum) and unidirectional (helical, circular, twirling) gliding modes. In summary, this work combines experiment and theory to present a framework for actomyosin self-organization during gliding motility.

### THE IMPACT OF ANTIGEN DOSE ON THE GENERATION, FUNCTION AND LONGEVITY OF LEISHMANIA-SPECIFIC CD4+ MEMORY T CELLS

Zhirong Mou<sup>1</sup>, Jude E. Uzonna<sup>2</sup>

<sup>1</sup>College of Medicine, University of Manitoba, Winnipeg, MB, United States, <sup>2</sup>College of Medicine, University of Manitoba, Winnipeg, MB, Canada

There is currently no approved vaccine against human cutaneous leishmaniasis (CL). This is due in part to insufficient knowledge regarding the immunodominant Leishmania antigens, the nature of T cells that respond to them and the factors that regulate the generation, function and longevity of different subsets of memory T cells against these antigens. Antigen dose is known to influence the magnitude and quality of the host immune response. Specifically, antigen dose has been shown to regulate the differentiation of naïve CD4+ T cells into Th1 effector cells that mediate resistance to CL. However, the influence of antigen dose on the magnitude and quality (cytokine production and function) of Leishmania-specific CD4+ T cells memory response is unknown. Recently, we identified Leishmania phosphoenolpyruvate carboxykinase (PEPCK) as protective antigen and showed that PEPCK335-351 peptide is the dominant CD4+ T cell epitope. We generated PEPCK specific TCR transgenic (PEG) mice and found that >90% of their CD4+ T cells express PEPCK-specific TCR. We found that PEG CD4+ T cells specifically respond to PEPCK in vitro and in vivo. Upon adoptive transfer into congenic mice followed by immunization with different doses (0.05, 0.5 or 5 nmol) of PEPCK 335-351 peptide, PEG cells proliferated robustly and produced IFN- $\gamma$  in a dose-dependent manner. Interestingly, high dose (5 nmol) PEPCK peptide induced higher frequency of polyfunctional (IFN- $\gamma$ +IL-2+TNF+) cytokine producing PEG cells and this was associated with higher expression of CD44, CCR7 and CD62L, markers that characterize central memory (T<sub>cm</sub>) phenotype. Moreover, PEG cells in mice immunized with high dose PEPCK peptide showed higher IFN- $\gamma$  recall response following secondary in vivo peptide or L. major challenge. This higher IFN- $\gamma$  response was associated with better protection against virulent L. major challenge. Collectively, these findings show that antigen dose influences the generation, magnitude and function of Leishmania specific CD4+ memory T cells.

### PD-1 LIMITS TREG IMMUNE SUPPRESSION DURING ACUTE TOXOPLASMOSIS

Joseph Perry<sup>1</sup>, J.T. Clark<sup>2</sup>, J. Gullicksrud<sup>2</sup>, J. DeLong<sup>2</sup>, L. Shallberg<sup>2</sup>, B. Douglas<sup>2</sup>, A. Hart<sup>1</sup>, C. Konrad<sup>2</sup>, J. Park<sup>2</sup>, A. Glatman-Zaretzky<sup>2</sup>, R. de Waal Malefyt<sup>3</sup>, D.A. Christian<sup>2</sup>, A.H. Sharpe<sup>4</sup>, C.A. Hunter<sup>2</sup>

<sup>1</sup>Department of Medicine, University of Pennsylvania, Philadelphia, PA, United States, <sup>2</sup>Department of Pathobiology, University of Pennsylvania, Philadelphia, PA, United States, <sup>3</sup>Merck & Co, Kenilworth, NJ, United States, <sup>4</sup>Department of Immunology, Harvard Medical School, Boston, MA, United States

While much is known about the factors that promote the development of diverse Treg cell responses, less is known about the pathways that constrain Treg cell activities. The studies presented here reveal that at homeostasis there is a population of effector Treg cells that express PD-1, and that blockade of PD-L1 or loss of PD-1 results in increased Treg cell activity. In response to infection with the parasite *T. gondii*, the early production of IFN- $\gamma$  results in widespread upregulation of PD-L1. Moreover, blockade of PD-L1, whole body deletion of PD-1, or lineage-specific deletion of PD-1 in Foxp3+ cells prevented the loss of the effector Treg cells

but resulted in reduced pathogen specific CD4+ T cell responses during infection. Thus, at homeostasis basal PD-L1 expression constrains and tunes the pool of Treg cells, but during infection the upregulation of PD-L1 provides a mechanism to contract the Treg cell population required to maximize the development of pathogen specific CD4+ T cell responses.

1407

### GUT MICROBIOTA COMPOSITION MODULATES THE SPLENIC GERMINAL CENTERS DURING PLASMODIUM INFECTIONS THROUGH IMMUNE DISTRACTION

Rafael Polidoro, Morgan L. Waide, Nathan W. Schmidt

Indiana University School of Medicine, Indianapolis, IN, United States

The gut microbiota has been shown to play a role in both human and rodent Plasmodium infections. Our lab recently demonstrated that gut microbiota composition can modulate the severity of malaria using mice from different vendors, susceptible (Tac) and hypersusceptible mice (CR). We found gut microbiota-dependent numbers of germinal center (GC) B cells and parasite-specific antibody titers between the two vendors. These findings were inversely correlated with parasite burdens of the mice. To further characterize the gut impact on infection, we harvested the Peyer Patches (PP), MLN, ILN and spleens from the mice before and on various days. We found differences between Tac and CR PP's before infection, with increased numbers of neutrophils,  $\gamma\delta$  T cells, T follicular helper cells, and GC B cells in CR mice, suggesting an active immune response at this site. Accordingly, flow cytometry analysis of IgA+ fecal bacteria confirms that CR mice have higher basal IgA+ bound bacteria, and both vendors have a proportional increase of IgA bound bacteria from day 8-10 post Plasmodium infection. As the infection progresses, CR starts to form splenic germinal centers, but these mice are not able to maintain splenic GCs against Plasmodium while also maintaining an active immune response in the gut, correlating to a lower ratio between splenic TFH and TFR cells in CR animals when compared to Tac. These results provide a mechanistic insight into the impact of the gut microbiota on the extra-gastrointestinal tract germinal center response and will be an important factor to consider in the development of optimal malaria treatments.
