## PHARMACOKINETIC PROPERTIES OF THE IRRUA-RIBAVIRIN-REGIMEN IN THE TREATMENT OF LASSA FEVER IN NIGERIA - A PROSPECTIVE OBSERVATIONAL STUDY

**Mirjam Groger**<sup>1</sup>, Cyril Oshomah Erameh<sup>2</sup>, Osahogie Isaac Edeawe<sup>2</sup>, Christine J. Kleist<sup>3</sup>, Sophie Duraffour<sup>4</sup>, Lisa Oestereich<sup>4</sup>, Julia Hinzmann<sup>4</sup>, Femi Oluwasola Babatunde<sup>5</sup>, Joy Nwaturor<sup>5</sup>, Jonas Müller<sup>4</sup>, Mette Hinrichs<sup>4</sup>, Meike Pahlmann<sup>4</sup>, Christine Wagner<sup>1</sup>, Francisca Naana Sarpong<sup>1</sup>, Till Koch<sup>1</sup>, Gloria Eifediyi<sup>2</sup>, Ephraim Ogbaini-Emovon<sup>2</sup>, Sylvanus Okogbenin<sup>2</sup>, Sebastian G. Wicha<sup>3</sup>, Stephan Günther<sup>4</sup>, Michael Ramharter<sup>1</sup>, Peter Ehizokhale Akhiden<sup>2</sup>

<sup>1</sup>Department of Tropical Medicine, Bernhard Nocht Institute for Tropical Medicine & I. Department of Medicine University Medical Center Hamburg-Eppendorf, Hamburg, Germany, <sup>2</sup>Institute of Lassa Fever Research and Control, Irrua Specialist Teaching Hospital, Irrua, Nigeria, <sup>3</sup>Department of Clinical Pharmacy, Institute of Pharmacy, University of Hamburg, Hamburg, Germany, <sup>4</sup>Department of Virology, Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, <sup>5</sup>Institute of Lassa Fever Research and Control, Irrua Specialist Teaching Hospital, Hamburg, Germany

Lassa fever is an acute infection with variable severity caused by the Lassa virus. Lassa virus causes annual outbreaks in many regions of West Africa with a marked surge in case numbers since 2018. The recommended antiviral therapy is ribavirin, the currently accepted regimens are the so-called McCormick regimen and the Irrua-ribavirin-regimen. However, evidence for ribavirin safety and efficacy in Lassa fever patients is poor and pharmacokinetic data for said regimens are not available. The Irrua-ribavirin-regimen is based on once daily dosing and thus became the standard of care in adult Lassa fever patients in Nigeria. The main objective of this research was to characterize the pharmacokinetic properties of the Irrua-ribavirin-regimen. A prospective, observational study was conducted at the Irrua Specialist Teaching Hospital in Edo State, Nigeria. PCR confirmed Lassa fever patients with mild to moderate disease severity that were to be treated according to the local standard of care were invited to participate. Blood samples for pharmacokinetic analyses were obtained 0.5, 1, 3, 5, 8, 12 and 24 hours after the 1<sup>st</sup>, 4<sup>th</sup> and 10<sup>th</sup> dose. Lassa signs and symptoms, hematology and biochemistry parameters were assessed every other day. During the 2020 and 2021 transmission seasons 20 patients were included. Plasma concentration time profiles of ribavirin were analyzed. The population pharmacokinetic analysis of the first 13 participants indicated that the PK was best described by a two-compartment model. The typical PK parameters were 10.6 L/h for clearance, 29.7 L/h for distribution clearance, 68.5 L for central and 644 L for peripheral volume of distribution. A low inter-patient variability of 25 %CV on clearance and 28.8 %CV on peripheral volume of distribution was found. This is the first clinical study describing the pharmacokinetics of intravenous ribavirin therapy of Lassa fever providing important insights into the potential mode of action of ribavirin in the treatment of Lassa fever. Despite the severity of the disease, drug exposure was remarkably consistent between subjects and PK of ribavirin was similar compared to other populations.

During the 2018-2020 Ebola virus disease (EVD) outbreak in North Kivu province in the Democratic Republic of Congo, EVD was diagnosed in a patient who had received the recombinant vesicular stomatitis virus-based vaccine expressing a ZEBOV glycoprotein (rVSV-ZEBOV) (Merck). His treatment included an Ebola virus (EBOV)-specific monoclonal antibody (mAb114), and he recovered within 14 days. However, 6 months later, he presented again with severe EVD-like illness and EBOV viremia, and he died. We initiated epidemiologic and genomic investigations that showed that the patient had had a relapse of acute EVD that led to a transmission chain resulting in 91 cases across six health zones over 4 months.

Persistently infected Ebola virus disease (EVD) survivors were first identified during the 2013-2016 West Africa EVD outbreak. Investigations into flare-up events after the end of active transmission between symptomatic individuals identified a role for sexual transmission from survivors. A further two cases expatriated to their home countries experienced recrudescence manifesting as detectable virus in ocular fluid or cerebrospinal fluid (CSF). The Democratic Republic of the Congo (DRC) has experienced multiple

EVD outbreaks, with the most recent occurring between 2018 and 2021 in the Nord Kivu and Ituri provinces. The National Biomedical Research Institute (INRB) in the DRC has sequenced over 24% of Ebola virus (EBOV)-positive samples taken during the outbreak. During the latter stages of the outbreak, four cases of infection from a persistent source were identified: a case of EVD relapse causing onwards transmission to 91 others, two cases of meningitis with EBOV positive CSF, and the resurgence of the outbreak in 2021, eight months after it was declared over, by a suspected sexual transmission of the virus from a survivor. However, during the peak of the outbreak, there were likely other cases of transmission from persistently infected sources that went unnoticed due to the overwhelming numbers of cases at the time. We undertook genomic and epidemiologic case investigations to identify and characterize probable cases infected from persistently infected sources throughout the epidemic. Phylogenetic analysis showed a reduced evolutionary rate on the branches leading to the cases, which acts as a hallmark of infection from a persistent source. We identified four further probable cases of EBOV infection from persistently infected sources, from four different health zones, and discuss the case reports for each one.

Recent disease outbreaks highlight the need to characterize the immune response to filoviruses to develop vaccines and therapies. We have used extensive mutation libraries to map the epitopes for >200 monoclonal antibodies (MAbs) targeting the EBOV surface glycoprotein, GP. We have extended these studies to Marburg virus (MARV) by generating an Ala-scan library of MARV  $\Delta$ mu<sub>2</sub> GP (Uganda strain). Initial maps of anti-MARV MAbs include those of two non-neutralizing MAbs MR228 and MR235, targeting the wing region of MARV GP, that showed therapeutic protection in animal models (MR228) or that increased binding (MR235) by neutralizing MAbs. The variety of EBOV MAbs mapped, many from survivors of ebolavirus infection, include cross-neutralizing MAbs targeting the GP membrane-proximal external region (MPER); a broadly cross-reactive MAb that blocks GP interaction with its endosomal receptor Niemann-Pick C1, and MAbs who synergistically transform a non-neutralizing MAb into a potent neutralizer. We also mapped GP binding activity in sera of mice injected with DNA encoding MAbs (DMAbs). The epitope maps have expanded our understanding of how the immune system recognizes EBOV GP, and allow correlation of epitopes with MAb neutralizing capabilities, to develop anti-EBOV therapeutics and vaccines. Mapping also identified mutations that increase the exposure of neutralizing epitopes, impacting future anti-ebolavirus vaccine strategies. To identify GP residues important for EBOV infectivity, we performed infectivity assays with the full GP mutation library, using a lentivirus pseudotype system. We identified critical residues whose mutation abrogated infectivity without affecting GP conformational integrity. Their locations suggest crucial roles in GP conformational changes that cause virus-host membrane fusion. Additionally, to identify uncharacterized EBOV cellular receptors, we assayed wild-type GP infectivity in non-permissive cells individually expressing 6,000 unique human membrane proteins of our membrane proteome array (MPA). This has identified candidate membrane proteins that enable EBOV infectivity.

Rift Valley Fever Virus (RVFV) is a zoonotic mosquito-borne pathogen endemic to sub-Saharan Africa and the Arabian Peninsula which causes Rift Valley Fever in ruminant livestock and humans. RVFV is a tri-segmented (L, M and S segment), negative/ambi-sense, single-stranded RNA virus, which can reassort with other RVFV strains during co-infection of a susceptible host. Reassortment (RA) events have the potential to lead to novel viruses with altered virulence, transmissibility, and/or host range. This is especially of concern in RVFV endemic regions that frequently use live attenuated RVFV vaccines for livestock vaccination. Previously, we evaluated the frequency of RA in mammalian cells and sheep using the following three strains of RVFV: the vaccine strain MP-12 and two wild-type strains, one from Kenya (128B-15) and one from Saudi Arabia (SA01-1322). Our results in mammalian hosts indicated that the frequency of RA is rather low. In the current study, we evaluated the RA frequency of RVFV in *Culex tarsalis* mosquitoes. Briefly, two groups of mosquitoes (n=200 per group) were co-infected via blood meals containing an equal titer of approximately 10<sup>7</sup> pfu/ml of MP-12 and Kenya 128B-15 strain (group 1), or 10<sup>6.5</sup> pfu/ml of Kenya 128B-15 and SA01-1322 (group 2), respectively. Midguts (MGs; n=30) and salivary glands (SGs; n=30) were dissected from fully engorged mosquitoes 14 days post exposure. MGs and SGs were homogenized, and virus plaques were isolated. The three genomic segments of fifty plaque-purified viruses from each tissue of group 1 and 2 were genotyped using strain-specific RT-qPCR genotyping (GT) assays. Reassortant viruses (RAVs) identified by GT assays were confirmed by Sanger sequencing. Our preliminary results show that >80% of plaque-purified viruses from the MGs of groups 1 and 2, and >60% of SGs plaque-purified viruses from group 1 are RAVs. Our current findings suggest a higher frequency of RA occurs in the mosquito vector when compared to the mammalian host.

Ebola virus disease (EVD) has caused several hemorrhagic fever outbreaks. Prior investigations have shown young children to be especially vulnerable, with high mortality rates. As such, there is a critical need for the rapid diagnosis of children so they can appropriately isolate and begin treatment. This study aimed to address knowledge gaps with the development of a predictive model to diagnose EVD in children at risk.

We analyzed retrospective data from patients presenting at International Medical Corps' Ebola Treatment Units in Liberia and Sierra Leone from 2014-2015. Candidate predictors, which included age, sex and 10 other variables from the current World Health Organization (WHO) guideline for identifying suspect Ebola cases, were entered into a logistic regression model to predict EVD diagnosis using forward stepwise regression with 10-fold cross validation. A 7-point risk score system was developed by converting the regression coefficient of each predictor in the final model to an integer. We assessed the discrimination and calibration using the Area Under the Receiver Operating Characteristic curve (AUC) and calibration-in-the-large respectively, for the derived model and risk score system. Of the 12 candidate predictors included in the analyses, 3 variables were positively associated with an EVD diagnosis: any bleeding (OR 7.5; 95% CI 3.7-16.0), a confirmed Ebola contact (OR 34.9; 95% CI 16.1-89.2) and unknown Ebola contact (OR 6.56; 95% CI 2.24-20.0). Abdominal pain (OR 0.30; 95% CI 0.17-0.53) was negatively associated with an EVD diagnosis. Model discrimination, measured using the AUC, was 0.87 (95% CI = 0.83 - 0.90). Both the model and the risk score system demonstrated a greater net benefit at risk score of 1 or higher (equivalent to 8% risk probabilities) compared to the WHO case definition for EVD diagnosis. Prompt diagnosis of pediatric EVD is challenging but this predictive model and risk score is more beneficial than the WHO case definition. To establish the utility of these tools, external validation is currently underway using data from the current EVD outbreak in the Democratic Republic of the Congo.

Hepatitis B virus (HBV) remains endemic in sub-Saharan Africa, despite an effective vaccine. Limited evidence suggests horizontal transmission within households or communities is an important driver of transmission and continued endemicity in sub-Saharan Africa, but the relative impact of horizontal versus vertical (mother-to-infant) transmission remains unknown. We are conducting a prospective, cross-sectional study to understand drivers of household transmission of HBV in urban Kinshasa, DRC. Households of HBV-positive (exposed households) and HBV-negative (unexposed households) mothers identified by screening during antenatal care at two high-volume maternity centers are eligible for enrollment. Household members undergo point-of-care HBV surface antigen (HBsAg) testing, provide blood samples for serological analysis and sequencing, complete questionnaires, and are offered HBV vaccine, if HBsAg-negative and exposed to HBV in the household. Since February 2021, 47 (24 HBV-exposed and 23 HBV-unexposed, by index mother status) of a target 200 households have been enrolled, totaling 296 individuals, including 185 children <18 years of age. Beyond known HBV+ index mothers, four additional household members tested HBsAg+, three from an HBV-exposed and one from an HBV-unexposed household. Of 172 individuals eligible for vaccination, only 39 have been vaccinated and 32 refused vaccination. The most common potential HBV exposures reported to-date are use of street salons (46% vs. 55% among HBV-exposed and unexposed households) and sharing nail clippers in the household (49%

vs. 46%). Additional household and community exposures assessed include shared razors, traditional scarring, blood transfusions, sexual activity, and pre-masticated food. Spatial and phylogenetic analyses will complement epidemiological survey data to identify risk factors for HBV and transmission networks in urban Kinshasa. This study of HBV transmission will shed light on primary transmission modes in the DRC, where HBV is endemic and healthcare infrastructure is limited.

0008

#### EFFECTIVENESS OF THREE TYPES OF DUAL ACTIVE INGREDIENT TREATED NETS COMPARED TO STANDARD LONG-LASTING INSECTICIDAL NETS AGAINST MALARIA OUTCOMES: RESULT FROM A CLUSTER RANDOMIZED CONTROLLED TRIAL IN TANZANIA

**Jacklin Franklin Mosha**<sup>1</sup>, Manisha A. Kulkarni<sup>2</sup>, Louisa A. Messenger<sup>3</sup>, Nancy Matowo<sup>3</sup>, Eliud Lukole<sup>1</sup>, Catherine Pitt<sup>3</sup>, Mark Rowland<sup>3</sup>, Alphaxard Manjurano<sup>1</sup>, Franklin W. Mosha<sup>4</sup>, Jackline Martin<sup>5</sup>, Charles Thickstun<sup>6</sup>, Immo Kleinschmidt<sup>3</sup>, Natacha Protopopoff<sup>3</sup>

<sup>1</sup>National Institute for Medical Research Tanzania, Mwanza, United Republic of Tanzania, <sup>2</sup>School of Epidemiology and Public Health, University of Ottawa, Ottawa, ON, Canada, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania, <sup>5</sup>Kilimanjaro Christian Medical University College, Kilimanjaro, United Republic of Tanzania, <sup>6</sup>School of Epidemiology and Public Health, University of Ottawa, Ottawa, ON, Canada

The massive scale-up of long-lasting insecticidal nets (LLINs) has led to major reductions in malaria burden in many sub-Saharan African countries. This progress is threatened by widespread insecticide resistance among malaria vectors. Next generation LLINs are urgently needed to reverse this trend. This trial evaluates the most promising LLINs combining two active ingredients (AI) with different mode of actions against malaria outcomes. A four parallel-arm, single-blind, cluster-randomized trial was conducted in 84 clusters in Misungwi district, North West Tanzania between October 2019 to February 2021. Interventions were assigned to 21 clusters each, the study arms were 1) Royal Guard<sup>®</sup>, combining two insecticides, pyriproxyfen (PPF) and the pyrethroid alpha-cypermethrin; 2) Interceptor<sup>®</sup> G2, combining chlorfenapyr (CFP) and alpha-cypermethrin; 3) Olyset<sup>®</sup> Plus, a LLIN combining a synergist, piperonyl butoxide (PBO) and the pyrethroid permethrin, and the reference arm 4) Interceptor<sup>®</sup>, a standard LLIN containing the pyrethroid alpha-cypermethrin only. Each household were allocated one net for every two people. Malaria infection prevalence was assessed in 50 children (aged 6 months to 14 years) per cluster at 12, 18 and 24 months post intervention. A cohort of 35 children (aged 6 months to 10 years) in each cluster was followed over 2 years to assess malaria cases incidence. Infection prevalence and case incidence were analysed using intention to treat comparing each of the dual AI LLIN to standard LLIN. Findings of these analysis will be presented. This is the first evaluation of Royal Guard and Interceptor G2 in a RCT and findings will constitute the body of evidence required by the WHO for a potential recommendation.

0009

#### EIGHT IS ENOUGH? ADDRESSING THE DESIGN AND ANALYSIS OF CLUSTERED TRIALS AIMED AT CONTROLLING VECTOR-BORNE DISEASES WITH LIMITED ACCESS TO LARGE NUMBERS CLUSTERS

**Conner L. Jackson**<sup>1</sup>, Kathryn Colborn<sup>1</sup>, Dexiang Gao<sup>1</sup>, Sangeeta Rao<sup>2</sup>, Hannah Slater<sup>3</sup>, Sunil Parikh<sup>4</sup>, Brian Foy<sup>2</sup>, John Kittelson<sup>1</sup>

<sup>1</sup>University of Colorado - AMC, Aurora, CO, United States, <sup>2</sup>Colorado State University, Fort Collins, CO, United States, <sup>3</sup>PATH, Seattle, WA, United States, <sup>4</sup>Yale, New Haven, CT, United States

Cluster randomized trials (CRTs) allow for the evaluation of a community or group (cluster) level intervention. For studies that require a CRT design

to evaluate cluster-level interventions aimed at controlling vector-borne diseases, it may be difficult to assess a large number of clusters while simultaneously performing the additional work needed to monitor participants, vectors, and environmental factors associated with the disease. One example of a CRT with few clusters was the “efficacy and risk of harms of repeated ivermectin mass drug administrations for control of malaria (RIMDAMAL)” trial. Although previous work has provided recommendations for analyzing trials like RIMDAMAL, additional evaluation is needed for study designs with count outcomes. We used a simulation study to apply two analysis frameworks (individual level and cluster level analyses) to three CRT designs (single-year, two-year parallel and two-year crossover) in the context of RIMDAMAL II, a two-year follow-up of RIMDAMAL. Both individual level (with adjustments for small sample sizes) and cluster level analyses yielded reliable results across different study designs. The crossover design generally yielded higher power relative to the parallel equivalent with only one model not achieving 100% power. For RIMDAMAL II, we recommend an individual level analysis that accounts for the small number of clusters because it can simultaneously yield high power (98.6%) and control the type-I error rate (4.91%) while providing greater flexibility relative to the cluster level analyses. Although RIMDAMAL II is already underway as a parallel trial, applying the simulation parameters to a crossover design yielded improved power, suggesting that crossover designs may be valuable in settings where the number of available clusters is limited. For studies aiming to control vector-borne diseases, when interventions must be randomized at the village level, it is vital to find a balance between the often-limited number of clusters and the often-conservative recommended statistical approaches. Through our work, we have shown that multiple analysis approaches can be reliable.

0010

#### COMMUNITY KNOWLEDGE AND PERCEPTION ON MALARIA PREVENTION AFTER INTRODUCTION OF NEW, DUAL ACTIVE INGREDIENT INSECTICIDE-TREATED NETS (ITNS) IN THE HEALTH DISTRICTS OF BANFORA, GAOUA, AND ORODARA IN BURKINA FASO

Moubassira Kagoné<sup>1</sup>, Federica Guglielmo<sup>2</sup>, Fatou Ouattara<sup>1</sup>, Aboubacar Fofana<sup>1</sup>, Samuel Poda<sup>1</sup>, Kenzie Tynuv<sup>3</sup>, Gauthier Tougri<sup>4</sup>, Moussa W. <sup>1</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>3</sup>PATH, Washington, DC, United States, <sup>4</sup>Programme National de Lutte contre le Paludisme, Ouagadougou, Burkina Faso, <sup>5</sup>PATH, Seattle, WA, United States

Malaria is a parasitic infection that is transmitted to humans through the bite of female *Anopheles* mosquitoes. Considering the emergence and intensification of insecticide resistance in key mosquito populations, dual active ingredient insecticide-treated nets (ITNs) that are effective against insecticide resistant mosquitoes have been developed. In 2019, standard pyrethroid, pyrethroid and piperonyl butoxide (PBO), and Interceptor® G2 (BASF) ITNs were deployed in Gaoua, Orodara, and Banfora districts, respectively. As part of the New Nets Project, we conducted a study to collect anthropological data and assess factors that could influence ITN uptake and usage. Anthropological data were collected in the three health districts from July to September 2019. We used a combination of in-depth interviews (n=146), structured observations (n=217), participant observations (n=469), and focus groups discussions (n=36). The study participants were mothers of children under the age of five, pregnant women, heads of households from different socio-professional backgrounds, and community leaders. A thematic analysis was conducted. All interviews were transcribed and analysed using NVivo software. Most respondents believe that mosquitoes transmit malaria. However, the sun, eating mangoes, going out in the rain, eating fatty foods, and excessive consumption of sugar and oil were also identified as factors that cause malaria. The best protection against mosquitoes is consistent use of an ITN. However, poor conditions of use of an ITN in some places limits the

optimization of protection against mosquitoes. Raising awareness on the primary cause of malaria and better use of nets following distribution campaigns could contribute to reduce malaria transmission.

0011

#### INVESTIGATING THE DURABILITY OF THE BIOEFFICACY OF NEXT GENERATION NETS FROM COMMUNITIES IN BENIN

Corine A. Ngufor

London School of Hygiene & Tropical Medicine, London, United Kingdom

A new generation of insecticide treated nets have been developed for malaria vector control and are being evaluated in communities across Africa. Clear guidelines to investigate the durability of the bio-efficacy of these nets in the field are however lacking. We performed a series of laboratory studies and experimental hut trials to help identify suitable procedures for investigating the durability of the entomological efficacy of pyrethroid-PBO nets (PermaNet 3.0), pyrethroid-chlorfenapyr nets (Interceptor G2) and pyrethroid-pyriproxyfen nets (Royal Guard) collected from communities in Benin at baseline and 6-12 months post distribution. To identify a suitable test method, we tested each net type in cone bioassays, tunnels tests and experimental huts. To identify an appropriate mosquito strain for monitoring each active ingredient, we tested susceptible and resistant mosquito strains with varying levels of resistance. For Royal Guard, we compared the use of mosquito egg laying to dissection of ovaries for monitoring pyriproxyfen in survivors. With PermaNet 3.0 and Royal Guard, cone bioassay mortality rates at baseline were >80% with the pyrethroid susceptible strain but reduced with Royal Guard as the level of pyrethroid resistance increased allowing for more survivors to assess the reproductive effects of pyriproxyfen. Full efficacy (>80% mortality) was achieved with Interceptor G2 using a pyrethroid-resistant strain in tunnel tests but not in cone bioassays. Bioassays results corroborated findings in experimental hut trials. The overall reduction in the fertility of mosquitoes which survived exposure to Royal Guard did not differ substantially between mosquito’s egg laying and dissection methods. The results show that cone bioassays may be suitable for monitoring the bioefficacy of pyrethroids, pyriproxyfen and PBO in nets while tunnel tests will be more suitable for chlorfenapyr. Pyrethroid-resistant strains will be more suitable compared to pyrethroid susceptible strains for monitoring the bio-efficacy of all three non-pyrethroid active ingredients (PBO, Pyriproxyfen and chlorfenapyr).

0012

#### USE OF A PORTABLE FIELD-ADAPTED LIQUID CHROMATOGRAPHIC SYSTEM (C-VUE MACHINE) TO DETERMINE THE QUANTITY OF DELTAMETHRIN ON INSECTICIDE-TREATED NETS PAIRED WITH WHO CONE BIOASSAYS TO DETERMINE ITN BIOEFFICACY AS PART OF A THREE-YEAR DURABILITY MONITORING IN MALI

Green<sup>7</sup>, Ousmane Koita<sup>1</sup>

<sup>1</sup>Laboratoire de Biologie Moleculaire Appliquee / Universite des Sciences des Techniques et des Technologies de Bamako (LBMA/USTTB), Bamako, Mali, <sup>2</sup>Programme National de Lutte Contre le Paludisme, Bamako, Mali, <sup>3</sup>PMI VectorLink Project, Bamako, Mali, <sup>4</sup>President Malaria Initiative USAID, Bamako, Mali, <sup>5</sup>International Development Group/ RTI International, Washington, DC, United States, <sup>6</sup>Entomology Branch, US Centers for Disease Control, ATLANTA, GA, United States, <sup>7</sup>Entomology Branch, US Centers for Disease Control, Atlanta, GA, United States

Monitoring insecticide levels and physical integrity over time is essential for assessing the durability of insecticide-treated bednets (ITNs), which largely depends on the net handling habits of users. The objective of this study was to assess the insecticide content of ITNs (Yorkool and PermaNet 2.0) at 6, 12, 24 and 36 months after a mass net distribution

carried out in Mali in December 2017. At each time point, 30 nets were randomly collected from households in the districts of Kenieba and Kita, together with information about ITN washing practices. The insecticidal effectiveness of the ITNs was assessed with the World Health Organization (WHO) cone test using a laboratory-reared susceptible colony of *Anopheles gambiae* (Nguosso) and the residual insecticide content measured by a non-destructive sampling technique with a portable field-adapted liquid chromatographic system (C-Vue®) that was validated running samples in parallel with standardized WHO - HPLC methods. At 12, 24 and 36 months post distribution, nets had been washed an average of three times over the previous 6 months, most commonly using detergent or bleach. For Yorkool nets, the average deltamethrin concentration was 0.69 mg/m<sup>2</sup> at 6 months and gradually decreased to 0.08 mg/m<sup>2</sup> at 36 months. The values for Permanet 2.0 nets were 0.46 mg/m<sup>2</sup> at 6 months and a final measure of 0.06 mg/m<sup>2</sup> at 36 months. Until the 24 months evaluation, the proportion of nets with minimal effectiveness (at least 75% Knock Down "KD" or 50% 24h mortality) was greater than 80% for both net types and both sites, however, the proportion of nets with optimal effectiveness (at least 95% KD or 80% mortality) was less than 80%. The WHO standardized cone test and C-Vue evaluation respectively demonstrated that the effectiveness and insecticide content of both net types were consistently lower than expected at 3 years. The C-Vue was used successfully for the first time in Mali to measure the insecticide concentration of ITNs and produced results that were consistent with cone bioassays. This new technology allows for an affordable and locally available method to perform ITN durability monitoring in malaria endemic countries.

0013

#### **(HALF) LIFE OF THE PARTY: EXPLORING THE IMPACT OF BEDNET DURABILITY AND RETENTION ON MALARIA BURDEN**

**Amelia Bertozzi-Villa**<sup>1</sup>, Helen Jamet<sup>2</sup>, Bruno Moonen<sup>2</sup>, Caitlin Bever<sup>1</sup>

<sup>1</sup>Institute for Disease Modeling, Seattle, WA, United States, <sup>2</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States

Insecticide-treated nets (ITNs) are one of the most widespread and cost-effective malaria prevention tools in sub-Saharan Africa, but maintaining high net coverage has proven challenging in many settings. Shorter-than-expected retention times are a major driver of low net coverage, as many households discard nets well before they are scheduled to receive new ones. The primary reason for net disposal is physical damage, which suggests that manufacturing more durable nets might lead to longer retention times and higher intervention efficacy. This study uses a microsimulation model to explore the potential impact of increased net retention on malaria incidence across a range of transmission intensities and seasonalities. We also explore these effects across different ITN coverage levels and insecticide efficacies. We find that increasing median ITN lifespans by one year could lead to significant reductions in malaria incidence, with stronger effects in high-transmission areas and at medium levels of net coverage. With a unit costing approach, we show the implications of longer net retention on cost per case averted. These results contribute to arguments for the value of including net durability as an official standard in ITN manufacturing.

0014

#### **A NOVEL ALGORITHM TO DEFINE ADEQUATE PROTECTION OF LONG-LASTING INSECTICIDAL NETS: INSIGHTS FROM LATIN AMERICA**

**Maria Eugenia Castellanos**<sup>1</sup>, Stephen C. Smith<sup>2</sup>, Jodi Vanden Eng<sup>2</sup>, Audrey E. Lenhart<sup>2</sup>, Norma Padilla<sup>3</sup>

<sup>1</sup>Public Health and Tropical Medicine, College of Public Health, Medical and Veterinary Sciences, James Cook University, Townsville, Australia,

<sup>2</sup>Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Center for Health Studies, Universidad del Valle de Guatemala, Guatemala, Guatemala

The life of a long-lasting insecticidal net (LLIN) is measured by estimating its durability, physical integrity, and bio-efficacy. However, there is a need to integrate these parameters in a way that allows public health workers to estimate the level of protection provided by LLINs in a community. Here we present a novel algorithm to integrate these various types of data from durability surveys, using the results of a cross-sectional survey conducted at 32 months after a Permanent 2.0 distribution in a malaria focus in Guatemala. In this survey, the durability, usage, physical integrity and insecticide content determined by X-ray fluorescence were measured following WHO guidelines. We developed a working definition of a LLIN providing adequate protection, which integrates these measurements, following a cascading sequence: if the net was received by the household, if it was still present in the household, if it was used at least once, if it was used the night before the survey, if it was in serviceable condition (based on physical integrity) and if the concentration of deltamethrin was above 10 mg/m<sup>2</sup>. Nets that met all these criteria were considered to be providing adequate protection. At 32 months, 66% of the nets were still present. Of these, 95% had been used at least once, 71% had been used the night before, 84% were in serviceable condition and 65% of the nets had a concentration above 10 mg/m<sup>2</sup>. However, the overall proportion of LLINs providing adequate protection based on our algorithm was estimated to be just 21%. The provision of LLINs is a cornerstone of global efforts for the control and potential elimination of malaria, which is now a near-term goal in several Latin American countries. Our algorithm is the first attempt to integrate durability, usage, physical integrity, and bio-efficacy data to estimate the protective effect of the nets in a community. From a programmatic point of view, if validated, this algorithm could be useful to guide LLIN replacement strategies and increase the impact of this critical intervention.

#### **BIOMARKERS OF INTESTINAL INJURY ARE ELEVATED IN SEVERE MALARIA AND PREDICT IN-HOSPITAL AND POST-DISCHARGE MORTALITY**

**Maithri L. Sarangam**<sup>1</sup>, Ruth Namazzi<sup>2</sup>, Dibadyuti Datta<sup>3</sup>, Robert O. Opoka<sup>2</sup>, Chandry C. John<sup>3</sup>, Andrea L. Conroy<sup>3</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>Makerere University, Kampala, Uganda, <sup>3</sup>Indiana University, Indianapolis, IN, United States

Malaria continues to be a significant cause of illness and mortality in children. Severe malaria increases the risk of invasive bacterial infections, and there is evidence suggesting increased gastrointestinal permeability in severe malaria (SM). Sequestration of malaria parasites is well described and *in vivo* assessment of microcirculatory blood flow in the rectal mucosa demonstrates marked disruptions. However, the extent of intestinal injury in SM is not well characterized. We analyzed biomarkers of intestinal damage in children with SM, and their association with clinical complications and mortality, in a prospective multi-site observational cohort study. We enrolled children 6 months to 4 years of age with SM (n=600) and asymptomatic community children (CC, n=120) and followed them for 12 months to assess post-discharge mortality and morbidity. Serum samples were analyzed for two markers of intestinal injury, trefoil factor 3 (TFF3) and intestinal fatty acid binding protein (iFABP). Both TFF3 and iFABP were significantly higher in children with SM compared to the CC (p=0.0006 and p=0.0001 for TFF3 and iFABP, respectively), and were markedly increased in children with acute kidney injury (AKI) and acidosis (p<0.0001 for all). TFF3 and iFABP both predicted in-hospital mortality (odds ratio (OR) [95% confidence interval (CI)], 4.6 [2.8, 7.7] and 2.3 [1.7, 3.1] for a natural log increase in TFF3 and iFABP, respectively). TFF3, but not iFABP, was associated with increased post-discharge mortality (OR 2.5, 95% CI 1.2, 5.2). At 1 month follow up, iFABP levels had returned to community levels, while TFF3 levels remained elevated. Our results suggest that intestinal injury is common in pediatric severe malaria, and is

associated with increased in-hospital and post-discharge mortality. Studies are ongoing to determine the contributions of the parasite and host to intestinal injury in severe malaria.

0016

## A COORDINATED TRANSCRIPTIONAL SWITCHING NETWORK MEDIATES ANTIGENIC VARIATION OF HUMAN MALARIA PARASITES

Xu Zhang

Weill Cornell Medicine, NYC, NY, United States

Malaria continues to cause substantial morbidity and mortality throughout the developing world. A key trait of malaria parasites is their ability to systematically alter the antigens they expose to the immune system, thereby circumventing adapting immunity. This requires tightly regulated transcriptional activation and silencing of individual members of large, multicopy gene families that encode variant surface antigens. Expression of these genes is mutually exclusive and controlled epigenetically, however how transcriptional switching is coordinated is unknown. Here we describe an unusual genetic network in which switching events are coordinated by a unique “node” within the network. Deletion of this single, highly conserved locus disrupts switching, resulting in parasites that have a drastically reduced ability to change *var* gene expression, thus disabling the process of antigenic variation that is required to maintain a chronic infection. The discovery of this network provides an explanation for how parasites possessing a relatively small repertoire of variant antigen encoding genes can limit antigen exposure, thereby maintaining chronic infections.

## TRANSCRIPTOMICS REVEALS PERTURBATIONS IN AUTOPHAGY AS A CENTRAL PROCESS IN KENYAN CHILDREN WITH SEVERE MALARIAL ANEMIA

Caroline Ndege<sup>1</sup>, Samuel B. Anyona<sup>2</sup>, Qiuying Cheng<sup>3</sup>, Ivy Hurwitz<sup>3</sup>, Evans Raballah<sup>4</sup>, Elly O. Munde<sup>5</sup>, Christophe G. Lambert<sup>3</sup>, Collins Ouma<sup>6</sup>, Douglas J. Perkins<sup>3</sup>

<sup>1</sup>University of New Mexico-Kenya Global Health Programs, Kisumu and Siaya, Kenya, <sup>2</sup>Department of Medical Biochemistry, School of Medicine, Maseno University, Maseno, Kenya, <sup>3</sup>Center for Global Health, University of New Mexico, Albuquerque, NM, United States, <sup>4</sup>Department of Medical Laboratory Sciences, School of Public Health Biomedical Sciences and Technology, Masinde Muliro University of Science and Technology, Kakamega, Kenya, <sup>5</sup>Department of Clinical Medicine, School of Health Science, Kirinyaga University, Kerugoya, Kenya, <sup>6</sup>Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Maseno, Kenya

Severe malaria anemia (SMA, Hb<5.0g/dL and any density parasitemia) is an immune-mediated inflammatory disease with complex etiology and acute progression, predominantly witnessed in children under 5 years residing in holoendemic *Plasmodium falciparum* malaria transmission regions, such as western Kenya. The pathogenesis of SMA remains only partially defined, creating barriers for clinical management. To provide insight into the molecular “signature pathways” that characterize the pathogenesis of SMA, differentially expressed genes (DEGs) were identified through transcriptomic analysis (mRNA-seq) using Next-Generation Sequencing on blood samples collected from children with acute malaria: non-SMA (Hb>5.0 g/dL, n=41) and SMA (n=29). Total RNA was isolated for library preparation by NEBNext Ultra II with PolyA+ Selection. RNA-seq was performed on an Illumina® NovaSeq S4 (Illumina, California, USA). Enrichment analysis of functional gene sets was performed using KEGG and Reactome with significance defined as *P*-value adjusted (*Padj*)<0.05. Additional enrichment analysis was conducted using MetaCore™ with DEGs (log<sub>2</sub>) and a false discovery rate (*FDR*)-adjusted *P*<0.05. There were 6,862 DEGs with SMA defined by 1,420 up-regulated and 3,442 down-regulated genes. Autophagy was among the top-ranked pathways in KEGG (n=59, *Padj*=1.58x10<sup>-4</sup>) and Reactome (n=57, *Padj*=1.58x10<sup>-3</sup>).

Analysis with MetaCore™ identified 17 protein coding genes in the autophagy pathway associated with SMA, with 13 genes (MTOR, UVRAG, BCL2, DAPK1, GABARAP, RB1CC1/FIP200, BECN1, AMBRA1, ATG13, ULK1, GABARAPL2/GATE-16, BCL2L1/Bcl-XL, and ATG14/Barkor) up-regulated and 4 genes (ATG3, ATG5, ATG7 and ATG10) down-regulated. Collectively, these results reveal, for the first time, that perturbations in autophagy pathways and processes are central to the pathogenesis of SMA.

0018

## DRAMATIC CONSEQUENCES OF DISRUPTING LIPID HOMEOSTASIS IN PLASMODIUM FALCIPARUM

Avantika I. Ahiya<sup>1</sup>, Suyash Bhatnagar<sup>1</sup>, Joanne Morrissey<sup>1</sup>, Josh Beck<sup>2</sup>, Arun Radhakrishnan<sup>3</sup>, Akhil Vaidya<sup>1</sup>

<sup>1</sup>Drexel University, Philadelphia, PA, United States, <sup>2</sup>Department of Biomedical Sciences, Ames, IA, United States, <sup>3</sup>Department of Molecular Genetics, Dallas, TX, United States

We have recently shown that a wide range of antimalarials targeting two different transmembrane proteins (PfATP4 and PfNCR1) cause rapid disruption of cholesterol homeostasis in *P. falciparum*. Neither the parasite nor its host RBC is capable of cholesterol synthesis, and thus proper dispensation of this important lipid requires redistribution of cholesterol that was endowed to the RBC at the time of its maturation. Here we report that depletion of accessible cholesterol from the RBC plasma membrane by methyl-β-cyclodextrin (MBCD) has dramatic consequences, resulting in an inability of the parasite to invade RBC as well as in inhibition of the parasite growth. These defects were complemented by reconstitution with cholesterol or epicholesterol but not with desmosterol. These results suggest an important role for the aliphatic portion of the sterol, but not the polar group, in parasite invasion and growth. Using live time-lapse videography of fluorescently tagged trophozoite stage parasites, we detected rapid expulsion of the parasite when exposed to MBCD for just 30 min. The propelled trophozoites were still surrounded by parasitophorous vacuolar membrane (PVM) while remaining tethered to intact RBCs. Electron microscopy revealed the PVM to be compromised in the extruded parasites. Remarkably, prior 2 h treatment with PfATP4 or PfNCR1 inhibitors prevented the extrusion of trophozoites when exposed to MBCD. Overall, these findings suggest a dynamic movement of accessible cholesterol within *P. falciparum*-infected RBC that is critical for parasite survival. It would be fruitful to explore molecular players participating in this hitherto unknown aspect of parasite physiology.

0019

## ADMISSION LACTATE DEHYDROGENASE PREDICTS RISK OF BLACK WATER FEVER IN CHILDREN WITH SEVERE MALARIA

Ruth Namazzi<sup>1</sup>, Andrea L. Conroy<sup>2</sup>, Dibyadyuti Datta<sup>2</sup>, Caitlin Bond<sup>2</sup>, Robert O. Opoka<sup>1</sup>, Chandry C. John<sup>2</sup>

<sup>1</sup>Makerere University, Kampala, Uganda, <sup>2</sup>Ryan White Center for Pediatric Infectious Disease and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States

Black water fever (BWF) is a form of severe malaria that is increasingly reported among children in malaria endemic countries. However, there is limited information on predictors of BWF in children with severe malaria. The aim of this study was to evaluate clinical and laboratory predictors of BWF in children surviving severe malaria. We conducted a prospective observational study enrolling 600 children with severe malaria (SM) and 120 community children (CC), aged 0.5–4 years, between 2014 and 2017 at two hospitals in Kampala and Jinja, Uganda. All children with SM received intravenous artesunate followed by oral artemisinin-combination therapy and were asked to return to the study hospital when sick over one year of follow-up. On admission, 23.6% (n=141) of children with SM had BWF. Over one year follow-up 70/556 survivors of SM (13%) had at least one sick visit for BWF, while only 1% (1/120) of CC had a sick visit for BWF. 75% of children with BWF were from the Jinja site. Of the 70 children with SM who had BWF during follow up, 26 (37%) had

multiple visits for BWF. Children with SM who had BWF during follow-up had higher initial admission white blood cell count, total bilirubin, and lactate dehydrogenase (LDH) levels compared to children without BWF over follow-up (mean (SD), WBC, 21.4 (16.7) vs. 14.9 (10.3)  $\times 10^3/\mu\text{L}$ ; total bilirubin, 2.2 (4.2) vs. 1.1 (2.1) mg/dl; LDH, 1526 (1365) vs. 848 (801) U/L,  $p < 0.001$  for all). There was no difference in age, sex or sickle cell status between children who had  $\geq 1$  episode of BWF during follow up compared to children who had none. Elevated admission levels of LDH, a marker of hemolysis and cellular injury, predicted risk of BWF in children with SM (incidence rate ratio 2.1 [95% CI 1.2, 3.7],  $p = 0.01$ ) after adjustment for child age, sex, and study site. Measurement of plasma LDH in children with severe malaria may help to identify children at risk of BWF after the episode of severe malaria.

## 0020

### A NOVEL AMINO ACID SUBSTITUTION IN AP2-G BLOCKS SEXUAL COMMITMENT IN PLASMODIUM FALCIPARUM

Surendra K. Prajapati<sup>1</sup>, Belinda J. Morahan<sup>2</sup>, Thoai Dotrang<sup>1</sup>, Michelle C. Barbeau<sup>1</sup>, Daniel Hupaló<sup>3</sup>, Matthew Wilkerson<sup>3</sup>, Clifton L. Dalgard<sup>3</sup>, Kim C. Williamson<sup>1</sup>

<sup>1</sup>Department of Microbiology and Immunology, Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>Monash University, Melbourne, Australia, <sup>3</sup>Department of Anatomy, Physiology & Genetics, Uniformed Services University of the Health Sciences, Bethesda, MD, United States

The dramatic transition from asexual reproduction to sexual differentiation in *Plasmodium* is essential for malaria transmission in the field. In *P. falciparum*, the expression of two genes has been shown to be critical for the initial switch, *gametocyte development 1 (gdv1)* and an *aptella 2* transcription factor (*ap2-g*). In this pathway, GDV1 protein is required to increase *ap2-g* expression levels and initiate gametocytogenesis. To further interrogate the underlying regulation, we targeted an *in silico* predicted serine/threonine kinase (STPK: PF06065w) which has an expression profile similar to *gdv1*. The resulting *P. falciparum* KO line ( $\Delta\text{STPK-3D7}$ ) showed a complete loss of gametocyte production. However, this phenotype was not reproduced in a subsequent independent KO attempt suggesting another unknown genetic event underlying gametocyte deficiency. Ring stage transcriptome analysis from  $\Delta\text{STPK-3D7}$  parasites revealed a downregulation of *ap2-g* as well as AP2-G dependent gene transcripts. This expression profile is consistent with an alteration in the pathway before or, possibly, at *ap2-g* since AP2-G is known to augment its own expression. Whole genome sequencing of  $\Delta\text{STPK-3D7}$  revealed a non-synonymous mutation in *ap2-g* in which valine (aa 2163, V<sub>2163</sub>) in the AP2 domain (aa 2160-2210) is replaced with leucine (L). Although V to L is a conservative substitution, it was not observed in any of the many field isolate sequences listed in PlasmoDB.org, consistent with a potentially essential function. To test directly whether the V<sub>2163</sub>-L mutation inhibits AP2-G function, we introduced the L<sub>2163</sub> mutation into *ap2-g* in gametocyte competent NF54 parasites, producing *NF54.ap2-g-L* and *NF54.ap2-g-L-GFP:FKBP* lines. Both L<sub>2163</sub> lines showed a complete loss of gametocytes. Moreover, switching L<sub>2163</sub> to the wild type allele (V) in  $\Delta\text{STPK-3D7}$  and *NF54.ap2-g-L-GFP:FKBP* lines, restored gametocyte production. This work clearly demonstrates the key role of a single aa change in the function of AP2-G providing a target for further drug development.

### PERIPHERAL PLASMODIUM FALCIPARUM INFECTION IN EARLY PREGNANCY IS ASSOCIATED WITH INCREASED MATERNAL MICROCHIMERISM IN THE OFFSPRING

Neta Simon<sup>1</sup>, Jaclyn Shallat<sup>1</sup>, John Houck<sup>2</sup>, Prasanna Jagannathan<sup>3</sup>, Mary Prael<sup>4</sup>, Mary Muhindo<sup>4</sup>, Abel Kakuru<sup>5</sup>, Peter Olwoch<sup>5</sup>, Margaret Feeney<sup>4</sup>, Whitney Harrington<sup>6</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>Seattle Children's Research Institute, Seattle, WA, United States, <sup>3</sup>Stanford University, Palo Alto, CA, United States, <sup>4</sup>University of California San Francisco, San

Francisco, CA, United States, <sup>5</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>6</sup>Seattle Children's Research Institute / University of Washington, Seattle, WA, United States

Rare maternal cells traffic into the fetus during human pregnancy and are maintained into adulthood, a phenomenon known as maternal microchimerism (MMc). Placental malaria has been associated with increased cord blood MMc, however, the impact of maternal peripheral malaria on MMc is unknown. Further, maternal cells acquired in the setting of pregnancy malaria may be functionally active in the offspring. We therefore sought to determine the impact of maternal peripheral *P. falciparum* parasitemia during pregnancy on MMc and to determine whether maternal cells expand during primary parasitemia in the offspring. We conducted a nested cohort study of maternal-infant pairs from a prior pregnancy malaria chemoprevention study. MMc was measured by quantitative PCR targeting a maternal-specific marker in genomic DNA from cord blood, first *P. falciparum* parasitemia, and pre-parasitemia. Logistic and negative binomial regression were used to assess the impact of maternal peripheral parasitemia, symptomatic malaria, and placental malaria on cord blood MMc. Generalized estimating equations were used to assess predictors of MMc during infancy. Maternal parasitemia before 20 weeks gestation was associated with increased detection of cord blood MMc (AOR=3.91,  $p = 0.03$ ), whereas late parasitemia, symptomatic malaria, and placental malaria were not. The first parasitemia episode in the infant was not associated with increased MMc relative to pre-parasitemia. Maternal parasitemia early in pregnancy may increase the amount of MMc acquired by the fetus. Future work should investigate the impact of this MMc on immune responses in the offspring.

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Nigeria Centre for Disease Control, Abuja, Nigeria, <sup>3</sup>UMB, Abuja, Nigeria, <sup>4</sup>Centers for Disease Control and Prevention, Abuja, Nigeria, <sup>5</sup>IHVN, Abuja, Nigeria, <sup>6</sup>UMB, Baltimore, MD, United States

Population-based serological testing can generate more accurate estimates of prior SARS-CoV-2 infections than routine surveillance data, which depend on testing rates and symptoms. From February 27—October 1, 2020, Nigeria reported 59,001 COVID-19 cases, though molecular testing rates were low. From September—October 2020, we conducted a household (HH) survey to assess SARS-CoV-2 seroprevalence in three states, Enugu (south), Gombe (north), and Nasarawa (central), which reported 1,234, 888, and 453 confirmed COVID-19 cases, respectively, by October 1, 2020. Two-stage cluster sampling was used, with 34 enumeration areas (EAs) sampled per state and 20 HHs per EA. All HH members were eligible. Participants were asked about behaviors and COVID-19 symptom history since March 2020; oral and nasopharyngeal swabs were taken for PCR and blood sampled for SARS-CoV-2 antibody and malaria rapid diagnostic testing. Abbott Architect IgG and Euroimmun NCP IgG assays were used for SARS-CoV-2 serology screening; samples positive on either assay were tested on the multi-antigen target Luminex xMAP assay. Luminex-positive samples were considered seropositive. Of 1,931 occupied HHs, 1,827 (94.6%) consented; of 8,823 eligible HH members, 8,356 (94.7%) consented. PCR detected 20 active SARS-CoV-2 infections in total. SARS-CoV-2 seroprevalence was 23.4% (95% CI: 18.1,

28.8) in Enugu, 8.8% (95% CI: 6.4, 11.2) in Gombe, and 18.7% (95% CI: 14.6, 22.7) in Nasarawa, with no significant differences by sex or urban/rural location. In all states, children <10 years had lower seroprevalence than those 10+ years (Enugu: 17.3% vs. 25.4%,  $p=0.0296$ ; Gombe: 4.7% vs. 10.9%,  $p=0.003$ ; Nasarawa: 12.7% vs. 21.4%,  $p=0.0002$ ). More than half (52.1%) of infections were asymptomatic. Prevalence of *P. falciparum* malaria was 21.0% in Enugu, 45.4% in Gombe, and 38.6% in Nasarawa; malaria was more prevalent among seropositive individuals in Enugu (24.5% vs. 19.9%,  $p=0.0184$ ), but not in other states. About 1 in 10 Nigerians in Gombe and 1 in 5 in Enugu and Nasarawa had evidence of prior SARS-CoV-2 infection as of October 2020; most of the population remains susceptible to COVID-19.

#### ESTABLISHING A SENTINEL SURVEILLANCE FOR THE NOVEL CORONAVIRUS DISEASE 2019 (COVID-19) IN BANGLADESH

**Pritimoy Das**<sup>1</sup>, Zubair Akhtar<sup>1</sup>, Syeda Mah-E- Muneer<sup>1</sup>, Md Ariful Islam<sup>1</sup>, Mohammed Ziaur Rahman<sup>1</sup>, Mahbubur Rahman<sup>2</sup>, Mallick Masum Billah<sup>2</sup>, Meerjady Sabrina Flora<sup>2</sup>, Tahmina Shirin<sup>2</sup>, Sayera Banu<sup>1</sup>, Fahmida Chowdhury<sup>1</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh (icddr,b), Dhaka, Bangladesh, <sup>2</sup>Institute of Epidemiology, Disease Control and Research (IEDCR), Dhaka, Bangladesh

icddr,b, in collaboration with the Institute of Epidemiology, Disease Control and Research (IEDCR), Government of Bangladesh, established a hospital-based surveillance platform for screening suspected COVID-19 patients to understand the COVID-19 situation in different regions where nearby testing facility (reverse transcription polymerase chain reaction, RT-PCR) was unavailable. We conducted the surveillance at three secondary level public and one tertiary level private hospital in different regions. Study staff enrolled suspected COVID-19 patients with any of the symptoms within the last 7 days- fever, cough, sore throat, and respiratory distress. They recorded clinical and epidemiological data, collected and transported nasopharyngeal swabs to icddr,b, Dhaka for SARS-CoV-2 test using RT-PCR. Findings were reported to the authorities over email and to the patients over short message service within 36 hours. Staff followed up with all patients after 30 days for the outcome of the illness over telephone. From 10<sup>th</sup> June to 31<sup>st</sup> August 2020, COVID-19 was detected in 39% (922/2345) enrolled patients. It was more common in outpatients with a peak positivity in July (54%). The median age of the confirmed COVID-19 cases was 38 years (IQR: 30-50), 71% were male, and 9% were healthcare workers. Among them, cough (67%) was the most common symptom followed by fever (53%). Diabetic patients were more likely to get COVID-19 than non-diabetic (48% vs. 38%,  $p<0.05$ ). The death rate among COVID-19 cases was 2.3% (21/922). Death was associated with age  $\geq$  60 years (OR:13.5; 95% CI: 5.4-33), shortness of breath (OR:14.4; 95% CI: 4.8-43), co-morbidity (OR:13.9; 95% CI: 3.2-60), smoking history (OR: 3.9, 95% CI: 1.5-9.8), hospital admission (OR:13.3; 95% CI: 5.3-33) and health care seeking in <2 days due to critical illness (OR: 5.4; 95% CI: 1.8-17). More than one-third of suspected patients attending surveillance hospitals had COVID-19. Our effort strengthened the government's capacity for rapid case detection, reporting and quick containment efforts. This surveillance should be continued to monitor the trends of COVID-19 over time.

The COVID-19 pandemic has resulted in severe shortages of personal protective equipment (PPE) necessary to protect front-line healthcare personnel. Shortages are critical, especially in low-resource settings, and underscore the urgent need for simple, efficient, and inexpensive methods to decontaminate SARS-CoV-2-exposed masks and respirators, enabling reuse when using crisis capacity strategies. We hypothesized that methylene blue (MB) photochemical treatment, which is used in multiple clinical applications including inactivation of virus in plasma, could decontaminate PPE exposed to coronavirus. We tested the ability of MB with light (MBL) treatment to inactivate coronaviruses on three N95 filtering facepiece respirator (FFR) and two medical mask (MM) models. We inoculated FFR and MM materials with three different coronaviruses, including two separate isolates of SARS-CoV-2, and treated the materials with 10- $\mu$ M MB followed by exposure to 50,000 lux of broad spectrum light (~1/3 the brightness of sunlight) or 12,500 lux of red light for 30 minutes. In parallel, we subjected intact FFRs/MMs to five cycles of MBL decontamination (5CD) to assess the impact on integrity using multiple standard test methods and compared the results to the FDA-authorized vaporized hydrogen peroxide plus ozone (VHP+O<sub>3</sub>) method. Overall, MBL robustly and consistently inactivated all three coronaviruses with 99.8 to >99.9% virus inactivation across all FFRs and MMs tested. FFR and MM integrity was maintained after 5CD of MBL treatment, whereas one FFR model failed after 5CD with VHP+O<sub>3</sub>. MB plus ambient light and pretreatment of FFRs with MB also resulted in complete inactivation of SARS-CoV-2. MBL decontaminated FFRs and MMs by inactivating three coronaviruses without compromising integrity through 5CD. MBL decontamination of FFRs and MMs is effective and low-cost, thus making it applicable in *all resource settings*. These attractive features support the utilization and continued development of this novel PPE decontamination method.

0025

## NON-ADHERENCE TO INFECTION PREVENTION AND CONTROL MEASURES FOR COVID-19 AMONG COMMUNITY HEALTH WORKERS: A POTENTIAL THREAT TO COMMUNITY HEALTH PROGRAMS IN UGANDA, 2020

Denis Okethwangu<sup>1</sup>, Anna Bowen<sup>2</sup>, Elizabeth Katana<sup>3</sup>, Bob Omoda<sup>3</sup>, Daniel Emong<sup>3</sup>, Peter Oumo<sup>3</sup>, Doreen Gonahasa<sup>3</sup>, Josephine Namayanja<sup>3</sup>, Aggrey Byaruhanga<sup>3</sup>, Phoebe Nabunya<sup>3</sup>, Patricia Thiwe<sup>3</sup>, Umaru Ssekabira<sup>1</sup>, Julie Harris<sup>4</sup>, Julie Gutman<sup>2</sup>, Shelby Cash<sup>2</sup>, Jessica Butts<sup>2</sup>, Lauren Lewis<sup>2</sup>

<sup>1</sup>Infectious Diseases Institute, Kampala, Uganda, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Uganda Public Health Fellowship Program, Kampala, Uganda, <sup>4</sup>Centers for Disease Control and Prevention, Kampala, Uganda

Community healthcare workers (CHWs) in Uganda provide integrated community case management (iCCM) of fever, cough, and diarrhea to children 2-59 months. COVID-19 has threatened the safety and continuity of these services. To assess COVID-19 perceptions and preparedness among CHWs, we conducted a cross-sectional survey in Moyo and Adjumani Districts in December 2020. We interviewed and observed randomly selected CHWs affiliated with each of 10 randomly sampled health facilities per district and collected data on CHWs' perceived COVID-19 risk, access to infection prevention and control (IPC) supplies, adherence to IPC measures when providing community-based services, and COVID-19 training received. We used logistic regression to assess associations between CHW characteristics and risk perception. We interviewed 231 CHWs (43% female). Median age was 38 (IQR: 32-46) years and median CHW tenure was 9 (IQR: 4-15) years; 66 had completed secondary education or higher. Most (92%) had attended training on COVID-19. Nearly half (44%) did not have access to a functional handwashing station (with soap and water); 37% did not have enough medical masks in the last month. Among 130 CHWs with access to functional handwashing stations, 31 (24%) did not adhere to proper handwashing practices. Among 145 CHWs with adequate masks in the last month, 104 (72%) did not regularly wear them. Most (89%) reported changing gloves between patients and maintaining social distancing at work (82%). Only 20% reported adhering to all four assessed IPC measures (i.e., wearing masks, washing hands, using/changing gloves between patients, maintaining social distance) and 24% perceived COVID-19 as a serious risk. Longer service as a CHW (21-30 vs. <10 years) was associated with higher perceived risk of COVID-19 (OR 3.4, 95% CI 1.2-10.1). While nearly all CHWs had COVID-19 training, there is a need to improve access to IPC supplies and adherence to all IPC measures, particularly use of masks and handwashing. Supportive supervision and behavior change approaches such as peer mentorship by more experienced CHWs, may help address these gaps and minimize disruption to iCCM.

0026

## COVID-19 VACCINATION INTENTION IN AN ARBOVIRAL COMMUNITY COHORT IN PONCE, PUERTO RICO

Liliana Sanchez-Gonzalez<sup>1</sup>, Chelsea G. Major<sup>1</sup>, Dania Rodriguez<sup>1</sup>, Abirami Balajee<sup>2</sup>, Kyle Ryff<sup>1</sup>, Olga Lorenzi<sup>1</sup>, Laura E. Adams<sup>1</sup>, Vanessa Rivera-Amill<sup>3</sup>, Melissa Rolfes<sup>4</sup>, Gabriela Paz-Bailey<sup>1</sup>

<sup>1</sup>CDC, San Juan, Puerto Rico, <sup>2</sup>Maximus Inc, Atlanta, GA, United States, <sup>3</sup>Ponce Health Sciences University, Ponce, Puerto Rico, <sup>4</sup>CDC, Atlanta, Puerto Rico

As of April 11<sup>th</sup>, 2021, more than 103,000 confirmed COVID-19 cases and 2,100 deaths have been reported in Puerto Rico, where COVID-19 vaccination started on December 15, 2020. In the Communities Organized for the Prevention of Arboviruses (COPA) study, a community-based cohort in southern Puerto Rico, we interviewed participants aged ≥14 years about COVID-19 vaccine intention from November 12, 2020 to March 31, 2021. We calculated frequencies and evaluated associations

between COVID-19 vaccine intention and participant demographics using Pearson  $\chi^2$ , Fisher exact tests, one-way ANOVA, and unadjusted relative risks. No significant changes were found after adjusting to account for sample size and age and sex, using a log-binomial model. Among 1,036 participants interviewed, 934 (90%) answered the vaccine intention questions, median age was 37 years (range 14-80), 539 (58%) were female, 870 (93%) identified as Latino, and 61 (7%) reported having been previously diagnosed with COVID-19. Most participants (79%) reported that they would be willing to receive a COVID-19 vaccine, 12% wouldn't receive it, and 9% were not sure. The most frequently reported reason for not intending to receive or not being sure about receiving a COVID-19 vaccine was concern about safety or side effects (61%). People previously diagnosed with COVID-19 (RR 1.3, 95%CI 1.2-1.3), who had contact with a COVID-19 case (RR 1.3, 95%CI 1.2-1.3), who believed vaccines are important to prevent diseases (RR 2.9, 95%CI 1.8-4.7), and who would accept a dengue vaccine if available (RR 3.1, 95%CI 2.4-4.0) were more likely to report they would receive a COVID-19 vaccine. Participants aged 31-40 were less likely to report they would receive a COVID-19 vaccine when compared to those aged 14-20 (RR 0.9, 95%CI 0.8-0.9). No differences were found by sex, race, or education. COVID-19 vaccine intention is high among COPA participants and is associated with a previous COVID-19 diagnosis or exposure and general positive attitudes towards vaccines. Public health messaging in Puerto Rico should address concerns regarding COVID-19 vaccine safety and side effects tailored to the local context.

0027

## DEVELOPING EVIDENCE-BASED RECOMMENDATIONS FOR FULLY VACCINATED TRAVELERS TO REDUCE RISK OF SARS-COV-2 SPREAD, MARCH 2021

Leah F. Moriarty, Allison Walker, Michael Johansson, Hannah Wolford, Cindy R. Friedman

Centers for Disease Control and Prevention, Atlanta, GA, United States

Travel is an important factor in the spread of SARS-CoV-2 including variants of concern (VOC). Recommendations for travelers during the pandemic require measures that protect individuals during the journey and in the communities where travelers visit and live. Travel risk reduction strategies have focused on a combination of pre- and post-travel testing and self-quarantine that can impose significant burden on both travelers and public health resources. During April 2021, with the increasing availability of SARS-CoV-2 vaccines, CDC re-examined the scientific rationale for US travel recommendations. We reviewed literature from studies that evaluated vaccine effectiveness (VE) against infection for FDA-authorized vaccines through March 17, 2021. To estimate the impact of vaccination combined with other prevention measures, we used vaccine effectiveness ranges of 60-90% in models previously developed to assess impact of testing and quarantine on travel-associated transmission risk. Models were also developed to assess travelers' risk of SARS-CoV-2 infection at travel origin and destination using vaccination coverage rates. At the time of our analysis, estimated VE for FDA-authorized vaccines was reported as 64%-92%. Models using a 90% effective vaccine showed that adding pre-and post-travel testing and a 7-day self-quarantine provided a median estimated 9.7% (range 8.6, 9.9) risk reduction beyond the impact of vaccination for vaccinated travelers. Models also showed that vaccination coverage impacts risk; with increasing vaccination coverage at origins and destinations, risk of introduction by a traveler were reduced proportionally. Our models showed that with an effective SARS-CoV-2 vaccine testing and quarantine provide only marginal additional risk reduction for the fully vaccinated traveler. Vaccination coverage and vaccine performance against emerging variants are important considerations, particularly for international travelers from locations where SARS-CoV-2 burden is high. As such, testing of international travelers continues to be a valuable public health tool.

## STRUCTURAL RACISM AND COVID-19 RESPONSE: HIGHER RISK OF EXPOSURE DRIVES DISPARATE COVID-19 DEATHS AMONG BLACK AND HISPANIC/LATINX RESIDENTS OF ILLINOIS, USA

Tobias M. Holden<sup>1</sup>, Damon T. Arnold<sup>2</sup>, Veronica Halloway<sup>2</sup>, Ngozi O. Ezike<sup>2</sup>, Melissa A. Simon<sup>1</sup>, Jaline Gerardin<sup>1</sup>

<sup>1</sup>Northwestern University, Chicago, IL, United States, <sup>2</sup>Illinois Department of Public Health, Springfield, IL, United States

Structural racism drives the social, economic, and community factors leading to decades of policies and conditions that have resulted in residential segregation, lack of employment opportunities that limit economic mobility, and poorer population health for minoritized populations. In 2020, Black and Hispanic/Latinx communities across the United States, including the state of Illinois, experienced disproportionately high rates of COVID-19 cases and deaths. Public health officials in Illinois implemented targeted programs at state and local levels to increase intervention access and reduce disparities. To quantify how disparities evolved through the epidemic, data on SARS-CoV-2 diagnostic tests, COVID-19 cases, and COVID-19 deaths were obtained from the Illinois National Electronic Disease Surveillance System for the period from March 1 to December 31, 2020. Relative risks of COVID-19 cases and deaths were calculated for Black and Hispanic/Latinx vs. White residents, stratified by age group and epidemic interval. Deaths attributable to racial/ethnic disparities in incidence and case fatality were estimated with counterfactual simulations. From March to May of 2020, the risk of a COVID-19 case for Black and Hispanic/Latinx populations was more than twice that of Whites across all age groups. The relative risk of COVID-19 death reached above 10 for Black and Hispanic/Latinx individuals under 50 years of age compared to age-matched Whites in the early epidemic. In all Illinois counties, the relative risk of a COVID-19 case was greater or not significantly different for minoritized populations compared to White. 79.3% and 86.7% of disparities in deaths among Black and Hispanic/Latinx populations respectively were attributable to differences in age-adjusted incidence compared to White populations rather than differences in case fatality ratios. Relative lack of access to health care, crowded living conditions, and high-risk occupations are the result of structural racism, which placed Black and Hispanic/Latinx populations at higher risk of exposure to SARS-CoV-2 and thus higher COVID-19 mortality rates.

## IMPACT OF CURRENT MALARIA INFECTION AND PREVIOUS MALARIA EXPOSURE ON THE CLINICAL PROFILES AND OUTCOME OF COVID-19 IN A HIGH MALARIA TRANSMISSION SETTING: A PROSPECTIVE COHORT STUDY

Jane Achan<sup>1</sup>, Asadu Serwanga<sup>1</sup>, Humphrey Wanzira<sup>1</sup>, Tonny Kyagulanyi<sup>1</sup>, Anthony Nuwa<sup>1</sup>, Godfrey Magumba<sup>1</sup>, Stephen Kusasira<sup>2</sup>, Isaac Sewanyana<sup>3</sup>, Kevin Tetteh<sup>4</sup>, Chris Drakeley<sup>4</sup>, Fredrick Nakwagala<sup>5</sup>, Helen Aanyu<sup>5</sup>, Jimmy Opigo<sup>6</sup>, Prudence Hamade<sup>7</sup>, Madeleine Marasciulo<sup>8</sup>, Byarugaba Batera<sup>5</sup>, James Tibenderana<sup>7</sup>

<sup>1</sup>Malaria Consortium, Kampala, Uganda, <sup>2</sup>Ministry of Defense, Kampala, Uganda, <sup>3</sup>Central Public Health Laboratories, Kampala, Uganda, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>5</sup>Mulago National Referral Hospital, Kampala, Uganda, <sup>6</sup>Ministry of Health, Kampala, Uganda, <sup>7</sup>Malaria Consortium, London, United Kingdom, <sup>8</sup>Malaria Consortium, Raleigh, NC, United States

Our understanding of the potential impact of SARS-CoV-2 and malaria co-infection on host susceptibility and pathogenesis remains unclear. We determined the prevalence of malaria and describe the consequences of SARS-CoV-2 and malaria co-infection in a high burden malaria setting. This was a prospective cohort study of hospitalized Covid-19 patients in Uganda. Malaria diagnosis was done using rapid diagnostic tests, microscopy and molecular methods. Previous *P. falciparum* exposure was assessed using serologic responses to a panel of *P. falciparum* antigens

using a multiplex bead assay. Additional evaluations included complete blood count, markers of inflammation and serum biochemistries. Of 597 PCR confirmed Covid-19 cases enrolled between 16th April and 30th October 2020, 500 (84.1%) were male and median age (1QR) was 36 (28-47) years. Overall prevalence of *P. falciparum* infection was 11.7% (70/597, 95% CI 9.4 to 14.6), with highest prevalence in the 0-20 years (21.7%, 5/23, 95% CI 8.7-44.8) and > 60 years (19.6%, 9/46, 95% CI 10.2-34.1) age groups. Confusion [5.7% (4/70) vs. 1.5%, (8/527), p=0.04] and vomiting [5.7% (5/70) vs. 1.0%, 5/527], p=0.007] were more frequent among patients with *P. falciparum* infection. Patients with low previous *P.falciparum* exposure had a higher frequency of severe/critical Covid-19 cases (30.2%, 16/53, p=0.001), a higher burden of comorbidities [hypertension (30.2%, 16/53, p=0.02) and diabetes (22.6%, 12/53, p=0.003)] and more deaths (3.8%, 2/53, p=0.01). Among patients with no comorbidities, those with low previous exposure still had a higher proportion of severe/critical Covid-19 cases (18.2%, 6/53 vs. 2.0%, 1/56, p=0.01) compared to those with high exposure. Prevalence of *P. falciparum* infection among Covid-19 patients was relatively high. Though Covid-19 patients with *P. falciparum* infection had a higher frequency of confusion and vomiting, co-infection with malaria did not seem deleterious. Low previous malaria exposure was associated with severe/critical Covid-19 and adverse outcomes.

## IMPACT OF COVID-19 ON PEOPLE LIVING WITH HIV/AIDS IN THAILAND: A PROSPECTIVE STUDY

Rapeephan Rattanawongnara Maude, Sasisopin Kiertiburanakul

Ramathibodi Hospital, Bangkok, Thailand

The pandemic of COVID-19 has effect to healthcare system particularly people living with HIV/AIDS (PLWHA). In Thailand, there are limited data regarding the effect of this emerging infectious disease with PLWHA. We hypothesized that COVID-19 would have substantial effect on PLWHA also using telemedicine may increase the quality of life and decrease the risk of contracting COVID-19 infection. Methods: The prospective telephone-based questionnaire study conducted from July 2020 to January 2021 in Ramathibodi hospital, Thailand. All PLWHIV over 18 years old seen in ID outpatient clinic were eligible. The prospective telephone-based questionnaire study conducted from July 2020 to January 2021 in Ramathibodi hospital Mahidol University, Bangkok, Thailand. All PLWHIV aged over 18 years old who are following-up in outpatient clinic were eligible. One thousand nine hundred and fourteen (74%) of 2,597 PLWHA participated in the study. Median age was 48 years old (IQR 40-55). Thirty eight percent were female, 62% male. Most people lived in Bangkok (52%) and others from 70 provinces across Thailand and other countries in Asia. Half were treated over 10 years. Fifty eight percent of participants who missed appointments reported to be due to COVID-19. Participants were asked to reschedule appointments were more from Bangkok (p =.0044). Seven percent of participants using telemedicine with 89% reported high satisfaction. Ninety two percent preferred to use telemedicine if possible. Nine percent received ART from the mailing service with high satisfaction rate of 83%. Twenty-two participants had privacy concern without significant correlation in educational level (p=.22). Thirty one percent preferred to receive medication by themselves at the clinic. Two percent missed their ART and it was unrelated to educational level (p=.14). There were challenge in the care of PLWHA during COVID-19 pandemic. The concern for privacy was still present. With ongoing epidemic of COVID-19 and possible future epidemic, understanding the effect and possible solutions will enhance the best possible care for PLWHA.

0031

### ATYPICAL PRESENTATION OF LEPROSY IN AN HIV POSITIVE PATIENT

**Netsanet Azene Gebeyehu**, Adane Ayele Legesse

*Addis Ababa University, Addis Ababa, Ethiopia*

Leprosy (Hansen's disease) is one of the neglected tropical diseases which is a curable, chronic infectious disease caused by bacteria called *Mycobacterium leprae* transmitted from person to person through respiratory droplets. It affects mainly nerves, skin, eyes, and nasal mucosa. Diagnosis of leprosy is most commonly based on clinical signs and symptoms. Atypical presentations like our case, calcinosis cutis-like presentation may be diagnosed with histopathology. Management is multi-drug treatment (MDT). A fifty-year-old known human immunodeficiency virus, a positive male patient, on antiretroviral medication, presented with a skin rash of one week duration. It began as a small raised painless swollen lesion on the forearm bilaterally and progressively involve the lower leg associated with occasional burning sensation and numbness on hand and foot. Upon examination, firm to hard nodule and papule on dorsal distal for-arm and hand, and shine. He had also an enlarged non-tender right and left ulnar nerve. Biopsy was done from the raised skin lesion showed diffuse foamy macrophage and around nerves which harbour numerous acid-fast bacilli. The patient managed multi-drug treatment with a good outcome.

0032

### EARLY-LIFE ENTERIC INFECTION AND ENTEROPATHY MARKERS ARE ASSOCIATED WITH CHANGES IN ADIPOKINE, APOLIPOPROTEIN AND CYTOKINE PROFILES LATER IN CHILDHOOD CONSISTENT WITH THOSE OF AN ADVERSE CARDIOMETABOLIC DISEASE RISK PROFILE IN A PERUVIAN BIRTH COHORT

**Josh M. Colston**, Margaret N. Kosek

*University of Virginia School of Medicine, Charlottesville, VA, United States*

Metabolic syndrome is a cluster of risk factors for cardiovascular disease that afflicts over a billion people worldwide and is increasingly seen in younger age groups and low-resource settings in the global south. Enteropathogen exposure and environmental enteropathy in infancy may lead to metabolic syndrome by disrupting the metabolic profile in ways that are detectable in cardiometabolic markers later in childhood. 217 subjects previously enrolled in a birth cohort in Amazonian Peru were followed up annually from ages 2 to 5 years. Blood samples collected in later childhood were analyzed for 37 cardiometabolic biomarkers, including adipokines, apolipoproteins, cytokines, and other analytes. These were matched to extant early-life markers of enteropathy ascertained between birth and 2 years of age. Multivariate and multivariable regression models were fitted to test for associations. Fecal and urinary markers of intestinal permeability and inflammation measured from birth to 2 years of age were independently associated with later serum concentrations of soluble CD40-ligand, a proinflammatory cytokine correlated with adverse metabolic outcomes. Fecal myeloperoxidase was also strongly, directly associated with later levels of the anti-inflammatory adipocytokine omentin-1. Cumulative enteric protozoa exposure before 2 years of age showed stronger associations with later cardiometabolic markers than enteric viruses and bacteria and overall diarrheal episodes. Early-life markers of enteric infection and enteropathy were associated with numerous changes in adipokine, apolipoprotein and cytokine profiles later in childhood consistent with those of an adverse cardiometabolic disease risk profile in this Peruvian birth cohort. Markers of intestinal permeability and inflammation measured in urine and stool during infancy, may predict disruptions to cytokine and adipocytokine production in later childhood that are precursors to metabolic syndrome in adulthood. Chronic enteric infections, such as by protozoan pathogens, may be more important drivers of these changes than symptomatic diarrhea or growth faltering.

0033

### CHARACTERIZATION OF TYPHOID INTESTINAL PERFORATION IN AFRICA: RESULTS FROM THE SEVERE TYPHOID FEVER SURVEILLANCE IN AFRICA (SETA) PROGRAM

**Megan Birkhold**<sup>1</sup>, Shrimati Datta<sup>1</sup>, Gi Deok Pak<sup>2</sup>, Justin Im<sup>2</sup>, Octavie Lunguya Metila<sup>3</sup>, Abraham Aseffa<sup>4</sup>, Ellis Owusu-Dabo<sup>5</sup>, Abdramane Soura Bassiahi<sup>6</sup>, Raphaël Rakotozandrainy<sup>7</sup>, Yaw Adu-Sarkodie<sup>5</sup>, Iruka N. Okeke<sup>8</sup>, Kathleen M. Neuzil<sup>1</sup>, Raphaël M. Zellweger<sup>2</sup>, Florian Marks<sup>2</sup>

<sup>1</sup>University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>International Vaccine Institute, Seoul, Republic of Korea, <sup>3</sup>Institut National de Recherche Biomédicale, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Armauer Hansen Research Institute, ALERT Campus, Addis Ababa, Ethiopia, <sup>5</sup>Kwame Nkrumah University of Science and Technology, Kumasi, Ghana, <sup>6</sup>Institut Supérieur des Sciences de la Population, Université de Ouagadougou, Ouagadougou, Burkina Faso, <sup>7</sup>University of Antananarivo, Antananarivo, Madagascar, <sup>8</sup>University of Ibadan, Ibadan, Nigeria

Typhoid intestinal perforation (TIP) is a severe, life-threatening complication of untreated or improperly treated typhoid fever. Mortality rates range from <1% in high-income countries to >30% in parts of sub-Saharan Africa. A lack of blood culture surveillance contributes to delays in diagnosis and management of typhoid fever, allowing progression to complications including TIP. Diagnostic challenges also limit understanding of incidence and mortality rates of TIP. The Severe Typhoid Fever Surveillance in Africa (SETA) program, a multi-country surveillance study, addresses these knowledge gaps by systematically collecting data on culture positive typhoid cases and characterizing the frequency, risk factors, and complications associated with typhoid fever, including epidemiology, presentation, and time trends of TIP. Patients with clinical suspicion of TIP, reporting abdominal pain with or without objective fever or history of fever, were enrolled. A venous blood sample was taken for culture investigation of *Salmonella* Typhi, and when surgery was performed, a sterile surgical site culture was obtained. Based on a combination of typhoid culture positivity and surgical verification of intestinal perforation, we classified TIP as confirmed, probable, possible, or suspect cases. We assessed 608 patients (353 males, 255 females) with clinically suspected TIP diagnoses from 6 African countries. Twenty of these were confirmed TIP cases, 9 probable, 195 possible, and 384 suspect cases. Ages ranged from 0-85 years, with the most seen between 5-10 years of age. Results from a generalized linear model indicate monthly typhoid cases were predictive of monthly TIP cases in the Democratic Republic of the Congo, Ethiopia, Ghana, and Nigeria, however, not in Burkina Faso or Madagascar. The overall mortality rate ranged from 2.7% (Ghana) to 27.3% (Madagascar). TIP mortality remains high in sub-Saharan Africa, with our data suggesting the burden is likely underestimated. A coordinated approach that includes vaccination with typhoid conjugate vaccine, access to care, and investments in infrastructure can help prevent this deadly disease.

0034

### NITROIMIDAZOLE VERSUS PAROMOMYCIN IN TREATMENT OF DIENTAMOEBIA FRAGILIS INFECTION; CLINICAL AND MOLECULAR EVALUATION

**Asaf Biber**, Shiraz Gefen-Halevi, Eli Schwartz

*The Chaim Sheba Medical Center, Ramat Gan, Israel*

*Dientamoeba fragilis* (DF), is a common gastrointestinal protozoan (second only to *Blastocystis* spp.). This parasite is associated with gastrointestinal symptoms, yet its pathogenicity is still controversial. To assess pathogenicity and treatment response, we prospectively evaluated all patients with chronic gastrointestinal symptoms and positive stool PCR for DF only (or co-infected with *Blastocystis* spp.). Treatment courses, clinical response and post-treatment molecular results were recorded. Clinical cure was defined as resolution of symptoms as reported by the patient and molecular response was defined as negative PCR for DF following treatment course. During 2 years of study period 46 patients

were eligible, 47.8% were male, median age 36.5 (range 3-83) years, and 75% had travel history prior to symptoms onset. The most common symptoms were loose stool (87%) and abdominal pain (85%) for an average period of 8 months before presenting at our clinic. Altogether, 74 treatment courses with clinical response were recorded. Treatment courses included mainly nitroimidazoles based regimens (54%) and paromomycin (31%) with clinical cure rates of 27% and 82% respectively ( $p < 0.0001$ ). Molecular response was evaluated in 39 samples with molecular response documented by negative stool in 20% of samples of patients with nitroimidazoles-based regimens while after paromomycin courses in 73.3% ( $p = 0.0024$ ). A high correlation was found between molecular cure and clinical response. In conclusion, our results support the notion that DF should be considered as a pathogenic protozoon since there was a correlation between DF eradication and clinical cure. Paromomycin should be the preferred treatment option.

0035

### VALIDATION OF A MOBILE HEALTH TOOL FOR VIRAL DIARRHEA ETIOLOGY PREDICTION IN YOUNG CHILDREN: A PROSPECTIVE MULTICENTER STUDY IN BANGLADESH AND MALI

**Stephanie C. Garbern**<sup>1</sup>, Monique Gainey<sup>2</sup>, Sabiha Nasrin<sup>3</sup>, Adama M. Keita<sup>4</sup>, Ben J. Brintz<sup>5</sup>, Henry Badji<sup>4</sup>, Joel Howard<sup>6</sup>, Mami Taniuchi<sup>7</sup>, James A. Platts-Mills<sup>7</sup>, Karen Kotloff<sup>8</sup>, Eric J. Nelson<sup>9</sup>, Nur H. Alam<sup>3</sup>, Rashidul Haque<sup>3</sup>, Samba Sow<sup>4</sup>, Adam C. Levine<sup>1</sup>, Daniel T. Leung<sup>5</sup>

<sup>1</sup>Alpert Medical School of Brown University, Providence, RI, United States, <sup>2</sup>Rhode Island Hospital, Providence, RI, United States, <sup>3</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>4</sup>Center for Vaccine Development, Bamako, Mali, <sup>5</sup>University of Utah, Salt Lake City, UT, United States, <sup>6</sup>University of Kentucky, Lexington, KY, United States, <sup>7</sup>University of Virginia, Charlottesville, VA, United States, <sup>8</sup>University of Maryland, Baltimore, MD, United States, <sup>9</sup>University of Florida, Gainesville, FL, United States

Diarrheal diseases are a leading cause of morbidity and mortality in children under five years in low- and middle-income countries. Determination of diarrhea etiology at the point-of-care is crucial for patient management especially appropriate antibiotic use. In this prospective observational study, our objective was to externally validate the accuracy of a new mobile health (mHealth) tool ("App") for predicting viral etiology of acute diarrhea in children 0-59 months. Patients were enrolled at sites in Dhaka, Bangladesh and Bamako, Mali. The App used previously-derived and internally validated models for the prediction of viral diarrhea using patient data entered by a nurse and external data including climate and seasonal viral data. Models included 1) current patient data only (age, bloody stool, vomiting, breastfeeding status, and mid-upper arm circumference) 2) current patient data + seasonality 3) current patient + local weather data 4) current patient + historical pre-test odds (historical rates of viral diarrhea by site and date) 5) current patient + recent patient pre-test odds. A stool sample was collected from patients for Taqman Array Card multiplex molecular diagnostic testing for 32 enteric pathogens for assignment of diarrhea etiology using an episode-specific attributable fraction (Afe) threshold of  $>0.5$ . Model performance was assessed with area under the receiver operating characteristic curve (AUC), calibration-in-the-large, and calibration slope. The current patient + seasonal model had an AUC of 0.754 (0.665 - 0.754) for both study sites combined, calibration-in-the-large of  $\alpha = -0.393$  (-0.455 - -0.331) and calibration slope of  $\beta = 1.287$  (1.207 - 1.367). Stratified by site, the current patient + pre-test odds model performed best with an AUC of 0.783 (0.705 - 0.86) in Mali, while the current patient + seasonal model performed best with an AUC of 0.71 (0.595 - 0.825) in Bangladesh. MHealth tools may adequately identify patients with high likelihood of viral-only etiology of diarrhea who do not warrant antibiotic use. Further studies are underway to evaluate the impact of this tool on antibiotic prescribing behaviors.

### INVESTIGATING MASS DRUG ADMINISTRATION COVERAGE AND CONTRIBUTORS TO PERSISTENT TRACHOMA TRANSMISSION IN MOROTO DISTRICT, UGANDA

**Alexander H. Jones**<sup>1</sup>, Lihan Lu<sup>1</sup>, Clara R. Burgert-Brucker<sup>1</sup>, Francis Mugume<sup>2</sup>, Gilbert Baayenda<sup>2</sup>, Otim Stephen<sup>3</sup>, Stella Agunyo<sup>4</sup>, Alex M. Rutagwabeyi<sup>4</sup>, Jeremiah Ngondi<sup>1</sup>, Elizabeth Plunkett<sup>1</sup>, Benjamin Binagwa<sup>4</sup>

<sup>1</sup>RTI International, Washington, DC, United States, <sup>2</sup>Ministry of Health, Kampala, Uganda, <sup>3</sup>Local Government, Moroto District, Moroto, Uganda, <sup>4</sup>RTI International, Kampala, Uganda

In Moroto District, Uganda baseline trachomatous inflammation-follicular (TF) prevalence was 57.1%. After nine mass drug administrations (MDAs), surveys show reduced TF prevalence, but it was still above the stop-MDA threshold ( $<5\%$ ). In December 2020, the Ministry of Health (MOH) conducted a coverage evaluation survey (CES) to validate reported coverage for a September 2020 MDA and to investigate potential contributors to persistent transmission in Moroto. A multi-stage, cluster-sample, household survey was conducted using a World Health Organization methodology. "Coverage" was defined as swallowing the drug during the last MDA. Standardized questionnaires were administered to collect demographic, programmatic, and behavioral data from consenting participants. In data analysis, logistic regression modelling was used to identify correlates of MDA coverage. The survey had 1,688 respondents and a response rate of 98.1%. In Moroto, surveyed MDA coverage was 81.2% (CI: 79.3-83.0) versus a reported coverage of 92.8%. Beyond validating MDA coverage, specific findings are actionable. Sub-county and survey cluster-level MDA coverage ranged from 40.6%-96.5% and 0-100%, respectively. Knowledge of trachoma was positively associated with coverage (OR=2.0, CI: 1.2-3.5). Farmers had lower coverage (OR=0.6, CI: 0.4-0.8); students had higher coverage (OR=1.8, CI: 1.2-2.8). Minority ethnic group membership, dominated by the Tepeth, was negatively associated with MDA coverage (OR=0.11, CI: 0.08-0.14) in a logistic regression model adjusting for age, sex, and education. Among non-covered respondents, 119 (38.1%,  $n=312$ ) were unaware of the MDA; 37 (11.9%) reported a drug stock out. About 80% of respondents live in households practicing open defecation. MOHs can use a CES to investigate areas with persistent transmission. In Moroto, the MOH achieved MDA coverage only slightly below target. And specific geographic areas and populations require increased resources. Pre-MDA social mobilization and advocacy for water, sanitation, and hygiene interventions are examples of district-wide priorities.

0037

### MALI ACHIEVES A CRITICAL MILESTONE TOWARD ELIMINATION OF LYMPHATIC FILARIASIS: ALL PREVIOUSLY ENDEMIC DISTRICTS HAVE MET CRITERIA TO STOP MASS DRUG ADMINISTRATION (MDA)

Massitan Dembele<sup>1</sup>, **Boubacar Guindo**<sup>2</sup>, Benoit Dembele<sup>3</sup>, Modibo Keita<sup>2</sup>, Yaya L. Coulibaly<sup>4</sup>, Salif S. Doumbia<sup>4</sup>, Mama Niele Doumbia<sup>2</sup>, Abdoulaye Guindo<sup>1</sup>, Moussa Mintou Koné<sup>1</sup>, Cleo Stern<sup>5</sup>, Steven D. Reid<sup>5</sup>, Fama Kondo<sup>2</sup>, Ouassa Sanogo<sup>2</sup>, Alex K. Brown<sup>2</sup>, Elisabeth Chop<sup>5</sup>, Brian Fuller<sup>5</sup>, Achille Kabore<sup>6</sup>, Yaobi Zhang<sup>5</sup>, Angela Weaver<sup>5</sup>

<sup>1</sup>Directorate General of Health, Ministry of Health and Public Hygiene, Bamako, Mali, <sup>2</sup>Helen Keller International, Bamako, Mali, <sup>3</sup>Helen Keller International, Regional Office for Africa, Dakar, Senegal, <sup>4</sup>Filariasis Unit, International Center of Excellence in Research, Faculty of Medicine and Odonto stomaology, Point G, Bamako, Mali, <sup>5</sup>Helen Keller International, New York, NY, United States, <sup>6</sup>Family Health International 360, Washington, DC, United States

In Mali, all 75 health districts (HD) were endemic for lymphatic filariasis (LF). Initial mapping with ICT cards in 2004 revealed an average national prevalence of 7.1% (ranging from 1% in the north to 18.6% in the south). The Government of Mali has committed to eliminating LF as a

public health problem by 2024. In 2005, the implementation of mass drug administration (MDA) for LF with albendazole and ivermectin began in areas co-endemic with onchocerciasis in southern Mali and scaled up to reach 100% geographical coverage in 2009. Due to political unrest and insecurity, 50 out of the 75 endemic HDs missed 1 to 3 annual rounds of MDA between 2011 and 2014. However, all HDs implemented at least 5 effective rounds of MDA before undergoing pre-transmission assessment surveys (pre-TAS), following the World Health Organization (WHO) guidelines. TAS1 in insecure HDs was also delayed by two to three years after successful pre-TAS. The Survey Sample Builder (SSB) was used to determine sample sizes and number of clusters for TAS1. By 2020, TAS1 were conducted in all 75 HDs (48 Evaluation Units - EUs) across Mali. Of 75 HDs, two conducted TAS 1 in 2012, 15 HDs in 2015, 33 HDs in 2016, 11 HDs in 2019 and 15 HDs in 2020. A community-based cluster sampling (in 40 EUs) and school-based cluster sampling (in 8 EUs) were used depending on school enrollment rates. All 48 EUs surveyed passed TAS1 with the number of positive cases being below the critical cut-off values determined by the SSB (18 or 20 positive cases) with a range of positive between 0 and 11 per EU. Currently, 100% (75/75) of the originally LF endemic districts have reached the criteria to stop MDA despite the delay caused by political unrest and insecurity, of which 62 are in post-MDA surveillance and 13 are in post elimination surveillance (passed TAS3). Current and future challenges for the LF program include establishing post elimination surveillance strategy for HDs passing TAS3 and those joining them in future years. Despite insecurity in the north causing delays in reaching LF elimination by 2020, Mali is on track to validate LF elimination as a public health problem by 2024.

0038

#### **IVERMECTIN, DIETHYLCARBAMAZINE AND ALBENDAZOLE MASS DRUG ADMINISTRATION: IMPACT ON PREVALENCE OF SCABIES, IMPETIGO AND SOIL-TRANSMITTED HELMINTH (STH) INFECTIONS IN THREE MUNICIPALITIES OF TIMOR-LESTE**

**Brandon Le<sup>1</sup>**, Merita A. Monteiro<sup>2</sup>, Salvador Amaral<sup>3</sup>, Alexander Matthews<sup>4</sup>, Sze Fui Hii<sup>5</sup>, Naomi Clarke<sup>1</sup>, Paul Arkell<sup>3</sup>, Rebecca Traub<sup>5</sup>, Jennifer Yan<sup>3</sup>, Daniel Engelman<sup>6</sup>, Nicholas Fancourt<sup>3</sup>, Andrew Steer<sup>6</sup>, John Kaldor<sup>1</sup>, Joshua R. Francis<sup>3</sup>, Susana V. Nery<sup>1</sup>

<sup>1</sup>Kirby Institute, University of New South Wales, Sydney, Australia, <sup>2</sup>Timor-Leste Ministry of Health, Dili, Timor-Leste, <sup>3</sup>Menzies School of Health Research, Darwin, Australia, <sup>4</sup>Royal Darwin Hospital, Darwin, Australia, <sup>5</sup>University of Melbourne, Melbourne, Australia, <sup>6</sup>Murdoch Children's Research Institute, Melbourne, Australia

Scabies and soil-transmitted helminth (STH) infections are neglected tropical diseases (NTDs) endemic in many developing countries, including Timor-Leste. In 2019, the Ministry of Health implemented an ivermectin, diethylcarbamazine, and albendazole (IDA) mass drug administration (MDA) programme for lymphatic filariasis control, which was also likely to have benefits for scabies and STH control. We aimed to evaluate the impact of IDA MDA on the prevalence of scabies, impetigo, and STH in Timor-Leste. Cross-sectional surveys were conducted in 6 schools across 3 municipalities prior to MDA and 18-months following MDA. At baseline, 1043 children underwent a clinical skin exam to assess scabies and stool samples were collected from 541 children for STH diagnosis. At follow-up (FU), 1196 children completed a skin exam and 621 provided a stool sample. Quantitative PCR was used to detect and quantify infection intensity of 6 STH species. Generalised linear models were built to estimate the relative and absolute differences in scabies, impetigo, and STH prevalence between timepoints while accounting for school-level clustering. The baseline prevalence of scabies was 37.7% (95% CI 29.2 - 46.1), which decreased to 13.3% (95% CI 7.5 - 19.1) at FU, corresponding to a relative reduction of 64.7% (95% CI 52.4 - 76.9,  $p < 0.000$ ) and absolute reduction of 24.4% (95% CI 17.6 - 31.1,  $p < 0.000$ ). Impetigo prevalence decreased from 12.3% (95% CI 8.2 - 16.5) to 2.2% (95% CI 1.0 - 3.4) at FU, corresponding to a relative reduction of 82.2% (95% CI 74.5 - 90.0,  $p < 0.000$ ) and absolute reduction of 10.1% (95% CI 6.6 - 13.7,  $p < 0.000$ ). The overall baseline STH prevalence

was 27.5% (95% CI 23.7 - 31.3) with *A. lumbricoides* being the most prevalent species (17.5% [95% CI 14.3 - 20.8]), followed by *N. americanus* (7.5% [95% CI 5.3 - 9.8]). STH diagnosis of follow-up samples is underway. This study demonstrates the impact of 1 dose of ivermectin delivered in the context of IDA MDA on scabies, impetigo, and STH, and can contribute to informing the integrated control of NTDs both locally and globally.

0039

#### **MEASURING THE IMPACT OF INTEGRATED MASS TREATMENT WITH IVERMECTIN AND ALBENDAZOLE FOR ONCHOCERCIASIS IN FOUR COUNTIES IN LIBERIA & ASSESSING THE EFFECTIVENESS OF THE PREVENTIVE CHEMOTHERAPY IN REDUCING TRANSMISSION OF INFECTION 2018 AND 2019**

**Alexlyn Secunda Monluo**, Vivian Ekie Monluo

Ministry of Health Liberia, Paynesville, Liberia

Onchocerciasis is among the neglected tropical diseases (NTDs) which remains a serious public health problem. Rapid Epidemiological Mapping of Onchocerciasis (REMO) was conducted in 1999 by the African Program for Onchocerciasis Control which estimated that the disease affected all the 15 counties in Liberia with 1,113,213 populations at risk. Unlike the other diseases (Lymphatic Filariasis, Schistosomiasis and STH) where the target is elimination as a public health problem, onchocerciasis has it's a goal of elimination of transmission by 2025. In accordance with the WHO guidelines, during the National Onchocerciasis Elimination Expert Committee (NOEEC) meeting in May 2017 it was decided that Liberia conduct an impact assessment using OV 16 to enable the committee to assess the impact of treatment and review progress towards elimination of onchocerciasis. By May 2018, the Ministry of Health conducted an epidemiological impact assessment that provided evidence on the status of transmission of Onchocerciasis in the Southwest Region and to determine the village level sero-prevalence of onchocerciasis in children using OV16 rapid diagnostic test (RDT), allowing assessment of recent or ongoing transmission of *Onchocerca volvulus* parasite in Liberia. The target was to test three thousand three hundred (3,300) children ages 5-9 years using OV16 rapid diagnostic test and DBS (Dried Blood Spot) in Bomi, Grand Cape Mount, Margibi and Grand Bassa counties. However, during the research, 2,432 children were successfully tested with 104 testing positives giving the prevalence rates of 3.7%, 3.2%, 1% and 0.7% across the four counties. Out of the negative samples collected, 10% were randomly selected for confirmatory testing using OV16 ELISA at the Filariasis Laboratory in Yaounde, Cameroon. Out of the 342 negative samples analysed, only 3.51% were tested positive. The results analysis indicates that there is slightly more Onchocerciasis detectable by ELISA than by RDT. This indicates that MDA has been successful in controlling the transmission of Onchocerciasis in Liberia and limiting exposure of children to the infection.

#### **EFFECT OF COVID-19 RISK MITIGATION MEASURES ON THE COVERAGE OF MASS TREATMENT CAMPAIGNS AGAINST SCHISTOSOMIASIS AND VITAMIN A SUPPLEMENTATION IN THE REGIONS OF KAYES AND SÉGOU IN MALI IN 2020**

**Modibo Keita<sup>1</sup>**, Marie Diakit<sup>1</sup>, Mahamadou Traore<sup>2</sup>, Adama B. Coulibaly<sup>3</sup>, Boubacar Guindo<sup>1</sup>, Fama Kondo<sup>1</sup>, Alkaya Kounta<sup>1</sup>, Aliou Bagayogo<sup>3</sup>, Alex Brown<sup>1</sup>, Mohamed L. Yattara<sup>1</sup>, Mama N. Doumbia<sup>1</sup>, Ouassa Sanogo<sup>1</sup>, Yaobi Zhang<sup>4</sup>, Djeinam Toure<sup>5</sup>, Cleo Stern<sup>4</sup>, David Dolodec<sup>5</sup>, Steven D. Reid<sup>4</sup>, Fatou Ndiaye<sup>5</sup>, Benoit Dembele<sup>5</sup>, Angela Weaver<sup>4</sup>

<sup>1</sup>Helen Keller International, Bamako, Mali, <sup>2</sup>Direction Generale de la Santé et de l'Hygiene Publique, Ministre de la Sante et du developpement social, PNLSH, Bamako, Mali, <sup>3</sup>Direction Générale de la Santé et de l'Hygiene Publique, Minist're de la Santé et du développement social, Division

nutrition, Bamako, Mali, <sup>4</sup>Helen Keller International, New York, NY, United States, <sup>5</sup>Helen Keller International, Regional Office for Africa, Dakar, Senegal

The Government of Mali organizes vitamin A supplementation (VAS) bi-annually for children under 5 years and mass drug administration (MDA) against neglected tropical diseases (NTDs), such as schistosomiasis (SCH) for school age children annually. The first COVID-19 case was confirmed in Mali on March 25, 2020. The first round of VAS (VAS1) was held between March 25-28, 2020. The second round of VAS (VAS2) and the SCH MDA began months later after the first COVID-19 case (October - December 2020). The VAS1 campaign was implemented at the start of the COVID-19 pandemic before any large-scale sensitization or national guidelines for the distribution of Vitamin A were developed. The VAS2 and SCH MDA campaigns took place after national programs had developed tools, such as guidelines, contingency plans, and standard operating procedures in the context of COVID-19. These tools were aligned with the WHO recommendations for NTD interventions in the context of COVID-19 and the Global Alliance for Vitamin A. The program coverage of VAS1 in the Kayes region, where one of the first cases of COVID-19 was confirmed, was 77%, while VAS2 achieved 88% coverage. In Ségou, the program coverage was 80% for the VAS1, while that of VAS2 was 86%. The VAS2 coverage was higher than VAS1 in both regions. Case refusals were reported in eight villages during VAS1 in Kayes region. The program coverage for the SCH MDA were 91% and 99% in Kayes and Ségou, respectively, comparable to program coverage in 2019 (94% in the region) before COVID-19. This analysis suggests that the availability and use of appropriate contingency tools and mitigation measures of COVID-19 may be one of many factors that contribute to adequate campaign coverage during the COVID-19 pandemic. The results indicate that preparation and availability of risk mitigation plans and tools should be prioritized during times of threat to a program (e.g. at the start of an epidemic) prior to the resumption of field-based activities.

0041

### EVALUATING THE ADOPTION OF COVID-19 PREVENTION MEASURES DURING MASS DRUG ADMINISTRATION IN ANAMBRA STATE, NIGERIA

Emily Griswold<sup>1</sup>, Adamu Sallau<sup>2</sup>, Attamah Isani Egeonu<sup>2</sup>, Emmanuel Obikwelu<sup>3</sup>, Emmanuel Miri<sup>2</sup>, Gregory S. Noland<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>The Carter Center, Nigeria, Jos, Plateau State, Nigeria, <sup>3</sup>Anambra State Ministry of Health, Awka, Anambra State, Nigeria

The COVID-19 pandemic has had profound impacts on health programs around the world. Anambra State in southern Nigeria instituted measures designed to prevent the spread of the virus during mass drug administration (MDA) for onchocerciasis, lymphatic filariasis, schistosomiasis, and soil-transmitted helminthiasis. We explored the adherence to and experience of these activities using a mixed methods approach beginning in December 2020. Training sessions and community-based MDA were observed using structured checklists. Semi-structured interviews and focus groups were conducted with health officials and community members. In 46 trainings of community drug distributors (CDDs), we observed 100% adherence to screening for symptoms and exposure to SARS-CoV-2. Ninety-eight percent of trainings were done outdoors with social distancing, while all required hand washing and small group sizes. Only 11% of observations saw CDDs being tested before participation. All CDDs in 108 MDA observations had access to masks (100%), but only a few wore gloves (10%). All CDDs wore their masks during distribution (100%), while 93% always wore them while moving between households. All washed their hands frequently. Dose poles, used to determine the number of pills to be given, were disinfected in 98% of observations. All CDDs encouraged physical distancing and gave COVID-19 prevention messages. Mitigation measures were less common in the general community, with only 43% wearing masks and 53% maintaining distance from other households in 108 observations. However, 97% of observations saw people washing their hands. The qualitative data

spoke to the upheaval caused by the pandemic, but that the program had adapted well to meet the challenge. Financial stressors, additional logistics, and intense health education messaging made this round of MDA more exhausting than in previous years, however the treatment coverage was high. The perception among health staff was that the public responded well to the messaging and respected the mitigation measures. Health staff were impressed with the response but noted that the extra measures were not likely to be sustainable.

0042

### OPPORTUNITIES AND BARRIERS TO HEALTH CAMPAIGN INTEGRATION DURING THE COVID-19 ERA ACROSS VITAMIN A, IMMUNISATION, NEGLECTED TROPICAL DISEASES, POLIO AND INSECTICIDE TREATED BEDNETS: A KEY INFORMANT INTERVIEW STUDY OF CAMPAIGN STAKEHOLDERS

Alison Krentel<sup>1</sup>, Afzaa Rajabali<sup>2</sup>, Olumide Ogundahunsi<sup>3</sup>, Tuoyo Okorosobo<sup>3</sup>, Carol McPhillips-Tangum<sup>4</sup>, Eva Bazant<sup>5</sup>, Margaret Gyapong<sup>6</sup>

<sup>1</sup>University of Ottawa, Ottawa, ON, Canada, <sup>2</sup>Bruyere Research Institute, Ottawa, ON, Canada, <sup>3</sup>University of Medical Sciences, Ondo, Nigeria, <sup>4</sup>CMT Consulting, LLC, Decatur, GA, United States, <sup>5</sup>Task Force for Global Health, Decatur, GA, United States, <sup>6</sup>University of Health and Allied Sciences, Ho, Ghana

In low and middle-income countries, health campaigns are used to rapidly deploy high-priority health interventions. Many distinct campaigns occur in communities every year. Campaign integration offers opportunities to increase efficiencies across programs and limit the strain on health systems. We aimed to understand the impact of COVID-19 on campaign delivery and the opportunities it brought for integration across five health domains (Vitamin A, Vaccine-preventable diseases, Polio, Malaria, and Neglected Tropical Diseases). We conducted 26 virtual in-depth interviews with purposively sampled informants among donors, implementing partners and Ministry of Health officials in Côte d'Ivoire, Ethiopia, Guyana, Indonesia, and Nigeria. All verbatim transcripts were analyzed using NVivo12. Due to the pandemic, delays to campaigns disrupted routine vaccination, bed net delivery schedules, and mass drug administrations. As campaigns restarted, informants faced challenges of restriction of movement, redirection of resources to COVID-19 activities, school closures affecting school-based campaigns, and increased expenditures on COVID-19 mitigation measures. Informants reported that communities had concerns about visiting health facilities and receiving people from outside their communities. Opportunities that COVID-19 brought for campaign integration included the possibility of aligning activities, funding, and commodities while reducing health worker workload. Combining delivery of some commodities resulted in higher coverage. Other areas of integration were public health surveillance, catch-up immunization, and integration of behavior change messages. Barriers to integration included complex data collection tools, number of indicators, and efficiency of supply chain management. Personal and professional relationships, leadership qualities, and political will facilitated campaign integration. The COVID-19 pandemic was described as an opportunity to integrate or consider integration of campaigns. The gains made towards effective integration and increased efficiencies should be maintained.

0043

### SINGLE-CELL RNA-SEQUENCING REVEALS DISTINCT IMMUNE POPULATIONS IN CEREBROSPINAL FLUID OF NEUROCYSTICERCOSIS PATIENTS AT EARLY AND LATE TREATMENT STAGES

Nina Tang, Paul Schaughency, Justin Lack, Thomas B. Nutman, Elise Michelle O'Connell

National Institutes of Health, Bethesda, MD, United States

Neurocysticercosis (NCC) is a parasitic infection that causes significant global morbidity. Subarachnoid NCC (SANCC), the most severe form of the disease, is associated with an exuberant inflammatory response that

leads to significant morbidity and mortality. At present, treatment of SANCC consists of anthelmintics and corticosteroids. However, frequent adverse events result from the prolonged use of these corticosteroids. A deeper understanding of the specific cell populations involved in the inflammatory response and how the inflammation evolves over the course of treatment would allow for the identification of more targeted, steroid-sparing anti-inflammatories. We used single-cell RNA-sequencing (scRNA-seq) of cryopreserved cells isolated from the cerebrospinal fluid (CSF) of 3 patients with subarachnoid neurocysticercosis both early and late in treatment to study changes in the immune milieu at these 2 disease stages. Using exome sequencing data from each of the patients and standard transcriptome analyses from the scRNA-seq allowed for the successful deconvolution of patient samples and identification of mononuclear cell populations including B cells, monocytes/macrophages, dendritic cells, T cells and NK cells. In all patients, the later timepoint was associated with an expansion of T cells when compared to early in treatment. Early timepoint samples (when the SANCC was most active) had a larger proportion of naïve CD4+ T cells, cytotoxic CD8+ T cells, and natural regulatory T cells (nTregs [FoxP3+, CD25+]) while later timepoints had a higher frequency of induced regulatory T cells (iTregs [FoxP3-, CTLA4+, LAG3+]), MAF+ lymphocytes, and B cells. From a methodological standpoint, this experiment demonstrated that transcriptomic data at a single-cell level can be extracted from cryopreserved CSF cells. This project has served as an important pilot study, providing us with a deeper understanding of the cellular milieu in the CSF of patients with SANCC, as well as a technological framework to more broadly assess the local inflammatory process that occurs before and after treatment.

0044

#### LONGITUDINAL METAGENOMIC SEQUENCING ANALYSIS OF THE GUT MICROBIOME OF HELMINTH INFECTED INDIGENOUS MALAYSIANS

**Soo Ching Lee**<sup>1</sup>, Mian Zi Tee<sup>2</sup>, Yi Xian Er<sup>3</sup>, Alice Easton<sup>4</sup>, Nan Jiun Yap<sup>3</sup>, Joseph Devlin<sup>5</sup>, Ze Chen<sup>4</sup>, Kee Seong Ng<sup>6</sup>, Shushan Sargsian<sup>7</sup>, Romano Ngui<sup>3</sup>, Kek Heng Chua<sup>2</sup>, Christopher Chiong Meng Boey<sup>8</sup>, Kenneth Cadwell<sup>7</sup>, Yvonne Ai Lian Lim<sup>3</sup>, P'ng Loke<sup>1</sup>

<sup>1</sup>Type 2 Immunity Section, Laboratory of Parasitic Diseases, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Department of Biomedical Science, University of Malaya, Kuala Lumpur, Malaysia, <sup>3</sup>Department of Parasitology, University of Malaya, Kuala Lumpur, Malaysia, <sup>4</sup>Department of Microbiology, New York University Grossman School of Medicine, New York, NY, United States, <sup>5</sup>Department of Microbiology, New York University Grossman School of Medicine, New York, NY, United States, <sup>6</sup>Department of Gastroenterology, Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia, <sup>7</sup>Kimmel Center for Biology and Medicine, Skirball Institute of Biomolecular Medicine, New York University Grossman School of Medicine, New York, NY, United States, <sup>8</sup>Department of Paediatrics, University of Malaya, Kuala Lumpur, Malaysia

The ecological relationship between intestinal helminths and gut-resident microbes in endemic human populations is complex and poorly understood. Here, we examined 669 metagenomes from a cohort of 426 indigenous Malaysians from 6 villages with different prevalence (14.9%-100.0%) of helminth infections. Samples were collected longitudinally before and after treatment with the anthelmintic albendazole. Standard mapping approaches to RefSeq complete genomes resulted in large numbers of unmapped reads, however mapping onto Human Reference Gut Microbiome (HRGM), which incorporates metagenome-assembled genomes (MAGs) resulted in >90% mapping. Additionally, we also conducted reference independent approaches such as using k-mers to estimate differences in diversity. By using Growth Rate Index (GRiD) analysis, we compared bacterial replication rates between groups and identified specific replicating taxa associated with helminth infection. Overall, we found that microbial community diversity and composition is most strongly associated with individual villages. Effects of albendazole treatment on metagenomes varied considerably depending on the village and can be observed even in helminth negative individuals. These results

indicated that effects of helminths on the microbiota is highly dependent on context and direct effects of albendazole on the microbiota can be confounding for the interpretation of deworming studies. In conclusion, our study identifies several key species and pathways associated with helminth infection and provides evidence for some co-abundance relationships, hence yielding a better understanding of helminth-microbe-host interactions.

0045

#### MODULATION OF SARS-COV-2-IMMUNE REACTIVITY BY HELMINTH ANTIGENS

**Tomabu Adjobimey**, Julia Meyer, Marijo Parcina, Achim Hoerauf  
*Institute for Medical Microbiology, Immunology and Parasitology, Bonn, Germany*

We investigated the ability of helminth antigens to modulate T cell-reactivity in 50 COVID-19 patients and 50 healthy unexposed individuals. PBMCs were stimulated with SARS-CoV-2-peptides alone or in combination with *Onchocerca volvulus*, *Brugia malayi*, or *Ascaris lumbricoides* antigens. Flow cytometry was used to identify the frequency of SARS-CoV-2-reactive T cells in CD4 and CD8 T cell populations according to the expression of CD154, CD69, and CD137. SARS-CoV-2-reactive CD4+ T cells were identified in 35.71 % of unexposed healthy individuals and 85.71 % of COVID-19 patients. Reactive CD8+ T cells were found in 29.17 % of healthy individuals, while 71.4 % of COVID-19 patients presented reactive CD8 T cells. The frequency of SARS-CoV-2 reactive CD4+ T cells was significantly reduced, both in healthy individuals and in COVID-19 patients, when stimulation with viral peptides was done in the presence of helminth antigens. In contrast, activation and proliferation of SARS-CoV-2 reactive CD8+ T cells were not affected but slightly increased in the presence of the helminth antigens. These findings suggest that helminth antigens shift the immune response to SARS-CoV-2 peptides towards cytotoxic T cell-mediated viral clearance while inhibiting helper T cell responses. To define the mechanisms underlying this differential modulation of CD4+ and CD8+ T cells by helminth antigens, the expression of different cytokines was quantified in the culture supernatants using a Luminex-based multiplex immunoassay. IL-10 concentrations were significantly increased in the presence of the helminth antigens, whereas IFN $\gamma$  and TNF $\alpha$  concentrations were decreased. Overall, our data support the hypothesis that in the presence of helminth antigens, immune responses to SARS-CoV-2 might be attenuated in regards to helper T cells and pro-inflammatory cytokines, while SARS-CoV-2 reactive cytotoxic T cells are maintained. This may ultimately shift the immune response to SARS-CoV-2 so that overreaction is avoided. These findings may at least partially explain why African countries endemic for helminth parasites are moderately affected by the COVID-19 pandemic.

0046

#### REPROGRAMMING MACROPHAGES TO DECREASE INFLAMMATORY RESPONSE IN CUTANEOUS LEISHMANIASIS

**Mauricio Nascimento**<sup>1</sup>, Augusto M. Carvalho<sup>1</sup>, Camila Amorim<sup>2</sup>, Daniel Beiting<sup>2</sup>, Phillip Scott<sup>2</sup>, Edgar M. Carvalho<sup>1</sup>, **Lucas P. Carvalho**<sup>1</sup>

<sup>1</sup>Instituto Gonçalo Moniz- Fiocruz, Salvador, Brazil, <sup>2</sup>University of Pennsylvania, Philadelphia, PA, United States

Cutaneous leishmaniasis (CL) lesions, due to *L. braziliensis* infection, present intense inflammatory infiltrate with high numbers of mononuclear phagocytes. Furthermore, few parasites are observed. High levels of TNF and IL-1 $\beta$  observed at lesion site of these individuals, is associated with tissue damage and lesion development. Eicosapentaenoic (EPA) and docosahexaenoic (DHA) polyunsaturated fatty acids are known to be natural ligands of peroxisomal proliferator-activated receptor-gamma (PPAR- $\gamma$ ). Activation of PPAR- $\gamma$  can trigger anti-inflammatory actions including inhibition of NF- $\kappa$ B. Our aim was to evaluate the role of PPAR- $\gamma$  ligands in regulating the inflammatory response observed in CL patients. Biopsies and serum were obtained from patients with CL and

healthy subjects (HS). The gene expression of PPAR- $\gamma$ , NF- $\kappa$ B, IL-1 $\beta$ , IL-6, TNF, ALOX5 were determined by RNAseq. PBMC was obtained from CL patients and cultured for 72 hours in the presence or absence of soluble *Leishmania* antigen (SLA), GW9662 (irreversible PPAR- $\gamma$  inhibitor), EPA, DHA and Pioglitazone for 72 hours. Macrophages were infected with *L. braziliensis* and treated with EPA, DHA and Pioglitazone for 2, 48 or 72 hours. Levels of TNF, IL-6, IL-1 $\beta$ , LTB4 and omega 3 were determined in culture supernatants or serum by ELISA. We observed that the genes NF- $\kappa$ B, IL-1 $\beta$ , IL-6, TNF and ALOX5 were increased in patient's lesions, whereas the PPAR- $\gamma$  gene was suppressed when compared to healthy skin. In addition, we found that the PPAR- $\gamma$  gene was negatively correlated with the NF- $\kappa$ B, IL-1 $\beta$  and IL-6. Higher concentrations of IL-6, IL-1 $\beta$ , and LTB4 were observed in patients' serum, but no difference was found on TNF and omega-3 levels between CL and HS. However, EPA and DHA negatively regulated the production of IL-6, TNF and IL-1 $\beta$ , but increased production of LTB4 in PBMC. Also, EPA and DHA increased LTB4 production by macrophages infected with *Leishmania* decreasing the percentage of infected cells and the number of amastigotes within these cells. Our results show that EPA and DHA decrease *in vitro* inflammatory response and enhance parasite killing in CL, and may serve as adjuvant therapy in CL.

### CELLULAR DYNAMICS OF IMMUNE EVASION DURING LEISHMANIA MAJOR INFECTION

**Romaniya Zayats**, Zhirong Mou, Atta Yazdanpanah, Wan Hon Koh, Paul Lopez, Jude E. Uzonna, Thomas Murooka

University of Manitoba, Faculty of Health Sciences, Department of Immunology, Winnipeg, MB, Canada

*Leishmania major* parasites elicit a strong T cell response yet evade complete clearance and persistently infect a small pool of cells. This mechanism of immune evasion remains unclear. Understanding of the persistence mechanisms is lacking, but *Leishmania major* driven induction of the immunosuppressive microenvironment through recruitment of regulatory T cells at the site of infection has been proposed to prevent parasite clearance *in vivo*. In the presented study, we used a novel TCR transgenic mouse model, where CD4<sup>+</sup> T cells recognize an immunodominant peptide derived from *Leishmania*- glycosomal phosphoenolpyruvate carboxykinase (PEPCK), to visualize the dynamics of anti-*L. major* CD4<sup>+</sup> T cell responses and to characterize mechanisms which restrain their effector function. We show that monocyte-derived macrophage:T cell interaction dynamics were transient at steady-state, but prolonged upon antigen recognition. This activation leads to a production of high levels of IFN $\gamma$  and can be significantly suppressed by PEPCK-specific Tregs *in vitro*, as compared to polyclonal Treg controls. Co-culture of PEPCK-specific CD4<sup>+</sup> T cells, *L. major*-infected monocyte-derived macrophages, and Tregs shows that antigen activation leads to a substantial increase in IL-10 levels, while decreasing IL-12, TNF, and IL-2 production in the culture. Intravital microscopy studies characterizing PEPCK-specific CD4<sup>+</sup> T cell migration dynamics and tissue localization within skin lesions directly in live mice show a significant recruitment of adoptively transferred effector T cells to the lesion site *in vivo*, displaying cellular behaviours consistent with antigen recognition. We are currently characterizing whether effector T cell responses are altered in healed lesions, where persistently-infected cells are readily observed. Collectively, our findings show for the first time that *Leishmania*-specific Tregs influence effector CD4<sup>+</sup> T cell responses and this could be a mechanism that derives antigen persistence in *L. major* infection.

0048

### DIMINISHED V $\delta$ 2+ $\gamma$ $\delta$ T CELL CYTOKINE PRODUCTION AND DEGRANULATION FOLLOWING *IN VITRO* MALARIA EXPOSURE

**Kathleen Dantzer**<sup>1</sup>, Sandy Klemm<sup>1</sup>, John Rek<sup>2</sup>, Felistas Nankya<sup>3</sup>, Isaac Ssewanyana<sup>2</sup>, Moses Kamy<sup>3</sup>, Brian Greenhouse<sup>4</sup>, Grant Dorsey<sup>4</sup>, Margaret Feeney<sup>4</sup>, William Greenleaf<sup>1</sup>, Prasanna Jagannathan<sup>1</sup>

<sup>1</sup>Stanford School of Medicine, Palo Alto, CA, United States, <sup>2</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>3</sup>Makerere University, Kampala, Uganda, <sup>4</sup>University of California at San Francisco, San Francisco, CA, United States

Natural immunity to *Plasmodium falciparum* (Pf) malaria provides some protection against symptomatic disease in older children and adults, but is unable to eliminate parasite replication. Though there are many unanswered questions surrounding this incomplete immunity, a major contributing factor is that innate immune cells that kill the malaria parasite also cause inflammation associated with clinical symptoms. In contrast, repeated malaria exposure leads to attenuation of the pro-inflammatory response from immune cells such as V $\delta$ 2+  $\gamma$  $\delta$  T cells, which associates with a reduced likelihood of symptoms upon subsequent infection. We are utilizing several innovative approaches to identify mechanisms underlying V $\delta$ 2+ T cell dysfunction among a longitudinal cohort in Uganda, as well as to replicate this phenotype *in vitro* using purified V $\delta$ 2+ T cells vs. V $\delta$ 2+ T cells in culture with other immune cells. In these *in vitro* assays, malaria-naïve V $\delta$ 2+ cells stimulated with Pf-infected red blood cells (iRBCs) or the phosphoantigen HMBPP produce less TNF $\alpha$  and IFN $\gamma$  and degranulate less in response to secondary stimulation compared to unstimulated cells. In contrast, 6-day stimulation with iRBCs or HMBPP does not impact the ability of the cells to respond to control stimuli, indicating that the reduced response is Pf-specific. Rest following stimulation could partially rescue the decreased responsiveness to iRBCs. The presence of monocytes did not impact purified V $\delta$ 2+ T cell response to iRBCs, indicating that V $\delta$ 2+ T cells may be able to recognize Pf antigens independent of other cell-cell interactions. In parallel, we are performing paired RNA-Seq and ATAC-Seq experiments among V $\delta$ 2+ cells from Ugandan children at multiple timepoints in order to define transcriptional and epigenetic changes underlying altered cell function following repeated malaria. Our *in vitro* system replicating this phenotype will enable a deepened understanding of mechanisms driving inefficient acquisition of antimalarial immunity. Ultimately, this work could inspire novel therapeutic approaches that enhance parasite clearance and/or reduce disease severity.

0049

### MALARIA-DRIVEN EXPANSION OF MATURE, SHORT-LIVED FUNCTIONAL CD56NEG NK CELLS CORRELATES WITH CLINICAL IMMUNITY TO MALARIA

**Maureen Ty**<sup>1</sup>, Lauren de la Parte<sup>1</sup>, Kathleen Dantzer<sup>1</sup>, Kattia van der Ploeg<sup>1</sup>, Perri Callaway<sup>2</sup>, Stephen Tukwasibwe<sup>3</sup>, John Rek<sup>4</sup>, Emmanuel Arinaitwe<sup>4</sup>, Isaac Ssewanyana<sup>4</sup>, Felistas Nankya<sup>4</sup>, Kenneth Musunguzi<sup>4</sup>, Grant Dorsey<sup>2</sup>, Michelle Boyle<sup>5</sup>, Margaret Feeney<sup>2</sup>, Moses Kamy<sup>4</sup>, Prasanna Jagannathan<sup>1</sup>

<sup>1</sup>Stanford University, Palo Alto, CA, United States, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>Makerere University, Kampala, Uganda, <sup>4</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>5</sup>QIMR Berghofer Medical Research Institute, Queensland, Australia

Natural Killer (NK) cells may play an important role in immunity to malaria, but whether repeated malaria modifies the NK cell response remains unclear. To profile the NK cell response, we utilized PBMCs collected from 290 Ugandan children followed in the East African International Centers of Excellence in Malaria Research (ICEMR) cohorts. NK cells were phenotypically defined as CD3-, CD14-, CD19-, CD7+ cells and classified by the expression of CD56 and CD16. We unexpectedly found that children living in highly endemic Tororo had significantly higher

percentages of CD56neg NK cells (31.2% vs 10.5%,  $P < 0.001$ ), and lower percentages of CD56dim NK cells (40.5% vs 65.7%,  $P < 0.001$ ) than children living in Jinja, a lower transmission setting. Among Tororo children, percentages of CD56neg NK cells positively correlated with household-level entomologic inoculation rate ( $R = 0.64$ ,  $P < 0.001$ ). CD56neg NK cells were CD57+, CD85j+ NKG2A+ and FcER1γ-, a phenotype of mature NK cells. Following stimulation with *Plasmodium falciparum* infected red blood cells (irbc), NK cells did not produce IFNγ, but in response to antibody opsonized-irbc, 27.9% CD56neg NK cells - compared to 10.1% CD56dim NK cells ( $P = 0.0084$ ) - degranulate, suggesting that CD56neg NK cells have heightened capacity to perform antibody-dependent cellular cytotoxicity. Children with higher levels of CD56neg NK cells had lower parasite densities ( $Rho = -0.36$ ,  $P < 0.0001$ ), and were less likely to show symptoms when infected, in the year following the immunologic assessment, independent of age. We assessed the stability of NK cell phenotypes over time by performing longitudinal assessments pre- and post- indoor residual spraying of insecticides (IRS). Six months following IRS in Tororo, the percentage of CD56neg NK cells significantly decreased (53.07% to 42.47%,  $P < 0.01$ ) with a concomitant increase of CD56dim cells. CD56neg NK cells also exhibited a reduced ability to degranulate in response to opsonized irbc post-IRS. Together, these data suggest that repeated malaria leads to expansion of mature, but short-lived, functional CD56neg NK cells that correlate with clinical immunity to malaria.

#### LESIONS OF FEMALE GENITAL SCHISTOSOMIASIS ARE ASSOCIATED WITH THE PRESENCE OF LIVE WORMS AS INDICATED BY CIRCULATING ANODIC ANTIGEN TESTING

Takalani G. Nemungadi<sup>1</sup>, Elisabeth Kleppa<sup>2</sup>, Siphosenkosi G. Zulu<sup>3</sup>, Govert J. van Dam<sup>4</sup>, Paul L. Corstjens<sup>4</sup>, Hashini N. Galappaththi-Arachchige<sup>2</sup>, Pavitra Pillay<sup>5</sup>, Svein G. Gundersen<sup>6</sup>, Birgitte J. Vennervald<sup>7</sup>, Patricia Ndlovu<sup>8</sup>, Myra Taylor<sup>3</sup>, Saloshni Naidoo<sup>3</sup>, Eyrun F. Kjetland<sup>2</sup>

<sup>1</sup>National Department of Health, Pretoria, South Africa, <sup>2</sup>Oslo University Hospital, Oslo, Norway, <sup>3</sup>University of KwaZulu-Natal, Durban, South Africa, <sup>4</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>5</sup>Durban University of Technology, Durban, South Africa, <sup>6</sup>University of Agder, Agder, Norway, <sup>7</sup>University of Copenhagen, Copenhagen, Denmark, <sup>8</sup>BRIGHT Academy, Durban, South Africa

*Schistosoma haematobium* ova in genital tissue may cause four different lesions: grainy sandy patches, homogenous yellow patches, rubbery papules and abnormal blood vessels. In areas where reinfection with schistosomiasis is rampant, it is not known if the lesions of Female Genital Schistosomiasis (FGS) are a consequence of live worms, or caused by dead ova. Live schistosome worms regurgitate Circulating Anodic Antigen (CAA). We sought to explore if the typical FGS lesions are associated with the presence of live worms. The study was conducted in randomly selected rural high schools on the East Coast of South Africa. Female learners aged 16 - 23 years who were willing to undergo gynecological examination were included in the study. We excluded virgins, pregnant women, and those who had undergone anti-schistosomal mass-treatment the last year. CAA was positive in 82/246 (33%) of the participants, while 39/243 (17%) had schistosome eggs in urine as measured by microscopy. Sandy patches were found in 123 (50%) of the study population. Current risk water contact was found in 118 (48%). Grainy sandy patches were found in 63 (26%) participants; 37/63 (59%) were CAA positive (Age-Adjusted Odds Ratio (AOR) 4.2, 95% Confidence Interval (CI) 2.3-7.8,  $p < 0.001$ ). Abnormal blood vessels were associated with CAA (AOR 3.0, 95%CI 1.5-4.5,  $p = 0.001$ ) whereas homogenous yellow patches were not associated with CAA ( $p = 0.57$ ). No rubbery papules were found. Thick and lumpy vaginal discharge and red urine were the only subjective symptoms associated with CAA. No association was found between CAA and warts, polyps or ulcers ( $p > 0.4$  for all). The study indicates that homogenous yellow patches may indicate chronic infection due to dead ova whilst grainy sandy patches and abnormal blood vessels may be associated with

more recent infection caused by the deposition of eggs from living worms. Further studies are needed to explore the implications for HIV transmission, reproductive health, patient information, prevention and treatment.

#### VILLAGE, HOUSEHOLD AND INDIVIDUAL LEVEL PREDICTORS OF BOVINE SCHISTOSOMIASIS INFECTION IN RURAL VILLAGES OF SICHUAN, CHINA

Elise Grover<sup>1</sup>, Sara Paull<sup>1</sup>, Ding Lu<sup>2</sup>, Yang Liu<sup>2</sup>, Elizabeth Carlton<sup>1</sup>

<sup>1</sup>University of Colorado School of Public Health, Aurora, CO, United States,

<sup>2</sup>Sichuan Center for Disease Control and Prevention, Chengdu, China

In China, several domestic animal species are known to be capable of carrying and transmitting *Schistosoma japonicum*. Of the domestic animals commonly found in rural farming villages, bovines have been repeatedly highlighted as a major reservoir of human schistosomiasis, with some estimates suggesting that they may be responsible for as much as 75% of human transmission. However, little is known about the individual and environmental conditions that drive bovine schistosomiasis infection. Using household surveys and infection data collected as a part of a longitudinal study conducted in 39 rural villages in Sichuan, China from 2007 to 2016, we aimed to identify the strongest individual, household and village-level predictors of bovine *S. japonicum* infection. Candidate predictors for this assessment included: 1) biological characteristics of bovines such as sex or age, 2) potential human sources of environmental schistosomes, such as human infection prevalence at the village-level, 3) socio-economic indicators such as the prevalence of improved sanitation, 4) presence of other animal reservoirs including cats, dogs and pigs and 5) agricultural factors including the area of rice planted by a given household. A Random Forests machine learning approach was used to determine which of our candidate predictors serve as the best predictors of bovine schistosomiasis infection in each survey year. Of the five categories of candidate predictors, human sources of schistosomes and agricultural factors were repeatedly found to be among the top predictors of bovine *S. japonicum* infection, highlighting the potential utility of presumptively treating bovines in households where one or more people have tested positive, and those who engage in high-risk agricultural practices such as planting rice. Additionally, household-level predictors tended to be better predictors of bovine infection than village-level predictors, suggesting that targeted, multipronged approaches can be used to address intra-village sources of transmission heterogeneities.

#### THE SENSITIVITY OF SCHISTOSOMA MANSONI CERCARIAE TO CHLORINE

Laura Braun<sup>1</sup>, Yasinta D. Sylvester<sup>2</sup>, Michael R. Templeton<sup>3</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>National Institute for Medical Research, Mwanza, United Republic of Tanzania,

<sup>3</sup>Imperial College London, London, United Kingdom

Schistosomiasis is a water-based neglected tropical disease acquired through contact with cercaria-infested water. Communities living in endemic parts of the world often rely on unsafe cercaria-contaminated freshwater bodies for their daily water contact activities (e.g. laundry, bathing), resulting in recurring schistosomiasis infection. Water treatment can provide safe water on a household or community scale. However, there are no water treatment guidelines that provide information on how to treat water containing cercariae. We tested the effectiveness of chlorine against *Schistosoma mansoni* cercariae under controlled conditions (pH 6.5, 7.0 or 7.5, and temperature of 20°C or 27°C). Chlorine was dosed at 1, 2 or 3 mg/l and experiments were run up to contact times of 45 minutes. 100 cercariae were used per experiment, thereby achieving up to 2-log inactivations of cercariae. Experiments were conducted with both fresh (<1 hour old) and aged (6-8h old) cercariae, and replicated under lab conditions and field settings at Lake Victoria, Tanzania. A CT value (product of the residual chlorine concentration and chlorine contact time) of 26±4 mg·min/l is required to achieve a 2-log (or 99%) inactivation

of *S. mansoni* cercariae under the most conservative condition tested (pH 7.5, 20°C). Field and lab-cultivated cercariae show similar chlorine sensitivities, and aged cercariae are significantly more sensitive than fresh cercariae. Overall, a CT value of 30 mg·min/l is recommended to disinfect cercaria-infested water, though additional safety factors may be required, depending on water quality and operating conditions. This CT value can be achieved with a chlorine residual of 1 mg/l after a contact time of 30 minutes, for example. The resulting chlorination recommendation can be used to treat water and provide schistosomiasis-endemic communities with safe water facilities (e.g. laundry or bathing stations).

0053

#### DEVELOPMENT OF A MULTIPLEX BEAD ASSAY FOR DETECTION OF ANTIBODIES AGAINST SCHISTOSOMA MANSONI INFECTION

**Sukwan Handali**, Yong Wang, John Noh, Sylvia Ossai, Olga Stuchlik, Matthew S. Reed, Pavel Svoboda, Hilda N. Rivera, Jan Pohl, William E. Secor

*Centers for Disease Control and Prevention, Atlanta, GA, United States*

*Schistosoma mansoni* is endemic across sub-Saharan Africa and in several South American and Caribbean countries. The CDC uses purified native *S. mansoni* antigens for serologic diagnoses of suspected cases among returning travelers/immigrants. The native antigens-based assay is challenging to produce for scale-up to evaluate larger populations. We, therefore, attempted to identify recombinant antigens appropriate for use in a multiplex-based assay (MBA) to detect antibodies indicative of *S. mansoni* infection. We collected the soluble fraction of *S. mansoni* adult worms, separated the proteins using size exclusion fast-performing liquid chromatography followed by 1-D gel electrophoresis, and screened immunoblots with sera from *S. mansoni* infected individuals. Fractions still reactive after carbohydrate disruption were subjected to tandem mass spectrometry (MS). From 3731 MS protein sequences, 99 proteins were selected based on size, presence of transmembrane domain, and signal peptide sequences. Selected proteins were expressed, purified, and tested for reactivity against positive sera on immunoblot. Thirty-eight of the expressed proteins were selectively recognized by IgG1 or IgG4 antibodies in sera from infected persons. We selected the top 22 proteins based on the strength of the signal-to-noise (S/N) ratio on immunoblot for the MBA evaluation. Twelve proteins showed good signal-to-noise (S/N) ratio: Sm-25, Sm-13, Sh-13, Sm-tubulin I, Sm-Krueppel-associated box (KRAB) domain-containing protein, Sm-peroxiredoxin (Prx 2), Sm calumenin B, Sm Cathepsin B, Sm-CD63-like, and Sm-adaptin ear-binding coat-associated protein (NECAP)-like, Sm-translational controlled tumor protein (TCTP). Although the sequences are all from *S. mansoni*, seven of the proteins had higher S/N ratios with sera from persons with *S. japonicum* infections. None of the antigens were recognized by sera of *S. haematobium*-positive individuals. In conclusion, we have identified antigens for *S. mansoni* serological diagnosis, and these antigens will be tested on an MBA to determine the best combination for diagnostic testing and serosurveillance.

0054

#### RAPID PARASITE DNA AMPLIFICATION USING A DIPSTICK WITH LAMP ASSAY

**Oyime P. Aula**<sup>1</sup>, Catherine A. Gordon<sup>1</sup>, Malcolm K. Jones<sup>2</sup>, Donald P. McManus<sup>1</sup>

<sup>1</sup>*Molecular Parasitology Laboratory, QIMR Berghofer Medical Research Institute, Herston, Australia*, <sup>2</sup>*School of Veterinary Science, Faculty of Science, The University of Queensland, Queensland, Australia, Gatton, Australia*

Schistosomiasis is a neglected tropical disease in many developing countries in tropical Africa, the Middle East, Asia, and Latin America. It affects the poorest communities and is a significant cause of morbidity and can be fatal. School-aged children are mostly at risk of infection. There have been increased efforts aimed at controlling and eliminating

schistosomiasis in recent decades; however, the global disease burden remains high, in part due to inadequate diagnostics. Molecular diagnostics are powerful tools for disease detection that are usually confined to the laboratory setting due to burdensome and expensive methods required to extract nucleic acids from biological samples. The DNA dipstick is a simple and rapid method for DNA extraction requiring minimal equipment and when combined with LAMP, may be an ideal tool for point-of-care diagnostics. This study aimed to determine the effectiveness of the dipstick in detecting *Schistosoma japonicum* in parasite and clinical samples. *S. japonicum* from different life cycles including cercariae, eggs and adult worms were isolated and purified from infected snails and livers of experimentally infected mice and homogenized in lysis buffer. The DNA was extracted by inserting dipsticks into the lysed samples, washed to eliminate contaminants, and dipped into the amplification mix, all in less than 30 secs. The mix was incubated at 65°C for 60 mins. Similarly, cell-free DNA was also extracted from mice and naturally infected human urine samples using dipsticks. The DNA dipstick successfully identified *S. japonicum* from infected snails, cracked eggs, worms and human urine spiked with cracked eggs or genomic DNA from *S. japonicum* as proof of concept. This method was able to detect as little as 0.01 fg/μl of target DNA in urine. Positive results were also obtained from experimentally infected mice and naturally infected human urine samples. The DNA dipstick combined with LAMP is a promising cost effective and simple method for detecting schistosomiasis infection in endemic regions.

0055

#### VALIDATION OF THE ISOTHERMAL RECOMBINASE POLYMERASE AMPLIFICATION (RPA) ASSAY FOR THE POINT-OF-CARE MOLECULAR DIAGNOSIS OF FEMALE GENITAL SCHISTOSOMIASIS USING CERVICOVAGINAL LAVAGE AND VAGINAL SELF-SWAB SAMPLES

**John Archer**<sup>1</sup>, Farhan Patwary<sup>2</sup>, Amy Sturt<sup>2</sup>, Emily Webb<sup>2</sup>, Comfort Rutty Phiri<sup>3</sup>, Tobias Mwine<sup>3</sup>, Lisette Van Lieshout<sup>4</sup>, Bonnie Webster<sup>5</sup>, Bustinduy L. Amaya<sup>2</sup>

<sup>1</sup>*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*, <sup>2</sup>*London School of Hygiene & Tropical Medicine, London, United Kingdom*, <sup>3</sup>*Zambart, Lusaka, Zambia*, <sup>4</sup>*Leiden Medical Center, Leiden, Netherlands*, <sup>5</sup>*Natural History Museum, London, United Kingdom*

Female Genital Schistosomiasis (FGS) is a gynaecological disabling condition caused by the parasite *Schistosoma haematobium* affecting over 56 million women across Sub-Saharan that gets confounded by sexually transmitted infections, as they share symptomatology. Africa. reproductive health and increases the risk of HIV-1 infection. Improved diagnostics, close to the point-of-care (POC) are urgently needed to increase surveillance. Molecular diagnostics offer the best way to diagnose active FGS by detection of *Schistosoma* DNA within cervical and vaginal samples. Our study validated and assessed the performance of a field-applicable isothermal Recombinase Polymerase Amplification (RPA) assay for *S. haematobium* on standard cervicovaginal lavage (CVL) and home-based self-collected vaginal swabs (VS) samples compared to the laboratory-based gold standard real-time polymerase chain reaction (qPCR). Samples were obtained from the Bilharzia and HIV (BILHIV) project in Zambia. DNA was extracted from the CVL samples using both a crude (CCVL) and traditional pure (PCVL) extraction method. VS samples were extracted using the pure method (PVS). Out of a total of 527 samples, 223 CCVL, 133 PCVL and 190 PVS samples were tested using the RPA assay that has been developed for urogenital schistosomiasis diagnosis. All data were evaluated using reference qPCR data available for each sample. For CVL samples, The RPA sensitivity for PCVL were 76.9% and 85.7%, for CCVL and 95% and 98.1% specificity respectively. For the self-collected PVS samples sensitivity and specificity was 94.1% and 97.7% respectively. PCR is currently unsuited for use at the POC. In contrast, the RPA assay is portable, rapid (~20 minutes) and can be performed on crude sample preparations relieving laboratory resource needs. In our study the RPA assay had optimal performance, particularly associated with self-collected

swab samples. Self-collected samples paired with the POC use of the RPA assay has great potential to support FGS diagnosis and surveillance in endemic settings.

### IDENTIFICATION OF NOVEL THERAPEUTICS AGAINST HUMAN SCHISTOSOMIASIS

Sevan Alwan<sup>1</sup>, Alexander Taylor<sup>1</sup>, Jayce Rhodes<sup>2</sup>, Michael Tidwell<sup>2</sup>, Stanton McHardy<sup>2</sup>, Philip LoVerde<sup>1</sup>

<sup>1</sup>UT Health at San Antonio, San Antonio, TX, United States, <sup>2</sup>University of Texas at San Antonio, San Antonio, TX, United States

Human schistosomiasis is a neglected tropical disease caused by parasitic worms. It affects over 250 million people globally. Most human infections are caused by *Schistosoma mansoni*, *S. haematobium*, and *S. japonicum*. Currently there is only one method of treatment for human schistosomiasis, the drug praziquantel. Constant selection pressure has caused a serious concern because of rise in resistance to praziquantel leading to the urgent need for additional pharmaceuticals, with a distinctly different mechanism of action, to be used in combination therapy with praziquantel. Previous treatment of *Schistosoma mansoni* included the use of oxamniquine (OXA), a prodrug that is enzymatically activated by a sulfotransferase, an enzyme produced by *S. mansoni*. Although sulfotransferases are produced by *S. haematobium* and *S. japonicum*, OXA is not effective against these two species. OXA kills about 90% of *S. mansoni* in 14 days *in vitro*. Structural data have allowed for directed drug development in reengineering oxamniquine to be effective against *S. haematobium* and *S. japonicum*. Guided by data from X-ray crystallographic studies and *Schistosoma* worm killing assays more than 300 OXA derivatives were designed synthesized and tested *in vitro* against the adult parasites. All of the derivatives synthesized are racemic mixtures. Currently, we were able to identify four of them as powerful derivatives that kill 100 % of all three *Schistosoma* species *in vitro*. Two of these derivatives were able to kill 100% of the three species in less than 7 days. Both derivatives were able to kill 100% of the three species with half the dose required for OXA. Although adult male worms produced higher amount of SULT than female worms, paired female and single-sex female worms were highly susceptible to CIDD-0150610 and CIDD-0150303 like paired males and single-sex males. In addition, our *in vivo* results show a significant reduction in worm burden when infected animals were treated with CIDD-0150303. Therefore, we conclude that CIDD-0150303 is a potential novel drug that can be used in combination with praziquantel to treat schistosomiasis.

0057

### FEATURE IMPORTANCE: OPENING A SOIL-TRANSMITTED HELMINTH MACHINE LEARNING MODEL WITH SHAP

Carlos M. Scavuzzo<sup>1</sup>, Juan M. Scavuzzo<sup>1</sup>, Micaela N. Campero<sup>1</sup>, Melaku Anegagrie<sup>2</sup>, Aranzazu A. Aramendia<sup>2</sup>, Agustín Benito<sup>3</sup>, Maria V. Periago<sup>4</sup>

<sup>1</sup>Instituto de Altos Estudios Espaciales Mario Gulich, Universidad Nacional de Córdoba - Comisión Nacional de Actividades Espaciales, Córdoba, Argentina, <sup>2</sup>Fundación Mundo Sano, Madrid, Spain, <sup>3</sup>National Centre for Tropical Medicine, Institute of Health Carlos III, Madrid, Spain, <sup>4</sup>CONICET/ Fundación Mundo Sano, Buenos Aires, Argentina

In the field of landscape epidemiology, the contribution of machine learning (ML) to modeling of epidemiological risk scenarios presents itself as a good alternative. This study aims to break with the black box paradigm that underlies the application of automatic learning techniques by using SHAP to determine the contribution of each variable in ML models applied to geospatial health. For this purpose, the prevalence of hookworm from an area of Ethiopia was used since the country bears the third-highest burden of hookworm in sub-Saharan Africa. The machine learning model XGBoost software was used to fit and analyze the data while the Python SHAP library was used to understand the importance of the variables as predictors in the trained model. The description

of the contribution of these variables on a particular prediction was obtained, using different types of plot methods. The results show that the ML models are superior to the classical statistical models; not only demonstrating similar results but also explaining, by using the SHAP package, the influence and interactions between the variables in the generated models. This analysis provides information to help understand the epidemiological problem presented and provides a tool for similar studies.

0058

### SAMPLE COMPUTATIONAL STRUCTURES TOWARDS AN EPIDEMIC SIMULATION TOOL COMPRISING COMMUNICATING PROGRAMS ON MOBILE PHONES AND SERVERS

Yael Evelyn Marshall

Y.E.M. Tech Developer, Brookline, MA, United States

Here we explore possible computational structures for an epidemic simulation tool comprising communicating programs on smart phones and a server or servers. Through calculations distributed among devices, such a tool or computational structure could in ~real-time access and directly incorporate the location or distance information of individual smart devices into an individual-level epidemiological model in order to assemble and collect simulated epidemic data; multiple epidemic simulations could be run simultaneously with various simulated control measures. We build programs towards the tool in phases. As a first phase, we built a rough sample individual-level model similar in structure but not rigor to what is found in the research literature. As a second phase, we simulated an epidemic simulation tool being used in a simulated world, with humans carrying smart devices which along with a server contain a distributed program for an epidemic simulation tool that uses either location-based or signal/distance-based interaction inference or simulation. As a third phase, we built a sample demo (demonstration) of the computational structure for the epidemic simulation tool. The demo comprises communicating processes running ~simultaneously on one computer for demonstrating program structures with multiple processes, one process for each smart device and one for a server, smart device detection of synthetic location information in time (fast-forwarded for the demo) for place-based interaction inference, and for each smart device a set of sim-humans (one for each epidemic simulation). Sample epidemic simulation outputs from these phases show what information each smart device can opt to see about its own sim-humans and what simulation data is assembled and gathered by the server. Through the descriptions and initial phases here, we contribute discussion towards some of the structural possibilities for such an epidemic simulation tool.

### LANGUAGE, POPULAR CULTURE AND MYTHOLOGY UPHELD FEMALE GENITAL CUTTING AND CHILD MARRIAGE IN SUDAN

Samira Elamin

UNICEF, Khartoum, Sudan

Harmful practices such as Female Genital Cutting (FGC) and Child Marriage (CM) are often upheld by core social norms such as differential treatment of girls and boys, of men and women and of children of different socio-economic groups. According to anthropological and historical research, FGC pre-dates Islam and Christianity tracing the practice to Egypt in the fifth-century BC and arguing that the practice is spread across wide cultures and in different parts of the world, suggesting that the practice may have independently existed among different groups and for various reasons. In Sudan FGC is known historically to have existed more than 30 centuries relating to cross border interaction in various directions. The persistent high prevalence rate has led the author to closely observe the practice. Through qualitative research and the use of focused group discussion among various sectors of the Sudanese society, the author attempts to unveil some of the unspoken of reasons

of the practice. The behavioral rules applying to practices such as FGC and CM identify the social constructs of the beliefs of members of a community embedded into scripts and are part of a thick network of beliefs and practices. It is assumed here that the empirical expectations for practicing stem from the connectivity of language and its connotations in the local value system coupled by myths that leads a sufficiently large group to uphold the practices. The normative expectations are beliefs that a sufficiently large subset of people is expected to conform such that the norm is almost universally endorsed. This generates a widespread conformity and the result is following the norm by the majority by preference. The FGC terminologies and the proverbs and stories of mythology are analyzed in this study and presented within the frame of normative expectations that have held FGC and CM in the Sudan for such a long time. It was found that the language by which FGC is labelled and the popular culture of proverbs, stories of mythology and statements transmitted through generations define the scripts that are adhered to and strongly uphold the practices.

### CLINEPIDB.ORG: LOWERING THE BARRIER FOR EXPLORATORY DATA ANALYSIS OF GLOBAL HEALTH STUDIES

**Nupur D. Kittur**<sup>1</sup>, Cristina Aurrecoechea<sup>1</sup>, John Brestelli<sup>2</sup>, Brian P. Brunk<sup>2</sup>, Danielle Callan<sup>2</sup>, Dave Falke<sup>1</sup>, Steve Fischer<sup>2</sup>, Danica Helb<sup>2</sup>, Jay Humphrey<sup>1</sup>, John Judkins<sup>2</sup>, Jessica C. Kissinger<sup>1</sup>, David S. Roos<sup>2</sup>, Steph W. Schulman<sup>2</sup>, Sheena S. Tomko<sup>2</sup>, Christian J. Stoeckert<sup>2</sup>, Jie Zheng<sup>2</sup>

<sup>1</sup>University of Georgia, Athens, GA, United States, <sup>2</sup>University of Pennsylvania, Philadelphia, PA, United States

Open access to data from epidemiological studies has tremendous potential to preserve data over time, increase secondary data use, and accelerate discovery and translational impact, but there are significant technical, practical, and confidentiality barriers. The clinical epidemiological database, ClinEpiDB.org, was developed three years ago to facilitate access to de-identified data from large, high-quality global health studies. As of April 2021, ClinEpiDB hosts data from over 1.1 million participants representing 29 global epidemiological studies in three major domains - maternal, newborn & child health; malaria; and neglected tropical diseases. These include case-control studies, longitudinal cohort studies, cross-sectional surveys, randomized controlled trials and surveillance datasets. ClinEpiDB enables investigators to not only meet, but surpass, the requirements of journals and funders to make data publicly available by integrating study data with standardized ontologies to make data more easily reusable. Linked study pages provide context and study-related documentation such as consent forms, case report forms and codebooks. The ClinEpiDB platform lowers barriers to data use with an intuitive point-and-click interface that allows users to understand complex epidemiological studies, visualize aggregate data, and explore associations between variables. Entire datasets or customized subsets may be downloaded for further analysis. We have implemented a tiered data access system with a simple interface for users to submit an access request and for data providers to manage requests. ClinEpiDB will expand in 2021 to encompass a new exploratory data analysis workspace, enhanced visualization tools, significant international user outreach and education, and integration of new datasets.

0061

### OPERATIONALIZING ROUTINE HMIS DATA FOR A DISEASE BULLETIN IN GUINEA

Adam M. Preston<sup>1</sup>, **Mamadou Balde**<sup>2</sup>, Thierno Diallo<sup>2</sup>, Eugène Kaman Lama<sup>3</sup>, Alioune Camara<sup>3</sup>, Nouman Diakit<sup>3</sup>, Elizabeth Fitch<sup>4</sup>, Donal Bisanzio<sup>5</sup>

<sup>1</sup>RTI International, Research Triangle Park, NC, United States, <sup>2</sup>Stop Palu+ Guinea, Conakry, Guinea, <sup>3</sup>NMCP Guinea, Conakry, Guinea, <sup>4</sup>RTI International, Durham, NC, United States, <sup>5</sup>RTI International, Nottingham, United Kingdom

The National Malaria Control Program (NMCP) in Guinea produces a monthly report, the Bulletin Mensuel de Paludisme, on the status of Malaria in the country. This report includes indicators describing the current status of malaria at a national and district level such as the number of confirmed cases, the number of tests conducted, and the number of treated cases. The NMCP distributes the bulletin as a Microsoft Word document by e-mail to a list of more than 400 people including MOH officials, implementation partners, and other stakeholders. However, compiling the report is time consuming and involves manual data cleaning. Thus, the NMCP wanted a new system to reduce the time to produce monthly reports. The PMI funded StopPalu+ project implemented by RTI International that delivers ongoing technical assistance to the NMCP provided a solution to this problem. By leveraging the data within Système National d'Information Sanitaire, and its DHIS2 software platform, the project team developed an open source DHIS2 module to fully automate the creation of the report. The module is called the Bulletin Mensuel de Paludisme Exportateur and runs in the national HMIS software in DHIS2 and leverages its data security framework. The process is more sustainable than what was in place before as it allows all users of the national HMIS, not just those with programming skills, to generate the monthly malaria report. If maintenance is required, the source code is publicly available and can be modified by a DHIS2 application developer. The structure of this app was designed to be a flexible framework that can be adapted to generate any type of disease bulletin in other health areas. Its small innovations like this one that can help the NCMP in Guinea eliminate data silos and provide timely and accurate data more efficiently.

0062

### SPATIOTEMPORAL VARIATION IN CHILDHOOD RISK OF ENTERIC SHIGELLA INFECTION: A GLOBAL PREDICTIVE MODEL AND RISK MAPPING TOOL

**Josh M. Colston**<sup>1</sup>, Hamada Badr<sup>2</sup>, Margaret N. Kosek<sup>1</sup>, Benjamin Zaitchik<sup>2</sup>

<sup>1</sup>University of Virginia School of Medicine, Charlottesville, VA, United States, <sup>2</sup>Johns Hopkins University, Baltimore, MD, United States

Diarrheal disease is a major cause of childhood illness caused by numerous, diverse species of infectious microorganisms, which are sensitive to environmental conditions. The bacterium *Shigella* is responsible for 64,000 annual deaths in young children and thrives in warm, moist conditions. This study aimed to model the spatiotemporal variation in pediatric *Shigella* infection risk using covariates with quasi-global coverage and use these to map the predicted prevalence of shigellosis across Low- and Middle-Income Countries (LMICs). Data were combined from numerous studies that used PCR to diagnose *Shigella* in stool samples collected from children aged ≤59 months in LMICs and a standard list of covariates was generated that included: household- and subject-level covariates ascertained at enrollment; environmental and demographic spatial covariates extracted from global rasters; time-varying hydrometeorological variables extracted from historical daily Earth Observation- and model-based re-analysis-derived estimates. Variable selection was carried out by forward stepwise addition of covariates and a predictive projection method was implemented. Spatiotemporal predictions were made separately for 0-11-, 12-23-, and 24-59-month age groups. The final database included results from over 64,000 stool samples collected from 21,000 subjects in 19 LMICs. Daily temperature averaged over a 7-day lagged time

window was the most important variable, followed by the interaction of precipitation with soil moisture. Accessibility to the nearest city was the most important non-hydrometeorological covariate. The model predicted wide belts of elevated *Shigella* risk in tropical Sub-Saharan Africa, India, and Brazil, as well as smaller pockets of high prevalence in New Guinea, Ethiopia, the Sahel, coastal Central America, and Colombia, among others. Once finalized, these predictions will be made available to the public via an online portal for use in decision-making, such as identifying populations living in hotspots of *Shigella* transmission risk that can be prioritized as vaccines become available.

0063

### EVALUATION OF A POINT-OF-CARE SCREENING DEVICE "GAZELLE" FOR CHILDREN WITH SICKLE CELL DISEASE IN GHANA

Catherine Segbefia<sup>1</sup>, Yvonne Dei-Adomakoh<sup>1</sup>, Enoch Mensah<sup>1</sup>, Anne Rocheleau<sup>2</sup>, Priyaleela Thota<sup>2</sup>, Isaac Odame<sup>3</sup>

<sup>1</sup>Korle Bu Teaching Hospital, Accra, Ghana, <sup>2</sup>Hemex Health, Portland, OR, United States, <sup>3</sup>The Global Sickle Cell Disease Network, Toronto, ON, Canada

Sickle cell disease (SCD) is the commonest genetic disorder in Ghana, affecting up to 16,000 newborns (approximately 2%) per year, which can lead to severe complications causing significant morbidity and mortality. Timely diagnosis is key to prevent or manage these complications. Current standard practices for diagnosing SCD are Haemoglobin electrophoresis high performance liquid chromatography (HPLC) and Isoelectric focusing. However, these methods rely on expensive laboratory systems which are time consuming or unavailable in resource-limited settings. Here, we describe the field performance of microchip based cellulose acetate electrophoresis "Gazelle™". The current study was conducted at Korle Bu Teaching Hospital, Accra, Ghana. Gazelle is a low-cost, point-of-care translation of the electrophoresis method that has been well established and widely applied in SCD diagnosis. Gazelle is a fast (<10 minutes), easy-to-use point of care test which can be performed by minimally trained personnel using only a finger-prick volume of blood. The primary study objective is to evaluate the utility of the Gazelle for the diagnosis of children with SCD. Blood samples were collected from 1250 subjects who were enrolled in the study, out of which 541 were newborn samples and 709 samples were from the vaccination clinic (age < 5 years). Each sample was tested with Gazelle, and the results compared to HPLC. Interim analysis of Gazelle yielded a high (99%) diagnostic accuracy for all Hb variants compared to HPLC. Gazelle demonstrated a high sensitivity of 100% for HbSS (sickle cell disease, SCD) and 97.9% for HbAS (sickle cell trait), and specificities of 99.3% for disease vs. HbAA, 100% for disease vs. trait, and 97.3% for trait. Gazelle demonstrated high sensitivity and high specificity for identifying SCD and sickle cell trait (HbAS). Gazelle™ offers an innovative and inexpensive solution, leveraging a novel engineering approach, to point of care (POC) diagnosis of SCD. Gazelle can be a potential clinical tool and hence will increase the rates of screening, diagnosis and timely treatment of SCD impacting the lives of underserved population.

### PUTTING POPULATIONS ON THE MAP: LANDSCAPING GEOSPATIAL SOLUTIONS FOR PRIMARY HEALTH CARE

Katelyn Woolheater<sup>1</sup>, Leungo Motlhabane<sup>1</sup>, Jillian Dunning<sup>1</sup>, Abigail Ward<sup>1</sup>, Marta Prescott<sup>1</sup>, Charlotte Dolenz<sup>1</sup>, Silvia Renn<sup>1</sup>, Arnaud Le Menach<sup>1</sup>, Justin Cohen<sup>1</sup>

<sup>1</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>2</sup>Geo-Referenced Infrastructure and Demographic Data for Development (GRID3), New York, NY, United States

Geography is a critical dimension for monitoring the health of populations, ensuring access to care, and formulating public health policies. However, population and other geospatial data are often out of date or not available at the resolution required for operational decision-making and strategic

planning. To address this challenge, the Geo-Referenced Infrastructure and Demographic Data for Development (GRID3) consortium generate geospatial data for development including population, settlements, infrastructure, and boundaries together with government agencies. While these products have been used extensively to plan vertical delivery campaigns, uptake into routine general health services has been limited. From 2020 to 2021, landscape assessments were conducted in nine countries: Burkina Faso, DRC, Ethiopia, Ghana, Kenya, Mozambique, Namibia, Sierra Leone, and Zambia. Assessments evaluated the availability and use of population datasets including GRID3 products, the stakeholders involved, and barriers to adopting novel geospatial products in primary health care planning and operations. General results will be presented detailing opportunities for GRID3 data to be integrated into existing processes and operations to improve primary health care outcomes, such as ensuring equitable access through expanded community-level healthcare delivery, improving targeting and forecasting of commodities, or designing and implementing universal health coverage reforms. Use-cases prioritized based on feasibility and impact will be tested by MoH and local partners with support from CHAI by conducting analysis using GRID3 and other geospatial data to inform activities related to the use-case. Through a consultative, inclusive process, this project aims to improve uptake of cutting-edge geospatial data use to improve primary health outcomes such as access to care and coverage of public health interventions.

### PROJECTING TEMPORAL AND SEASONAL PATTERNS OF DENGUE CASES USING CLIMATE ADJUSTED MODELS IN THREE BRAZILIAN METROPOLITAN AREAS

Andrew M. Secor, Mohamed Albirair, Aldina Mesic, Paul K. Drain  
University of Washington, Seattle, WA, United States

Global dengue incidence may be increasing due to climate factors and globalization. Brazil is estimated to have the highest dengue caseload globally. We assessed the temporal and seasonal patterns of dengue in three Brazilian metropolitan areas (Rio de Janeiro, Fortaleza, and Belo Horizonte) from 2009 to 2019. We analyzed monthly dengue surveillance data from the national Notifiable Diseases Information System (SINAN) using Seasonal Auto-Regressive Integrated Moving Average (SARIMA) models with precipitation (total), temperature (min, mean, or max), and humidity (mean) as covariates. To determine a best-fit model, we generated a matrix of all combinations of 0 to 4 months of lag for the climate covariates (for 575 possible models per city), and selected models that minimized the root-mean-square error. We used SARIMA models to forecast monthly dengue cases during the year 2020 in three ways: using unadjusted models, models adjusted with actual 2020 climate data, and models adjusted with simple climate data projections (5-year monthly averages). Reported annual dengue incidence was highly variable between cities and year (from 6.9/100,000 in Rio in 2014 to 4,401/100,000 in Belo Horizonte in 2016). Per the model structure SARIMA(p,d,q)(P,D,Q)[m], best fit models were: Rio de Janeiro (1,0,1)(1,1,1)[12]; Fortaleza (2,0,0)(0,0,1)[12]; and Belo Horizonte (2,0,2)(1,0,0)[12]. All adjusted models included the three climate covariates but with different lag combinations. Ljung-Box tests indicated that all models achieved stationarity. Actual monthly 2020 dengue cases in the three cities were within 50% prediction intervals for 36.1% (13/36) of months in the unadjusted models, 63.9% (23/36) in the real climate data models, and 61.1% (22/36) in the climate projection models. These results suggest that climate adjusted SARIMA models can forecast dengue cases with moderate accuracy even in areas with highly variable seasonal and temporal dengue patterns given sufficient baseline data. Simple climate projections may be sufficient for use in future forecasts, which can help to inform outbreak prevention and treatment efforts.

## INTRODUCING A MULTIFACETED PLATFORM TO ENGAGE COMMUNITIES IN FIGHTING AGAINST VECTOR CONTROL AND CLIMATE CHANGE

**Maggy Sikulu-Lord**

*Disease Adviser, Brisbane, Australia*

The Global Vector Control Response (2017-2030) outlines a new strategic plan to strengthen vector control programs worldwide by improving capacity building and surveillance, better coordination and integrated action across government sectors and diseases. However, the 2020 World Health Organisation malaria report indicates progress towards malaria elimination has stalled. One of the pillars proposed within this strategic plan is engagement and mobilisation of communities through increased basic and applied research and innovation. Innovative vector control strategies continue to emerge while climate change is taking a turn for the worse. Lack of community participation continues to undermine the progress of many emerging innovative interventions and climate change policies around the world. Through a program known as "introducing Science, Technology, Engineering and Math for Vector Control and Climate Change" (iSTEMVCCC), we have established a network of vector control and climate change experts across the world to design a platform through which communities can be educated, participate and provide feedback to enhance the performance of vector control programs and mitigate climate change. The main aim of iSTEMVCCC's is to bridge the gap between stakeholders, vector control/climate change experts and the communities by educating the community on 1) existing vector control/climate change problems, 2) interventions available to solve the problems, 3) how these interventions work and 4) how the communities can enhance the effectiveness of these interventions. The role of iSTEMVCCC is to partner with stakeholders and vector control programs in various countries to design, implement and evaluate progress of vector control by developing capacity building through structured community engagement programs to ensure a streamlined introduction of new interventions and ensure interventions remain as effective as intended. We will discuss the development and implementation of iSTEMVCCC and ways through which the platform can be adopted worldwide for effective community engagement in vector control and climate change programs.

0067

## PERCEPTIONS AND BARRIERS RELATED TO ROUTINE IMMUNIZATION AND COVID-19 VACCINE HESITANCY AND ROLE OF MHEALTH & ELECTRONIC MEDIA IN PAKISTAN DURING THE PANDEMIC: PRELIMINARY DATA FROM AN EXPLORATORY STUDY

**Abdul Momin Kazi**<sup>1</sup>, Nazia Ahsan<sup>1</sup>, Waliyah Mughis<sup>1</sup>, Saima Jamal<sup>1</sup>, Raheel Allana<sup>1</sup>, Ayub Khan<sup>1</sup>, Osama Afzal<sup>1</sup>, Syeda Quratulain Zaidi<sup>1</sup>, Mehreen Raza<sup>1</sup>, Qudsia Anwer<sup>1</sup>, Fauzia A. Malik<sup>2</sup>

<sup>1</sup>Aga Khan University, Karachi, Pakistan, <sup>2</sup>Yale University, New Haven, CT, United States

Social media is influential in dissemination of mis/information regarding the pandemic and vaccines. Routine immunization has been affected globally by the COVID-19 pandemic. Attitudes towards adult COVID-19 vaccine are unknown in Pakistan. Our study purpose is to use m-Health and social media interventions in improving childhood immunization coverage during the COVID-19 pandemic, exploring perceptions and barriers among caregivers of infants <1 year of age, and healthcare providers (HCP) towards CRI during the pandemic, and exploring the need for COVID-19 vaccination. This exploratory qualitative study (depending on saturation) utilizes virtual IDIs (60) and FGDs (18) on phone and Zoom calls in urban, peri-urban, rural sites. Preliminary data indicate that irrespective of the COVID-19 pandemic, caregivers favor CRI completion for their infants. Hesitancy towards adult COVID-19 vaccine is more prominent in rural and peri-urban than urban sites. There is high vaccine acceptance among healthcare providers at all sites. HCP are aware of COVID-19 preventive measures, but lack of SOP implementation is observed in

hospital and non-hospital settings, while most caregivers in rural and peri urban sites are uncertain about the pandemic's existence. However, caregivers coming to urban hospital for CRI are aware of the pandemic and COVID-19 vaccines. Caregivers and families are skeptical about federal/provincial lockdowns & the resulting financial/psychological impact. Urban caregivers have access to smart phones and social media apps, while rural/peri-urban participants access information about the pandemic and vaccines from local TV/radio news channels & non-smart phones. HCP regularly use social media apps WhatsApp, Facebook on smartphones. Majority caregivers and HCP feel caller tone messaging (updates about the pandemic, vaccines, SOPs) is useful for creating awareness among general population. This work in progress is among the first studies in the region to examine perceptions and barriers related to the role of mHealth in improving childhood routine immunization and COVID-19 vaccine acceptance and uptake.

0068

## SUPPORTIVE SUPERVISION VISITS TO IDENTIFY GAPS IN DATA MANAGEMENT AND USE AT THE PROVINCIAL LEVEL IN THE DEMOCRATIC REPUBLIC OF CONGO

**Johanna Karemere**<sup>1</sup>, Jadhoul Nkongolo<sup>1</sup>, Erick Tshikamba<sup>1</sup>, Roddy Panga wa Banza<sup>1</sup>, Hyacinthe Kaseya Ilunga<sup>2</sup>, Jean Marie Ngbichi<sup>1</sup>, Brittany Schriver Iskarpatyoti Iskarpatyoti<sup>3</sup>, Yazoume Ye<sup>1</sup>

<sup>1</sup>U.S. President's Malaria Initiative Measure Malaria/ICF, Chapel Hill, NC, United States, <sup>2</sup>National Malaria Control Program, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>U.S. President's Malaria Initiative Measure Malaria/UNC, Chapel Hill, NC, United States

Generating quality data remains a challenge for the malaria surveillance system in the Democratic Republic of Congo. The U.S. President's Malaria Initiative (PMI) Measure Malaria project supports the National Malaria Control Program (NMCP) to improve the quality of routine malaria data and promote data use, including supportive supervision visits to health facilities (HFs). The NMCP team led supportive supervision visits in 58 HFs and 30 health zones (HZs) in the 9 PMI-supported provinces from Oct.-Dec. 2020. Teams reviewed data reporting and management tools, data analysis and use practices and discussed planning and monitoring of malaria activities. Findings revealed that all HFs had data collection tools but only 11% of those tools met the national standards. At the HZs, all providers coordinating malaria activities were trained in District Health Information Software 2 (DHIS2) and data management but only 50% had computers to access DHIS2; 22% had data collection tools and none could identify their need for data reporting tools. Regarding data analysis and use, 78% of HFs held data analysis meetings but only 33% had dashboards and graphs displayed. For HZs, all held data analysis meetings but only 56% had dashboards and graphs displayed; none sent feedback to HFs. In terms of monitoring malaria control activities, 89% of HFs had a micro plan, all received supportive supervision visits from HZs, but none received training in surveillance, monitoring, and evaluation (SME). For HZs, none had a supervision visit schedule and none had received any formal supervision or feedback from the Provincial Health Division on SME. Most of the HFs and HZs did not have optimal data management capacity, and the key reasons for the gaps were a lack of standardized manuals for completing data collection tools, lack of feedback to the HFs, and limited capacity in the use of data at HFs. In response to these findings, corrective actions have been taken at the HFs and HZs. Regular supportive supervision visits help identify and address SME challenges at HFs, and they should be streamlined and supported to optimize data use to inform malaria service delivery.

0069

### INITIAL ASSESSMENT OF THE QUALITY OF MALARIA SURVEILLANCE DATA IN SELECTED HEALTH FACILITIES SUPPORTED BY THE U.S. PRESIDENT'S MALARIA INITIATIVE IN THE DEMOCRATIC REPUBLIC OF THE CONGO

Erick Tshikamba<sup>1</sup>, Johanna Karemere<sup>1</sup>, Curtis Mukumba<sup>1</sup>, Jadhoul Nkongolo<sup>1</sup>, Hyacinthe Kaseya<sup>2</sup>, Jean Marie N'Gbichi<sup>1</sup>, Brittany Schriver Iskarpatyoti<sup>3</sup>, Yazoume Ye<sup>1</sup>

<sup>1</sup>U.S. President's Malaria Initiative Measure Malaria/ICF, Chapel Hill, NC, United States, <sup>2</sup>National Malaria Control Program, Ministry of Public Health, Democratic Republic of the Congo, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>U.S. President's Malaria Initiative Measure Malaria, University of North Carolina, Chapel Hill, NC, United States

Quality data is required for measuring progress of malaria control interventions. Since 2014, to improve data quality and use in the Democratic Republic of the Congo (DRC), the country has reformed the national Health Information System (HIS) by revising the normative framework and integrating District Health Information Software 2 (DHIS2) as the platform for managing routine health data. The National Malaria Control Program (NMCP) with support from the U.S. President's Malaria Initiative (PMI) Measure Malaria project, assessed malaria surveillance data quality in the second and third quarters of 2020, covering 99 health facilities (HFs) in 33 of the 178 health zones (HZs) in the 9 PMI-supported provinces, based on geographic accessibility and reporting performance. Data quality and the data management system were assessed through monthly activity reports, data collection and reporting tools, and operational action plans. Of the 99 HFs visited, 90% had source documents and 68% had standard data collection and reporting tools. Regarding outpatient register data completeness, 62% of HFs had at least one missing value related to either general information or malaria diagnosis and treatment. Regarding data accuracy, 85.9% of HFs had inconsistent indicator data and differences were observed between data from the monthly summary form and DHIS2. In terms of the data management system, there was lack of training for data managers, a backlog for data quality verification, lack of standard definitions for data elements, and inadequate data collection and reporting tools. Training for providers was not adequately supported by HZ senior teams and feedback was almost nonexistent. Continued challenges in data quality are linked to the under-supported data management system. There is a need to improve the availability of data management tools, develop an instruction manual for data management and analysis including a data dictionary, and train providers on data management, analysis, and validation. The NMCP and HIS department would benefit from prioritizing regular data quality monitoring in HZs and should consider electronic reporting from HFs.

0070

### USE OF BULK SMS TO SUPPORT HEALTH WORKER KNOWLEDGE RETENTION ON ANTENATAL CARE AND USE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY DURING COVID-19 IN BOSSO LOCAL GOVERNMENT AREA OF NIGER STATE, NIGERIA

Charity Anoke<sup>1</sup>, Orji Bright<sup>1</sup>, Joseph Enne<sup>1</sup>, Bartholomew Odio<sup>1</sup>, Christina Maly<sup>2</sup>, Amina Zimro<sup>3</sup>, Ibrahim Idris<sup>3</sup>, Elizabeth Njoku<sup>1</sup>, Oniyire Adetiloye<sup>1</sup>, Emmanuel Dipo Otolorin<sup>1</sup>, Elaine Roman<sup>2</sup>

<sup>1</sup>Jhpiego, Abuja, Nigeria, <sup>2</sup>Jhpiego, Baltimore, MD, United States, <sup>3</sup>Niger State Ministry of Health, Minna, Nigeria

Considering COVID-19 travel restrictions, bulk SMS were used to support knowledge retention of health workers following an in-person training held before the pandemic. In December 2019, 72 facility health workers and 260 community health workers (CHWs) in Bosso local government area of Niger State, Nigeria participated in a 12-day training about benefits of early antenatal care (ANC) attendance, CHW referrals to ANC, and use of intermittent preventive treatment in pregnancy (IPTp) with sulphadoxine-pyrimethamine to prevent malaria. In-person supervision visits were conducted 3 months following training, although three months

later in-person supervision was no longer possible due to COVID-19 related travel restrictions. Post-training support transitioned to use of bulk SMS which were sent twice a week to each cadre for two 3-month rounds of messaging. Knowledge tests comprised of 10 multiple choice questions linked to key ANC and IPTp guidelines were administered at 5 time points: 1) baseline; 2) post-training; 3) at in-person supervision visit 3 months after training; 4) after first round of bulk SMS (6 months post-training); and 5) after second round of bulk SMS (9 months post-training). Average test scores for each cadre were calculated at each time point and T-tests were used to assess differences in scores. The results show that facility health workers scored an average of 53% on the pre-test followed by scores of 76%, 74%, 86%, and ending at 80% 9 months following training. CHWs started with an average score of 49% which increased to 67% post-training; subsequent average scores were 83%, 74%, and 94%. Results were compelling with facility health worker knowledge improving from 76% immediately post-training to 80% 9 months later (p-value<0.05) and for CHWs the improvement was from 67% to 94% (p-value<0.05). These findings suggest that use of SMS can support knowledge retention of key ANC and IPTp guidelines following an in-person training. Program managers, trainers and supervisors may consider using this approach to support health workers where resources and/or movement are restricted.

0071

### ASSESSING NURSING EDUCATIONAL NEEDS AND BARRIERS TO CARE THROUGH SEMI-STRUCTURED INTERVIEWS IN A LOW RESOURCE SETTING: A QUALITATIVE STUDY OF PEDIATRIC NURSES IN PORT AU PRINCE, HAITI

Alice Ruscica<sup>1</sup>, Stacey Stokes<sup>2</sup>, Jennifer Rogers<sup>3</sup>

<sup>1</sup>Columbia University, New York Presbyterian, New York, NY, United States, <sup>2</sup>Children's National Hospital, Washington, DC, United States, <sup>3</sup>Bernard Mevs Hospital, Port au Prince, Haiti

After Port Au Prince's 2010 earthquake, Hospital Bernard Mevs (HBM) developed a collaborative with international medical volunteers. While initially providing clinical care, the volunteer role evolved to include medical education. With limited literature addressing volunteer coordination efforts to support low-resource setting nursing educational needs, there has been little coordination amongst volunteers or input from local providers about ways volunteers can best serve the clinical, educational, or material needs of the hospital. Objectives for this qualitative study included classifying barriers to clinical care at HBM, identifying strengths of the hospital, and eliciting commonly encountered diagnoses, perceived educational needs and preferred modes of learning. In October 2020, HBM pediatric nurses from the neonatal and pediatric intensive care units and general pediatric ward participated in semi-structured small group interviews that were transcribed, underwent content analysis and were coded independently by two investigators. Forty percent of the pediatric nursing staff was interviewed. The most common barrier to care identified was lack of clinical supplies. The most common strengths were team dynamics and training. Interviewees highlighted education provided by both HBM and international volunteers as a strength of the hospital. Requested future training topics had a neurologic and resuscitation focus, and preferred education modalities were didactics and hands-on workshops. Based on our findings, plans at HBM include development of an educational curriculum prioritizing preferred learning modalities with identified relevant and requested content. Coordination amongst volunteers and sharing of educational content may enable volunteers to meet the educational needs of the HBM team in a robust and systematic way. By providing education to Haitian pediatric providers, we hope to support autonomy and capacity building in an efficient and coordinated fashion. This model may inform other programs with a volunteer presence in resource limited countries to promote autonomy and self-directed learning.

## INFECTION PREVENTION AND CONTROL KNOWLEDGE AND PRACTICES OF FRONTLINE HEALTH CARE WORKERS DURING THE COVID-19 PANDEMIC IN NIGERIA

**Bright Orji**<sup>1</sup>, Elizabeth Oliveras<sup>2</sup>, Emmanuel Ugwa<sup>3</sup>, Bartholomew Odio<sup>1</sup>, Herbert Onuoha<sup>1</sup>, Christina Maly<sup>2</sup>, Ibrahim Idris<sup>4</sup>, Festus Okoh<sup>5</sup>, Emmanuel Dipo Otolorin<sup>1</sup>, Elaine Roman<sup>2</sup>

<sup>1</sup>Jhpiego, Abuja, Nigeria, <sup>2</sup>Jhpiego, Baltimore, MD, United States, <sup>3</sup>Federal Medical Center, Birnin kudu, Jigawa state, Nigeria, <sup>4</sup>Niger State Ministry of Health, Minna, Nigeria, <sup>5</sup>National Malaria Elimination Program, Federal MOH, Abuja, Nigeria

Given the importance of infection prevention and control (IPC) measures for reducing the transmission of COVID-19, a cross-sectional, mixed-methods study was conducted to assess IPC knowledge and practices of frontline health workers – both facility- and community-based health workers (CHWs) – in three local government areas (LGA) in Nigeria: Akure South, Bosso and Ohaukwu. In November 2020, a structured survey was administered to 622 health workers – 294 facility-based (47%) and 328 CHWs (53%) – at 174 primary health care centers. In each LGA, key informant interviews (KII) were conducted with health department management teams; 5 members from LGA and 3 from State health teams. Of all health workers surveyed, 58% had been trained in IPC during COVID and 5 of 11 questions were correctly answered by >94% of providers; however, 3 questions were correctly answered by 65% or fewer. More health workers reported that they practiced recommended IPC behaviors during than before the COVID 19. Significant differences were seen for reported washing hands before glove use (70.5% vs 95.2% during COVID), washing hands after glove use (70.5% vs 95.2%), and using a surgical mask in the workplace (61.7% vs 97.6%). There was no change in reported washing and disinfecting of hands after contact with each patient (69.0% vs 68.6%) or use of an N95 mask in the workplace (8.2% vs 9.1%). Incorrect use of hand sanitizer when hands are visibly soiled however increased (35.8% vs 95.7%). The KIIs confirmed these findings. As one CHW in Ohaukwu said, “We increased our use of face masks, hand sanitizer and gloves,” while a facility-based health worker from Bosso said, “. . . now we take more precaution than then . . . unlike before we palpate with our hands but now we use gloves.” KII showed that fear of contracting the disease was the reason for change in behaviors. Despite reports of improved IPC measures, use of N-95 masks and hand sanitizer practices remain sub-optimal. There is need for continued support for correct hand hygiene, and to reinforce the relative importance of different IPC practices to ensure adherence to COVID-19 preventive measures.

## TRENDS AND SOCIOECONOMIC-RELATED INEQUALITIES IN CHILD GROWTH FAILURE FROM 2000 TO 2016 IN ETHIOPIA: A DECOMPOSITION ANALYSIS

**Tolesa Bekele Okuba**, Patrick Rawstorner, Bayzidur Rahman, Marylouise McLaws

*University of New South Wales, Sydney, Australia*

Despite continued investment by the government of Ethiopia and partners, levels of child growth failure (CGF) are still high. This study examined trends, socioeconomic-related inequalities in CGF and determinants that potentially explain inequalities from 2000 to 2016 in Ethiopia. A total of 43029 child-mother pairs were sampled between 2000 and 2016. Children aged 0 to 59 months and mothers aged 15 to 49 years were included. We categorized CGF indicators (stunting, underweight and wasting) based on height/weight-for-age z-scores. We plotted margins of predicted probabilities to estimate trends of CGF. Concentration curve and indices were used to estimate socioeconomic-related CGF inequalities. Following this, we decomposed the concentration index to identify predictors of CGF inequalities. Margin plot showed evidence of decline in CGF between 2000 and 2016. This reduction varied over time and reached a low between 2005 and 2011. This may be attributable to large-scale

nutrition programs over this time. Despite this reduction, we found strong evidence that socioeconomic-related CGF inequalities are increasing and highly concentrated at the lower tail of economic distribution. Between 2000 and 2016, the absolute values of concentration index have increased from -0.072 to -0.139 for stunting, -0.088 to -0.131 for underweight and -0.015 to -0.050 for wasting. These disparities could be explained by key socioeconomic predictors. We found stunting inequalities were mainly explained by geographic region (49.37%), wealth quintile (46.17%) and number of antenatal care visits (31.40%). While underweight was explained by geographic regions (82.21%), wealth quintile (29.18%), access to handwashing (18.59%) and improved water facilities (-17.55%). Wealth quintile (52.91%) and normal body mass index (-66.06%) have explained wasting inequalities. The increased disparities may help us to understand why CGF levels continue to be higher in Ethiopia compared with the World Health Organization cut-offs for public health concern. Multisectoral interventions tailored towards addressing these CGF disparities are required.

## FACTORS RELATED TO CHANGES IN HEALTH FACILITY ATTENDANCE AMONG PREGNANT WOMEN DURING THE COVID-19 PANDEMIC IN THREE LOCAL GOVERNMENT AREAS OF NIGERIA

**Oniyire Adetiloye**<sup>1</sup>, Bright Orji<sup>1</sup>, Elizabeth Oliveras<sup>2</sup>, Emmanuel Ugwa<sup>3</sup>, Aishatu Bintu Gubio<sup>4</sup>, Edima Akpan<sup>5</sup>, Bartholomew Odio<sup>1</sup>, Herbert Onuoha<sup>1</sup>, Ibrahim Idris<sup>6</sup>, Emmanuel Dipo Otolorin<sup>1</sup>, Elaine Roman<sup>2</sup>

<sup>1</sup>Jhpiego, Abuja, Nigeria, <sup>2</sup>Jhpiego, Baltimore, MD, United States, <sup>3</sup>Federal Medical Center, Birnin kudu, Jigawa state, Nigeria, <sup>4</sup>National Malaria Elimination Program, Federal Ministry of Health, Abuja, Nigeria, <sup>5</sup>Reproductive Health Division, Federal Ministry of Health, Abuja, Nigeria, <sup>6</sup>Niger State Ministry of Health, Minna, Nigeria

COVID-19 disrupted public health interventions and weakened global and national health systems. We used a mixed-methods study to explore factors related to changes in health facility attendance during the COVID-19 pandemic in three local government areas (LGAs) in Nigeria: Ohaukwu, Akure South and Bosso. Three hundred fifteen pregnant women seen for antenatal care (ANC) in November 2020 participated in a survey about their attendance before and during the pandemic; 198 women participated in focus group discussions (FGDs). One quarter of women surveyed reported that they reduced the frequency of their visits or did not visit during the pandemic. The biggest reported changes in visits were for immunization (47% visited before the pandemic versus 30% during the pandemic,  $p < 0.001$ ) and other outpatient services (66% to 57%,  $p = 0.027$ ), with small but statistically significant declines in ANC (99% to 94%,  $p = 0.002$ ) and family planning (11% to 5%,  $p = 0.002$ ). Both LGA and religion were significantly correlated with reduced/no visits during the pandemic; other socio-demographic characteristics were not. Whereas 33% of Christian women reported reduced/no care seeking, only 7% of Muslim women did ( $p < 0.001$ ). Women in Ohaukwu were most likely to report reduced/no visits (39%), followed by those in Akure South (26%), and Bosso (7%) ( $p = 0.012$ ). During FGDs transport issues, proximity to health facilities, and fear of contracting COVID-19 or being labeled as COVID-positive were the most common reasons mentioned for not seeking care during the pandemic. Differences by LGA are likely related to differences in both levels of transmission and the State-level response to the pandemic. Ebonyi state, where Ohaukwu is located, had the longest lockdown and most restricted movement; better understanding of differences in the pandemic and state response could inform future actions. The FGDs findings highlight the need for health systems to consider how to facilitate service utilization during a pandemic, such as providing safe transport or increasing outreach, and to minimize stigma for those seeking care.

0075

### COMMUNITY ENGAGEMENT TO MANAGE RUMORS IN HEALTH RESEARCH A CASE FROM ETHIOPIA

Ketema Begna<sup>1</sup>, Markus Breines<sup>2</sup>

<sup>1</sup>Haramaya University, Ethiopia, Harar, Ethiopia, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The majority of health research projects are conducted for the benefit of public health, but people in many parts of the world often fear or do not trust researchers. WHO (2008) has recognized that communities need to have a voice in health research projects to reduce rumors and suspicions. Still, in many cases, there is more focus on the clinical aspects than on community values, priorities, & interests. In Ethiopia, the Child Health and Mortality Prevention Surveillance (CHAMPS) Network is using community engagement as a key tool in the research. Community engagement includes working with local groups ('Iddirs' and 'Afoshas'), women's associations, health institutions, religious leaders, chief of villages, & health extension programs to encourage notifications when children under five pass away. In addition, radio programs, theatre performances with actors from the communities & regular meetings with Community Advisory Boards are used both for regular feedback and to disseminate information & research findings to the communities. These activities have helped build trust, form relationships & facilitate mutual sharing of knowledge about child & maternal health. Through the involvement of community members in the research, the team has been able to manage rumors about organ theft and vampires & other suspicions about why CHAMPS is focusing on dead children. These engagements contributed to the participation in the research & helped reduce the challenges of conducting the clinical activities. Demonstrating the importance of community engagement in Ethiopia to manage rumors and suspicion, we suggest that health research planning, implementation & outcomes should be developed through close collaboration with local communities.

0076

### WESTERN AUSTRALIAN AND PAPUA NEW GUINEAN EUCALYPTUS SPECIES KINOS: VALIDATION FOR THE TRADITIONAL MEDICINAL USES OF KINOS

Martha W. Yahimbu<sup>1</sup>, Rima Caccetta<sup>2</sup>, Ricky R. Lareu<sup>2</sup>

<sup>1</sup>University of Papua New Guinea, Port Moresby, Papua New Guinea, <sup>2</sup>Curtin Medical School and Curtin Health Innovation Research Institute, Curtin University, Perth, Australia

Tropical diseases are persistent in tropical developing and underprivileged communities in developed counties where there is lack of water and non-adherence to simple regulations for sanitation and hygiene. Disadvantaged populations use alternative traditional medicines when approved, conventional drugs are inaccessible and costly. Kinins are astringent dried exudates from certain Eucalyptus species and they are used to treat gastrointestinal infections, wounds, fever, and sores by First Australians. In contrast, there is no documentation of traditional medicinal uses of kinins from Papua New Guinean eucalyptus species. This study aimed at validating some of the claims of the First Australian communities for the treatment of various infections with kinins. The kinins from Western Australian *Eucalyptus calophylla* and Papua New Guinean *E. confertiflora* were tested for their immuno-modulatory effects on LPS-stimulated RAW267.4 macrophages *in vitro*. Assays included Enzyme-linked immunosorbent assays for TNF $\alpha$ , interleukin (IL) 6 and 10, and the Griess reaction for nitric oxide. Phagocytic activity of macrophages to Gram-negative and Gram-positive bacteria was evaluated with flow cytometry. Phytochemical screening of the kinins extracts was also performed in this study. Cytokine profiles and phagocytic activity were investigated by treating the cells with different kinin concentrations (62.5-250  $\mu\text{g/mL}$ ) at specific time points (6 and 12 hr for IL6, IL10 and TNF $\alpha$ ; 24 hr for nitric oxide). Interleukin 6, IL10 and nitric oxide levels were significantly reduced in a dose-dependent manner (from  $p < 0.05$  to  $p < 0.0001$ ) while TNF $\alpha$  significantly increased (from  $p < 0.05$  to  $p < 0.0001$ ). The phagocytic activity of kinin-exposed macrophages increased for both Gram-positive and

Gram-negative bacteria. Mostly phenolic compounds and tannins were detected in the kinins. The results show that the kinins of the Eucalyptus species possess immuno-modulatory activity, impacting cytokine profiles and phagocytic activity.

0077

### UNDERSTANDING ANTIMICROBIAL RESISTANCE THROUGH THE LENS OF ANTIBIOTIC VULNERABILITIES IN PRIMARY HEALTH CARE IN RURAL MALAWI

Eleanor MacPherson<sup>1</sup>, Joanna Reynolds<sup>2</sup>, Chimwemwe Phiri<sup>1</sup>, John Mankhomwa<sup>1</sup>, Justin Dixon<sup>3</sup>, Clare I. Chandler<sup>3</sup>

<sup>1</sup>Malawi-Liverpool-Wellcome, Blantyre, Malawi, <sup>2</sup>Sheffield Hallam University and Capacity Q, Sheffield, United Kingdom, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

The diminishing effectiveness of antimicrobials raises serious concerns for human health. While policy makers grapple to reduce the overuse of antimicrobial medicines to stem the rise of antimicrobial resistance, insufficient attention has been paid to how this applies to low-income rural contexts. We provide an in-depth understanding of antimicrobial prescribing at primary health care level in rural Chikwawa District, Malawi. Fieldwork took place over 18 months (2018-2020). We surveyed all 22 health facilities in the district, observed 1348 health worker-patient consultations, and carried out 45 in-depth interviews with staff and patients. Care was centred around provision of an antimicrobial. Amid chronic lack of essential medicines and other resources, clinic interactions were tightly scripted, providing patients little time to question or negotiate their treatment. We develop the concept of antibiotic vulnerabilities to reveal the multiple ways in which provision of antimicrobials in rural Malawi impacts people living in extreme scarcity. Antibiotics are central and essential to primary care. As targets for optimal antimicrobial prescribing take a more central role in global policy, we must track the ramifications of this for the delivery of care to ensure that efforts to stem resistance do not undermine the goal of improved health for all.

0078

### ENGAGING ISLAMIC RELIGIOUS SCHOLARS AND LEADERS TO INCREASE ACCEPTANCE OF MINIMALLY INVASIVE TISSUE SAMPLING PROCEDURE IN A MORTALITY SURVEILLANCE PROGRAM IN RURAL BANGLADESH

Faruque Hussain<sup>1</sup>, Emily S. Gurley<sup>2</sup>, John Blevins<sup>3</sup>, Maria Maixenchs<sup>4</sup>, Md. Saiful Islam<sup>5</sup>, Sanwarul Bari<sup>1</sup>, Abdullah Al Masud<sup>1</sup>, Abdus Suban Mulla<sup>1</sup>, Abu Uzayer<sup>1</sup>, Afroz Zahan<sup>1</sup>, Aziz Ahamed<sup>1</sup>, Shikha Datta Gupta<sup>1</sup>, Suruj Ali<sup>1</sup>, Sazzad Hossain Khan<sup>1</sup>, Tonmoy Sarkar<sup>1</sup>, Dalia Yeasmin<sup>1</sup>, Palash Mutsuddi<sup>1</sup>, Shams El Arifeen<sup>1</sup>, Shahana Parveen<sup>1</sup>

<sup>1</sup>icddr, Dhaka, Bangladesh, <sup>2</sup>John Hopkins University, Maryland, MD, United States, <sup>3</sup>Emory University, Atlanta, GA, United States, <sup>4</sup>ISGlobal, Barcelona, Spain, <sup>5</sup>University of New South Wales, Sydney, Australia

Minimally invasive tissue sampling (MITS) post-mortem is an alternative to full autopsies to determine etiology of deaths. After obtaining family consent, Child Health and Mortality Prevention Surveillance conduct MITS on stillborn babies and deceased children under-5 years to identify causes of death. Previous studies in Muslim countries revealed Islamic religious challenges to MITS acceptance, which influence and determine broader social acceptance. We aimed to establish endorsement of the MITS procedure among Islamic religious leaders and expand social acceptance in Baliakandi sub-district, a predominantly Muslim community in rural Bangladesh. From May 2017 to December 2020, we arranged two group discussions with four Muftis (qualified legal Islamic religious scholars) and 21 senior Imams. We then conducted 84 meetings with Imams at local Mosques with community residents. We circulated 246 copies of a Fatwa (interpretation on a point of Islamic Shariah) on MITS procedure among Muftis, Imams, presidents, and secretaries of Mosque committees. Muftis agreed to the MITS procedure and senior Imams concurred with their views but noted the importance of continuously engaging with

local level religious leaders and community residents to enhance MITS acceptance. Two Muftis and 10 Imams actively supported explaining the MITS procedure to families when the team approached them for consent, communicating cause of death and providing report to families and contributed with their suggestions (i.e.: importance of resolving 'seepage' from deceased body after MITS is performed) to enhance religious acceptance of MITS. Of the 185 families approached for MITS, 37% consented to the procedure. Among refusals, only ~9% reported religious beliefs as the reason for non-acceptance, which declined over the time, from 50% (3/6) in 2017 to 4.5% in 2020 (1/22). Islamic religious scholars and religious leaders are key stakeholders to endorse and extend religious acceptance of MITS at the community level. Public health programs that include evaluations of deaths or needle biopsy must engage religious scholars and religious leaders throughout the study.

0079

### COGNITIVE OUTCOMES AT 18 MONTHS: FINDINGS FROM THE EARLY LIFE INTERVENTIONS FOR CHILDHOOD GROWTH AND DEVELOPMENT IN TANZANIA (ELICIT) TRIAL

**Tarina Parpia**<sup>1</sup>, Erling Svensen<sup>2</sup>, Sarah Elwood<sup>1</sup>, Anne Wanjuhi<sup>1</sup>, Ladislaus Blacy<sup>3</sup>, Eliwaza Bayo<sup>3</sup>, Eric Houpt<sup>1</sup>, Elizabeth Rogawski McQuade<sup>1</sup>, Mark DeBoer<sup>4</sup>, James Platts-Mills<sup>1</sup>, Estomih Mduma<sup>3</sup>, Rebecca Scharf<sup>1</sup>

<sup>1</sup>University of Virginia Division of Infectious Diseases & International Health, Charlottesville, VA, United States, <sup>2</sup>Haukeland University Hospital, Bergen, Norway, <sup>3</sup>Haydom Global Health Research Centre, Haydom Lutheran Hospital, Haydom, United Republic of Tanzania, <sup>4</sup>University of Virginia Department of Pediatrics, Charlottesville, VA, United States

Seasonal subsistence communities are predisposed to seasonal patterns of hunger, micronutrient deficiencies, and enteric pathogens, all of which may be risk factors for long-term child growth and development. Cognitive testing is the most accurate assessment of developmental progress; however, stunting (length-for-age Z-score more than 2 standard deviations below the mean) is frequently used as a surrogate because direct cognitive assessments are harder to measure. Here we assess cognitive outcomes in children enrolled in the ELICIT randomized, placebo-controlled trial in Haydom, Tanzania. The Malawi Developmental Assessment Tool (MDAT), which includes gross motor, fine motor, language, and social assessments, was a pre-specified secondary outcome. There was no effect of the study interventions of nicotinamide (change in development-for-age-Z-score (DAZ) -0.08; 95% CI: -0.16, 0) or antimicrobials (change in DAZ 0.04; 95% CI: -0.06, 0.13) on the overall MDAT score. Additional analyses of MDAT subscores and within subgroups defined by gender, socioeconomic status, birth weight, and birth season showed no effect of the interventions. We then used linear regression to identify risk factors for developmental outcomes. We identified birth in the pre-harvest season (-0.16 difference in DAZ vs. birth in the post-harvest season, 95% CI: -0.26, -0.06) and higher socioeconomic status (SES) (0.26 difference in DAZ score compared to lowest SES quartile, 95% CI: 0.12, 0.40) as factors associated with cognitive outcomes. Interestingly, we found that birth during the pre-harvest season was not associated with attained length at 18 months (estimate -0.02, 95%CI: -0.14, 0.10). This study cohort represents a high-risk population for whom interventions to improve child growth and development are urgently needed. Further analysis of this cohort is needed to determine the best surrogates for cognitive outcomes and the best timing for such interventions to improve cognitive outcomes.

0080

### ARE NATIONAL MALARIA CONTROL PROGRAMS (NMCPs) EMBEDDED TECHNICAL ADVISORS MAKING AN IMPACT? LESSONS LEARNED FROM NMCPs IN WEST, CENTRAL, AND EAST AFRICA

**Djenie Esther Danjoint**, Katy Gorentz, HRH2030-CBM Advisors --, HRH2030 Project Management Unit

*Chemonics International Inc, Arlington, VA, United States*

National Malaria Control Programs (NMCPs) must have robust institutional capacity and an empowered health workforce to achieve malaria control and elimination. Since 2016, the USAID Human Resources for Health in 2030 Program (HRH2030) has embedded long-term technical advisors (LTTA) into 10 NMCPs (Burundi, Cameroon, Central African Republic, Chad, Cote d'Ivoire, The Gambia, Guinea, Niger, Sierra Leone, and Togo) to build leadership, management, and governance (LMG) capacity to make the best use of Global Fund grants and U.S. President's Malaria Initiative resources. HRH2030 implemented two evaluation methods to assess effectiveness of the LTTA model: The Capability Maturity Model (CMM) (adapted from Carnegie Mellon University) assesses institutional capacity to implement NMCP functions. The LTTA collaborates with NMCP colleagues to rate organizational performance along a five-scale scoring system ranging from «initial» to «optimizing» and identify actions for maturation. The Confidence Assessment (adapted from the LMG Project approach) is a retrospective self-assessment that elicits NMCP staff feedback on how technical assistance influenced their individual confidence to perform key tasks. These models are complemented by output indicators tracking LTTA activities and Global Fund performance indicators. CMM results in Burundi, Cameroon, The Gambia, and Sierra Leone showed significant organizational capacity improvements from an average of 3.2 to 4.0 out of 5. Confidence assessments in Cameroon, Niger, and Sierra Leone showed an average increase in NMCP staff confidence of 29% (from 4.4 to 5.6 out of 7); most NMCP staff indicated the LTTA had some (37.1%) or significant influence (46.4%) in their confidence. The Niger NMCP's Global Fund grant performance rating increased from B2 in 2015 to A1 in 2018. Other country data collection is ongoing. These approaches illuminate the multi-faceted impact of LTTAs. For stakeholders looking to adapt these approaches, HRH2030 recommends establishing NMCP baseline capacity and using evaluation tools as collaborative opportunities to engage and empower in-country stakeholders.

0081

### POPULATION CHANGE IN RURAL EASTERN ETHIOPIA BETWEEN 2007 TO 2019: FINDINGS FROM AN OPEN DYNAMIC COHORT DEMOGRAPHIC SURVEILLANCE

**Nega Assefa Kassa**<sup>1</sup>, Gezahegn Mengesha<sup>1</sup>, Merga Dheresa<sup>1</sup>, Solveig A. Cunningham<sup>2</sup>

<sup>1</sup>Haramaya University, Harar, Ethiopia, <sup>2</sup>Emory University, Atlanta, GA, United States

In the face lack of a vital records system, demographic surveillances are an efficient, cost effective and reliable method to collect population-based data in a resource limited setting. This report focuses on characterizing the population of Kersa Health and demographic Surveillance System (Kersa HDSS) in Eastern Ethiopia, under surveillance since 2007, to examine population and demographic changes over the 12-year period. Kersa HDSS was established by enumerating population in catchment of 12 sub-districts. At the baseline the population was 50,692 and at the end of 2019 it was 136,650. A person-time analysis was used to determine population increase, population growth rate, birth and death rates, sex ratio, and dependency ratio. The surveillance had produced 1,026,580 person-year over 12-year period. The overall population sex ratio was balanced at 102.7, while the overall sex ratio at birth was 110. The young dependency ratio had reduced from 88.8% in 2008 to 73.3% in 2019 and the old dependency ratio had slightly increased from 3.9 to 5.6% for the same period. The crude birth and death rates were 31.9 and 11.2 in 2008 and became 24.3 and 5.9 in 2019. The average crude population

increase was 2.4 per year. The life expectancy had increased by 11.8 from 56.1 in 2008 to 67.8 in 2019. There is a significant change in life expectancy as a result of significant reduction in mortality. More young population is entering to the productive segment of the population. There is an opportunity to harness these work force for the national development.

0082

### TOWARDS A SUSTAINABLE CONFERENCING: COMPARING THE CARBON FOOTPRINT OF IN-PERSON, VIRTUAL AND HYBRID ASTMH EDITIONS

Teun Bousema<sup>1</sup>, Kate Whitfield<sup>2</sup>

<sup>1</sup>Radboudumc, Nijmegen, Netherlands, <sup>2</sup>ISGlobal, Barcelona, Spain

The carbon footprint of academic conferencing exceeds that of some countries. Carbon emissions contribute to the climate crisis that has severe consequences for human health. In the years prior to the COVID-19 pandemic, thousands of participants from across the globe travelled to the Annual Meeting of the American Society of Tropical Medicine and Hygiene (ASTMH). In 2020, a virtual conference was organized that will be followed by a hybrid meeting in 2021. For the 68<sup>th</sup> edition of ASTMH in National Harbor, Maryland (2019), we determined the most likely route of travel based on country or state of residence. We used this to determine total distance travelled and the CO<sub>2</sub> equivalent (CO<sub>2</sub>e) emissions, considering differences in emissions per km between long- and short-haul flights, and accounting for indirect emissions from radiatively active substances and aerosol formation. The 4834 participants together travelled an estimated 27.7miles/44.6 kilometres, or the distance of 58 return trips to the moon. The estimated CO<sub>2</sub>e emissions were 8646 metric ton. In the coming months, we will calculate the CO<sub>2</sub>e emissions from the 69<sup>th</sup> ASTMH conference in 2020 that was a virtual edition with 4011 participants, incorporating network-, laptop- and server-related emissions at 240 gCO<sub>2</sub>e/kWh. The 70<sup>th</sup> edition of ASTMH will be held in National Harbor, Maryland in 2021 and offers a choice of in-person and virtual attendance. In the month prior to the conference, we will acquire an approximation of the number of virtual and in-person participants and calculate their carbon footprint. In conclusion, in addition to the quality of knowledge dissemination and networking, securing annual revenues to maintain ASTMH as an organization, the carbon footprint of conferencing is an increasingly important factor that needs to be considered when organizing conferences. Data from the 68<sup>th</sup>, 69<sup>th</sup> and 70<sup>th</sup> editions of ASTMH offer an opportunity to directly quantify these emissions to support discussions on how to best organize this conference in this era of climate change.

0083

### FACILITATORS AND BARRIERS TO ADOPTING SUSTAINABLE PRACTICES IN GLOBAL HEALTH INSTITUTIONS

Alexandru Cretu<sup>1</sup>, Kate Whitfield<sup>1</sup>, Justin Cohen<sup>2</sup>, Teun Bousema<sup>3</sup>

<sup>1</sup>ISGlobal, Barcelona, Spain, <sup>2</sup>Clinton Health Access Initiative, New York, NY, United States, <sup>3</sup>Radboud University Medical Centre, Nimega, Netherlands

The climate crisis threatens human health and wellbeing and disproportionately affects populations in low and middle-income countries. Given that the purpose of global health institutions is to improve the health of populations, they have a critical role to play in mitigating the health effects of climate change as well as rapidly reducing greenhouse gas emissions from the global health enterprise. This study examines how global health institutions are reducing the greenhouse gas emissions from their own operations and analyzes the facilitators and barriers to achieving decarbonization goals. We reviewed the sustainability goals and implementation plans of 10 global health universities from the 'TropEd' network, and the top 10 international non-governmental organizations (NGO) ranked by 'NGO Advisor' working in a health-related field. We systematically collected information from institutional websites and annual reports. Through online interviews, key informants

validated the information and shared their opinions regarding what factors are helping their institutions decarbonize and what factors are hindering progress. Initial findings show that 9/10 universities sampled have a sustainability policy, 6/10 have specific decarbonization goals, and 8/10 have implementation plans. However, the systematic online search shows that only 3/10 non-governmental organizations sampled have a sustainability policy, 1/10 have specific decarbonization goals, and 1/10 have implementation plans. Findings from the interviews with the key informants of the 10 global health universities are summarized. Institutions across all sectors need to rapidly decarbonize to mitigate the worst effects of climate change, but results suggest institutional responses are lagging amongst global health NGOs. This study identifies lessons and best practices that global health institutions are utilizing to successfully decarbonize their operations as well as highlighting critical gaps that still need to be tackled.

0084

### LESSONS LEARNED FROM THE EXPERIENCE OF MOBILIZING COMMUNITY VOLUNTEERS FOR REAL-TIME IDENTIFICATIONS OF STILLBIRTHS AND < 5 CHILD DEATHS IN A CHILD HEALTH PROGRAM IN RURAL BANGLADESH

Abdullah Al Masud<sup>1</sup>, Emily S. Gurley<sup>2</sup>, Faruque Hussain<sup>1</sup>, Sanwarul Bari<sup>1</sup>, Saiful Islam<sup>1</sup>, John Blevins<sup>3</sup>, Mohammad Zahid Hossain<sup>1</sup>, Qazi Sadeq-ur Rahman<sup>1</sup>, Atique Iqbal Chowdhury<sup>1</sup>, Kyu Han Lee<sup>2</sup>, Abu Mohammad Saleheen<sup>1</sup>, Palash Mutsuddi<sup>1</sup>, Probin Kumer Dey<sup>1</sup>, Shams El Arifeen<sup>1</sup>, Shahana Parveen<sup>1</sup>

<sup>1</sup>icddr, Dhaka, Bangladesh, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Rollins School of Public Health, Emory University, Atlanta, GA, United States

The Child Health and Mortality Prevention Surveillance (CHAMPS) uses minimally invasive tissue sampling (MITS), a post-mortem procedure, at 3 sentinel facilities and in the community in a rural sub-district *Baliakandi*, Bangladesh to identify the causes of stillbirths and <5 child deaths. The major challenge of conducting MITS among children who die in the community is receiving notification of death before burial so that the team can approach the guardians about participation in the MITS procedure. To receive rapid notifications, we recruited 1,190 community volunteers from 261 villages in 2018 and requested them to notify stillbirths and <5 deaths through a CHAMPS hotline number. Later, we contacted 296 volunteers from March-November 2019 over the phone, to explore the barriers why they missed notifying 156 deaths in their villages that were later notified by the Demographic Surveillance System of the CHAMPS. The major reasons stated by the volunteers were: The residence of the deceased child was not nearby their house, the hotline number was not saved in their mobile phone, they heard about the death once the body had already been buried, and the CHAMPS hotline number was unreachable due to poor network connection. In response, we took certain actions to overcome the barriers. We identified 63 places in the catchment area where no volunteer was available and recruited new volunteers. We included an additional hotline mobile number. We arranged refresher training from December 2019 to February 2020 with 995 volunteers where we ensured all volunteers saved hotline numbers in their mobile phones on the spot and also clarified that they should report any deaths even if the body was already buried. We have done a comparative analysis between two equal durations before and after implementing the necessary actions to assess the changes in receiving notifications. We found that after implementing the necessary actions, overall the number of notifications rose 30%; those within 5 hours rose 23%. Identifying the bottleneck of an ongoing community-based death notification system and implementing need-based actions increased the number of notifications.

0085

## THE IMPACT OF CLIMATE CHANGE ON NEGLECTED TROPICAL DISEASES OF THE SKIN

Eva Rawlings Parker

*Vanderbilt University Medical Center, Nashville, TN, United States*

The climate crisis is a serious threat to global human health, disproportionately affecting low-resource settings and vulnerable populations. Importantly, climate change increases the incidence of neglected tropical diseases (NTDs) of the skin, which WHO lists as Buruli ulcer, cutaneous leishmaniasis, leprosy, mycetoma, yaws, onchocerciasis, lymphatic filariasis, scabies and fungal infections. Global warming drives changes in precipitation and humidity and increases extreme weather events. Alterations in these climatic variables increase the risk of bacterial and fungal infections and expand the range and odds of survival of insects, leading to a rising incidence in vector-borne skin NTDs and the emergence of these diseases in new geographic regions. Increasingly, millions are fleeing climate change-related alterations in their natural environment as impacts from climate change such as extreme weather events, sea-level rise, and drought exacerbate food insecurity and civil unrest, fueling mass migration. Consequently, rising rates of skin NTDs among climate refugees are observed due to poor nutrition and hygiene, overcrowding, and confinement in refugee settlements, enhancing the transmission of highly communicable diseases such as scabies and yaws. Extreme weather events also curtail surveillance and treatment efforts aimed at reducing skin NTDs. During wildfires, flooding and storms, rapid evacuation may result in lost or forgotten medications and access to health care services becomes severely limited. Additionally, community surveillance programs and mass drug administration services may be suspended, and damage to telecommunications infrastructure diminishes accessibility to remote health care services delivered on digital platforms including telehealth. Skin NTDs are associated with substantial morbidity and disfigurement, resulting in stigmatization that reinforces socioeconomic barriers such as discrimination and poverty. The impact of climate change on the incidence of skin NTDs must be emphasized. Moreover, lack of climate mitigation risks serious setbacks to controlling skin NTDs globally.

0086

## DENGUE TRANSMISSION RISK IN A CHANGING CLIMATE: BANGLADESH COULD EXPERIENCE A LONGER DENGUE FEVER SEASON IN THE FUTURE

Kishor Kumar Paul<sup>1</sup>, Ian Macadam<sup>2</sup>, Donna L. Green<sup>2</sup>, David G. Regan<sup>1</sup>, Richard T. Gray<sup>1</sup>

<sup>1</sup>*Kirby Institute, UNSW Sydney, Sydney, Australia*, <sup>2</sup>*Climate Change Research Centre, UNSW Sydney, Sydney, Australia*

Our changing climate is already affecting the transmission of vector borne diseases such as dengue fever. This issue presents a significant public health concern for some nations, such as Bangladesh, which already experience regular seasonal outbreaks of dengue fever under present day conditions. To provide guidance for proactive public health planning to potentially mitigate future infections, we explore the impact of climate change on dengue infections by calculating the change in vectorial capacity of *Aedes aegypti* mosquito at a seasonal level for all regions in Bangladesh for two atmospheric greenhouse gas concentrations for the period 2050-2099. For each of the four climate models used, and for both scenarios, our analysis reveals that the annual vectorial capacity remains at a level that would enable potential dengue epidemic transmission in all regions during the time period examined. We found a slight decline in vectorial capacity in half of the regions examined during the last two decades of 21<sup>st</sup> Century for the lower-concentration scenario, with a pronounced decline in vectorial capacity in all geographic regions beginning in 2060 for the higher-concentration scenario. The likely reason is that in many regions greenhouse warming is leading to temperatures beyond the optimum for mosquito breeding. However, seasonal differences in vectorial capacity dissipate as the climate warms, to the point that there is almost no observable seasonality for the higher-

concentration scenario during the last two decades of the century. This suggests the potential for the dengue season to extend all year, with outbreaks occurring at any time. These findings suggest that disease surveillance and control activities would need to be geographically and temporally adapted to mitigate dengue epidemic risk.

## PRIORITIES FOR VECTOR-BORNE DISEASE RESEARCH UNDER A PLANETARY HEALTH FRAMEWORK: A SCOPING REVIEW AND BIBLIOMETRIC ANALYSIS OF CLIMATE CHANGE AND AEDES-VECTORED DISEASES IN AUSTRALIA AND INDO-PACIFIC REGION

Esther Achieng Onyango, Brendan Mackey, Hamish McCallum  
*Griffith University, Brisbane, Australia*

In recent years, three key arboviruses transmitted by *Aedes* mosquitoes, Zika, Chikungunya and Dengue have emerged and re-emerged in both hemispheres of the world to cause major human epidemics. The distribution if these viruses are driven by changes in climate and it is estimated that by 2050, almost half the world's population will live in areas where *Aedes* mosquitoes have established. The two main vectors transmission, *Aedes aegypti* and *Aedes albopictus* have already caused outbreaks and epidemics of dengue, chikungunya and Zika in the Pacific region and in the Torres Strait in Australia. Understanding the distribution and spread of these diseases under future climate scenarios therefore remains a priority. We conducted a scoping review of peer-reviewed literature from five scientific databases with the aim of providing a synthesis of the current state of literature on the emergence and re-emergence of the mosquito-borne arboviruses to identify key drivers of transmission, changing risk under climate change and other drivers, current strategies for risk management and research gaps and priorities. We analyse these studies through the lens of an integrated risk framework based on the theoretical concepts of planetary health and the IPCC risk assessment framework to identify key drivers of hazard, exposure and vulnerability. We found that compared to other regions, there are limited studies (n=43) that address climate change and *Aedes* vectored arboviruses. Further we find that 32% of these studies are review studies, providing a broad overview of the research landscape. While the remaining studies acknowledged the influence of climate on spread of disease, only 6 studies assessed how climate factors and/or climate change will influence disease transmission and all of these studies were on Dengue virus. This study highlights the need for more understanding of factors driving risks of emergence and re-emergence of *Aedes*-vectored arboviruses in the region.

## CLIMATE CHANGE AND MALARIA RISK IN EAST AFRICA - UNPACKING IMPACTING FACTORS AND INTERVENTION OPTIONS USING BAYESIAN NETWORK MODELLING: A PLANETARY HEALTH APPROACH TO A WICKED PROBLEM

Esther Achieng Onyango<sup>1</sup>, Oz Sahin<sup>2</sup>, Shannon Rutherford<sup>3</sup>, Cordia Chu<sup>4</sup>, Brendan Mackey<sup>5</sup>

<sup>1</sup>*Griffith University, Centre for Planetary Health and Food Security, Brisbane, Australia*, <sup>2</sup>*Griffith University, School of Engineering, Gold Coast, Australia*, <sup>3</sup>*Griffith University, School of Medicine, Brisbane, Australia*, <sup>4</sup>*Griffith University, Centre for Environment and Population Health, Brisbane, Australia*, <sup>5</sup>*Griffith University, Climate Change Response Program, Gold Coast, Australia*

Malaria is a disease with a complex transmission cycle, influenced by biophysical and socio-ecological drivers. While malaria is the most studied mosquito-borne disease in the context of climate change, there are limited studies that model the many inter-related pathways of causality and hierarchical relationships between these drivers of transmission. Thus, model projections still contain a high degree of uncertainty. We address this uncertainty using a participatory systems approach and Bayesian Network modelling. We develop the model using key drivers of

malaria transmission. We parametrize the BN model using quantitative and qualitative data from global climate change models, Demographic and Health Surveys, Malaria Indicator Survey, Expert knowledge, key informant interviews and focus group discussions to provide a robust assessment of malaria risk. We estimate the posterior probability of risk of malaria infection given conditional prior probabilities under different climate change scenarios to suggest potential adaptation options for risk management. Results of our sensitivity analysis indicate that under baseline conditions, health system services, agricultural land use and sand quarrying are significant drivers of optimum malaria transmission at the community level. Under RCP4.5 projected to 2080, air temperature and to a lesser extent, sand quarrying, health system services and agricultural land use are the significant drivers of malaria risk. Under RCP8.5 projected to 2080, air temperature is the significant driver of optimum malaria transmission. Our results suggest that in the short-term, interventions to manage climate change and malaria transmission risk at the community level should focus on health systems strengthening and sustainable land use practice while in the long term, focus should shift to managing the risks associated with higher temperatures. Our results highlight which adaptation interventions are likely have the most influence on risk reduction under changing climate and have important implications for climate change and health adaptation policy and practice.

#### CLIMATOLOGICAL VARIABLES AND THE INCIDENCE OF LEPTOSPIROSIS IN CARTAGENA DE INDIAS, COLOMBIA: AN ECOLOGICAL STUDY FROM 2008 TO 2017

Eder Cano-Pérez<sup>1</sup>, Jaison Torres-Pacheco<sup>1</sup>, Fabián Espitia-Almeida<sup>2</sup>, Steev Loyola<sup>2</sup>, Dacia Malambo-García<sup>1</sup>, **Doris Gomez-Camargo<sup>1</sup>**

<sup>1</sup>UNIMOL Research Group, Faculty of Medicine, University of Cartagena, Cartagena de Indias, Colombia, <sup>2</sup>Doctorate in Tropical Medicine, Faculty of Medicine, University of Cartagena, Cartagena de Indias, Colombia

Leptospirosis is an acute febrile illness caused by bacteria of the genus *Leptospira*. The prevalence of human leptospirosis largely varies across geographic locations and is frequently associated with occupational factors and exposure to animals and rodents. Seasonality and climatic factors also describe as consistent factors related to the increase of leptospirosis cases in humans. Here, we described the relationship between the incidence of Leptospirosis cases and multiple climatological variables in Cartagena de Indias - Colombia from 2008 to 2017. Cases were collected from the National Public Health Surveillance System of Colombia (SIVIGILA), and meteorological data regarding precipitation, days with precipitation, relative humidity, and average temperature were obtained from the Oceanographic and Hydrographic Research Center (CIOH) located in Cartagena. Additionally, the Oceanic Niño Index (ONI) was used to monitor the “El Niño” and “La Niña” phenomenon across the evaluated period. We identified a total of 360 laboratory-confirmed cases through the study period and an increased incidence of leptospirosis during wet periods with heavy rainfall and rainy days. Almost half of the cases (156/360, 43.4%) occurred during 2010 and 2011. Remarkably, these years had the highest accumulated precipitation. The highest incidence periods consistently occurred during August to December, months that constitute the rainy season in Cartagena. Additionally, “El Niño” and “La Niña” seem to affect the occurrence of leptospirosis cases. Our findings suggest that wet periods and rains are correlated factors to leptospirosis outbreaks in Cartagena. For this reason, these variables could potentially be used as early indicators to establish prevention and control policies in affected areas with a high risk of contagion

0090

#### THE ROLE OF THE UGANDA PUBLIC HEALTH FELLOWSHIP PROGRAM IN UGANDA'S COVID-19 RESPONSE

**Julie R. Harris<sup>1</sup>**, Daniel Kadobera<sup>2</sup>, Steven N. Kabwama<sup>3</sup>, Benon Kwesiga<sup>2</sup>, Lilian Bulage<sup>2</sup>, Amy L. Boore<sup>1</sup>, Alex Ario Riolexus<sup>2</sup>

<sup>1</sup>CDC, Kampala, Uganda, <sup>2</sup>Uganda National Institute of Public Health, Kampala, Uganda, <sup>3</sup>Ugandan National Institute of Public Health, Kampala, Uganda

Local, trained field epidemiologists are key to health security. However, many countries still face shortages in this workforce. Uganda has been working since 2015 to build its field epidemiology capacity through the Public Health Fellowship Program (PHFP). We describe the PHFP and its role addressing COVID-19 in Uganda. PHFP is a two-year, full-time, post-Master's degree field epidemiology training program integrated into the Uganda Ministry of Health (MoH). It is implemented by the US CDC, Makerere University School of Public Health (MakSPH), and MoH. Fellows work in MoH priority host sites under close supervision from host site mentors, PHFP, CDC, and MakSPH staff, and others. They lead outbreak investigations and respond to public health emergencies, conduct planned epidemiologic studies, analyze surveillance data, undergo leadership training, conduct quality improvement projects, and write and present their work. Since 2015, 52 fellows have graduated; 27 are enrolled. Most graduates work for MoH or partners. PHFP fellows conducted 44 COVID-19 response activities from February 2020-March 2021, including 24-hour airport screening, contact tracing, operational readiness assessments at health facilities, investigating infection clusters, evaluating adherence to prevention measures, assessing the impact of COVID-19 among refugees and truckers, and many others. Graduates working for MoH and partners oversaw major activities, including designing and overseeing contact tracing databases and activities, tracking healthcare worker infections, conducting COVID-19 death investigations, designing and executing district trainings, and mentoring investigators. Such activities were sometimes, but not always, responses to direct requests from the MoH or MakSPH. In conclusion, Uganda's response to COVID-19 was strongly supported by PHFP fellows and graduates, who filled key roles and provided critical skillsets otherwise not available in the workforce. Similar programs should be considered to address needs in other countries and increase capacity to respond to public health emergencies.

0091

#### EFFECT OF ALTITUDE ON COVID-19 MORTALITY IN ECUADOR: AN ECOLOGICAL STUDY

**Adriana Campos<sup>1</sup>**, Bridget Scheveck<sup>1</sup>, Jeegan Parikh<sup>1</sup>, Santiago Hernandez-Bojorge<sup>1</sup>, Enrique Terán<sup>2</sup>, Ricardo Izurieta<sup>1</sup>

<sup>1</sup>University of South Florida, Tampa, FL, United States, <sup>2</sup>Universidad San Francisco de Quito, Quito, Ecuador

The SARS-CoV-2/ COVID-19 pandemic has claimed nearly 900,000 lives worldwide and infected more than 27 million people. Researchers worldwide are studying ways to decrease SARS-CoV-2 transmission and COVID-19 related deaths. Several studies found altitude having a negative association with COVID-19 incidence and mortality. Using publicly available province-level Ecuadorian data we performed an ecological study to explore a relationship between altitude and COVID-19. ANOVA, correlation statistics, and a multivariate linear model explored the relationship between different Ecuadorian altitudes against incidence, mortality, and case-fatality rates. Population statistics attributed to COVID-19 were included in the linear model to control for confounding factors. Statistically significant differences were observed in the Amazónica, Sierra, and Costa regions for incidence, mortality, and case fatality rates, suggesting an association between altitude and SARS-CoV-2 transmission and COVID-19 disease severity (p-value  $\leq 0.05$ ). In the univariate analysis, altitude had a negative association to mortality rate with a 1-unit change in altitude resulting in the decrease of 0.006 units in mortality rate (p-value = 0.03). The multiple linear model adjusted for population statistics showed a statistically significant negative association of altitude with mortality

rate ( $p$ -value = 0.01) with a 1-unit change in altitude resulting in the decrease in mortality rate by 0.015 units. This study suggests altitude may influence mortality associated with COVID-19. More research is needed to understand why altitude may have a protective effect against COVID-19 mortality and how this may be applicable in a clinical setting.

0092

### SETTING UP A HEALTH AND DEMOGRAPHIC SURVEILLANCE SYSTEM IN A SEMI-INFORMAL SETTLEMENT: INITIAL EXPERIENCES AND FINDINGS FROM MANYATTA CHAMPS SITE IN KISUMU, KENYA 2016-2018

**Thomas Misore**

*Kenya Medical Research Institute -KEMRI, Kisumu, Kenya*

Lack of effective and comprehensive national civil registration and vital statistics systems in low-middle income countries (LMICs) entail the need for tracking population health using Health and Demographic Surveillance Systems (HDSS). As part of Child Health and Mortality and Prevention Surveillance (CHAMPS), we established an HDSS in Manyatta urban informal settlement in Kisumu county, Kenya to provide a platform for conducting high-priority research and as a primary alternative source of data to extrapolate estimates of national cause-specific mortalities among children < 5 years. We hired and trained a local community-based research team; planned and held consultative meetings with national and community based administrative, political and health leaders; conducted community and household consenting. We mapped boundaries and locations of households and villages from November 2016 to February 2017. We performed an initial population-based census enumeration in 2017 and subsequently repeated household follow up census visits in 2018. Overall, 121 villages, 31,000 households and resident population of 77,800 people (including 11,866 (15.3%) children < 5 years) were mapped and enumerated in 2017. In 2018, the number of mapped households was 3.0% lower than baseline (30,074) and the resident population dropped by ~1% (77,339 people who included 10,016 (12.9%) children < 5 years, 4,900 (6.3%) in-migrants and 1,575 (2%) new births (1,575)). Out-migration and deaths accounted for 5,960 (7.7%) and 204 (0.3) of reduction in the baseline population and 0.1% of initially enumerated households refused further participation. The HDSS launch coincided with the general election held in Kenya in August 2017 and subsequent disputed election results. However, hiring members of our study team from the study region enabled basic surveillance despite displacement of populations due to post-election violence. Although experience in setting up a new HDSS site might vary globally, our Kenyan experience demonstrates feasibility of a strategy that could potentially be replicated in other similar settings.

### PERCEPTIONS AND IMPACT OF COVID-19 ON RESIDENTS IN RURAL COMMUNITY IN BANGLADESH: A QUALITATIVE RAPID ASSESSMENT

**Shahana Parveen<sup>1</sup>**, Maria Maixenchs<sup>2</sup>, Sazzad Hossain<sup>1</sup>, Tonmoy Sarkar<sup>1</sup>, Dalia Yeasmin<sup>1</sup>, Faruq Hussain<sup>1</sup>, Md Shariful Sumon<sup>1</sup>, Kanij Fatima Chanda<sup>1</sup>, Md Reaj Babar<sup>1</sup>, Sanwarul Bari<sup>1</sup>, John Blevins<sup>3</sup>, Emily S. Gurley<sup>4</sup>, Shams El Arifeen<sup>1</sup>

<sup>1</sup>*icddr, Dhaka, Bangladesh*, <sup>2</sup>*ISGlobal, Hospital Clinic-Universitat de Barcelona, Barcelona, Spain*, <sup>3</sup>*Emory Global Health Institute, Atlanta, GA, United States*, <sup>4</sup>*Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States*

Bangladesh has taken multiple steps, to control COVID-19 spread, including restricting human movement. We conducted 16 key informant interviews and 2 focus group discussions (FGD) in rural Baliakandi, Bangladesh to explore perceptions of COVID-19, including transmission and prevention; and the impact of pandemic response on food consumption, healthcare, and livelihoods. Participants included residents previously diagnosed with COVID-19, healthcare providers, drug sellers, and local volunteers with a child health project. Respondents perceived

that international travelers introduced 'Corona' to the country and it then spread from cities to rural areas. Local spread continued through social interactions in public places including mosques, local markets and public transport. To prevent spread, respondents washed hands, wore masks, drank hot water or herbal tea, disinfected household surfaces, refrained from shaking hands and avoided crowds. Residents erected a fence to isolate households of those testing positive but also supplied food and necessities to the household residents. During lockdown, residents primarily sought healthcare, including antenatal and pediatric care, from village doctors or drug shops because of fear of infection from health facilities. Respondents believed that childbirth by unskilled birth attendants increased while movement was restricted. One woman who recovered from COVID-19 and experienced a miscarriage reported that she had not been able to attend antenatal visits and blamed the lockdown for her miscarriage. Healthcare providers reported a low PPE (overall) supply, noting that PPE reuse increased the risk of infection. Food insecurity and financial hardship were widely noted. Members of low-to-middle income groups lost their jobs as businesses were shut. Due to this hardship, residents cut out high-protein foods and stopped non-essential expenditures. Some took out micro-credit loans or sold their land. The findings demonstrate the importance of ensuring access to essential food and healthcare, if movement restrictions are used, to avoid any adverse maternal and child health outcomes.

0094

### MALARIA RESPONSE SYSTEM - A FOUNDATION FOR TARGETED COVID-19 INTERVENTIONS AMONG VULNERABLE POPULATIONS IN SURINAME

**Hedley Cairo**, Erick Oliva Babastro, Geilys Rodriguez Castro, David Rodriguez Lado, Yanexis Calunga Maseo, Alis Anaya Frometa, Loretta Hardjopawiro, Helene Hiwat

*MoH Malaria Program, Paramaribo, Suriname*

To assess the contribution of the Suriname Malaria Program to the national COVID-19 response toward mobile migrant populations. Following the first case of COVID-19 in Suriname in March 2020 the Malaria Program, with support from the Ministry of Health, established capacity for COVID-19 response with a focus on its own priority risk population of mobile migrants. COVID-19 diagnosis was implemented according to national guidelines and protocol, using the structures and expertise that were in place for malaria elimination. Outreach was done using multi-lingual communications, via formal and social media and via the Malaria community health workers. Low threshold access to COVID-19 diagnosis was established by the multilingual health personnel in the Malaria Program clinic. A total of 1446 people were tested for COVID-19 at the Malaria Program clinic between June and December 2020. This constituted 4.5% of the national number of people tested during this period. The overall trend of number of cases over time was in line with the national trend. Non-Surinamese subjects tested (29% of total) were primarily of Brazilian Cuban, Chinese, Venezuelan, and Dominican nationality. A total of 317 people tested COVID-19 positive. The majority of these (91%) were aged between 15 and 59 years old. The overall positivity rate was 21.9% (varying from 5.45.% to 64.79.% per month). High overall positivity rates were found among people of Brazilian (54.03%) and Venezuelan (47.2%) nationalities. Mortality was zero. The health structures and expertise that were in place for Malaria Elimination in Suriname aided a quick and effective COVID-19 response of the Ministry of Health toward (mobile) migrant populations, who were considered a key vulnerable risk group. The high positivity rate among migrants of Brazilian and Venezuelan origin confirmed the need for inclusion of these populations in the national response as well as the need for a targeted approach. This is an example of how (emerging) priority health services can be provided to marginalized populations by integrating them in the capacities already established for infectious diseases, such as malaria.

0095

## USING MHEALTH SMS SURVEYS FOR ACTIVE SURVEILLANCE OF FEBRILE ILLNESS IN KENYA

Javarcia Davon Ivory<sup>1</sup>, Aslam Khan<sup>1</sup>, Francis Mutuku<sup>2</sup>, Bryson Ndenga<sup>3</sup>, Charles Ronga<sup>4</sup>, Omar Godana<sup>5</sup>, Khamisi Mwangosho<sup>5</sup>, Laura Wanjala<sup>4</sup>, Victoria Okuta<sup>4</sup>, Zainab Jembe<sup>5</sup>, Gladys Agola<sup>2</sup>, Amrik Kang<sup>1</sup>, Angelle Desiree LaBeaud<sup>1</sup>

<sup>1</sup>Stanford University, Stanford, CA, United States, <sup>2</sup>Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>4</sup>Jaramogi Odinga Teaching Hospital, Kisumu, Kenya, <sup>5</sup>Likoni Health Center, Mombasa, Kenya

Febrile illness is a common symptom of disease and motivates a substantial portion of healthcare seeking behavior. Current research underestimates the burden of febrile disease, especially in low- to mid-resource settings, such as sub-Saharan Africa, where some febrile illness goes undetected by clinical presentation and passive surveillance. Surveillance data requires advancements to document baseline occurrence and identify etiologies of fever in these settings, such as the contribution of arboviral disease outbreaks. mHealth surveys are an accessible method to report febrile symptoms. Starting in October 2020, we distributed semiweekly, incentivized mobile SMS surveys to a randomized sub-cohort of adult household representatives (n=750) from a larger cohort of participants (n=1353 households) across two clinical study sites in Kisumu and Mombasa, Kenya to surveil febrile disease. Our survey captured the presence and amount of fever in a household, identity of the febrile individual(s), and healthcare-seeking behaviors in five questions. Mean response rates are 55% per survey, and 13% of households report fever on average with minor mean difference across sites (2.2%, p<.01) but comparable temporal trends. The most cited reasons for not seeking care were insufficient money and utilizing home remedies. Using logistic regression, we found respondents who complete over 65% of surveys have more education (OR for college =2.52 [1.58,4.06]) but did not differ on other demographic variables. Survey referrals accounted for 30.9% of clinic sick visits but lacked differences in percentage febrile at presentation compared to walk-in clinic visits. And cases referred via survey follow-up had associations with diagnoses of tonsillitis/pharyngitis (OR=2.71 [1.66,4.45]), upper respiratory tract infections (OR= 0.66 [.46,.95]), and possibly urinary tract infections (4.49 [1.40, 17.01]) but not malaria (OR= 0.82 [.55, 1.21]). Though challenges with validity of self-reported fever, non-response, and technological hurdles remain, these results suggest mHealth surveys may improve follow-up in clinical research efforts.

0096

## GEOGRAPHIC REPRESENTATION OF ACUTE FEBRILE ILLNESS SURVEILLANCE: AN UPDATED GLOBAL SCOPING REVIEW

Casey J. Siesel<sup>1</sup>, Madeline Farron<sup>1</sup>, Angella Sandra Namwase<sup>1</sup>, Grishma A. Kharod<sup>1</sup>, Daniel Rhee<sup>2</sup>, Adam L. Cohen<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>International Vaccine Institute, Seoul, Republic of Korea

Fever is a common symptom that brings many patients to health facilities worldwide. However, etiology can vary significantly by region, exposure, and patient. Moreover, acute febrile illness (AFI) surveillance lacks a clear case definition and a standardized approach, leading to limitations in comparing and interpreting results across settings to understand etiologies. We updated a previously published scoping review (from January 2005-December 2017) to characterize recently published AFI research and identify knowledge gaps to inform future studies and programs. In the update, publications from December 2017-December 2020 were obtained through searches of databases with search terms including “undifferentiated fever,” “acute febrile illness,” and “non-specific fever.” After de-duplication, 258 titles and abstracts were screened; 155 (60%) were excluded as they did not identify AFI etiology or were case reports, clinical trials, outbreak investigations, or lab comparisons. An additional 33 articles were excluded after full text review and the remaining 70 publications were combined with the previous review (190 publications).

Data extraction was performed on 260 publications using a standardized tool to obtain characteristics of study designs and results. Of the six World Health Organization Regions, the South-East Asian Region (SEAR) is most commonly represented in AFI publications (104) with the fewest studies in the European (EUR, 5) and Eastern Mediterranean (19) Regions. Country coverage within all regions was below 50%, with EUR and the African Region (AFR) having the lowest percentage of countries represented in studies (6% and 29%). AFR had the greatest diversity of pathogens investigated (82 pathogens), followed by the Western Pacific Region (60) and SEAR (54). We found significant increases in publications in SEAR and the Region of the Americas, compared with other regions (p<0.05). While the annual number of publications increased from 2005-2020, future AFI studies should aim to expand regional and global understanding of the causes and burden of AFI by focusing on underrepresented geographic settings.

0097

## ACUTE FEBRILE ILLNESS SURVEILLANCE IN TWO URBAN HEALTH FACILITIES IN LIBERIA TO IDENTIFY ENDEMIC AND NEW PATHOGENS

Amanda Balish<sup>1</sup>, Elijah Paa Edu-Quansah<sup>2</sup>, Madeline Farron<sup>1</sup>, G. Burgess Gbelee<sup>3</sup>, Daniel Martin<sup>1</sup>, Gulu Gwesa<sup>4</sup>, Denise Roth Allen<sup>5</sup>, Maame Amo-Addae<sup>2</sup>, Ashaaba Davis<sup>2</sup>, John Dogba<sup>3</sup>, Fahn Taweh<sup>3</sup>, Lekilay Tehmeh<sup>3</sup>, Thelma Nelson<sup>6</sup>, Diabe Dore<sup>7</sup>, Williametta Williams-Gibson<sup>8</sup>, Darwin Operario<sup>9</sup>, Jie Liu<sup>10</sup>, Eric Houpt<sup>9</sup>, Adam Cohen<sup>1</sup>, Marta Guerra<sup>1</sup>, Terrence Lo<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>AFENET, Monrovia, Liberia, <sup>3</sup>National Public Health Reference Laboratory, Monrovia, Liberia, <sup>4</sup>Centers for Disease Control and Prevention, Liberia, Liberia, <sup>5</sup>Centers for Disease Control and Prevention, Monrovia, Liberia, <sup>6</sup>National Public Health Institute of Liberia, Monrovia, Liberia, <sup>7</sup>Star of the Sea Health Center, Monrovia, Liberia, <sup>8</sup>Redemption Hospital, New Kru Town, Liberia, <sup>9</sup>University of Virginia, Charlottesville, VA, United States, <sup>10</sup>University of Virginia, Charlottesville, VA, United States

Little is known about the causes of acute febrile illness (AFI) in Liberia. AFI surveillance can identify known and newly emerging diseases of potential public health importance to inform public health responses, improve clinical care, and build laboratory capacity. We enrolled patients who had measured temperatures of  $\geq 37.5^{\circ}\text{C}$  or self-reported fever in the past seven days in two urban health facilities in Monrovia, Liberia. We collected demographic, clinical, and exposure data. We collected blood samples and conducted an analysis using real-time polymerase chain reactions in the TaqMan Array Card (TAC) format for more than 20 viral, bacterial, and parasitic pathogens. Testing was performed at Liberia's National Public Health Reference Laboratory. We enrolled 1,506 patients with AFI recruited between 12/2018 and 3/2020. Using TAC, we were able to detect an etiology in 47% of the patients that presented with a fever or a history of fever. The median age was 18 years (IQR 7-27) and 463 (31%) were hospitalized. The most commonly detected etiologies included *Plasmodium* spp. [670 (44%)], dengue [16 (1%)], *Streptococcus pneumoniae* [13 (0.8%)], *Rickettsia* spp. [10 (0.7%)], hepatitis E [2 (0.1%)], *Salmonella enterica* [2 (0.1%)], *Neisseria meningitidis* [2 (0.1%)], Lassa Fever [1 (0.07%)], and *Leptospira* spp. [1 (0.07%)]. In conclusion, AFI surveillance and the use of TAC identified nine pathogens, including three (dengue, *Leptospira* spp., and *Rickettsia* spp.) not previously detected in Liberia. Knowledge of circulating high consequence pathogens such as Lassa fever will assist policymakers and public health systems with improved prevention and response. Our findings highlight the need for expanded surveillance systems and laboratory testing capacity for infectious diseases that are endemic or newly emerging in Liberia. Enhanced AFI surveillance will assist with efforts to improve public health systems, clinical care, and laboratory capacity.

## EVALUATION OF OCCUPATIONAL CADRE AND EBOLA VIRUS DISEASE RISK PROFILES DURING PREVENTIVE VACCINATION CAMPAIGN - SOUTH SUDAN, 2019

Rachael Zacks<sup>1</sup>, Sudhir Bunga<sup>2</sup>, Richard Lino Lako<sup>3</sup>, Aimee Summers<sup>1</sup>, John H. Gray<sup>4</sup>, Rosalind Carter<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Centers for Disease Control and Prevention, Juba, South Sudan, <sup>3</sup>Ministry of Health, Juba, South Sudan, <sup>4</sup>World Health Organization, Juba, South Sudan

Healthcare workers are at increased risk for Ebola Virus Disease (EVD) infection due to occupational and community exposures. In response to the 2018-2020 EVD outbreak in the Democratic Republic of Congo (DRC), South Sudan implemented EVD vaccination targeting frontline and health care workers in high-risk states bordering DRC. We described demographics (age), occupational cadre, and EVD risk profiles of vaccinated individuals in South Sudan. Paper campaign vaccination records (January-July 2019) were transcribed into an electronic database to obtain age and occupation. An EVD risk variable was based on the likelihood of occupational exposure with a known or unknown symptomatic EVD infected person and/or body fluids. The variable levels were high, medium, or low. High risk occupations included activities with direct patient contact or direct contact with bodily fluids (e.g., clinicians, cleaners, and laboratorians). Jobs with limited exposure to body fluids were classified as medium risk (e.g., vaccinators and security). The remaining occupations (e.g. social mobilizers, community health workers) were labeled as low risk. Frontline workers included occupations not associated with a designated health facility (e.g., burial team, rapid response team). A total of 2,931 individuals were vaccinated. Of those, all had information on age and 97% (2844/2931) had occupations with identifiable job descriptions. The mean age of vaccinated individuals was 41.1 (SD ±12.6) years. Nursing was the most commonly vaccinated occupation [20% (601/2844)], followed by cleaners [14% (404/2844)] and clinical officers [8% (227/2844)]. High risk occupations made up 61% (1749/2844) of vaccinations, followed by low risk [26% (740/2844)] and medium risk [12% (355/2844)]. Frontline workers made up 4.7% (135/2844). The majority of vaccinations in South Sudan included high risk occupational groups, serving to protect vital occupations and prevent further transmission in the event of an EVD outbreak. In the future, preparedness efforts in countries at risk for EVD outbreaks should prioritize persons in high-risk occupations for vaccination.

## COMMUNITY-BASED SURVEILLANCE OF RESPIRATORY SYNCYTIAL VIRUS IN INFANT MORTALITY: PROTOCOL FOR MINIMALLY INVASIVE TISSUE SAMPLING STUDY IN PAKISTAN

Waliyah Mughis<sup>1</sup>, Saima Jamal<sup>1</sup>, Nazia Ahsan<sup>1</sup>, Ayub Khan<sup>1</sup>, Yasir Rauf<sup>1</sup>, Christina Arif<sup>1</sup>, Farah N. Qamar<sup>1</sup>, Zeeshan Uddin<sup>1</sup>, Fauzia A. Malik<sup>2</sup>, Saad B. Omer<sup>3</sup>, Abdul Momin Kazi<sup>1</sup>

<sup>1</sup>Aga Khan University, Karachi, Pakistan, <sup>2</sup>Yale School of Public Health, Yale University, New Haven, CT, United States, <sup>3</sup>Yale School of Public Health; Yale Institute for Global Health, Yale University, New Haven, CT, United States

The burden of hospitalization and mortality of young infants due to respiratory syncytial virus (RSV) is estimated to be high, compounded by challenges in obtaining post-mortem specimens in religiously conservative community settings. To understand the underlying pathology of RSV and to improve classification of upper respiratory tract infections in deceased infants, minimally invasive tissue sampling (MITS) was incorporated into an ongoing parent study of community-based nasopharyngeal specimen collection from recently deceased infants. The primary study objective is to assess and analyze the burden and determinants of respiratory syncytial virus mortality by obtaining nasopharyngeal swabs and lung/thorax MITS specimens in deceased infants (<6 months of age) in peri-urban HDSS

catchment areas of Karachi, Pakistan. Outcome measures include RT-PCR findings of nasopharyngeal swab specimens and lung tissue, and a histopathology report of lung tissue specimens, to improve classification of upper respiratory tract infections. Specimens were collected in a designated purpose-built vehicle parked outside community households. During the study formative phase, strategies to implement surveillance were formulated, such as using religious rulings and key community partners to help gain parental consent, and a purpose-built van was used in community-based specimen collection for infant mortality surveillance in Pakistan for the first time. Innovations included bringing the laboratory to the household and developing an in-house data program (e-CRFs, monitoring system through live dashboard and social media platform) for documenting death alerts and specimen collection. These measures allowed us to collect 13 lung/thorax tissue and 14 nasopharyngeal specimens between November 2020 and March 2021. There are many operational, cultural challenges in obtaining minimally invasive tissue specimens from deceased infants in the community. A designated vehicle can be utilized, along with community mobilizers, health workers and leaders advocating for the study procedure to obtain parental consent for lung/thorax MITS.

## ADDRESSING COVID-19 RUMORS AND BEHAVIORS USING THEORY IN GUYANA

Camille Adams<sup>1</sup>, Bolanle Olapeju<sup>2</sup>, Joann Simpson<sup>1</sup>, Sean Wilson<sup>1</sup>, Gabrielle Hunter<sup>2</sup>, TrishAnn Davis<sup>3</sup>, Lyndsey Mitchum<sup>3</sup>, Alicia Martin<sup>4</sup>, Shabana Shaw<sup>4</sup>, Jennifer Orkis<sup>3</sup>, Douglas Storey<sup>3</sup>

<sup>1</sup>Breakthrough ACTION Guyana, Georgetown, Guyana, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, BALTIMORE, MD, United States, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>4</sup>Guyana Ministry of Health, Georgetown, Guyana

The USAID-funded Breakthrough ACTION project, in collaboration with the Guyana Ministry of Health, developed a theory-based rumour tracking system to inform the existing national COVID-19 communication campaign. Breakthrough ACTION used the Extended Parallel Processing Model (EPPM) to identify rumors that reflected perceived vulnerability to COVID-19 ("Is the rumour associated with a belief that people are vulnerable to COVID-19?") and self-efficacy to engage in recommended COVID-19 prevention behaviors ("Is the rumour associated with the belief that people feel enabled/able to take action to mitigate COVID-19?"). Rumors were categorized as high versus low perceived vulnerability and self-efficacy, respectively. Contextually relevant social and behavior change messages, called "MythBusters", were designed based on the EPPM rumor classification model. Most rumors emanated from Region 4 (29%) and Region 8 (25%). Two-thirds of the rumors (67%) were recurring. Rumors were typically related to COVID-19 treatment (32%) and transmission (31%). Most rumors (38%) reflected high perceived vulnerability and low self-efficacy, 29% reflected low perceived vulnerability and low self-efficacy, 24% reflected high perceived vulnerability and high self-efficacy, while 9% reflected low perceived vulnerability and high self-efficacy. A total of 38 MythBusters were developed to address these rumors. These were integrated into the national COVID-19 communication campaign, disseminated via radio, television, and Facebook, and are estimated to have reached the majority of the Guyanese population. The EPPM was found to be a particularly useful tool in giving direction on countering myths with appropriate messaging to affect relevant behaviours. The COVID-19 MythBusters provided the Guyanese public with valid and verifiable information in addition to promoting preventive and protective behaviours.

### IMPLEMENTATION OF MULTIPLEX BEAD ASSAY AT THE NATIONAL REFERENCE LABORATORY, NIGERIA CENTRE FOR DISEASE CONTROL, GADUWA, ABUJA-NIGERIA: A AESOURCE LIMITED SETTING

**Mudiaga K. Esiekpe**<sup>1</sup>, Ayuba B. Dawurung<sup>1</sup>, Patricia Nathan<sup>1</sup>, Elizabeth Adeboyejo<sup>1</sup>, Ndidi Agala<sup>1</sup>, Erasogie Evbuomwan<sup>2</sup>, Chimaoge Achugbu<sup>2</sup>, Ado Abubakar<sup>1</sup>, Nnaemeka Ndodo<sup>2</sup>, Stacie Greby<sup>3</sup>, Nnaemeka Iriemenam<sup>3</sup>, McPaul Okoye<sup>3</sup>, Orji Bassey<sup>3</sup>, Eric Rogier<sup>4</sup>, Gretchen Cooley<sup>4</sup>, Melissa Coughlin<sup>4</sup>, Nishanth Parameswaran<sup>4</sup>, Sarah Gwyn<sup>4</sup>, Mahesh Swaminathan<sup>3</sup>, Diana Martin<sup>4</sup>, Nwando Mba<sup>2</sup>, Chikwe Ihekweazu<sup>2</sup>

<sup>1</sup>Institute of Human Virology Nigeria, Abuja, Nigeria, <sup>2</sup>Nigeria Centre for Disease Control, Abuja, Nigeria, <sup>3</sup>United States Centers for Disease Control and Prevention, Nigeria Country Office, Abuja, Nigeria, <sup>4</sup>United States Centers for Disease Control and Prevention, Atlanta, Atlanta, GA, United States

Serologic assays can monitor population exposure to pathogens and population immunity estimates for vaccine-preventable diseases (VPDs). Multiplex bead assays (MBA) test for multiple analytes simultaneously, which has cost and time advantages compared to single-analyte immunoassays. We used dried blood spot (DBS) specimens collected from the Nigeria HIV/AIDS Indicator and Impact Survey (NAIS), a nationally-representative sample of >200,000 people of all ages, to assess for exposure to 19 infectious diseases VPDs, and malaria antigens. We established an MBA Laboratory equipped with MAGPIX™ instruments at the National Reference Laboratory (NRL), Nigeria Centre for Disease Control (NCDC), in Gaduwa, Nigeria. A year of planning included development and approval of a study protocol, identification of support for funding from multiple sources, and establishing a laboratory workflow for high-volume antibody and antigen testing. DBS from children 0-14 years of age and a subset of women of reproductive age (WRA) were prioritized. Staff from US Centers for Disease Control and Prevention conducted site visits to NRL to assess infrastructure requirements and coordinate support. MBA laboratory leads were first trained on MBA laboratory management and then staff were trained on testing DBS using MBA. Infrastructure support, including equipment and supplies, was provided. A plan for ongoing technical assistance and logistical support, including monthly in-person site visits and routine shipments, was started in 2019. The plan was heavily modified in 2020 due to COVID mitigation efforts in Nigeria and the United States. Weekly videoconferences replaced site visits when travel was restricted. Within five months of starting testing, the NRL MBA Laboratory completed antibody and antigen assays for approximately 42,000 NAIS specimens (~10,000 DBS from WRA and ~32,000 DBS from children 0-14 years). Data from these assays supported Nigerian requests for funding for the childhood immunization program and the next round of malaria program support from Global Fund. The remaining specimens from adults are currently undergoing analysis.

### FORMATIVE PHASE OF COMMUNITY-BASED SURVEILLANCE OF INFANT RESPIRATORY SYNCYTIAL VIRUS - MINIMALLY INVASIVE TISSUE SAMPLING STUDY IN PAKISTAN

**Nazia Ahsan**<sup>1</sup>, Waliyah Mughis<sup>1</sup>, Saima Jamal<sup>1</sup>, Syeda Quratulain Zaidi<sup>1</sup>, Farah N. Qamar<sup>1</sup>, Fauzia A. Malik<sup>2</sup>, Saad B. Omer<sup>2</sup>, Norman Goco<sup>3</sup>, Christina Paganelli<sup>3</sup>, Abdul Momin Kazi<sup>1</sup>

<sup>1</sup>Aga Khan University, KARACHI, Pakistan, <sup>2</sup>Yale University, New Haven, CT, United States, <sup>3</sup>RTI International, Durham, NC, United States

We conducted a community-based RSV mortality surveillance and minimally invasive tissue sampling study in deceased infants in low-income areas of Karachi, Pakistan. Our study objective is to explore the acceptability of minimally invasive tissue sampling (MITS) of lungs/thorax and nasopharyngeal swab collection from deceased infants under 6 months of age and stillbirths, in 2 peri-urban areas of Karachi. We conducted 21 in-depth interviews and 2 focus group discussions with key

stakeholders, including parents of deceased infants, community leaders and elders, religious leaders, graveyard undertakers, bathers, burial good vendors, and physicians to ascertain perceptions and barriers regarding MITS. The stakeholders commented on the feasibility and appearance of a potential MITS collection van, that the van should be like a fully equipped ambulance. Most agreed that the sampling van could be parked outside households for sample collection. Formative phase findings indicated community fears about the MITS procedure involving removal of body organs from infants. Religious leaders recommended obtaining and using MITS religious rulings (fatwas) & seeking permission from different ethnicities/communities. Respondents also identified possible challenges in taking the infant body from household to van, since it is not religiously permissible to cause pain or harm to the deceased body, but parents would require counseling concerning the benefits of MITS to save upcoming generations. Respondents' beliefs, religious and community buy-in are the key to success of MITS surveillance phase. The deceased infant's parents appreciated grief support home visits, counseling and cause of death consultation visit by a doctor. This study showed bereaved parents want to know more about their child's cause of death. This study suggests community stakeholders' involvement along with healthcare professionals to explain MITS procedure and purpose of collecting MITS samples in a van in the community. Potential barriers and facilitators were identified at the community level, for local tailoring of exhortations for future MITS surveillance studies.

0103

### IMPROVING VITAMIN A COVERAGE THROUGH INTEGRATION WITH SEASONAL MALARIA CHEMOPREVENTION: AN IMPLEMENTATION RESEARCH IN RURAL AND URBAN SETTINGS IN NIGERIA

**Olusola B. Oresanya**<sup>1</sup>, Abimbola Phillips<sup>1</sup>, Ebenezer Ikechukwu<sup>1</sup>, Emmanuel Shekerau<sup>2</sup>, Ogechi Akalonu<sup>3</sup>, Perpetua Uhomobhi<sup>2</sup>, Nneka U. Onwu<sup>3</sup>, Helen Counihan<sup>4</sup>, Jane Achan<sup>5</sup>

<sup>1</sup>Malaria Consortium, Abuja, Nigeria, <sup>2</sup>National Malaria Elimination Programme, Abuja, Nigeria, <sup>3</sup>National Primary Health Care Development Agency, Abuja, Nigeria, <sup>4</sup>Malaria Consortium, London, United Kingdom, <sup>5</sup>Malaria Consortium, Kampala, Uganda

Vitamin A deficiency is associated with a 3 to 12-fold increase in mortality from acute gastroenteritis, pneumonia, and measles. Though vitamin A supplementation (VAS) can reduce all-cause under-five mortality by 24 percent, its coverage remains low in Nigeria (49%). Seasonal malaria chemoprevention (SMC), targeting children under-five in the Sahel region, including over 12 million children in Nigeria, provides a ready platform for VAS delivery to improve coverage and access. A preliminary feasibility study integrating SMC and VAS in one local government area (LGA) in northwest Nigeria in 2019 provided evidence for improved VAS coverage (from 2% to 59%, p-value =0.001). While it also demonstrated a good fit with the SMC infrastructure and high acceptability among providers and beneficiaries, there were other questions unanswered. A follow up study aims to provide more answers and strengthen the evidence to support policy adoption regarding full integration of VAS with SMC campaigns at scale, targeting twice as many children as the initial pilot. The study objectives are therefore, to design and implement, in collaboration with key stakeholders, an integrated SMC plus VAS campaign in diverse settings – urban and rural; develop and implement a research uptake plan; assess the feasibility (including effectiveness, equity, efficiency, safety and cost), and acceptability of integration among caregivers, field implementers, and policy makers. The primary research question is: what is the effect of full integration of SMC and VAS at scale on vitamin A coverage, SMC coverage, safety, equity, efficiency and cost? This implementation research will use a convergent mixed methods approach to arrive at an overall descriptive evaluation of feasibility and acceptability. The study is planned to take place between May and October 2021 in two LGAs, Bauchi State, Northeast Nigeria. The data sources will include cross-sectional pre- and post-intervention surveys with a sample size of 540 children aged 6-59

months; focus group discussions among health workers, caregivers and community distributors, and key informant interviews among key stakeholders.

0104

### UNDERSTANDING INDIVIDUAL AND COMMUNITY CARE-SEEKING BEHAVIORS DURING COVID-19 PANDEMIC IN NIGERIA

**Oluseye Ayodele Ajayi<sup>1</sup>**, Olanbojo Okunlola Ogunsola<sup>1</sup>, Kucheli Wudiri<sup>1</sup>, Yewande Toluwabori Akinro<sup>1</sup>, Olatunbosun Abolarin<sup>1</sup>, Prosper Okonkwo<sup>1</sup>, McPaul Okoye<sup>2</sup>, Michele Montandon<sup>3</sup>, Laura Steinhardt<sup>4</sup>, Julie Gutman<sup>4</sup>, Jessica Butts<sup>5</sup>, Shelby Cash<sup>5</sup>

<sup>1</sup>APIN Public Health Initiatives, Abuja, Nigeria, <sup>2</sup>Division of Global HIV/AIDS and Tuberculosis, Center for Global Health, Centers for Disease Control and Prevention, Abuja, Nigeria, Abuja, Nigeria, <sup>3</sup>Maternal and Child Health Branch, Division of Global HIV and Tuberculosis, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, Atlanta, GA, United States, <sup>4</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, Atlanta, GA, United States, <sup>5</sup>U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, Atlanta, GA, United States

Understanding individual and community care seeking behaviours is important for maximizing receipt of critical health services. Factors that influence sub-optimal use of health services, especially during public health emergencies like COVID-19, should be determined to tailor behavioural interventions to promote continued prompt care seeking. A cross-sectional household (HH) survey was conducted in January–February 2021 among women of reproductive age in Benue and Plateau states, Nigeria, to assess predictors of intentions to seek care for fever during the COVID-19 pandemic. A compact segment sampling technique was used to select 500 HH from catchment areas of 50 health facilities (HF); one woman was interviewed per HH. Factors assessed were knowledge on fever care, risk perception, self-efficacy to seek care, attitude towards care-seeking, perception of outpatient department (OPD) providers, and community norms on care seeking. Individual factors and sample means of settlement clusters for community factors, including proportion of HH who normally seek fever care (0: < 25%, 1: ≥25% <50%, 2: ≥50% <75%, 3: ≥75%), decision-making autonomy for fever care (0 = index respondents, 1 = others), and community perceptions of HF safety during COVID-19 (0 = unsafe, 1 = safe) were included in a logistic regression model. We interviewed 500 women; 92.8% were married. Mean age was 31 years. Individuals' knowledge of fever care (OR = 1.31, p = 0.05), risk perception of fever illness (OR = 1.40, p <0.01), self-efficacy to seek care (OR = 1.58, p <0.01) and positive perceptions of OPD providers (OR = 1.28, p = 0.001) were positively related to intention to seek fever care. Those that perceived care seeking for fever as a community norm were more likely to seek fever care (OR = 3.20, p = 0.05). Fever care seeking behaviour was associated with individual- and community-level factors. Effective social and behavioural change programs in the era of COVID-19 may benefit from a holistic approach that addresses both individual and community level factors. In this study population, such an approach would engage women caregivers as well as their catchment HF and providers.

0105

### NEGOTIATING MYANMAR'S LAW AND (DIS)ORDER AMIDST ANTIMICROBIAL RESISTANCE POLICY IMPLEMENTATION

**Yuzana Khine Zaw<sup>1</sup>**, Ja Seng Baw<sup>2</sup>, Coll de Lima Hutchison<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Independent Consultant, Yangon, Myanmar

The WHO has declared antibiotic resistance (often referred to as antimicrobial resistance, AMR) an emergency and co-authored a Global Action Plan (GAP) to address it. Over a hundred countries have already followed the WHO's prescription and adopted their own national action plans. Myanmar, prior to the 2021 coup, was one of them and had actively

promoted their NAP as the solution to the issue of AMR in Myanmar. Additionally, global health policymakers have identified Myanmar, like other countries in Asia, as a source of high drug resistance and informal pharmaceutical markets, in need of tighter state regulation. On paper, the Myanmar government appeared to be following the WHO's AMR GAP. However, in our article we show that in practice the realities are very different, this difference is further pronounced after the February 2021 military coup. We foreground historical and contemporary aspects of Myanmar and draw on extensive in-depth ethnographic research to explore how global plans for AMR, such as restricting access to antibiotics, when it merges with national action on drug regulation can end up dramatically deviating from the intentions of the WHO GAP and its values. Our paper argues that those working to promote the regulation of medicines must attend more carefully and explicitly to different modes of political governance, state sovereignty, histories of health systems and rule of law rather than uncritically and apolitically pushing state-centric programmes. Otherwise, they risk contributing to, if not intensifying, already existing health inequities and social injustices, whilst also failing to generate their intended outcomes, such as meaningful changes to antibiotic sales and reductions in resistance.

0106

### PROTECTING HEALTHCARE PERSONNEL FROM COVID-19 INFECTION: ARE WE DOING ENOUGH? NIGERIA EXPERIENCE

**Olanbojo Okunlola Ogunsola<sup>1</sup>**, Yewande Toluwabori Akinro<sup>1</sup>, Oluseye Ayodele Ajayi<sup>1</sup>, Kucheli Wudiri<sup>1</sup>, Olatunbosun Abolarin<sup>1</sup>, Prosper Okonkwo<sup>1</sup>, Michele Montandon<sup>2</sup>, Paul Malpiedi<sup>3</sup>, McPaul Okoye<sup>4</sup>, Shelby Cash<sup>5</sup>, Jessica Butts<sup>5</sup>, Julie Gutman<sup>6</sup>, Laura Steinhardt<sup>6</sup>

<sup>1</sup>APIN Public Health Initiatives, Abuja, Nigeria, <sup>2</sup>Division of Global HIV/AIDS and Tuberculosis, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, Atlanta, GA, United States, <sup>3</sup>Division of Healthcare Quality Promotion, National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, Atlanta, GA, United States, <sup>4</sup>Division of Global HIV/AIDS and Tuberculosis, Center for Global Health, Centers for Disease Control and Prevention, Abuja, Nigeria, Abuja, Nigeria, <sup>5</sup>U.S. President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, USA, Atlanta, GA, United States, <sup>6</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, USA, Atlanta, GA, United States

Health workers (HWs)' risk for contracting COVID-19 increases in settings with higher community transmission of COVID-19 and strained health systems. It is vital for health systems to protect HWs as they carry out their duties. We conducted an evaluation to assess measures for COVID-19 prevention among health facilities (HFs) and HWs in Benue (30 HF) and Plateau (20 HF) states in Nigeria. Various HF types (public, private, primary health centres, hospitals) supported by PEPFAR or PMI were purposively sampled. HF assessments of COVID-19 prevention measures were conducted in January–February 2021 using a checklist adapted from CDC infection prevention and control (IPC) tools. The HF in charge and 1-2 additional HWs providing clinical care were randomly selected, interviewed, and observed on COVID-19 prevention measures and compliance using pretested tablet-based questionnaires. Data were analysed using Stata 16. Only 27 of 50 HFs (54%) had an IPC committee, and 10 (20%) had written IPC policies. While 34 (68%) HFs had functional hand hygiene stations, only 7 (14%) had uninterrupted supplies of personal protective equipment (PPE). Of 199 HWs interviewed, 81 (41%) had been trained on IPC in the context of COVID-19; 112 (56%) reported continuous access to medical masks during patient consultations, and 163 (82%) had access to functional hand hygiene stations. Half (n=100) of the HWs interviewed perceived their HF had adequate PPE to keep them and their patients safe from COVID-19 exposure. Survey teams observed HWs during patient consultations and reported that all HWs practiced hand hygiene during patient consultations in only 28 (56%) HFs. Similarly, all HWs were observed wearing face masks in only 6 (12%) HFs. Overall, gaps existed in IPC administrative structures, HW trainings, access to COVID-19

IPC materials, and compliance with COVID-19 prevention measures among HFs and HWs in these two states of Nigeria. Additional support for establishing IPC committees, training HWs on IPC measures, and provision of continuous PPE and IPC materials is warranted to improve IPC practices in health care settings.

0107

### FACTORS INFLUENCING INTENTIONS TO SEEK CARE FROM COMMUNITY HEALTH WORKERS FOR CHILDHOOD ILLNESS IN THE COVID-19 CONTEXT IN UGANDA—DECEMBER 2020

Denis Okethwangu<sup>1</sup>, Shelby Cash<sup>2</sup>, Elizabeth Katana<sup>3</sup>, Bob Omoda<sup>3</sup>, Daniel Emong<sup>3</sup>, Peter Oumo<sup>3</sup>, Doreen Gonahasa<sup>3</sup>, Josephine Namayanja<sup>3</sup>, Aggrey Byaruhanga<sup>3</sup>, Phoebe Nabunya<sup>3</sup>, Patricia Thiwe<sup>3</sup>, Umaru Ssekabira<sup>1</sup>, Julie Harris<sup>4</sup>, Lauren Lewis<sup>2</sup>, Anna Bowen<sup>2</sup>, Julie Gutman<sup>2</sup>, Jessica Butts<sup>2</sup>

<sup>1</sup>Infectious Diseases Institute, Kampala, Uganda, <sup>2</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Uganda Public Health Fellowship Program, Kampala, Uganda, <sup>4</sup>Centers for Disease Control and Prevention, Kampala, Uganda

Management of childhood illness by community health workers (CHW) is a critical component of healthcare in Uganda; unfortunately, care-seeking from CHWs declined during the COVID-19 pandemic. We conducted a cross-sectional household survey in Moyo and Adjumani Districts in December 2020 to assess caregivers' intentions to seek care for sick children, attitudes, and perceptions of CHWs, and community norms during the COVID-19 pandemic. We used composite scores to evaluate responses, logistic regression to identify factors associated with intentions to seek care, and Pearson's chi-squared test to compare proportions. Of 306 women (18-49 years) interviewed, intention to seek prompt care from a CHW was higher for fever (94%) than cough (67%;  $p$ -value<0.01). Most (93%) respondents perceived that CHWs provide high quality services; 89% were confident in CHW's COVID-19 preventive measures. The perception that they and their family were at risk for COVID-19 was higher among respondents intending to seek care for a child's cough than for fever (86% vs. 78%,  $p$ -value=0.03). Respondents intending to seek care recognized that cough (42%) and fever (47%) could have potentially severe consequences. Of those intending to seek fever and cough care, 87% and 80%, respectively, believed the majority of their community would also promptly seek care for similar symptoms (perceived norms). The multivariable analysis included COVID-19 risk perception, perceived symptom severity and community norms; intention to seek prompt cough care was significantly associated with COVID-19 risk perception (adjusted odds ratio (aOR)=2.8, 95%CI: 1.3-5.3) and perceived norms (aOR=3.0, 95%CI: 1.4-4.7). Intention to seek prompt fever care was not significantly associated with any explored variable. Despite overall positive regard for CHWs, including their COVID-19 prevention measures, there is a behavioral gap in prompt care-seeking from CHWs, particularly for cough. Social and behavior change interventions highlighting risks of COVID-19 and promoting community norms of prompt care-seeking could help to close this gap and improve the health and safety of communities.

0108

### COVID-19 SEROLOGY CONTROL PANEL FOR SEROSURVEILLANCE AND CALIBRATION OF IMMUNOLOGICAL TEST PLATFORMS

William Jonathan Windsor<sup>1</sup>, Molly M. Lamb<sup>1</sup>, Leah Huey<sup>2</sup>, Gillian Andersen<sup>2</sup>, Patricia Merkel<sup>2</sup>, Vijaya Knight<sup>2</sup>, May Chu<sup>1</sup>

<sup>1</sup>University of Colorado, Aurora, CO, United States, <sup>2</sup>Children's Hospital Colorado, Aurora, CO, United States

Currently, there are >60 serology diagnostic tests on the FDA EUA list and 70 serology test kits in the CE-marked European market. A review of 200 serosurveillance papers showed there are many more laboratory-developed tests being used in clinics and research laboratories. With so many tests in use and lack of standardized material to evaluate their performance, it is imperative that we prioritize quality calibration of test performance,

especially in low resource settings. In summer of 2020, the University of Colorado developed the COVID-19 Serology Control Panel (CSCP), a kit of five well-characterized dried tube specimens with strong/weak/negative SARS-CoV-2 reactivity for laboratories to use: (1) to evaluate SARS-CoV-2 serology platforms, (2) as a training resource, and (3) as an inter/intra-laboratory comparator. The CSCP materials were sourced from pooled donor convalescent plasma and characterized by multiple test platforms (ELISA, multiplex bead array, focus reduction neutralization, and pseudovirus neutralization) against target antigens (S, N, RBD). The CSCP kit contains 5 coded samples: strong/ reactive, weak reactive and non-reactive. All dried CSCP samples retained reactivity for up to 6 months after continuous storage at -20°C, 4°C, and 25°C. The strong reactive CSCP sample had equivalent reactivity to the WHO International Standard (NIBSC 20/136). Samples were stable at ambient temperature for international shipments to laboratories in Australia, Africa, and Asia. Preliminary CSCP results from 15 laboratories showed 88%, 70% and 90% inter-laboratory concordance respectively for the strong/weak/negative samples. Widespread use of the CSCP to compare COVID-19 antibody tests will help laboratories reinforce confidence in their results and deter other laboratories from poorly performing tests. Additionally, the CSCP will help clinical laboratories inform their decision when choosing COVID-19 antibody tests. The CSCP could serve as the connecting calibrator samples in vaccine efficacy and serosurveillance studies.

0109

### THE EFFECT OF NOVEL SCABICIDES ON SCABIES-ASSOCIATED BACTERIAL PATHOGENS

Sara Taylor<sup>1</sup>, Deonne Walther<sup>2</sup>, Kylie Agnew-Francis<sup>2</sup>, Deepani D. Fernando<sup>1</sup>, Craig Williams<sup>2</sup>, Katja Fischer<sup>1</sup>

<sup>1</sup>QIMR Berghofer MRI, Brisbane, Australia, <sup>2</sup>University of Queensland, Brisbane, Australia

Scabies has a prevalence of approximately 300 million cases, and is one of the most common infectious dermatological diseases. As of 2017 it is recognised as a neglected tropical disease by the World Health Organization. Prevalence is high in tropical regions where there is an established link between scabies and severe secondary bacterial infections. Research has demonstrated that scabies mites promote opportunistic bacterial infections, especially with *Staphylococcus aureus* and *Streptococcus pyogenes*. As scabies is a neglected disease the molecular biology of these mites and their associated pathogens is poorly understood. We aim to provide the fundamental knowledge required to deliver better treatment outcomes to patients, and to understand the role scabies mites play in severe secondary bacterial infections. This research investigated the antimicrobial effects of emerging scabicides on the most relevant scabies pathogens. Using the broth micro dilution method, the Minimum Inhibitory Concentration (MIC) and the Minimum Bactericidal Concentration of these drugs was determined for 3 strains each of *S. aureus*, *S. pyogenes* and *A. baumannii*. The strains investigated were selected to provide an overview of clinical, laboratory and pathogenic strains. The research found that Manuka Oil and its Beta-Triketones exhibit antimicrobial activity on *S. aureus*, *S. pyogenes* and *A. baumannii*. The MIC for these pathogenic bacteria are lower than the effective concentration for scabies mites and eggs. The emerging head lice treatment Abametapir also exhibited antimicrobial activity against gram positive bacteria but had limited effectiveness on gram negative bacteria. Pre-clinical trials are underway to determine the effectiveness of Abametapir and Manuka Oil on scabies mites, and on the associated microbial communities to determine the effectiveness of these drugs at controlling scabies-associated secondary bacterial infections. This research will help to determine new effective treatment protocols for the control of scabies and its associated diseases.

### SURVEILLANCE GAP ANALYSIS AND ECOLOGICAL NICHE MODELING OF MEDICALLY IMPORTANT TICK DISTRIBUTIONS IN EAST AFRICA

Alec G. Richardson<sup>1</sup>, Michael E. von Fricken<sup>2</sup>, David B. Pecor<sup>1</sup>, Alexander Potter<sup>1</sup>, Mary Frances Kearney<sup>3</sup>, Graham A. Matulis<sup>2</sup>, Stephanie Mitchell<sup>4</sup>, Rachel Wofford<sup>2</sup>, Dawn Zimmerman<sup>5</sup>, Katherine Mertes<sup>6</sup>, James Hassell<sup>5</sup>, Yvonne Marie Linton<sup>1</sup>

<sup>1</sup>Walter Reed Biosystematics Unit (WRBU/WRIR/ISI), Suitland, MD, United States, <sup>2</sup>George Mason University, Fairfax, VA, United States, <sup>3</sup>University of Michigan, Ann Arbor, MI, United States, <sup>4</sup>Center for Species Survival, Smithsonian Institution National Zoological Park and Conservation Biology Institute, Washington, DC, United States, <sup>5</sup>Global Health Program, Smithsonian Institution National Zoological Park and Conservation Biology Institute, Washington, DC, United States, <sup>6</sup>Conservation Ecology Center, Smithsonian Institution National Zoological Park and Conservation Biology Institute, Front Royal, VA, United States

Tick-borne disease outbreaks impacting human and animal health are a growing concern in East Africa. Effective disease mitigation depends on accurate vector distribution data, elucidation of variables governing habitat suitability, and development of robust ecological niche models (ENMs) to accurately predict disease risk and inform health policy decision-makers. A comprehensive distribution compendium detailing tick distributions in five East African countries (Chad, Djibouti, Ethiopia, Kenya, Uganda) was generated using surveillance data produced by our project, VectorMap records, and a systematic online literature search of over 300 published papers. Collection records represented 721,628 counts of 105 tick species distributed in 1358 unique occurrences in 30 of the 52 collective states of these countries. *Amblyomma variegatum* and *Rhipicephalus appendiculatus* accounted for 11% of total observations and 39% of total abundance, respectively. Tick occurrence and abundance rates were highest in Ethiopia (45%) and Kenya (52%), respectively, and lowest in Chad (0.2% and 0.1%). Species diversity was highest in Kenya (based on incidence) and Djibouti (based on abundance) and lowest in Chad, likely reflecting limited historical faunal surveys. Surveillance gap analysis identified key sites for future surveillance to increase sample size, minimize sampling bias, and provide a geospatially equitable distribution of sampling effort for future modeling analyses. Significant topographic and bioclimatic covariates governing habitat suitability were identified for each targeted medically important species. Statistically robust ENMs were developed using species-specific covariates in the MaxEnt maximum entropy model to generate habitat suitability maps. Model predictions reflected the geospatial distribution of the collection records. Regions of low predicted suitability may be due to unfavorable environmental conditions and/or inadequate sampling effort. Sampling bias can be alleviated iteratively by sampling targeted sites, augmenting collection records for modeling, and conducting follow-up gap analyses.

0111

### SEROPREVALENCE OF SPOTTED FEVER GROUP AND TYPHUS GROUP RICKETTSIAE IN THREE INDIGENOUS COMMUNITIES OF THE PERUVIAN AMAZON

Maria Alejandra Caravedo, Miguel Cabada, Lucas Blanton  
University of Texas Medical Branch, Galveston, TX, United States

Spotted fever group (SFG) and typhus group (TG) rickettsiae are widely distributed vector-borne bacteria. Infection results in an acute undifferentiated febrile illness. In Peru, rickettsioses are seldom recognized - likely due to their undifferentiated signs and symptoms and lack of testing capability. We conducted a study to determine the seroprevalence of SFG and TG antibodies in an indigenous population in the southeastern Peruvian rainforest. An evaluation of a Water-Sanitation-Hygiene Education program was performed in three communities (Yomibato, Tayacome and Huacaria) of the southeastern Peruvian rainforest in October 2019. Asymptomatic children and adults were asked to answer a health questionnaire, provide a stool sample to evaluate for helminth infections,

and a blood sample to evaluate for anemia. One drop of this blood was blotted on Whatman paper, left to dry at room temperature, and packed individually. The dry blood blots were identified only by the subjects' code and sent to the University of Texas Medical Branch for serologic analysis for rickettsiae. The subjects belonged to the Matzigenska ethnic group living in isolation inside the Manu Natural Reserve. Sera were eluted by cutting a 4 mm punch from each blood blot and placing in 250 µl of phosphate buffered saline at 4°C overnight. Samples were tested for SFG and TG antibodies using the indirect immunofluorescence assay (IFA). Samples were considered reactive if titers were ≥ 1:128. Sera from 352 participants were tested by IFA. The mean age was 15.9, females represented 52.1%, and 59.8% were from the community of Yomibato. SFG antibodies were detected in 4/352 (1.1%). From reactive samples, 2 were from Yomibato and 2 from Tayacome communities. None of the specimens demonstrated reactive TG antibodies. In conclusion, in this indigenous young asymptomatic population from the Peruvian Amazon, we found a low but demonstrable seroprevalence to SFG rickettsiae. We found no evidence of seropositivity to TG organisms. Additional studies to determine circulating rickettsial agents and vectors in this region should be pursued.

0112

### RNA INTERFERENCE IN SARCOPTES SCABIEI EGGS: A USEFUL TOOL TO FIND NOVEL OVICIDAL DRUGS

Deepani D. Fernando<sup>1</sup>, Robin B. Gasser<sup>2</sup>, Katja Fischer<sup>1</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>2</sup>University of Melbourne, Melbourne, Australia

Scabies is a parasitic skin disease caused by the burrowing mite *Sarcoptes scabiei*. It is a worldwide problem with high morbidity and the secondary complications caused by pathogenic bacteria can be life threatening. Current treatments for scabies are suboptimal, mainly due to their lack of ovicidal activity. A female mite lays 2-3 eggs per day and this is the main amplification step in the scabies mite life cycle. RNA interference (RNAi) is a powerful tool to investigate genes encoding proteins that can potentially be targeted in therapeutic intervention. RNAi has not been widely established for parasitic mite eggs. Here we establish a method to introduce double-stranded RNA (dsRNA) into scabies mite eggs and induce gene silencing. Eggs were treated with sodium hypochlorite to increase the eggshell permeability. Double stranded RNA (dsRNA) intake was determined using fluorescent tagged dsRNA. *S. scabiei* Deadpan, a single copy gene with predicted functions in embryo development, was used as the target gene. Eggs were incubated with 2.5 µg/µl of dsRNA encoding a fragment of the target gene or the *E. coli* LacZ gene (negative control) at room temperature for 24h. Gene expression was quantified by quantitative PCR and the data were normalised with expression data of the *S. scabiei* EF1alpha gene. The results were analysed by student t test. RNAi-treated eggs were also incubated at 37°C for 3 days to observe hatchability. Eggs immersed in *S. scabiei* Deadpan dsRNA showed significant reduction ( $p < 0.05$ ) in gene expression ( $21913 \pm 7536$  copies/µl) compared to the negative control ( $105620 \pm 25190$  copies/µl). In addition,  $46.67 \pm 7.265\%$  hatchability reduction was observed when incubated with Deadpan dsRNA compared to the negative control. Our findings suggest that the RNAi can be achieved in the scabies mite eggs *in-vitro*. The *S. scabiei* Deadpan gene is potentially contributing to egg hatching and may be a therapeutic target.

### ANALYSIS OF IGG RESPONSES TO THE 34K2 SALIVARY PROTEINS FROM AEDES ALBOPICTUS AND AE. AEGYPTI TO ASSESS HUMAN EXPOSURE TO ARBOVIRAL VECTORS

Sara Buezo Montero<sup>1</sup>, Paolo Gabrieli<sup>2</sup>, Anne Poinsignon<sup>3</sup>, Bi Zmable Hubert Zamble<sup>3</sup>, Franck Remoue<sup>3</sup>, Bruno Arci<sup>1</sup>

<sup>1</sup>Sapienza University of Rome, Rome, Italy, <sup>2</sup>University of Milan, Milan, Italy, <sup>3</sup>MIVEGEC, University of Montpellier, IRD, CNRS - Montpellier, France, Montpellier, France

The rapid world-wide spread of *Aedes albopictus*, a vector of arboviral diseases like chikungunya, dengue or Zika, points up the need for better

vector surveillance and control. Human antibody response to mosquito salivary antigens is emerging as a relevant additional tool to directly assess vector-human contact, monitor efficacy of control interventions and evaluate the risk of arboviral transmission. Recently, we showed that IgG responses to the *Ae. albopictus* 34k2 salivary protein (al34k2) appear suitable to evaluate seasonal and spatial variations of human exposure to *Ae. albopictus* in conditions of natural exposure in a non-endemic area of Italy. The aim of this study was the validation of the al34k2 antigen in epidemiological settings with ongoing arboviral transmission maintained by *Ae. albopictus*. ELISA were used to measure human IgG responses to the al34k2 in adults from an area of Reunion Island where *Ae. aegypti* is absent and *Ae. albopictus* represents the unique vector of chikungunya. In addition, to check the specificity and/or cross-reactivity of this biomarker, we also analyzed the IgG responses i) of the same individuals from Reunion Island to the orthologous 34k2 salivary protein from *Ae. aegypti* (ae34k2) and ii) of Bolivian subjects, only exposed to *Ae. aegypti*, to both al34k2 and ae34k2. A group of French individuals, not exposed to either *Ae. albopictus* and *Ae. aegypti*, was used as control group. Individuals from Reunion showed significantly higher IgG responses to al34k2 than to ae34k2 validating this antigen as a good and specific marker of human exposure to *Ae. albopictus* in an endemic area. In contrast, IgG responses to the ae34k2 showed in both areas a low specificity and yielded a relatively high background, even in unexposed controls. These results provided a clear evidence that IgG responses to al34k2 may represent a suitable marker of human exposure to *Ae. albopictus*. On the contrary, the *Ae. aegypti* orthologue ae34k2 does not appear suitable as marker of human exposure to *Ae. aegypti* due to the unspecific IgG response and a high background.

#### PRELIMINARY BLOOD MEAL ANALYSIS OF CULICOIDES SPECIES IN LEISHMANIA (MUNDINIA) ENRIETTII COMPLEX- ENDEMIC REGION IN GHANA

Godwin Kwakye-Nuako<sup>1</sup>, Priscilla Abena Ankamaa Opare<sup>1</sup>, Mba-Thissommah Mosore<sup>2</sup>, Seth Offei Addo<sup>2</sup>, Mary E. Wilson<sup>3</sup>

<sup>1</sup>University of Cape Coast, Cape Coast, Ghana, <sup>2</sup>Department of Parasitology, U.S. Naval Medical Research Unit No. 3, Noguchi Memorial Institute for Medical Research, University of Ghana, Legon, Accra, Ghana, <sup>3</sup>University of Iowa, Departments of Internal Medicine, Infectious Diseases, Microbiology and Immunology, and the Veterans' Affairs Medical Center, Iowa City, IA, USA, Iowa City, IA, United States

Cutaneous leishmaniasis (CL), since 1992, has been endemic in the south-eastern part of Ghana. During the periods 2002 and 2003, a total of 8876 human leishmaniasis were recorded in this endemic focus. The *Leishmania* parasites have long been known to be transmitted by female phlebotomine sand fly vectors. However, in recent laboratory models of infection studies, the new species of *Leishmania* belonging to the *Leishmania* (*Mundinia*) *enriettii* complex found in Ghana does not survive in sand flies but rather, multiply and develop successfully in *Culicoides* species. *Culicoides* species are distributed worldwide and are capable of transmitting several infectious agents including parasites. In this study we analyze the hosts feeding preferences of *Culicoides* found in the leishmaniasis endemic foci in Ghana to expedite the study of a member of *Leishmania* (*Mundinia*) *enriettii* complex transmission routes and vector implication. The biting midges were collected in August to December 2019 at two weeks intervals using CDC light traps and sweep nets. A total of 185 midges were collected, pooled together in groups of ten and subjected to DNA extraction. Molecular analyses were conducted using the universal mammalian primers (Mammal-F, Mammal-R) in the meantime. PCR revealed that 34.7% of flies collected fed on mammalian hosts. The primers amplified the 772bp band size which is the identical to the size of the mammalian amplified product. This result indicates that the *Culicoides* analyzed so far prefer mammalian host for blood meal. The preliminary results obtained indicate the host preferences of some *Culicoides* species feed on mammals. We conclude that *Culicoides* species collected in the

CL endemic communities can potentially serve as a vector for the novel *Leishmania* species found in Ghana. Keywords: Ghana, *Leishmania* (*Mundinia*) *enriettii* complex, *Culicoides* species

0115

#### INCRIMINATING CULICOIDES BITING MIDGES AS VECTORS OF HUMAN CUTANEOUS LEISHMANIASIS IN GHANA AND VALIDATION OF STANDARD LIGHT TRAPS AGAINST EXPLICIT HUMAN BITING RATES

Priscilla Abena Ankamaa Opare<sup>1</sup>, Godwin Kwakye-Nuako<sup>1</sup>, Marion England<sup>2</sup>

<sup>1</sup>University of Cape Coast, Cape Coast, Ghana, <sup>2</sup>The Pirbright Institute, Surrey, United Kingdom

Human cutaneous leishmaniasis (CL) is a neglected tropical disease endemic to some communities in Ghana and is caused by a newly identified species of *Leishmania* belonging to the *L. enriettii* complex. The vector(s) responsible for transmitting human CL in Ghana remain unknown as very few sandflies have been collected in the various endemic foci in Ghana. Previous laboratory investigations have shown that the new species of *Leishmania* colonized and replicated successfully within the gut of *Culicoides* biting midges. In this study, we validated CO<sub>2</sub>-baited CDC light traps against human landing catches (HLC) for *Culicoides* and sandflies caught in the endemic Ho district of Ghana and characterised the *Culicoides* fauna to incriminate species of *Culicoides* as vector candidates responsible for CL in Ghana. *Culicoides* biting midges and sandflies were collected from May 2020 to August 2020 using CO<sub>2</sub>-baited CDC light traps and filtered mechanical aspirators for HLCs. Light traps and human volunteers were rotated around four collection locations using a Latin square design. A morphological key was developed for the identification of *Culicoides* midges collected. Statistical analyses were carried out using R to determine whether CO<sub>2</sub>-baited light traps could be accurately used as a proxy for human biting rates. Significantly, more *Culicoides* were collected by HLCs than by the traps (p<0.001) showing that CO<sub>2</sub>-baited CDC traps do not accurately reflect biting rates of *Culicoides* on humans. *Culicoides grahami* (98.5%) were the predominant species identified from both CDC traps and HLCs. Other species were identified in very small numbers (1.5%) and included *C. imicola*, *C. inornatipennis*, and *C. leucostictus*. Therefore, *C. grahami* is proposed as the putative vector of *Leishmania* in the Ho District of Ghana.

0116

#### UTILITY OF MALDI-TOF MS IN SPECIES IDENTIFICATION AND BLOOD MEAL ANALYSIS

Jonathan K. Karisa, Kelly Ominde, Martin Rono, Philip Bejon, Joseph Mwangangi, Maureen Laroche, Marta Maia  
KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya

Jonathan Karisa<sup>1,2,3</sup>, Kelly Ominde<sup>3</sup>, Martin Rono<sup>1,2,3</sup>, Philip Bejon<sup>3,4</sup>, Joseph Mwangangi<sup>1,3</sup>, Maureen Laroche<sup>3</sup>, Marta Maia<sup>3,4</sup>

<sup>1</sup>Pwani University, Department of Biological Sciences, <sup>2</sup>Pwani university Bioscience Research Centre (PUBReC), <sup>3</sup>KEMRI-Wellcome Trust Research Program, Bioscience department, <sup>4</sup>University of Oxford, Centre for Global Health and Tropical Medicine, Oxford, UK

Protein profiling using MALDI-TOF MS is a promising technology in the field of medical entomology. Studies have shown its ability to rapidly identify mosquito species and their associated blood meal sources. The technology overcomes challenges posed by the current methods used for entomological surveillance. The purpose of this study was to test the discriminative power of MALDI-TOF MS to distinguish between members of *An. gambiae* complex collected in coastal Kenya and their trophic preferences. Template mosquitoes obtained from the field and insectary were characterized using gold standard approaches. Proteins were extracted from legs and abdomens of individual mosquitoes for spectra acquisition and ClinProTools software was used for preprocessing and database creation. A total of 167 *An. gambiae* produced quality spectra

that were subsequently used for database creation and validation (query). These comprised of *An. merus* (143), *An. arabiensis* (n=34) and a pool of 45 *An. gambiae* s.s. (Kilifi strain) mosquitoes from the insectary were also processed. MALDI-TOF MS provided accurate identification of members of *An. gambiae* complex collected in the field including *An. arabiensis* (31/31) and *An. merus* (139/139) and insectary (*An. gambiae* s.s.) (40/40). Analysis of abdominal proteins of blood fed mosquitoes provided accurate identification of host sources. Majority of the samples had fed on Goat (n=63), Bovine and Human (n=6) and the rest (n=3) had fed goat-bovine. This study provides further evidence on the utility of MALDI-TOF MS approach for entomological surveillance by accurately identifying *An. gambiae* sibling species and their associated blood meals.

### SPOTLIGHT REPORTS: TICKS AND TICK-BORNE DISEASE THREATS IN ETHIOPIA

**Rachel Wofford<sup>1</sup>**, Graham Matulis<sup>1</sup>, David Pecor<sup>2</sup>, Alexander Potter<sup>2</sup>, Michael von Fricken<sup>1</sup>, Bersissa Kumsa<sup>1</sup>, Dawn Zimmerman<sup>3</sup>, Yvonne-Marie Linton<sup>2</sup>

<sup>1</sup>George Mason University, Fairfax, VA, United States, <sup>2</sup>Walter Reed Biosystematics Unit (WRBU), Suitland, MD, United States, <sup>3</sup>Smithsonian's National Zoological Park and Conservation Biology Institute, Washington, DC, United States

Tick-borne diseases are a rising health concern across Africa. Understanding the geographic distribution of ticks at the country level can inform Ethiopian and international stakeholders about potential pathogens in circulation. Over 6,000 peer-reviewed articles from 1901-2020 were systematically screened for data meeting our inclusion/exclusion criteria. A total of 116 articles met final inclusion criteria with data extraction and geo-referencing, before being combined into a single database. Tick species identified came from seven different genera including five hard ticks (*Amblyomma*, *Haemaphysalis*, *Hyalomma*, *Ixodes*, and *Rhipicephalus*) and two soft tick genera (*Argas* and *Ornithodoros*). Fifteen species of *Rhipicephalus* ticks were reported, followed by 11 different species of *Hyalomma* ticks. The most commonly survey tick species was *Amblyomma variegatum* (Fabricius, 1794) with approximately 64% of articles detecting this species; with *Rhipicephalus decoloratus* Koch, 1844 and *Rhipicephalus evertsi* s.l. in 61% and 57% of studies, respectively. A total of 28 pathogens were reported in Ethiopian ticks, including medically important genera: *Anaplasma*, *Borrelia*, *Coxiella*, *Ehrlichia*, *Haemoplasma*, *Rickettsia*, *Theileria*, and *Trypanosoma*, along with four viruses (Congo, Dugbe, Jos and Thogoto). *Amblyomma* and *Rhipicephalus* ticks were the most commonly reported genera with identifiable pathogens. The data collected from this systematic review provides valuable information on historic high-risk areas for transmission of tick-borne disease, as correlated with tick vector distributions, and can be used to enhance ongoing surveillance and targeted sampling efforts.

### STUDY OF RED MEAT ALLERGY USING A MOUSE MODEL WITH BITES OF THE LONE STAR TICK, *AMBLYOMMA AMERICANUM*

**L. Paulina Maldonado-Ruiz**, Gunavanthi D. Boorgula, Yoonseong Park

Kansas State University, Manhattan, KS, United States

Recent studies have provided strong evidence supporting the Lone star tick bites as a cause of red meat allergy (RMA) in humans. RMA is caused by an increase of Immunoglobulin E (IgE) antibody production against galactose-alpha-1,3-galactose (aGal), which is a common glycan in mammals with the exceptions of old world monkey and human. The main factor causing the RMA, the lone star tick (*Amblyomma americanum*), is broadly distributed throughout the East and Midwest of the United States, which is also a vector of a wide range of human and animal pathogens. We previously found that the salivary glands of male and female ticks contained high levels of aGal epitopes after

feeding on bovine blood. In our current work, we aimed to test whether the ticks mediate the transmission of the aGal sensitizer, acquired from non-human blood to humans through salivary secretions. In the course of tick feeding in the field, intrastadial host switches in completely fed ticks could occur as an episode of transmission of the aGal sensitizer. To test this hypothesis, we used an alpha-galactosyltransferase knockout mutant mouse (aGT-KO) model system, where untreated ticks (unfed) and pretreated ticks (partially fed with bovine blood) were placed. Using the enzyme-linked immunosorbent assay (ELISA), we measured the IgE and IgG levels, the total and specific antibody against aGal, after tick feedings with the pretreated ticks. Our results showed that aGT-KO mice significantly responded to tick feedings and injections of aGal (Gal $\alpha$ 1-3Gal $\beta$ 1-4GlcNAc) conjugated to human serum albumin or mouse serum albumin (aGal-HAS or aGal-MSA) by increased total IgE and aGal-specific IgE compared to those in C57BL/6 control mice. All the treatments by tick feedings with pretreated and untreated ticks functioned as sensitizer for increased specific IgE against aGal with large individual variations. This study confirmed that the aGT-KO mouse can be used as the model for RMA study while more study is required for understanding the individual variations in the immune responses to aGal.

Ticks and their associated pathogens pose a significant risk to animal and human health in the Sahel, where pastoralist lifestyles increase the interface and possibility of zoonotic spillover. To augment our surveillance activities in Chad, to develop effective risk assessments for tick-borne diseases of humans and livestock, additional high-quality surveillance data is needed to better document the distribution and pathogen-association of ticks in Chad. A systematic literature review was conducted to compile tick surveillance data from peer-reviewed literature. In this systematic review, terms were searched within titles and abstracts in PubMed, CABI, Web of Science, Scopus, with date limits of 1901–2020 in languages limited to English and French. Reported surveillance findings were standardized using

the VectorMap data schema and collection localities were georeferenced. This search generated 114 unique titles for literature in Chad, of which 35 articles met inclusion criteria for a full review and 2 articles produced extractable data meeting *a priori* inclusion criteria. These articles produced surveillance records for two unique taxa: *Hyalomma impeltatum* Schulze and Schlottke, 1930; *Rhipicephalus decoloratus* Koch, 1844 as well as an unconfirmed collection of *Hyalomma* spp. Limited pathogen detection data indicates TBDs may be found in Chad, however more surveillance is needed to confirm prevalence. While rigorous in approach, our literature search produced a limited output of useable data again highlighting the need for additional surveillance. Chad remains largely un-surveyed, increasing the importance of our current active biosurveillance efforts in the country.

0120

### MOSQUITOES FROM CO-ENDEMIC AREAS OF MALARIA AND DENGUE IN CENTRAL EASTERN AND SOUTHWESTERN VIETNAM: BIODIVERSITY AND BARCODE

Vu Sinh Nam<sup>1</sup>, Nicholas J. Martin<sup>2</sup>, Hertz C. Jeffrey<sup>2</sup>, Trang Cong Tu<sup>1</sup>, Tran Vu Phong<sup>1</sup>, Dang Duc Anh<sup>1</sup>, Tran Nhu Duong<sup>1</sup>, Maysa T. Motoki<sup>3</sup>

<sup>1</sup>National Institute of Hygiene and Epidemiology, Hanoi, Viet Nam, <sup>2</sup>U.S. Naval Medical Research Unit TWO, Singapore, Singapore, Singapore, <sup>3</sup>Walter Reed Biosystematics Unit, Entomology Department, College Park, MD, United States

A mosquito survey with focus on those recognized as vectors of malaria and dengue was carried out to assess the diversity of mosquitoes (Diptera: Culicidae) in Khanh Thanh and Cau Ba communes, Khanh Hoa Province (central-eastern), and Bu Gia Map and Dac O communes, Binh Phuoc Province (south-western) in October 2018 and March 2019. In order to confirm species level diversity, an integrated identification approach based on morphological diagnostic characters of adult mosquitoes using taxonomic keys, in conjunction with DNA barcoding sequences was conducted. A total of 4,702 specimens were collected, including 23 taxa. Among them, many specimens of the main dengue vectors, *Aedes (Stegomyia) aegypti* (Linnaeus) and *Ae. (Stg.) albopictus* (Skuse), and many secondary vectors were found in greater abundance. Although, fewer of the main malaria vectors, *An. (Cel.) dirus* Peyton and Harrison and *An. (Cel.) minimus* Theobald were found. Sequences of the mitochondrial DNA (mtDNA), cytochrome c oxidase subunit I (*COI*) gene are presented for 42 individuals. *Anopheles dissidens* Taai & Harbach and *An. wejchoochotei* Taai & Harbach comprise new country records. Sequences of *COI* were useful to distinguish species complex/groups. The high density of secondary malaria vectors was not adequate to estimate the risk of malaria transmission. However, in both studied provinces malaria is still a problem, and dengue a major threat. Additional ecological and vector status studies are required to understand the importance of sympatric secondary malaria and primary dengue vector species, which may impact the implementation of strategies to prevent human infections of both diseases in Vietnam. This study provides diversity and molecular taxonomic information and emphasizes the significance on the use of molecular data as an integrated systematic approach in mosquito taxonomy.

0121

### METAGENOMIC PROFILE OF THE MICROBIAL COMMUNITIES ASSOCIATED WITH ANOPHELES DARLINGI FROM NORTHWESTERN COLOMBIA

Juan C. Hernández-Valencia<sup>1</sup>, Giovan F. Gomez<sup>2</sup>, Stefani Piedrahita<sup>1</sup>, Juan P. Velez<sup>1</sup>, Margarita M. Correa<sup>1</sup>

<sup>1</sup>Grupo de Microbiología Molecular, Escuela de Microbiología, Universidad de Antioquia, Medellín, Colombia, <sup>2</sup>Grupo de Investigatin Bioforense, Tecnológico de Antioquia Institucion Universitaria, Medellín, Colombia

*Anopheles* mosquitoes harbor microbial communities that carry out an essential role in their biology given the functional association with their host. *Anopheles darlingi* is the main malaria vector in the Neotropics,

and one of the primary malaria vectors in Colombia. In this work, the metagenomic profile of the *Anopheles darlingi* microbiota was characterized in mosquitoes from an important malaria-endemic region of Colombia using RNA-seq methodology. Field collected *An. darlingi* were grouped into two pools of 15 specimens each. RNA was extracted, and rRNA depleted cDNA libraries were prepared. Sequencing was performed on Illumina NovaSeq at 60M PE reads. Sequencing quality was determined with FastQC, and host reads were excluded from analysis by mapping against the *An. darlingi* genome (A\_darlingi\_v1). The metagenomic classification was performed through *K-mer* matches ( $K = 31$ ) against the One-Codex Database under the *Lowest Common Ancestor* concept (LCA). A total of 137,977,398 reads were obtained; 1,562,976 of these were classified as of microbial origin. Fungi comprised the highest number of reads (55.7%), followed by Bacteria (39.5%), Protista (4.8%), and Archaea (0.02%). The phyla with the highest number of reads were, in Bacteria: *Proteobacteria*, *Actinobacteria*, *Bacteroidetes*, and *Firmicutes*; Fungi: *Basidiomycota* and *Ascomycota*, and Protists: *Bacillariophyta* and *Apicomplexa*. Only 230 reads corresponded to Archaea with the phyla *Euryarchaeota* and *Crenarchaeota*. Furthermore, the sequencing depth and workflow implemented allowed identifying more than 800 microbial genera in the two *An. darlingi* pools. This work shows the first microbial profile for *An. darlingi* and confirms previous observations about the wide microbial diversity in mosquitoes. The results showed that metagenomic classification by RNA-seq allows a reasonable resolution of this mosquito microbiota composition. Determining the microbial-communities composition of disease vectors will allow future work to investigate the effect of these microorganisms on mosquito biology and the detection of vector control candidates.

0122

### A HABITAT SUITABILITY MODEL FOR AMBLYOMMA AVARIEGATUM (FABRICIUS, 1794) IN KENYA

Mary F. Kearney<sup>1</sup>, Graham Matulis<sup>2</sup>, Michael von Fricken<sup>3</sup>, David B. Pecor<sup>4</sup>, Alexander Potter<sup>4</sup>, Alec G. Richardson<sup>4</sup>, Maureen Kamau<sup>5</sup>, Laura Caicedo-Quiroga<sup>4</sup>, Dawn Zimmerman<sup>6</sup>, James Hassell<sup>6</sup>, Yvonee-Marie Linton<sup>4</sup>

The tick *Amblyomma variegatum* (Fabricius, 1794) is an important vector of both human and animal diseases across Africa. In Kenya alone, numerous etiological agents of parasitic, bacterial, and viral diseases have been detected in this species. Thus, understanding the ecological parameters governing the distribution of this species is imperative to predict and mitigate disease outbreaks. This study investigated the potential distribution of *A. variegatum* in Kenya by creating an ecological niche model, using presence-only collection data compiled during a systematic literature review of data records (1901–2020), and accessing publicly available data resources such as VectorMap. A covariate significance analysis was performed to assess the relative significance of 25 environmental and climatic variables associated with predicting habitat suitability. Six significant covariates were determined through the covariate significance analysis: flow accumulation, soil demography, precipitation seasonality, isothermality, precipitation of wettest quarter, and

annual precipitation. These variables were used to model *A. variegatum* distribution in Kenya using the maximum entropy (MaxEnt) approach. Our results indicate distinct variation in habitat suitability and highlight the need for additional *A. variegatum* surveillance in some regions of Kenya.

0123

### DISSECTING THE ROLE OF ORNITHINE DECARBOXYLASE IN SUGAR- AND BLOOD-FED AEDES AEGYPTI FEMALES

Natthida Petchampai<sup>1</sup>, Jun Isoe<sup>2</sup>, Patricia Y. Scaraffia<sup>1</sup>

<sup>1</sup>Tulane University, New Orleans, LA, United States, <sup>2</sup>The University of Arizona, Tucson, AZ, United States

We previously reported that ornithine decarboxylase (ODC) mRNA levels increased in the fat body of RNAi-driven xanthine dehydrogenase1-deficient *Aedes aegypti*, suggesting that polyamines play a key role in mitigating ammonia and free radical toxicity. To identify the potential role of polyamines in the regulation of nitrogen (N) disposal we performed several molecular and biochemical analysis on ODC (EC 4.1.1.17), an enzyme that catalyzes the decarboxylation of ornithine into putrescine, the first and rate-limiting step in the polyamine synthesis. First, we monitored the ODC gene expression in tissues dissected from sugar- and blood-fed mosquitoes by qPCR. We found that ODC transcript levels in fat body increased at 6 h post blood meal (PBM) and reached a peak of expression at 36 h PBM compared to control, whereas the relative abundance of ODC mRNA in midgut and Malpighian tubules increased between 12 h and 36 h PBM. These peaks of ODC expression coincide with the timing of intense blood meal digestion (12-24 h) and N waste synthesis and excretion (12-48 h). In thorax, the ODC mRNA abundance increased at 12 h and 24 h PBM and reached a peak of expression at 36 h PBM, whereas in ovary, ODC transcript levels increased at 72 h PBM and reached the highest abundance at 96 h PBM. Next, we monitored the ODC protein expression in mosquito tissues by western blotting using a custom-made *A. aegypti* ODC antibody. We observed a distinct ODC protein expression in different tissues dissected from sugar- and blood-fed mosquitoes during the first gonotrophic cycle. We are currently analyzing the phenotypes of ODC knockdown by RNAi. Mosquitoes injected with dsRNA-ODC started to exhibit a significant mortality at 48 h PBM compared to control group. A dramatic decrease in survival at 10 days post-injection was observed, with approximately 66% survival rate compared to the control group. At 22 days after dsRNA injection, 100% of dsRNA-ODC mosquitoes died. In addition, we have observed that ODC deficiency causes a reduction of N waste excretion and a decrease of female fecundity. Overall, our results indicate that ODC plays a critical role in blood-fed *A. aegypti* metabolism.

0124

### FLYNAP (TRIETHYLAMINE) IS A SUITABLE ANESTHETIC FOR BIOLOGICAL ASSAYS IN MOSQUITOES

Keri Oxendine Harp<sup>1</sup>, Katelyn Cavender<sup>1</sup>, Ilse A. Ortega Eguia<sup>1</sup>, Catherine Hunt<sup>1</sup>, Priscila Bascunan<sup>1</sup>, Mark Q. Benedict<sup>1</sup>, Ellen M. Dotson<sup>2</sup>

<sup>1</sup>CDC Foundation, Atlanta, GA, United States, <sup>2</sup>Centers for disease control and prevention (CDC), Atlanta, GA, United States

Mosquitoes are often anesthetized when studying certain physiological and behavioral life-history traits. Cold and CO<sub>2</sub> are commonly used sedatives for several insect species; however, these require samples to be continuously exposed to low temperatures or CO<sub>2</sub>, which can adversely affect their fitness. Some alternatives include chemical compounds such as chloroform and triethylamine (commercially known as FlyNap<sup>®</sup>). Chloroform is frequently used for entomological procedures and requires safety measures because of its toxicity, whereas FlyNap is a non-toxic component that has long been used in *Drosophila* spp. studies. However, the effectiveness and potential fitness cost of using these compounds for mosquito experimentation have been poorly evaluated. We analyzed the effectiveness of using a small volume (20µl) of chloroform or of FlyNap on a cotton ball placed over the mesh of a cup containing 30 mosquitoes and introduced into a glass container with a lid. Male and

female *Anopheles gambiae* were independently exposed to one of the two chemicals at different exposure times (30 sec, 1 min, 5 min), and their recovery and survival rates were recorded over three days. Results from three biological replicates indicated that FlyNap-treated mosquitoes remained anesthetized for significantly ( $P < 0.05$ ) longer (2-5 hrs.) than chloroform-treated individuals (15 min-1 hr.) regardless of exposure time or sex. Also, survival was not affected by either sedative when exposed for 30 sec, however, increased mortality was observed when exposing mosquitoes to FlyNap for 1 or 5 minutes compared to shorter exposure times or any of the exposures with chloroform. Our results indicate that FlyNap is an alternative for mosquito anesthesia, with a significantly longer recovery time and no impact on survival when using 20µl for up to 30 sec compared to chloroform. The effectiveness of FlyNap and chloroform on other vector species (*Aedes aegypti*, *Culex quinquefasciatus*) as well as on forced mating and fecundity, fertility, and pupation rates in *Anopheles dirus* are currently being assessed. \*Use of this product does not constitute an endorsement.

### THE IMPACT OF PARTIAL BLOOD MEALS ON MOSQUITO MIDGUT INTEGRITY AND ARBOVIRUS DISSEMINATION

Rebecca Johnson, Duncan Cozens, Zannatul Ferdous, Philip Armstrong, Douglas Brackney

The Connecticut Agricultural Experiment Station, New Haven, CT, United States

Studies of vector competence rarely consider the impacts that successive blood meals have on arboviral transmission by mosquitoes. *Aedes aegypti* mosquitoes readily feed more than once and often take partial blood meals. The effect this behavior has on viral transmission needs to be better understood and incorporated into models of mosquito-borne disease epidemics. Previously it was shown that *Ae. aegypti* infected with dengue virus (DENV) via a primary blood meal had earlier viral dissemination when given a second non-infectious blood meal three days later. Evidence suggests that gut distention during blood feeding leads to damage of the midgut basal lamina and faster viral escape. While mosquitoes are usually allowed to feed to repletion in the laboratory, mosquitoes in the wild are often interrupted and only acquire partial blood meals. Therefore, we examined the effects that partial blood feeding has on midgut basal lamina damage and DENV dissemination. To assess midgut basal lamina integrity, we performed a collagen hybridizing assay on cohorts of *Ae. aegypti* given either a full, partial or no blood meal. *Ae. aegypti* provided a partial blood meal had an intermediate degree of damage compared to fully engorged or naive cohorts. We also assessed whether the size of a second blood meal impacted damage and if damage accumulated across blood meals. Mosquitoes given a partial blood meal three days after an initial full feed had less midgut damage than mosquitoes given a full second blood meal, but more damage than the cohorts provided no additional blood meals. Thus, midgut damage appears proportional to distention and feeding volume and is not cumulative. Consistent with this, individuals provided a partial second blood meal had an intermediate early dissemination phenotype for DENV. This indicates that damage from a partial feed is sufficient to cause accelerated dissemination, further demonstrating the significance of sequential blood meals on arbovirus epidemiology. This work has strong implications for our understanding of disease transmission in the field and will be useful in creating more accurate models of viral spread and maintenance.

### A NEW MOSQUITO MIDGUT PROTEIN AGAP008138 FACILITATES PLASMODIUM FALCIPARUM TRANSMISSION IN ANOPHELES GAMBIAE MOSQUITOES

Julian Ramelow<sup>1</sup>, Guodong Niu<sup>2</sup>, Diana Romero<sup>2</sup>, Jun Li<sup>3</sup>

<sup>1</sup>Herbert Wertheim College of Medicine, Florida International University, Miami, FL, United States, <sup>2</sup>Biological Sciences, Florida International University, Miami, FL, United States, <sup>3</sup>Biological Sciences and Biomolecular Sciences Institute, Florida International University, Miami, FL, United States

Malaria is one of the most dangerous tropical infectious diseases: up to 229 million new clinical infections occur every year, with an annual death toll of about 500,000. The malaria mosquito vector, *Anopheles gambiae*, is largely responsible for *Plasmodium falciparum* transmission and spreading of malaria. Some mosquito midgut proteins are critical for malaria invasion, as the *P. falciparum* ookinetes travel through midgut endothelial cells and develops into oocysts between the endothelia and basal membrane. Hence, the discovery of a new key protein facilitating the invasion of ookinetes into the mosquito midgut will aid to uncover a molecular infection mechanism. To date, parasite transmission and the many specific pathways the parasite utilizes to gain access into the midgut, remain unclear and paradoxical. We hypothesize that parasitic malaria transmission to humans relies on the interaction with specific mosquito midgut proteins. Earlier groundwork by our lab revealed several protein candidates, including AGAP008138, that have shown to interact with parasites. In order to investigate the transmission potential of AGAP008138 and carry out further analysis, mosquitoes were infected with *P. falciparum* parasites and anti-AGAP008138 IgG at various concentrations. The oocysts and mosquitoes were dissected 7 days post-infection. The results demonstrated that IgG antibodies specifically target AGAP008138 and significantly reduce the number of oocysts as compared to the control. This shows that AGAP008138 assists in malaria transmission and could be a potent target for malaria control.

### X-RAY TOMOGRAPHY AS A USEFUL TECHNIQUE TO EXPLORE THE TIMELINE OF MOSQUITO PROBOSCIS DEVELOPMENT

Irene Arnoldi<sup>1</sup>, Paolo Gabrieli<sup>2</sup>

<sup>1</sup>IUSS, Pavia, Italy, <sup>2</sup>University of Milan, Milan, Italy

We characterized the morphological features of the head and the buccal apparatus of larvae, pupae and adult mosquitoes of the species *Aedes albopictus*, *Aedes aegypti* and *Anopheles stephensi* using X-ray Tomography. The datasets were acquired using a synchrotron light source. This approach represents a valid alternative to Transmission Electron Microscopy analysis, due to challenging embedding and sectioning into resins of the cuticular layer covering appendices of mosquito proboscis and pupal case. The adult mosquito proboscis is composed of an external sheet retracted during feeding, the labium, and of a fascicle of stylets which penetrates the host skin. The labrum forms the entry of the food channel, the hypopharynx carries the salivary duct, and two pair of mandibles and toothed maxillae are used to penetrate the host skin. How and when this apparatus forms during development is unknown. We collected a total of 48 datasets, 25 from *Aedes albopictus* (4<sup>th</sup> instar larva, 24 female pupae at different time points after pupation, 7 male pupae, female and male adults), 11 from *Aedes aegypti* (4<sup>th</sup> instar larva, 9 female pupae and the female adult), 12 from *Anopheles stephensi* (4<sup>th</sup> instar larva, 10 female pupae and the female adult). The datasets were analysed in both the absorption based and edge-enhanced radiography using Gridrec and Paganini reconstruction pipelines at the synchrotron facility. 3D reconstruction and segmentations have been carried out using Slicer 3D software. Our analyses provide new insights into the development of mosquito during pupal metamorphosis, particularly our focus was the mouth apparatus. We were able to compare male and female differential development and highlight similarity and differences comparing close-related (*Ae. aegypti* Vs *Ae. albopictus*) or distantly related species (*Aedes*

vs *Anopheles*). Our study sets a step-forward in the study of mosquito development and the datasets that we have generated might be used to study other organs.

0128

### TOWARDS A MALE LETHAL SEXING STRAIN OF ANOPHELES STEPHENSI MOSQUITOES FOR THE MANUFACTURE OF PFSPZ VACCINES

Ehud Inbar<sup>1</sup>, Abraham G. Eappen<sup>1</sup>, Robert A. Harrell<sup>2</sup>, Robert T. Alford<sup>2</sup>, Maryam Hosseini<sup>1</sup>, Donald Ward III<sup>1</sup>, B. Kim Lee Sim<sup>1</sup>, Stephen L. Hoffman<sup>1</sup>, Peter F. Billingsley<sup>1</sup>

<sup>1</sup>Sanaria Inc., Rockville, MD, United States, <sup>2</sup>Biotechnology Research, University of Maryland, Rockville, MD, United States

Sanaria® PfSPZ Vaccine and PfSPZ-CVac vaccines are composed of aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ), and are manufactured using aseptically grown *Anopheles stephensi* female mosquitoes. Removing male mosquitoes at the embryonic stage using conditional expression of a male specific lethal gene will make the aseptic rearing process of immature mosquito stages up to 100% more efficient at no additional cost. We identified a number of unique regions on the Y-chromosome that are targets for CRSPR/Cas9 homology directed repair (HDR) to integrate lethal gene for male specific expression. As a first step, we generated a transgenic line of *A. stephensi* in which 2 *locus of X (lox)* sites and a fluorescent eye color marker DsRed, under the control of eye specific 3xP3 promoter, were integrated into the Y-chromosome. In this line, only male mosquitoes are fluorescent, suggesting Y-chromosome specific integration and male specific expression of DsRed. Work is in progress to integrate the lethal gene, dominant negative of the immune gene Relish 2 (*dnrel2*) which we have shown previously to be lethal to *A. stephensi*. *dnrel2* will be placed under the control of the Tet-on regulatory sequence, TRE (tetracycline responsive element), and integrated using *Cre/lox* recombination to the *lox* site to generate the effector line. In parallel, a driver *A. stephensi* transgenic line was created using *piggyBac* transposon-mediated integration of rtTA (reverse tetracycline-controlled transactivator) under the regulation of the early embryonic bZip1 promoter. Gene expression analysis of this driver line demonstrated that rtTA is expressed only in the early embryonic stages. To test the proof of concept, the driver line will be crossed with the effector line. In the resulting progenies, addition of oxytetracycline induces bZip1 promoter to express TRE in embryos which will drive the expression of the lethal *dnrel2* gene only in males, resulting in selective male embryo lethality, leaving female embryos alive for vaccine manufacturing.

0129

### GENETICALLY ENGINEERED ENDOSYMBIONTS OF MOSQUITOES FOR USE IN PARATRANSGENESIS

Emma Harris<sup>1</sup>, Tek Hyung Lee<sup>2</sup>, Magdalena Franco<sup>2</sup>, Mimi Yung<sup>2</sup>, Victoria Lao<sup>2</sup>, Nicole Collette<sup>2</sup>, Brad Borlee<sup>1</sup>, Monica Borucki<sup>2</sup>, Rebekah Kading<sup>1</sup>

<sup>1</sup>Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Lawrence Livermore National Laboratory, Livermore, CA, United States

Paratransgenic control of vector-borne viruses and other infectious disease agents can be achieved through exploitation of the bacterial microbiome constitutively present in mosquito populations. Bacteria in the genus *Enterobacter*, among others, have previously been identified as symbionts of the midgut and salivary glands of *Aedes* mosquitoes. Appropriate implementation of *Enterobacter* as a paratransgenic tool requires further analysis of bacterial re-colonization within the mosquito post-genetic manipulation. We hypothesized that if a genetically modified version of *Enterobacter* or *Asaia* is capable of re-colonization of *Ae. aegypti* and/or *An. gambiae* midgut and salivary glands then expression of anti-viral effector molecules can disrupt viral transmission. *Enterobacter* and *Asaia* expressing fluorescent proteins were first screened for multi-organ dissemination within the mosquito. Female mosquitoes 7-10 days old, were exposed to either *Enterobacter* (mCherry) or *Asaia* (GFP) via 1)

blood, 2) protein-rich artificial, or 3) sugar meal. Mosquitoes positive for exposure were then collected at 3, 7, and 14 days. Mosquito midgut, crop, and salivary glands were removed, mounted, and viewed for bacterial colonization via microscopy. Our results demonstrate *Enterobacter* and *Asaia* dissemination is restricted to the midgut and crop when mosquitoes are exposed to infectious sugar meal. Analysis of exposure via blood or alternative protein sources is ongoing. Results of this study will inform future experiments seeking to understand the mosquito microbiome and develop paratransgenic tools to counteract spread of emerging viruses.

0130

### WARBURG EFFECT IS REQUIRED FOR IMMUNITY IN MOSQUITOES

Alex S. Moon, Jiannong Xu

New Mexico State University, Las Cruces, NM, United States

Immune activities require immune cell proliferation. It has been shown in vertebrates that the Warburg effect, i.e., aerobic glycolysis, allows immune cells to turn pyruvate into lactic acid via lactate dehydrogenase (LDH) in the presence of oxygen rather than the traditional path of pyruvate to acetyl-CoA for the tricarboxylic acid cycle. Warburg metabolism provides intermediates and energy required for immune cell proliferation. In this study, we provided phenotypic and genetic evidence that Warburg metabolism is required for immunity in *Anopheles gambiae*, the malaria vector. First, the lactate abundance, measured by a lactate assay, was increased in mosquitoes which survived a hemocoelic infection via a bacterial challenge, as compared to the injury controls. Second, when the glycolytic enzyme GAPDH was inhibited pharmacologically by the compound dimethyl fumarate, the antibacterial immunity was compromised as demonstrated by higher mortality upon hemocoelic infection with bacteria. Lastly, the genes *Gapdh* and *Ldh* were knocked down, and mosquitoes exhibited higher mortality upon bacterial challenge. With the pharmacological and genetic evidence, we conclude that the Warburg metabolism is crucial for mosquito immunity.

0131

### THE WHOLE-GENOME SEQUENCING AND IMPROVED HYBRID ASSEMBLY OF TWO GEOGRAPHICALLY DISTINCT STRAINS OF THE MALARIA VECTOR ANOPHELES ALBIMANUS

Dieunel Derilus<sup>1</sup>, Dhvani Batra<sup>1</sup>, Michael W. Vandewege<sup>2</sup>, Ananias A Escalante<sup>3</sup>, Audrey Lenhart<sup>1</sup>, Gareth D. Weedall<sup>4</sup>, Lucy Mackenzie Impoinvil<sup>1</sup>

<sup>1</sup>U.S. Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, <sup>2</sup>Eastern New Mexico University, Portales, NM, United States, <sup>3</sup>Temple University, Philadelphia, PA, United States, <sup>4</sup>School of Biological and Environmental Sciences, Liverpool John Moores University, Liverpool, United Kingdom

A principal vector of malaria in the Americas, *Anopheles albimanus*, exhibits diverse geographical distribution and phenotypic variation. Hence, a high-quality reference genome from geographically distant populations is essential to understand and capture genetic variation in this species. In this study, we sequenced and assembled the whole genome sequences of two reference strains of *An. albimanus*, originating from El Salvador (STECLA) and Colombia (Cartagena, CART), using a combination of long-read PacBio and short-read Illumina-HiSeq technologies. Assemblies were scaffolded against a published reference assembly (AalbS3) using MaSurCA and gap-filled using TGS-GapCloser. Each assembly was then compared with the published reference genomes AalbS2 and AalbS3. Our hybrid assembly approach generated reference-quality genomes for each strain and recovered 96% of the expected genome size (173 Mbp). The genome assemblies of STECLA and CART consisted of 109 and 150 contigs, respectively, organized in 3 chromosomes, with estimated genome sizes of 167.5 Mbp ( $N_{50}$ =88 Mbp) and 167.1 Mbp ( $N_{50}$ =87 Mbp), respectively. They contained a smaller number of gaps and total missing bases than either of the two published reference genomes for

this species. Previously generated RNA-Seq Illumina paired-end reads (18 Gb) were mapped to the assembled genomes, providing an overall higher mapping rate (STECLA: 98%, CART: 83.3%) than the previously published assemblies (AalbS2: 61.5%, AalbS3 : 59.8%), suggesting a considerable improvement in the quality and completeness of the assemblies. In addition, unreported complete mitogenomes of both CART (14 Mbp) and STECLA (15 Mbp) were recovered. Ongoing analysis of transposable elements, gene family characterization and SNP analyses will provide a comprehensive picture of genetic variation between the two strains. Taken together, these preliminary results suggest that the newly assembled genomes of the two geographically distinct *An. albimanus* strains are of high quality and will serve as key resource for future research in genetics and genomics of this important malaria vector.

0132

### FINE-SCALE POPULATION GENETIC STRUCTURE OF ANOPHELES VECTORS OF MALARIA IN PAPUA NEW GUINEA: PANMIXIA, HIGH GENE FLOW AND GENETIC BOTTLENECK FOLLOWING AN INSECTICIDAL BEDNET CAMPAIGN

John B. Keven<sup>1</sup>, Rebecca Vinit<sup>2</sup>, Michelle Katusese<sup>2</sup>, Stephan Karl<sup>3</sup>, Edward D. Walker<sup>1</sup>

<sup>1</sup>Michigan State University, East Lansing, MI, United States, <sup>2</sup>Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, <sup>3</sup>James Cook University, Townsville, Australia

Villages in coastal and inland regions of northern Papua New Guinea are long term study sites for malaria transmission and control through implementation of long-lasting insecticidal bednets (LLIN). *Anopheles* vectors in villages within these regions may represent isolated populations which respond differentially to such interventions. To address this question, population genetic structure of *Anopheles farauti* sampled from 5 coastal villages in Sumkar district, Madang province from 2010 to 2017 and *Anopheles punctulatus* from 4 hilly inland villages in Drekikier district, East Sepik province from 2008 to 2010 were analyzed using microsatellite allele frequency. Analysis of molecular variance and Bayesian clustering method were used to infer population structure and number of distinct populations. Gene flow among villages was estimated based on effective number of migrants per generation using Wright's formula  $N_m = (1 - F_{st})/4F_{st}$ , where  $F_{st}$  is fixation index. Genetic bottlenecks were assessed with tests of excess heterozygosity. Results show that *An. farauti* in Sumkar comprised a single panmictic population with high gene flow ( $N_m$ : 31-125) between villages. Comparison of this population to one from Kivori, Central province revealed population structure and low gene flow ( $N_m < 4$ ) between the two geographically isolated regions (500 km apart). Panmixia and high gene flow was also observed in *An. punctulatus* both before and after LLIN distribution, however, gene flow among villages dropped significantly after LLIN from a mean  $N_m$  of  $37 \pm 5$  to  $17 \pm 2$  ( $t$ -test:  $t = 3.8$ ,  $df = 6$ ,  $P = 0.009$ ). Significant excess heterozygosity was observed for *An. punctulatus*, indicating a genetic bottleneck associated with the LLIN, which was not observed for *An. farauti*. These findings show that the demographic impact of LLIN was stronger on *An. punctulatus* than *An. farauti*. Panmixia and high gene flow may enable emergence of phenotypes such as insecticide resistance to spread rapidly in the region. Discussion of factors affecting heterogeneity in behavior and ecological attributes of malaria vectors can be made with knowledge of their underlying population structure.

0133

### GENETIC VARIABILITY WITHIN POPULATIONS OF ANOPHELES COUSTANI FROM MADAGASCAR

Tarasoa Malala Andrianarivomanana<sup>1</sup>, Catherine Dauga<sup>2</sup>, Catherine Bourgouin<sup>3</sup>, Romain Girod<sup>1</sup>

<sup>1</sup>Medical Entomology Unit, Institut Pasteur de Madagascar, Antananarivo, Madagascar, <sup>2</sup>Arboviruses and Insect Vectors Unit, Institut Pasteur, Paris, France, <sup>3</sup>Functional Genetics of Infectious Diseases Unit, Institut Pasteur, Paris, France

Malaria remains a major public health concern in Madagascar despite multiple malaria control and prevention measures. Aside from the primary malaria vectors (*Anopheles gambiae* s.l. and *Anopheles funestus*), the anthropophilic tendency of secondary or local vectors, primarily zoophilic, suggests their potential contribution to malaria transmission. Secondary vectors, such as *Anopheles coustani*, are thought to be of minor importance and thus understudied in terms of population structure and vectorial competence, despite being found infected with *Plasmodium* in many African countries. The current study is a preliminary molecular analysis to investigate the presence of distinct genetic populations or even sibling species within Malagasy *An. coustani* and potential link with different roles in malaria transmission in Madagascar. Morphologically identified *An. coustani* mosquitoes were collected in two villages (Ambohitromby and Miarinarivo, Maevatanana district) in northwestern Madagascar using human landing catches (HLC) and catches in zebu parks. Additional samples came from a zebu park in the eastern part of the country (Vavatenina, Toamasina). The genetic diversity of twenty-two *An. coustani* was explored using the mitochondrial cytochrome c oxidase subunit I (COI) and the ribosomal internal transcript spacer region 2 (ITS2) markers. Our current analysis based on COI sequences revealed the presence of two phylogenetic groups of *An. coustani*, supported by mutation signatures. These two groups included mosquito samples collected in each of the three geographic areas surveyed and were collected using different collection methods. No variation of ITS2 sequences was found in the current study. Our current data suggest the existence of differentiated *An. coustani* populations in Madagascar. To refine these findings and properly determine genetic variations within this species, additional mosquito specimens from other locations of Madagascar, as well as different collection methods, will be analyzed.

0134

### AEGYPTI ATLAS: A NEW TRANSCRIPTOMIC RESOURCE REVEALS DETAILED FUNCTIONAL ORGANIZATION OF THE MOSQUITO BODY AND GUT

Bretta L. Hixson, Xiaoli Bing, Xiaowei Yang, Alessandro Bonfini, Peter Nagy, Nicolas Buchon

Cornell University, Ithaca, NY, United States

Mosquitos are important vectors for human diseases. A clear understanding of mosquito physiology is required to develop informed genetic manipulations and potentiate the development of new strategies of control. Large scale transcriptomics are instrumental both to understanding mosquito physiology and engaging in reverse genetic approaches. I will introduce Aegypti Atlas, a new open-source online database hosting transcriptomes of body parts (head, thoracic carcass, abdominal carcass, gut, Malpighian tubules, ovaries) and gut regions (crop, proventriculus, anterior midgut, posterior midgut, hindgut) of female *Aedes aegypti* mosquitoes, as well as a timeseries of transcriptomes from the blood-fed gut. I will present biological messages from these data encompassing the dynamics of the blood-meal response, the organization of immune defenses, and a cross-species comparison of regional function in the midguts of *Ae. aegypti* and *An. gambiae* mosquitoes.

0135

### APPLICATION OF METAGENOMICS AND METABARCODING TO CHARACTERIZE RNA VIRUSES CIRCULATING AMONG BITING MIDGES (CERATOPOGONIDAE) AND RELATED DIPTERA IN KENYA

Solomon Kipnetich Langat<sup>1</sup>, Fredrick Eyase<sup>2</sup>, Wallace Bulimo<sup>1</sup>, Joel Lutomiah<sup>1</sup>, Samuel O. Oyola<sup>3</sup>, Mabel Imbuga<sup>4</sup>, Rosemary Sang<sup>1</sup>

<sup>1</sup>Centre for Virus Research, Kenya Medical Research Institute, Nairobi, Kenya, <sup>2</sup>Department of Emerging Infectious Diseases, United States Army Medical Research Directorate-Africa, Nairobi, Kenya, <sup>3</sup>International Livestock Research Institute (ILRI), Nairobi, Kenya, <sup>4</sup>Jomo Kenyatta University of Agriculture and Technology (JKUAT), Nairobi, Kenya

Vector-borne diseases account for more than 17% of all infectious diseases worldwide and are responsible for over 700,000 deaths each year. The mitigation and response strategies to fight vector-borne diseases are heavily reliant on surveillance programs. These programs enable early detection and control of vector-borne diseases. Vector surveillance programs rely on insect trapping, taxonomic identification, and subsequent pathogen screening in the trapped vectors. The traditional methods of screening the trapped vectors are prohibitively expensive. In this study, we used metagenomics and metabarcoding as relatively low-cost approaches to identifying RNA viruses and their vector hosts among biting midges from various locations in Kenya. Midges were collected from arid and semi-arid areas of Kenya including Baringo, Kacheliba, Turkana, and Isiolo. The specimens were collected using CDC light-traps that were set near resting places for livestock in the afternoon and collected the following morning. The collected specimens were transported to the laboratory then sorted into pools of less than 50 specimens each, then kept in the freezer for subsequent processing. They were screened for RNA viruses using metagenomics approaches. Simultaneously, the specimens were taxonomically characterized using the metabarcoding method. We detected a total of 15 phylogenetically distinct viruses. These viruses are classified into five different families, with one virus falling under the recently proposed negevirus taxon. The 5 virus families include partitviridae, iflaviridae, tombusviridae, solemoviridae, totiviridae and chuviridae. In addition, we identified many vector species that were possibly associated with the identified viruses. The Ceratopogonidae family contributed the majority of the vectors identified. Others included the Chironomidae and Cecidomyiidae families. In conclusion, we successfully characterized 15 RNA viruses from Kenyan midges and demonstrated the simultaneous application of metagenomics and metabarcoding methods as cost-effective approaches to virus surveillance and vector characterization.

0136

### COMPARATIVE TRANSCRIPTOMICS REVEALS IMMUNE REGULATION SPECIFICITIES IN TWO MAJOR MOSQUITO VECTORS

Louise Huot<sup>1</sup>, Xiaowei Yang<sup>1</sup>, Bianca Morejon Viteri<sup>2</sup>, Kristin Michel<sup>2</sup>, Nicolas Buchon<sup>1</sup>

<sup>1</sup>Cornell University, Ithaca, NY, United States, <sup>2</sup>Kansas State University, Manhattan, KS, United States

Mosquitoes are responsible for the transmission of various tropical diseases pathogens. Decreasing their abilities to host and transmit them is a promising strategy to eradicate these diseases. Such approaches will require an extensive knowledge of the mosquitoes' immune systems, of how they interact with human pathogens and of how it affects overall host physiology. Until now, the study of mosquitoes' immunity has mainly focused on specific aspects that are directly involved in defense against major human pathogens. However, our basic knowledge of mosquitoes' immune systems and of their interactions with other physiological components remains very fragmented. I will present the first step in a more global project aiming at characterizing the response to microbial challenges of two major mosquito vectors: the arbovirus-transmitting species *Aedes aegypti* and the malaria vector *Anopheles gambiae*. It

consists in a detailed and comparative analysis of their transcriptomic responses to diverse immune challenges, including sterile wound as well as injections of live and dead microbes (fungi, Gram-negative bacteria and Gram-positive bacteria). I will describe the repertoires of immune and non-immune responses identified in each species, their respective dynamics as well as their differentiations across the conditions. These results establish key features of the two mosquitoes' responses to immune challenge and reveal unexpected and specific modes of regulation of their immune responses.

0137

#### YEAST INTERFERING RNA LARVICIDES TARGETING CONSERVED FEMALE SPECIFIC LARVAL LETHAL LOCI FACILITATE SEX SEPARATION IN MULTIPLE SPECIES OF DISEASE VECTOR MOSQUITOES

**Keshava Mysore**, Ping Li, Joi Misenti, Joseph B. Roethele, Longhua Sun, John Kosmach, Molly Duman-Scheel

*Indiana University School of Medicine, South Bend, IN, United States*

Although clusters of sex-specific loci are believed to shape the boundaries of the M/m sex-determination locus of the dengue vector mosquito *Aedes aegypti*, the identities of these genes are not yet known. Female-specific larval lethal screens uncovered multiple loci adjacent to the M/m locus that are required for survival of female larvae. Larval consumption of *Saccharomyces cerevisiae* (yeast) strains engineered to express interfering RNA corresponding to these genes resulted in significant female death yet had no impact on *A. aegypti* male survival or fitness. Moreover, silencing orthologs of these M/m locus region genes in other mosquitoes, including *Aedes albopictus*, *Anopheles gambiae*, and *Culex quinquefasciatus*, revealed a conserved female-specific larval requirement for these genes among different species of mosquitoes. Integration of the female-specific yeast larvicides into mass culturing protocols permitted scaled production of fit adult male mosquitoes, suggesting that RNAi-based larvicides could benefit mosquito population control strategies that require mass rearing and release of adult males. These studies, which provide insight into the evolution of mosquito sex chromosomes, indicate that sex-specific yeast interfering RNA larvicides may facilitate sex separation in multiple species of disease vector mosquitoes.

0138

#### HERPES SIMPLEX VIRUS GENE VARIANTS AMONG ASYMPTOMATIC WOMEN IN GHANA: PROOF-OF-CONCEPT STUDY

**Oksana Ryabinina Debrah**<sup>1</sup>, Emmanuel Timmy Donkoh<sup>2</sup>, Richard Harry Asmah<sup>3</sup>, Gabriella Essuman Amoakoma Ama<sup>4</sup>, Francis Agyemang-Yeboah<sup>5</sup>

<sup>1</sup>*Ghana Health Service, Accra, Ghana*, <sup>2</sup>*University of Energy and Natural Resources, Sunyani, Ghana*, <sup>3</sup>*University of Health and Allied Sciences, Ho, Ghana*, <sup>4</sup>*University of Ghana, Legon, Accra, Ghana*, <sup>5</sup>*Kwame Nkrumah University of Science and Technology, Kumasi, Ghana*

Herpes simplex virus infections account for a large burden of disease worldwide. HSV-1 is traditionally considered to cause orofacial infections, whereas HSV-2 is known for genital infections. Several studies have suggested an increase of genital herpes infections caused by HSV-1. As reporting of diseases caused by herpes simplex virus is not mandatory in Ghana, reliable statistics on the epidemiology of infections are not available. We took advantage of the Cervicare program in Ghana to screen for the presence of HSV variants 1 and 2 among a convenient subset of asymptomatic women presenting for cervical screening in Accra, Ghana (n=94). Genetic markers for both HSV 1 and 2 were detected in cervical swabs. There was a preponderance of HSV-1 (12.8%) genital infections in our study sample: compared to HSV-2 (4.8%). HSV-1 and 2 co-infection was detected in 4.3% of study population. Among positive cases for HSV-1 DNA, 92% had confirmed seropositive HSV-1 status and 8% were borderline result. All positive HSV-2 DNA were confirmed seropositive HSV-2 status. We have successfully demonstrated the presence of herpes

simplex virus type 1 and type 2 gene variants in genital swabs. Owing to the lack of epidemiological data on genital HSV-1 infection in Ghana, the role of sexual transmission for HSV-1 is unclear: the findings of our pilot study have important public health implications. A bigger surveillance study is recommended in Ghana to identify the etiology of genital herpes and estimate the true burden of asymptomatic herpes infection in the population.

0139

#### A DIAGNOSTIC METHOD FOR SPECIFIC DETECTION OF ALPHAVIRAL EXPOSURE

**Aya Tal-mason**<sup>1</sup>, Ruiyu Pu<sup>2</sup>, Jean-Paul Carrera<sup>3</sup>, Crystal L. Moyer<sup>4</sup>, Amy Y. Vittor<sup>1</sup>

<sup>1</sup>*Department of Medicine, University of Florida College of Medicine, Gainesville, FL, United States*, <sup>2</sup>*Comparative, Diagnostic & Population Medicine, University of Florida College of Veterinary Medicine, Gainesville, FL, United States*, <sup>3</sup>*Department of Research in Virology and Biotechnology, Gorgas Memorial Institute of Health Studies, Panama City, Panama*, <sup>4</sup>*Mapp Biopharmaceutical Inc, San Diego, CA, United States*

In Darién, Panama, arboviral diseases are on the rise and thus a target for epidemiological investigation. Alphaviruses such as Venezuelan equine encephalitis virus (VEEV) and Madariaga virus (MADV, previously known as South American equine encephalitis virus) are of particular public health interest. VEEV has been endemic as a human pathogen in the country since 1960, while is MADV actively emerging in the region of Darién. One method of alphaviral disease surveillance is through assessing population exposure to these viruses. A current method of detecting alphaviral exposure is through Enzyme-Linked Immunosorbent Assay (ELISA) that utilizes whole virus as the antigen. This method is apt at determining general alphaviral exposure but is lacking when there is a need to distinguish between viral species. Plaque reduction neutralization tests (PRNT) are the gold standard for species-specific diagnosis, but require high levels of technical expertise, biosafety, and time. We set out to develop a species-specific IgG diagnostic method to detect alphaviral exposure. We utilized 65 samples from a Panamanian cohort, comparing VEEV and MADV results for whole virus ELISAs as well as PRNTs. For the antigen, we utilized VEEV IAB and MADV recombinant envelope protein (Mapp Biopharmaceutical, Inc.). Results were plotted and a diagnostic cutoff was determined for each test, where both sensitivity and specificity were maximized. MADV assay sensitivity increased from 77.8% to 88.9%, while specificity increased from 74.5% to 91.5%. For the VEEV assay, results demonstrate a decrease in sensitivity from 100% to 95.7% and specificity from 95.1% to 92.9%. These results imply superiority of the modified recombinant protein ELISA for MADV exposure detection, while the whole virus ELISA remains superior for detection of VEEV exposure. Moreover, in the modified ELISA, an overall decrease in species cross-reactivity was observed. These findings pave the way for a new, species-specific standard for detecting alphaviral exposure.

0140

#### SPATIOTEMPORAL OVERLAPPING OF DENGUE, CHIKUNGUNYA, AND MALARIA INFECTIONS IN CHILDREN IN KENYA

**Aslam Khan**<sup>1</sup>, Donal Bisanzio<sup>2</sup>, Francis Mutuku<sup>3</sup>, Bryson Ndenga<sup>4</sup>, Zainab Jembe<sup>5</sup>, Priscilla Maina<sup>5</sup>, Philip Chebi<sup>5</sup>, Charles Ronga<sup>4</sup>, Laura Mwambing<sup>4</sup>, Victoria Okuta<sup>4</sup>, Desiree LaBeaud<sup>1</sup>

<sup>1</sup>*Department of Pediatrics, Division of Infectious Diseases, Stanford University, Stanford, CA, United States*, <sup>2</sup>*RTI International, Washington, DC, United States*, <sup>3</sup>*Department of Environment and Health Sciences, Technical University of Mombasa, Mombasa, Kenya*, <sup>4</sup>*Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya*, <sup>5</sup>*Vector borne Disease control Unit, Msambweni County Referral hospital, Msambweni, Kenya*

Malaria, chikungunya (CHIKV), and dengue (DENV) are recognized as endemic causes of fever among children in Kenya. These infections have

a transmission cycle sustained by different mosquito vectors present in human settlements. The high resolution overlapping of these diseases and factors affecting their spatial heterogeneity has not been investigated in Kenya. We conducted this study to investigate the spatiotemporal pattern of mosquito-borne infections as well as factors linked with exposure risks in Kenya. From 2014 through 2018, we prospectively followed a cohort of children (1-12 years of age) every 6 months recruited from four communities in both coastal and western Kenya. After enrollment the children were followed every 6 months and demographic data such as travel, GPS data, activity, symptoms, and household factors were collected. At each visit demographic surveys were administered, and blood was collected and tested by IgG ELISA to CHIKV and DENV and by microscopy to identify malaria-positive subjects. A local hot-spot analysis test was performed to identify areas with a high number of cases for the three diseases. Kendall's concordance test was applied to compare the spatial pattern of DENV, CHIKV, and malaria across the study period. Spatiotemporal mixed model regression was performed to identify those demographic and environmental factors linked with exposure risk. Over the five years of the study, 3,521 children were tested for CHIKV, DENV, and malaria. Overall, 9.8% were CHIKV seropositive, 5.5% were DENV seropositive, and 39.1% were malaria positive. The spatial analysis identified hot-spots for all three diseases in each site and in multiple years. The location of CHIKV, DENV, and malaria hot-spots were consistent through the study period (Kendall's  $W > 0.7$ ,  $p < 0.05$ ) and also overlapped in the sites (Kendall's  $W > 0.6$ ,  $p < 0.05$ ). The results of the model showed that the risk of exposure was linked to demographics and demographic factors common for the three diseases and will be further explored in this analysis. These insights are of high importance to improve surveillance and targeted control of mosquito-borne diseases in Kenya.

#### EVALUATION OF THE GROWTH KINETICS OF GETAH VIRUS IN A SCOPE OF MAMMALIAN AND MOSQUITO CELL CULTURES

**Faustus Akankperiwen Azerigyik<sup>1</sup>**, Daisuke Kobayashi<sup>2</sup>, Michael Amo-a-Bosompem<sup>1</sup>, Astri Nur Faizah<sup>3</sup>, Shiroh Iwanaga<sup>1</sup>, Haruhiko Isawa<sup>2</sup>

<sup>1</sup>Tokyo Medical and Dental University, Bunkyo, Japan, <sup>2</sup>National Institute of Infectious Diseases, Shinjuku, Japan, <sup>3</sup>University of Tokyo, Bunkyo, Japan

Thirty (30) years since the last reported incidence of Getah virus infection in Japan, there have been sporadic outbreaks of Getah virus (GETV) among race houses and pigs in some prefectures of Japan. This can be attributed to a disproportionate maintenance of alphaviruses and a broad-scale difference in the ecology of existing potential vectors. The detection of GETV in *Aedes vexans nipponii* and multiple isolates of a GETV12IH26 strain from *Culex tritaeniorhynchus* have led to intimations of these mosquitoes being the principal vector(s) for the equine GETV infection. Due to the risk of other potential vectors perpetuating transmission, this study bridges this gap in knowledge using an *in vitro* setup to identify a subset that would be representative of GETV *in vivo* infection life cycle of GETV, and amenable to *in vitro* model applications. We evaluated a panel of mosquito derived cell cultures, Ar-3 (*Armigeres subalbatus*), C6/36 (*Aedes albopictus*, RNAi dysfunction), NIID-CTR (*Culex tritaeniorhynchus*), and MSQ43 (*Anopheles stephensi*), to ascertain GETV activity. GETV (strain 12IH26) was inoculated at MOI of 0.01 in the cell lines and virus harvested at 12-hrs and 24-hrs intervals post-infection. Plaque assays were then performed in Vero cells to estimate virus titres. GETV induced severe cytopathic effect (CPE) in all the mosquito cell lines. Continuous cell culture of GETV in C6/36 showed highest titration of GETV replication and a severe CPE in MSQ43. Our findings showed NIID-CTR as a suitable *in vitro* culture system for GETV12IH26 replication studies. Also, early events such as RNAi of the cell and GETV induced-CPE may determine the outcome of the virus replication. Our study highlights vector-derived cell culture susceptibility studies can be a surveillance criterion for effective assessment of entomological risk of GETV transmission.

#### PERFORMANCE OF AN ANTIBODY-BASED RAPID DIAGNOSTIC TEST FOR CHIKUNGUNYA AMONG FEBRILE PATIENTS IN RIO DE JANEIRO, BRAZIL: A PROSPECTIVE, DIAGNOSTIC ACCURACY STUDY

**Jose Moreira<sup>1</sup>**, Janaina Barros<sup>1</sup>, Karen Trinta<sup>2</sup>, Leticia Fernandez-Carballo<sup>3</sup>, Camille Escadafal<sup>3</sup>, Patricia Brasil<sup>1</sup>, Sabine Dittrich<sup>3</sup>, Andre M. Siqueira<sup>1</sup>

<sup>1</sup>Instituto Nacional de Infectologia Evandro Chagas, Rio de Janeiro, Brazil, <sup>2</sup>Bio-Manguinhos, Rio de Janeiro, Brazil, <sup>3</sup>Foundation for Innovative New Diagnostics, Geneva, Switzerland

There is a need to develop new strategies for Chikungunya (CHIKV) diagnosis that do not rely entirely on reverse transcriptase-polymerase chain reaction (RT-PCR). CHIKV antibody-based rapid diagnostic tests (RDTs) are available to meet this need, but little information exists regarding their performance. Thus, we evaluated the performance of an antibody based RDT for detecting CHIKV in febrile patients seeking care in Rio de Janeiro. Next, we examined the performance of the CHIKV's clinical case definition endorsed by the World Health Organization (WHO) against RT-PCR, especially in the context of an outbreak, where resources for compulsory laboratory confirmation are not practical. We prospectively enrolled non-severe febrile patients aged 2-65 years presenting as an outpatient between October 2018-July 2019. Serum samples were tested for CHIKV antibodies using the DPP<sup>®</sup> ZDC IgM/IgG (Bio-Manguinhos, Fundacao Oswaldo Cruz, Brazil) compared against the CHIKV RT-PCR and Enzyme-Linked Immunosorbent Assay (ELISA). Five hundred participants were enrolled. 232/263 (88.2%) tested ELISA-antibody positive, 100/294 (34%) CHIKV RT-PCR positive, and 117/495 (23.6%) RDT-antibody positive. The sensitivity of the IgM, IgG, and the combined IgM/IgG component ranged from 5-24%, while the specificity ranged from 75-85%. The sensitivity of the RDT components gradually increased over the days pass after the onset of illness. There was a slight agreement between RDT IgM and ELISA IgM ( $k$  coefficient = 0.01), whereas there was a substantial agreement between RDT IgG and ELISA IgG ( $k$  coefficient = 0.70). The WHO' CHIKV clinical definition had a sensitivity, specificity, positive predictive value, and negative predictive value of: 88 (79.9-93.6) %, 74 (68-80) %, 64.2 (58.2-69.8) %, and 92.3 (87.6-95.3) %, respectively. Our study revealed that the antibody-based RDT kit evaluated had a poor performance and needed significant improvement before widespread implementation. The development of accurate CHIKV RDTs is urgently needed to inform disease control strategies, strengthen the efficacy of health systems, and improve patient outcomes.

0143

#### CHIKUNGUNYA: SAFETY UP TO DAY 29 OF PHASE 3 CLINICAL DEVELOPMENT OF A SINGLE-SHOT LIVE-ATTENUATED VACCINE

**Martina Schneider**, Marivic Narciso, Sandra Hadl, Robert McMahon, Sebastian Toepfer, Robert Mader, Juan-Carlos Jaramillo, Katrin Dubischar, Oliver Zoihs, Nina Wressnigg, Susanne Eder-Lingelbach

Valneva Austria GMBH, Vienna, Austria

Chikungunya is a mosquito-transmitted outbreak disease with potentially debilitating consequences and no available causative treatments or preventative vaccines. VLA1553 is a live-attenuated chikungunya virus (CHIKV) vaccine candidate designed for active immunization as a prophylactic measure for travelers to endemic areas or areas at risk for an upcoming outbreak, as well as for the general population living in endemic regions. A double-blinded, multicenter randomized, pivotal phase 3 study comprising approximately 4,060 adult volunteers randomized in a 3:1 ratio to receive the live-attenuated CHIKV vaccine candidate VLA1553 or placebo is currently ongoing (NCT04546724). VLA1553 or placebo were administered as a single intramuscular immunization. The primary objective of the study is to evaluate the immunogenicity and safety of VLA1553 28 days after immunization. Subjects in this study were stratified into

two age strata of 18 to 64 years and 65 years of age or above. Solicited adverse events (AE) were monitored for the first ten days after vaccination and unsolicited AE throughout the study, whereas AE of special interest (AESI, defined as events potentially resembling a CHIKV-like infection) were monitored between days 2 and 21 after immunization. To date, recruitment is completed and 4,131 volunteers have been vaccinated. The study is progressing and analysis on safety up to Day 29 will be available mid 2021.

0144

#### DENGUE AND CHIKUNGUNYA VIRUS EXPOSURE AMONG URBAN POPULATIONS IN WESTERN AND COASTAL KENYA

**Eleonora Migliore<sup>1</sup>**, Francis M. Mutuku<sup>2</sup>, Bryson A. Ndenga<sup>3</sup>, Gladys Agola<sup>4</sup>, Jael Sagina<sup>4</sup>, Zainab Jembe<sup>4</sup>, Charles Ng'ang'a<sup>4</sup>, Omar Godana<sup>4</sup>, Prathik Kalva<sup>1</sup>, Christopher J. Puntasecca<sup>1</sup>, Anika Sharma<sup>1</sup>, Amrik S. Kang<sup>1</sup>, A. Desiree LaBeaud<sup>1</sup>

<sup>1</sup>Stanford University School of Medicine, Department of Pediatrics, Division of Infectious Diseases, Stanford, CA, United States, <sup>2</sup>Technical University of Mombasa, Department of Environment and Health Sciences, Mombasa, Kenya, <sup>3</sup>Kenya Medical Research Institute, Centre For Global Health Research, Kisumu, Kenya, <sup>4</sup>Msambweni Hospital, Vector Borne Disease Unit, Msambweni, Kenya

Dengue (DENV) and chikungunya (CHIKV) viruses are well-known causes of severe illnesses in Kenya, but little is known about the risk factors for their transmission in urban Kenya across all age groups. In this project, we recruited children (infants and  $\geq 1$  year old to 18) and adult participants into two urban cohorts from Ukunda [coast] and Kisumu [west], for a total of 2779 participants, 1621 adults and 1135 children respectively. Participants were followed during febrile illness and every 6 months. Questionnaire data were collected to describe demography, socioeconomic status (SES), and household environment, as well as blood samples for detection of CHIKV and DENV IgG antibodies by ELISA. Of 2779 tests results obtained, 581 participants (21%) tested positive for CHIKV, with 539 (33%) adults and 49 (4%) children respectively. In particular, 11 CHIKV seropositive children were within 0-5 years age range, 22 CHIKV seropositive within 6-12 years age range, and 16 CHIKV seropositive within 13-17 years age range. No significant differences were observed comparing the two study sites for CHIKV seropositivity (24% in the west and 19% in the coast,  $p=0.34$ ). 638(23%) participants tested positive for DENV, 533 (33%) were adults and 105 (9%) were children, with 19 DENV seropositive children within 0-5 years age range, 54 DENV seropositive within 6-12 years age range and 32 DENV seropositive within 13-17 years age range. DENV seropositivity was significantly higher on the coast (36%) than on the west (6%) ( $p<0.001$ ). Strong association between increasing age and CHIKV-DENV exposure was also observed ( $p\leq 0.001$ ). Co-exposure to CHIKV and DENV was observed in both study sites (3% in the west versus 11% on the coast,  $p<0.001$ ), with more co-exposure in adults (203 (7%)) than in children (13 (1%) ( $p<0.001$ )). Furthermore, exposure was highly associated with a low level of education for CHIKV and poor socioeconomic status for DENV ( $p\leq 0.001$ ). Past history of malaria in adult participants was also associated with CHIKV and DENV exposure ( $p\leq 0.001$ ), highlighting the importance of social determinants of health in risk mitigation for arboviral disease threats.

0145

#### EFFICACY AND IMMUNOGENICITY OF A CHIKUNGUNYA VIRUS-LIKE PARTICLE VACCINE IN A HIGH-DOSE CHIKUNGUNYA INFECTION MODEL IN CYNOMOLGUS MACAQUES

**Ravi Anantha<sup>1</sup>**, Koen Van Rompay<sup>2</sup>, Lark L. Coffey<sup>2</sup>, Christopher M. Weiss<sup>2</sup>, Anil Singapuri<sup>2</sup>, Katherine J. Olstad<sup>2</sup>, J. Rachel Reader<sup>2</sup>, Rebecca Sammak<sup>2</sup>, Lo Vang<sup>1</sup>, Christopher S. Morello<sup>1</sup>, Jeff Alexander<sup>3</sup>, Darly Manayani<sup>3</sup>, Kelly L. Warfield<sup>1</sup>

<sup>1</sup>Emergent BioSolutions, Gaithersburg, MD, United States, <sup>2</sup>University of California, Davis, CA, United States, <sup>3</sup>Formerly Emergent BioSolutions, Gaithersburg, MD, United States

Chikungunya virus (CHIKV) causes acute illness characterized by fever, fatigue, and severe joint pain, which can lead to debilitating chronic manifestations including arthralgia. There is no licensed vaccine for prevention of CHIKV infection or disease. Emergent BioSolutions is developing a CHIKV virus-like particle (VLP) vaccine that has demonstrated a robust immune response in nonclinical and Phase 1 and 2 clinical studies and has shown protection against viremia after virulent challenge in mice and rhesus macaques. To determine whether the CHIKV VLP vaccine is protective against CHIKV-induced joint disease, a cynomolgus macaque model using intravenous administration of a high challenge dose was employed. In a non-clinical pilot study, a dose of  $10^7$  pfu of CHIKV LR2006-OPY1 was selected based on joint histopathology scores and clinical signs of disease. Next, groups of 5 animals were vaccinated twice via intramuscular injection, 28 days apart, with three varying doses of CHIKV VLP  $\pm$  alum adjuvant. Four animals received alum adjuvant alone. Vaccinated animals all developed high serum neutralizing antibody titers, which peaked after the second immunization (all  $NT_{80}$  values  $> 3$  log). Following CHIKV challenge 28 days after the second vaccination, all adjuvant-only control animals developed viremias that peaked 2 days after challenge and subsided to low or undetectable levels within 10 days. These control animals also developed clinical signs of infection, required supportive care, and displayed joint histopathology and high levels of viral RNA (vRNA) in joint-associated tissues upon necropsy. In contrast, animals immunized with all doses of CHIKV VLP had no detectable circulating infectious virus and significantly reduced vRNA levels in plasma, fewer clinical signs, and required less supportive care compared to control animals. Immunized animals had lower joint histopathology scores and vRNA levels in joint-associated tissues. This study demonstrated the ability of the CHIKV VLP vaccine to protect cynomolgus macaques from disease after high-dose CHIKV challenge, including joint histopathology indicative of arthritis.

0146

#### ELUCIDATING THE CELLULAR AND MOLECULAR DETERMINANTS OF ARBOVIRAL INDUCED CARDIOMYOPATHIES

**Maria Gabriela Noval<sup>1</sup>**, Payal Damani-Yokota<sup>1</sup>, Stephen T. Yeung<sup>1</sup>, Franco Izzo<sup>2</sup>, Bruno A. Rodriguez-Rodriguez<sup>1</sup>, Karina Gonzalez-Carta<sup>3</sup>, Igor Morr<sup>4</sup>, Ivan Mendoza<sup>5</sup>, Adrian Baranchuk<sup>6</sup>, Kamal M. Khanna<sup>1</sup>, Kenneth A. Stapleford<sup>1</sup>

<sup>1</sup>Microbiology Department, NYU Grossman School of Medicine, NYC, NY, United States, <sup>2</sup>Weill Cornell Medicine and New York Genome Center, NYC, NY, United States, <sup>3</sup>Mayo Clinic, Rochester, MN, United States, <sup>4</sup>Institute of Tropical Cardiology, Maracay, Bolivarian Republic of Venezuela, <sup>5</sup>Institute of Tropical Medicine, Central University of Venezuela, Caracas, Bolivarian Republic of Venezuela, <sup>6</sup>Queen's University, Kingston, ON, Canada

Chikungunya virus (CHIKV) is an arbovirus that has re-emerged in the past decade, affecting millions of people. Here, we report a patient with documented normal ECG and cardiac function who developed acute myocarditis after CHIKV infection. This patient developed ECG alterations and progressive left ventricular dysfunction early after symptom onset. Cases of myocarditis, dilated cardiomyopathy, and heart failure have been

recurrently associated with CHIKV and other arboviral infections and are linked to increased mortality. However, the underlying mechanisms driving arbovirus-induced heart disease are unknown. To study how CHIKV induces heart disease, we established a mouse model of CHIKV heart infection using C57BL/6 mice. We found that CHIKV replicates and generates infectious particles in the heart, inducing pro-inflammatory immune markers and infiltration of monocytes and neutrophils. Bulk RNA-seq of CHIKV-infected hearts showed upregulation of the interferon, innate, and adaptive immune response pathways. In addition, we found elevated levels of serum cardiac troponin-T at 2 days post infection, indicative of cardiac damage. Notably, mice deficient in components of the antiviral innate immune response (*Ifnar<sup>-/-</sup>* or *Mavs<sup>-/-</sup>*) showed increased susceptibility to CHIKV cardiac infection. Particularly, *Mavs<sup>-/-</sup>* mice showed delayed clearance of the infection from the heart. In addition, positive staining of cleaved caspase-3 in CHIKV-infected *Ifnar<sup>-/-</sup>* hearts showed that CHIKV is inducing apoptosis in cardiac tissue. These results suggest that the interferon pathway plays a central role in CHIKV clearance from the heart and cardiac tissue damage. Overall, our results indicate CHIKV induces cardiomyopathies through infection of the cardiac tissue. These results underscore the importance of monitoring cardiac function in patients with CHIKV infections, and lay the foundation for the development of new approaches to prevent viral-induced cardiomyopathies. Further studies will focus on understanding the role of polymorphisms in innate immune response components and its correlation with arboviral induced-heart disease.

0147

#### REEMERGENCE OF CHIKUNGUNYA VIRUS AMONG THE PARTICIPANTS IN THE UNDIFFERENTIATED FEBRILE ILLNESS STUDY IN CAMBODIA, 2020

**Marvin Joel Sklar<sup>1</sup>**, Sokha Dul<sup>1</sup>, Limseng Sok<sup>1</sup>, Pidori Ouch<sup>1</sup>, Phireak Hip<sup>1</sup>, Chontida Supaprom<sup>1</sup>, Vireak Heang<sup>1</sup>, Agus Rachmat<sup>1</sup>, Chenda Yi<sup>1</sup>, Robert D. Hontz<sup>2</sup>, Chhea Chhorvann<sup>3</sup>, Ian Sutherland<sup>1</sup>

<sup>1</sup>NAMRU-2, DPO AE, AE, United States, <sup>2</sup>NAMRU-2, FPO, AE, United States, <sup>3</sup>National Institute of Public Health, Phnom Penh, Cambodia

In 2020 Cambodia experienced a resurgent Chikungunya virus (CHIKV): after many years of very low levels of detection, a widespread outbreak swept the Kingdom. An RNA arbovirus of Alphavirus genus, family Togaviridae spread and was transmitted by infected *Aedes* mosquitoes. CHIKV was first detected in Cambodia in 1961 and more recently, an East Central South African genotype was detected in Cambodia in larger clusters in 2012. The Naval Medical Research Unit 2 laboratory regularly conducts real-time reverse transcription PCR (RT-PCR) and serology studies of infectious disease pathogens. Samples collected in 2020 for the Global Emerging Infections Surveillance funded passive surveillance study: "Surveillance and Etiology of Acute Undifferentiated Febrile Illnesses in Cambodia" found gradually rising CHIKV cases in the months preceding the declared outbreak. In 2020, 1,193 Cambodian nationals were enrolled at referral hospitals and health centers from five provinces and provided samples for testing. Of 1,152 acute-phase serum samples tested for African CHIKV PCR and 691 samples tested for IgM, 6.9% were PCR positive, while 19.7% were IgM positive. Of those positive samples, 76.3% and 53.7% (CHIKV and IgM respectively) originated in Kandal province. One case of CHIKV had co-infection with dengue (DENV-2) and five cases had detectable dengue IgM. Seventy-nine of 80 CHIKV positive cases were identified in the months of July to December. Sixty percent of CHIKV positive cases were males while 66.2% of IgM positive were adults. The CHIKV positivity rates among the males group is significantly higher than the females ( $p=0.037$ , OR (95%CI) = 1.6 (1.1-2.6)). There were no other specific symptoms than fever ( $\text{temp} \geq 38^\circ\text{C}$ ) for the CHIKV and IgM positive cases. After many years of apparent dormancy and limited detection in Cambodia, CHIKV made a dramatic appearance starting in 2020, with widespread and symptomatic disease. Even those datasets with consecutive years of CHIKV surveillance have deficiencies in robustness and reporting. Increased CHIKV surveillance could provide specific and early assistance in outbreak prediction and modeling.

0148

#### MULTIPLE BLOOD MEALS ENHANCE EARLY DISSEMINATION OF ARBOVIRUSES IN THREE MEDICALLY RELEVANT MOSQUITO GENERA

**Zannatul Ferdous<sup>1</sup>**, Hannah Sproch<sup>1</sup>, Constantin Dieme<sup>2</sup>, Rebecca Johnson<sup>1</sup>, Alexander Ciota<sup>3</sup>, Philip Armstrong<sup>1</sup>, Doug Brackney<sup>1</sup>

<sup>1</sup>Connecticut Agricultural Experiment Station, New Haven, CT, United States, <sup>2</sup>Wadsworths Center, New York State Department of Health, Slingerlands, NY, U.S.A, New York, NY, United States, <sup>3</sup>Wadsworths Center, New York State Department of Health, Slingerlands, NY, U.S.A, New York, CT, United States

Numerous anautogenous mosquito vectors have the propensity to acquire multiple blood meals within a single gonotrophic cycle; however, incorporation of this feeding phenotype into laboratory vector competence studies is rarely done. We have previously shown that this frequent feeding behavior can enhance the early dissemination of Zika virus, dengue virus, and chikungunya virus in *Aedes aegypti* and *Aedes albopictus* mosquitoes, yet it is unknown if arboviruses show a similar trend in non-*Aedes* species mosquitoes under a sequential feeding regimen. To test this, we evaluated the impact of a second non-infectious meal on the vector competence of *Ae. aegypti*, *Anopheles quadrimaculatus*, and *Culex quinquefasciatus* for Mayaro virus (MAYV) and *Cx. quinquefasciatus* for West Nile virus (WNV). Mosquitoes were offered an infectious MAYV or WNV bloodmeal and three days later the double-feed group (DSG) was offered a second non-infectious bloodmeal. Midgut infection and dissemination rates were determined by RT-qPCR between 5-10 days post infection. For MAYV, midgut infection rates were comparable between the single-feed group (SFG) and DFG for all three species; however, infection rates were extremely low in *Cx. quinquefasciatus* and, therefore, the double-feed phenotype is being evaluated in this species using WNV. Consistent with other viruses, MAYV dissemination rates were significantly higher in the *Ae. aegypti* DFG compared to the SFG at earlier timepoints. Similarly, the *An. quadrimaculatus* DFG displayed higher rates of dissemination compared to the SFG at earlier timepoints. Our results suggest that frequent blood-feeding improves MAYV dissemination in *Ae. aegypti* and *An. quadrimaculatus* and may allow for higher levels of viral transmission than previously expected. Further, these findings suggest that the shortened extrinsic incubation period of arboviruses associated with sequential blood feeding is generalizable across some, if not most, virus-vector pairings.

0149

#### CARDIOMYOPATHY AND DEATH FOLLOWING CHIKUNGUNYA INFECTION: AN INCREASINGLY COMMON OUTCOME

**Elizabeth Traverse<sup>1</sup>**, Hannah Hopkins<sup>1</sup>, Vedana Vaidhyathan<sup>2</sup>, Kelli Barr<sup>1</sup>

<sup>1</sup>University of South Florida, Tampa, FL, United States, <sup>2</sup>Baylor University, Waco, TX, United States

Chikungunya virus (CHIKV) is vectored by *Aedes aegypti* and *Aedes albopictus* mosquitoes and is found throughout tropical and sub-tropical regions. Although most infections cause mild symptoms such as fever and arthralgia, there have been cases in which cardiac involvement has been reported. In adults, case reports include symptoms ranging from tachycardia and arrhythmia, to myocarditis and cardiac arrest. In children, case reports describe symptoms such as arrhythmia, myocarditis, and heart failure. Case reports of perinatal and neonatal CHIKV infections have also described cardiovascular compromise, including myocardial hypertrophy, ventricular dysfunction, myocarditis, and death. Myocarditis refers to inflammation of the heart tissue, which can be caused by viral infection, thus becoming viral myocarditis. Since viral myocarditis is also linked as a possible causative factor of other cardiomyopathies, including dilated cardiomyopathy, in which the heart muscle weakens and fails to pump blood properly, the connection between CHIKV and the heart is

concerning. We searched Pubmed, Embase, LILACS, and Google Scholar to identify case reports of CHIKV infections where cardiac symptoms were reported. We utilized NCBI Virus, and NCBI Nucleotide to explore the lineage/evolution of strains associated with these outbreaks. Statistical analysis was performed to identify which clinical features were associated with death. Phylogenetic analysis determined that CHIKV infections with cardiac symptoms are associated with the Asian, East Central South African, and the Indian Ocean lineages. Of patients admitted to hospital, death rates ranged from 26-48%. Myocarditis, hypertension, pre-existing conditions and the development of heart failure were significantly correlated with death. As such, clinicians should be aware in their treatment and follow-up of patients.

0150

### THE RISK AND RISK FACTORS OF CHIKUNGUNYA VIRUS RHEUMATOLOGICAL SEQUELAE IN A FIVE-YEAR VIRTUAL COHORT OF U.S. MILITARY HEALTH SYSTEM BENEFICIARIES

Simon Pollett<sup>1</sup>, Hsing-Chuan Hsieh<sup>1</sup>, Dan Lu<sup>1</sup>, Melissa Grance<sup>1</sup>, Gosia Nowak<sup>2</sup>, Carlos Morales<sup>1</sup>, Charlotte Lanteri<sup>1</sup>, David Tribble<sup>1</sup>, Timothy Burgess<sup>1</sup>

<sup>1</sup>Infectious Diseases Clinical Research Program, Bethesda, MD, United States, <sup>2</sup>EpiData Center, Navy and Marine Corps Public Health Center, Portsmouth, VA, United States

Understanding chikungunya virus (CHIKV) rheumatic sequelae across a range of populations is critical. Using the electronic medical records of U.S. Military Health System (MHS) beneficiaries, we established a 'virtual cohort' of CHIKV infections to identify the risk and risk factors of post-CHIKV rheumatic sequelae. MHS beneficiary CHIKV infections diagnosed 2014-2018 were identified from the Disease Reporting System Internet, TRICARE Encounter Data Non-Institutional, and Comprehensive Ambulatory Professional Encounter Record systems. Controls were matched (1:4) by age, gender, beneficiary status, and encounter date. The frequency of comorbidities and incident rheumatic diagnoses were derived from ICD codes. Logistic regression models derived the association of CHIKV infection with rheumatic sequelae, compared to controls, and risk factors for post-CHIKV sequelae. 195 CHIKV cases were diagnosed between July 2014 and December 2018. The mean age was 42 years, and 43.6% were active duty. 63/195 (32.3%) of CHIKV cases had an incident rheumatic diagnosis, including arthralgia, polyarthritis, polymyalgia rheumatica, and/or rheumatoid arthritis. Those with rheumatic CHIKV sequelae had a median 7 healthcare encounters (IQR 3 -15). Compared to controls, CHIKV infection was associated with short-term ( $\leq 3$  month) and long-term ( $> 3$ month) rheumatic sequelae (aOR = 6.41,  $p < 0.001$ ; aOR = 1.43,  $p = 0.09$  respectively) after adjusting for prior rheumatic disease, age, sex, and race. Among CHIKV infections, we found no association between post-CHIKV rheumatic sequelae and age, sex, race, active-duty status, service branch, or comorbidities. In conclusion, CHIKV infection is associated with rheumatic sequelae among US Military Beneficiaries. 25% of post-CHIKV rheumatic sequelae cases required at least 15 healthcare visits, indicating a substantive burden of disease. No demographic, clinical, or occupational variables were associated with post-CHIKV rheumatic sequelae, suggesting that prediction of these complications is challenging in those presenting with a CHIKV diagnosis.

### A SYSTEMATIC REVIEW AND META-ANALYSIS OF THE POTENTIAL NON-HUMAN ANIMAL RESERVOIRS AND ARTHROPOD VECTORS OF THE MAYARO VIRUS

Michael Celone<sup>1</sup>, Barbara Han<sup>2</sup>, Brett Forshey<sup>3</sup>, Assaf Anyamba<sup>4</sup>, James Dunford<sup>1</sup>, George Rutherford<sup>5</sup>, Neida M. Mendoza<sup>6</sup>, Simon Pollett<sup>7</sup>

<sup>1</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>Cary Institute of Ecosystem Studies, Millbrook, NY, United States, <sup>3</sup>Armed Forces Health Surveillance Division, Silver Spring, MD, United States, <sup>4</sup>NASA/Goddard Space Flight Center & University Space

Research Association Goddard Earth Science and Technology Research (USRA/GESTAR) Biospheric Sciences Laboratory, Greenbelt, MD, United States, <sup>5</sup>Institute for Global Health Sciences, University of California, San Francisco, San Francisco, CA, United States, <sup>6</sup>Department of Microbiology and Immunology, SUNY Upstate Medical University, Syracuse, NY, United States, <sup>7</sup>Infectious Disease Clinical Research Program, Department of Preventive Medicine and Biostatistics, Uniformed Services University of the Health Sciences, Bethesda, MD, United States

Mayaro Virus (MAYV) is an *Alphavirus* endemic to Latin America that is transmitted through a sylvatic transmission cycle. Improving our understanding of MAYV ecology is critical to guide disease/vector surveillance and risk assessment. We conducted a PRISMA-adherent systematic review of the literature to identify potential arthropod vectors and non-human animal reservoirs of MAYV. We searched PubMed, Embase, Web of Science, SciELO and grey-literature sources including PAHO databases. Original research studies were included if they assessed MAYV occurrence in field-caught, domestic, or sentinel animals or in field-caught arthropods. We conducted an animal seroprevalence meta-analysis using a random effects model and the  $I^2$  statistic as a measure of heterogeneity. Of 1024 literature results, 55 studies were eligible. Nineteen studies reported MAYV in wild mammals or birds, and five studies reported MAYV in domestic animals. MAYV positivity was reported in 55 wild-caught vertebrate species overall, including 16 in the order Charadriiformes, 15 in the order Primate, and six in the order Rodentia. Sixteen studies detected MAYV in wild-caught mosquito genera including *Haemagogus*, *Aedes*, *Culex*, *Psorophora*, *Coquillettia*, and *Sabethes*. Animals or arthropods with MAYV were detected in Brazil, Panama, Peru, French Guiana, Colombia, Trinidad, Venezuela, Argentina, and Paraguay. Among mammals, the primate order had the highest pooled prevalence (PP) at 0.11 (95% CI: 0.05-0.21,  $I^2 = 95\%$ ,  $p < 0.01$ ). From the most studied primate genera (*i.e.*,  $N > 100$  across all studies) we noted the highest prevalence in *Alouatta* (PP: 0.41, 95% CI: 0.24-0.60,  $I^2 = 69\%$ ,  $p = 0.01$ ), followed by *Callithrix* (PP: 0.12, 95% CI: 0.00-0.83,  $I^2 = 44\%$ ,  $p = 1.00$ ), and *Cebus* (PP: 0.08, 95% CI: 0.03-0.18,  $I^2 = 77\%$ ,  $p = 0.02$ ). MAYV occurs in a wide range of vectors beyond *Haemagogus* sp. MAYV is most frequent in non-human primates but has a potentially broad range of vertebrate reservoirs. These findings support further risk emergence prediction, guide field surveillance efforts, and prompt further *in-vivo* studies to better define the ecological drivers of MAYV emergence.

### CHIKUNGUNYA VIRUSES CONTAINING THE A226V MUTATION DETECTED RETROSPECTIVELY IN CAMEROON FORM A NEW GEOGRAPHICAL SUBCLADE

Terrel Sanders<sup>1</sup>, Bright Agbodzi<sup>1</sup>, Anne Fox<sup>1</sup>, Mba Mosore<sup>1</sup>, Karla Prieto<sup>1</sup>, Ronald Bentil<sup>1</sup>, Michael Wiley<sup>1</sup>, Naiki Attram<sup>1</sup>, Selassie Kumordjie<sup>1</sup>, Shirley Nimo-Paintsil<sup>1</sup>, Joseph Kofi Bonney<sup>1</sup>, Rhoel Dinglasan<sup>1</sup>, Chaselynn Watters<sup>1</sup>, Andrew Letizia<sup>2</sup>

<sup>1</sup>NAMRU-3, Marion, SC, United States, <sup>2</sup>NMRC, Silver Spring, MD, United States

Chikungunya virus has been associated with sporadic outbreaks throughout many of the combatant command areas of responsibility in West Africa. The debilitating impact of CHIKV on deployed forces detrimentally impacts force health protection especially in tropical environments. CHIKV is classified into three main evolutionary genotypes: West African, East/Central/South African, and Asian. Recent viral WGS efforts have revealed the emergence of evolutionary distinct sub-lineages prompting the need for constant genomic surveillance. This study generated viral whole genomes to analyze the origins of recent Cameroon CHIKV outbreak strains; whole blood samples collected between 2016-2019 during CHIKV outbreaks in Cameroon were analyzed. Three coding complete CHIKV genomes were obtained from samples originating from the urban capital of Yaoundé and from the rural town of Mfou. Phylogenetic analysis revealed that all three strains belong to an emerging sub-lineage of the ECSA genotype. The new sequences formed a monophyletic taxon with strains previously isolated in Gabon, Congo,

and a 2006 Cameroon isolate, which we have named the new Central African clade and that appears to be evolving at  $3.0 \times 10^{-4}$  nucleotide substitutions per site per year (95% HPD interval of  $1.94 \times 10^{-4}$  and  $4.1 \times 10^{-4}$ ). Comparative genomic analysis revealed 87 amino acid substitutions across the coding regions of the genomes, with many of these being described for the first time. Mutations in the envelope proteins (E1-A226V, E2-L210Q, and E2-I211T) that are known to enhance CHIKV adaptability and infectious potential in *Aedes albopictus* were present in all strains; Yaoundé strains mapped to established high-density *Aedes albopictus* populations in both urban and suburban areas. These new CHIKV strains constitute a conserved genomic pool of an emerging sub-lineage of the ECSA genotype, reflecting a putative vector host adaptation to *Aedes albopictus*, which has practically displaced *Aedes aegypti* from Yaoundé and many smaller towns in the Guinean sub-equatorial region of Cameroon.

### IMMUNOLOGICAL INSIGHTS BASED ON ANTIBODY BINDING EPITOPES ON THE CHIKUNGUNYA VIRUS ENVELOPE

Edgar Davidson<sup>1</sup>, Rachel H. Fong<sup>1</sup>, Rebecca Rimkunas<sup>1</sup>, Jing Jin<sup>2</sup>, Graham Simmons<sup>2</sup>, Michael S. Diamond<sup>3</sup>, Benjamin J. Doranz<sup>1</sup>

<sup>1</sup>Integral Molecular, Inc., Philadelphia, PA, United States, <sup>2</sup>Vitalant Research Institute, San Francisco, CA, United States, <sup>3</sup>Department of Molecular Microbiology, Washington University School of Medicine, St. Louis, MO, United States

To identify the Chikungunya virus (CHIKV) structures that elicit a protective immune response, we have epitope mapped over 70 monoclonal antibodies (MAbs) against the CHIKV envelope glycoprotein E2/E1, using a comprehensive shotgun mutagenesis library of 910 E2/E1 alanine-scan mutants. Published studies used epitope maps to characterize broadly cross-reactive and ultrapotent neutralizing MAbs that blocked post-attachment steps, and whose binding mapped to functionally important E2 domains A or B, suggesting that MAbs inhibit virus-host membrane fusion by preventing exposure of the E1 fusion loop. Other studies characterized MAbs that induce structural changes on E2 domains A and B, or that target the E1 protein. We also isolated 7 human MAbs against CHIKV E2/E1, including previously unreported cross-reactive, but non-neutralizing, MAbs against the highly conserved E1 fusion loop. Neutralizing epitopes are confined to the exposed topmost and outer surfaces of the E2/E1 trimer, providing a rationale for using the trimer for vaccine design and therapeutic MAb development. Our most potent MAb, IM-CKV063, was highly neutralizing (50% inhibitory concentration, 7.4 ng/ml), showed high-affinity binding (320 pM), and gave therapeutic and prophylactic protection in animal models up to 24 h post-exposure. Epitope mapping identified an inter-subunit conformational epitope on E2 domain A. Subsequent studies demonstrated that IM-CKV063 blocks both virus entry and virus release, and that optimal therapeutic activity required interaction of MAb Fc region with Fcγ receptor. We also used CHIKV E2/E1 mutants to map the binding site of cell adhesion molecule Mxra8, identified as an entry mediator for CHIKV, and other alphaviruses, by infectivity screens of cells targeted by CRISPR/Cas9 gene knockouts. Mxra8 enhanced virus attachment and internalization into cells, and mapping suggests that Mxra8 binds to E2 A and B domains. Mxra8-Fc protein or anti-Mxra8 MAbs blocked CHIKV infection in multiple human cell types and in mice, suggesting Mxra8 as a target for therapeutics against CHIKV and other arthritogenic alphaviruses.

### THE DIGITAL TRANSFORMATION OF THE HIV CARE AND TREATMENT PROGRAM AT JUBA MILITARY HOSPITAL IN SOUTH SUDAN

Minallah Bilal<sup>1</sup>, Awın Changjowk<sup>1</sup>, Ally Lasu<sup>2</sup>, Katie Grimes<sup>2</sup>, Adam Preston<sup>2</sup>

<sup>1</sup>RTI International, Juba, South Sudan, <sup>2</sup>RTI International, Durham, NC, United States

The goal of the Department of Defense HIV/AIDS Preventing Program (DHAPP) in South Sudan is to strengthen the capacity of the South Sudan Peoples Defense Forces (SSPDF) HIV Secretariat to implement its HIV prevention, care, and treatment program and to cover the unmet need of soldiers, their dependents, and the communities. As the implementing partner, RTI International monitors status across 8 program areas and regularly reports program results into two separate reporting systems: including DATIM, the U.S. President's Emergency Plan for AIDS Relief's (PEPFAR's) online reporting database and DC2, DHAPP's online reporting database. To comply with the data reporting requirements of these two systems the RTI team was expending significant effort to ensuring consistency and accuracy across these two platforms. To address this challenge, the RTI turned to the Principle for Development in designing a solution. The Principles for Digital Development are nine living guidelines designed to help digital development practitioners establish best practices into technology enabled programs. The result is the HIV Care and Treatment Database for SSPDF, a database built on the popular DHIS2 platform. This database provides a centralized repository for all program data, interoperability with partner systems, and data entry capabilities. In this case study we discuss some emerging best practices, operational approaches, challenges and opportunities modernizing monitoring and evaluation in the age of interconnected data systems.

### EPITOPE BIOMARKERS FOR THE DETECTION OF ANTI-DENGUE ANTIBODIES IN HUMAN SERA

Francesca Falconi-Agapito<sup>1</sup>, Karen Kerkhof<sup>1</sup>, Marjan Van Esbroeck<sup>2</sup>, Xiomara Merino<sup>3</sup>, Michael Talledo<sup>3</sup>, Kevin A. Ariën<sup>1</sup>

<sup>1</sup>Department of Biomedical Sciences, Unit of Virology, Institute of Tropical Medicine, Antwerp, Belgium, <sup>2</sup>Department of Clinical Sciences, National Reference Center for Arboviruses, Institute of Tropical Medicine, Antwerp, Belgium, <sup>3</sup>Virology Unit, Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

In a world with an increasing population at risk of arthropod-borne Flaviviruses infection, access to timely and accurate diagnostic tests impact profoundly on the management of cases. Unfortunately, there is a poor deployment of laboratory-based diagnostic capacity in low-resource settings (LRS) that can identify and discriminate the infectious agent when needed. The relative simplicity and affordability of serological assays make them good candidates to be implemented in LRS. However, flavivirus serology-based diagnosis is hindered by low test specificity, as consequence of the high genetic and antigenic similarities among the flavivirus family eliciting cross-reactive (CR) antibodies (Abs) upon infection. Replacement of conventional antigens such as viral lysates or recombinant proteins by epitope biomarkers could have the potential to discriminate type-specific from CR Abs. Previously, using a microarray peptide covering the entire proteome and diversity of dengue (DENV), Zika (ZIKV) and yellow fever (YFV) viruses, we identified 20 DENV derived peptides widely recognized by IgM or IgG Abs from dengue infected individuals. The 9 selected peptides recognized by IgM Abs are located in the E, NS1, NS2a, NS2b, NS3 and NS4b proteins, while the 11 peptides recognized by IgG Abs are located in the prM, E, NS1, NS2b, NS3, NS4b and NS5 proteins. To further investigate the discriminatory potential of these peptides, we set-up a bead-based multiplex peptide immunoassay. The peptides were coupled to Luminex paramagnetic beads to determine Ab binding levels to each peptide/antigen over a panel of 224 human serum samples. These are derived from individuals either infected with different flaviviruses,

including the four DENV serotypes, ZIKV, YFV, tick-borne encephalitis (TBEV), West Nile and Japanese encephalitis (JEV) viruses, or receiving vaccination against YFV, TBEV or JEV. This screening will demonstrate the capability of the peptides to differentiate dengue infected individuals from other flavivirus-exposed subjects and will be instrumental for future development of diagnostic tests with better specificity characteristics.

### DENGUE AND CHIKUNGUNYA SURVEILLANCE IN CAMBODIA, 2015-2020

**Robert D. Hontz<sup>1</sup>**, Sokha Dul<sup>2</sup>, Vireak Heang<sup>2</sup>, Phireak Hip<sup>2</sup>, Chenda Yi<sup>2</sup>, Agus Rachmat<sup>2</sup>, Chonthida Supaprom<sup>2</sup>, Marvin J. Sklar<sup>2</sup>, Jose A. Garcia-Rivera<sup>2</sup>, Chhea Chhorvann<sup>3</sup>, John S. Brooks<sup>2</sup>, Ian W. Sutherland<sup>2</sup>

<sup>1</sup>*U.S. Naval Medical Research Unit TWO (NAMRU-2), Singapore, Singapore,* <sup>2</sup>*U.S. Naval Medical Research Unit TWO (NAMRU-2), Phnom Penh, Cambodia,* <sup>3</sup>*National Institute of Public Health, Phnom Penh, Cambodia*

The U.S. Naval Medical Research Unit No. 2 (NAMRU-2) maintains a network of nine surveillance sites in Cambodia, comprising urban locations in Kampong Speu and Kandal and rural sites in Battambang, Kratie, Preah Vihear, Retanakiri, Sihanoukville, Stung Treng, and Svay Rieng. Cambodian nationals experiencing symptoms of acute undifferentiated febrile illness (AUI) arrive for treatment and are offered the opportunity to participate in this study. Anyone eligible for inclusion must be two years of age or over and present with symptoms of febrile illness at least 24 hours prior to the time of enrollment with no longer than 10 days of duration with or above an oral or tympanic temperature of 38.0°C or axillary temperature of 37.5°C. After providing consent, blood samples were collected for laboratory testing using RT-PCR and IgM/IgG ELISA targeting dengue (DENV) and chikungunya (CHIKV) infections. Between 2015 and 2020, blood samples were collected from 14,244 participants (54.3% male, 60.7% adults 18 y/o or over, mean = 25 y/o); in total, 4,078 samples were tested for CHIKV and 11,341 samples were tested for DENV using a standard testing algorithm, which also includes Zika virus, Leptospira, and rickettsia. Our DENV surveillance data during this period indicate a spike in percent positivity in Quarter 2 (Q2, April - June) and/or Quarter 3 (Q3, July - September) each year. Similarly, DengueNet and WHO data indicate similar increases in DENV cases during the April - September timeframe. These findings align with National Center for Medical Intelligence (NCMI) and CDC assessments that indicate DENV seasonality, with rainy season peak transmission (June - August). Our data also shows an increase in percent positivity between 2017 and 2019, with a peak in Q2 2019. Trends in CHIKV data 2015 - 2020 generally spike in percent positivity in Q3 (July-September) or Q4 (October - December) each year, except for a Q1 spike (January - March) in 2018. DENV and CHIKV continue to present a health risk to Department of Defense personnel in Cambodia, and surveillance networks such as this are critical to capturing disease trends in regions where military forces operate.

### DEVELOPMENT AND CHARACTERIZATION OF A MULTIPLEX ASSAY TO QUANTIFY COMPLEMENT-FIXING ANTIBODIES AGAINST DENGUE VIRUS

**Eduardo J. M. Nascimento**, Brooke Norwood, Allan Parker, Ralph Braun, Hansi J. Dean

*Takeda Vaccines, Cambridge, MA, United States*

The complement system (CS) is an arm of innate immunity that functions as an effector mechanism of the humoral response. Antibodies against dengue virus (DENV) and other flaviviruses can mediate CS activation. For over two decades, a complement-fixing antibody test has been used to measure the ability of DENV-specific serum antibodies to activate the CS. As originally developed the test is time-consuming, cumbersome and uses reagents that are difficult to standardize. In addition, it has lower sensitivity for DENV diagnosis relative to neutralizing or hemagglutination inhibiting antibody assays. An improved method is needed for quantifying

complement-fixing antibodies against all 4 DENV serotypes. We have developed and characterized a novel multiplex anti-DENV complement-fixing assay based on the Luminex platform to quantitate serum antibodies against structural proteins of all 4 serotypes (DENV1-4) that can activate CS based on their ability to fix the complement component C1q. The assay has good precision and linearity as well as high sensitivity and specificity relative to a microneutralization assay. In non-human primates, antibodies produced in response to primary DENV1-4 infection induced CS activation against homologous and heterologous serotypes. Higher complement-fixing antibody titers were found against the homologous serotype. Moreover, inter-serotype cross-reactivity was associated with homology of the envelope protein. Interestingly, antibodies produced following vaccination against Zika virus, but not yellow fever virus, Japanese encephalitis virus, West Nile virus and tick-borne encephalitis virus activated CS against DENV structural proteins. The anti-DENV complement fixing antibody assay represents an alternative approach to determine the quality of antibodies produced following DENV natural infection and a biomarker for dengue serostatus, while providing insights about flavivirus-specific antibody cross-reactivity.

0158

### VARIATION IN DENGUE SEVERITY ACROSS PREGNANCY STATUS FROM 2017-2018 IN MEXICO: AN INTERACTION BETWEEN PREGNANCY AND DENGUE SEROTYPE

**Esther Annan<sup>1</sup>**, Jesús Treviño<sup>2</sup>, Ubydul Haque<sup>1</sup>

<sup>1</sup>*University of North Texas Health Science Center, Fort Worth, TX, United States,* <sup>2</sup>*Universidad Autónoma de Nuevo León, San Nicolás de los Garza, Nuevo León, Mexico*

Infection with dengue fever during pregnancy is associated with miscarriages, intrauterine fetal death, and maternal mortality. There is, however, a gap in literature portraying how the severity of dengue in pregnancy and its occurrence in individuals with other comorbidities is modified by dengue serotype. The aim of this study was therefore to determine if the severity of dengue was dependent on the interaction between, pregnancy and/or other comorbidities and dengue serotype, in Mexico. The association between pregnancy and specific serotypes will guide policies related to dengue prevention in Mexico. Dengue surveillance data was acquired from the nationally notifiable disease reporting system of Mexico's Ministry of health. The dataset contains non-identifiable health information collected from notifying health units in 2,469 Mexican municipalities. Since the main variable of interest was pregnancy, the analysis was restricted to women (N= 15608). SAS 9.4 by SAS Institute Inc., Cary, NC, USA was used to conduct all analysis. Overall, 21.4% of our sample experienced signs of dengue hemorrhagic fever. Of those who had signs of dengue hemorrhagic fever, 65.2% were infected with dengue serotype 2, 33.1% were associated with serotype 1, 1.69% were associated with serotype 3 and none were associated with serotype 4. Of those with dengue serotype 1, being pregnant was associated with 40% (CI: 17% - 68%) higher prevalence odds of dengue hemorrhagic fever compared to non-pregnant women. Among those infected with dengue serotype 3, being pregnant was associated with 2.5 times (CI: 1.04 - 6.06) the prevalence odds of developing hemorrhagic fever compared to non-pregnant women. Most women with dengue hemorrhagic fever were found to have either dengue serotype 1 or 2. However, among pregnant women, serotypes 1 and 3 were associated with more severe presentations compared to non-pregnant women. Hence, while preventive efforts should be geared towards eradicating dengue in Mexico, targeting dengue serotypes 1 and 3 in vaccine development or adjusting to a more aggressive management in pregnant women infected with serotypes 1 and 3 seems prudent.

0159

### CORRELATION OF THROMBOCYTOPENIA WITH GALL BLADDER WALL THICKNESS: A PREDICTIVE ANALYSIS FOR BLEEDING RISK AND NEED OF PLATELET TRANSFUSION IN DENGUE INFECTION

Muhammad Sohaib Asghar, Saira Anwar, Farah Yasmin  
Dow University of Health Sciences, Karachi, Pakistan

Severe dengue is characterized by an increase in capillary permeability. Increased gallbladder wall thickening (GBWT) is one manifestation of increased capillary permeability and can be detected by a bedside abdominal ultrasound. This study was carried out to link the severity of GBWT with the bleeding risk and the need for platelet transfusion. The study was conducted as a retrospective design including all the patients with a diagnosis of dengue infection either via Dengue nonstructural protein-1 (NS-1) antigen or IgM antibody. Pearson's correlation, multiple linear regression and receiver operating characteristic (ROC) curves were used for predictive analysis of GBWT with an event of bleeding and need for transfusion of platelets during the hospital stay. A total of 177 dengue-infected patients were included in the analysis with a mean age of 33.17 ± 13.63 years. Mean GBWT was found to be 0.37 ± 0.15 cm, with 46.3% of patients had a thickness greater than 0.30 cm. A total of 16 patients were documented with bleeding events out of which 7.3% had minor bleeding and 1.7% had a major bleeding event. Increased GBWT was found correlating with decreased platelet count on admission ( $p=0.006$ ) and lowest platelet counts during hospital stay ( $p=0.001$ ). While lowest platelet counts were also found correlating with increased length of hospital stay ( $p=0.020$ ). Multiple linear regression analysis showed increased GBWT was found associated with decreased platelet count on admission ( $p=0.002$ ) and lowest platelet counts ( $p=0.004$ ). ROC curves showed GBWT at a cut-off value of 0.385 cm was predictive of bleeding event with an area under the curve of 0.821, sensitivity of 92.3% and specificity of 66.5% ( $p<0.001$ ). The same cut-off was predictive of platelet transfusion with an AUC of 0.932, sensitivity of 100% and specificity of 71.9% ( $p<0.001$ ). GBWT was found predictive of bleeding event and transfusion of platelets at higher sensitivity and specificity than platelet count on admission and lowest platelet counts during hospital stay. Hence, GBWT should also be assessed in every dengue patient to predict the risk of bleeding and a prompt need for platelet transfusion.

0160

### CHARACTERIZATION OF THE NEUTRALIZING ANTIBODY RESPONSE IN BASELINE SERONEGATIVE CHILDREN, ADOLESCENT AND ADULT RECIPIENTS OF A TETRAVALENT DENGUE VACCINE

Melissa Zahralban-Steele<sup>1</sup>, Maima Kaiser<sup>1</sup>, Tim Rindfleisch<sup>1</sup>, Kelly Bohning<sup>1</sup>, Brooke Norwood<sup>1</sup>, David Dominguez<sup>1</sup>, Christina DeMaso<sup>1</sup>, Mayuri Sharma<sup>1</sup>, Hansi Dean<sup>1</sup>, DEN-304 & DEN-301 study groups

<sup>1</sup>Vaccine Business Unit, Takeda Pharmaceuticals, Cambridge, MA, United States

Takeda's live attenuated tetravalent dengue vaccine (TAK-003) is comprised of structural proteins from each of the four serotypes in an attenuated dengue virus 2 (DENV-2) genomic backbone. Data from the pivotal phase 3 clinical trial (DEN-301) showed no important safety risk observed and that TAK-003 demonstrated overall efficacy against dengue infection and associated hospitalizations by any DENV serotype regardless of baseline dengue serostatus in children and adolescents from dengue endemic regions. The production of neutralizing antibodies (nAbs) consisting of both cross-reactive (CR) and serotype-specific (TS) nAbs are thought to contribute to vaccine-elicited protection against dengue, although a correlate of protection against dengue has not been identified so far. In this study, we characterized the frequency and magnitude of TS and CR nAb responses to DENV-1, DENV-3 and DENV-4, post-depletion of DENV-2 nAbs, using the dengue reporter virus particle (RVP) neutralization assay. Post-vaccination serum samples from TAK-003 recipient children

and adolescents from dengue endemic regions in DEN-301, and US-based adults from another phase 3 trial (DEN-304) were used in these assessments. The data from these evaluations revealed that TAK-003 elicits a mixture of CR and TS nAbs against DENV-1 and DENV-3, and a predominantly TS response against DENV-4 in baseline seronegative children, adolescents and adults. The magnitude and frequency of TS nAb responses against DENV-1 and DENV-3, were comparable, and higher for DENV-4 across trials and age groups. Our results indicate that each component of TAK-003 contributes to the serotype-specific response elicited by the vaccine, and the frequency and magnitude of TS nAb responses may be independent of the magnitude of overall nAb response. To understand the roles for CR and TS nAb responses elicited by TAK-003 in protection against dengue, characterization of nAb responses in the context of vaccine efficacy is currently underway.

0161

### TAK-003 VACCINE-DRIVEN NEUTRALIZATION OF DIVERSE DENGUE GENOTYPES CIRCULATING IN ASIA PACIFIC AND LATIN AMERICA REGIONS

Lovkesh Karwal<sup>1</sup>, Maima Kaiser<sup>1</sup>, Kelly Bohning<sup>1</sup>, Melissa Zahralban-Steele<sup>1</sup>, Eduardo J. Nascimento<sup>1</sup>, Christina DeMaso<sup>1</sup>, Whitney Baldwin<sup>1</sup>, Stefan Fernandez<sup>2</sup>, Mayuri Sharma<sup>1</sup>, Hansi Dean<sup>1</sup>, DEN-301 study group<sup>1</sup>

<sup>1</sup>Takeda Pharmaceuticals Inc., U. S. A., Cambridge, MA, United States,

<sup>2</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand

Dengue disease is caused by four related, but distinct, virus serotypes. The virus envelope (E) protein, the main target of the neutralizing antibody (NAb) response, has accumulated intra-serotype genetic diversity with heterogeneous distribution worldwide. Substitutions in E protein amino acids could potentially allow specific strains to escape neutralization, become more virulent and cause severe dengue disease. Therefore, it is critical to develop a dengue vaccine that provides protection against diverse genotypes across dengue serotypes. Takeda's live attenuated tetravalent dengue vaccine (TAK-003) is comprised of structural proteins from each serotype in an attenuated dengue virus type 2 (DENV-2) genomic backbone. Data from a pivotal, phase 3 efficacy trial of TAK-003 (DEN-301, NCT02747927) showed no important safety risk and demonstrated overall efficacy against virologically-confirmed dengue, and associated hospitalizations irrespective of dengue serotype or serostatus. Due to dengue virus (DENV) evolution, an evaluation of cross-genotype immunity is essential to assess vaccine coverage in different parts of the globe. We evaluated the ability of post-vaccination serum from baseline seronegative TAK-003 recipients from DEN-301 to neutralize diverse genotypes using a panel of dengue reporter virus particles (RVPs) carrying E genes from contemporary dengue strains representing viruses circulating in Asia-Pacific and Latin American countries during 2002-18. Preliminary results indicate that TAK-003-elicited antibodies are capable of neutralizing both vaccine-matched DENV-3 sequences and DENV-3 genotypes responsible for recent outbreaks in the Asia Pacific region. Neutralization assays using DENV-1, -2 and -4 RVPs representing the E genes of contemporary, circulating strains is underway, and similar studies with viruses causing dengue cases during the trial will be undertaken in the future. Continued evaluation will help predict the ability of TAK-003 to elicit NABs capable of neutralizing contemporary dengue strains of diverse genotypes circulating in areas of high endemicity around the world.

## SAFETY AND IMMUNOGENICITY OF TAKEDA'S TETRAVALENT DENGUE VACCINE ADMINISTERED DURING THE SECOND HALF OF ITS 24-MONTH SHELF-LIFE

Sanjay S. Patel<sup>1</sup>, Peter Winkle<sup>2</sup>, Sonja Moua<sup>3</sup>, Alice Faccin<sup>1</sup>, Francesco Nordio<sup>3</sup>, Claudia Galindo-Tsoukas<sup>3</sup>

<sup>1</sup>Takeda Pharmaceuticals, Glattpark-Opfikon (Zurich), Switzerland, <sup>2</sup>Anaheim Clinical Trials, Anaheim, CA, United States, <sup>3</sup>Takeda Pharmaceuticals International Inc., Cambridge, MA, United States

Illness owing to infection by any of the four co-circulating dengue virus serotypes ranges from asymptomatic disease to fatality. Infection with one serotype produces life-long homologous immunity but increases the risk of severe disease following a secondary heterotypic infection, so a dengue vaccine should ideally generate protective responses against all four serotypes. Takeda's tetravalent live-attenuated dengue vaccine candidate, TAK-003, comprises four dengue virus strains: an attenuated dengue serotype 2 strain (DENV-2), and three recombinant strains with the DENV-2 backbone and the pre-Membrane (prM) and Envelope (E) genes of DENV-1, DENV-3, and DENV-4. This open-label single-arm phase 3 trial evaluated the effect of administering TAK-003 vaccine after storage at 2°C to 8°C for >1 year (ie, >half of its anticipated 2-year shelf-life): two TAK-003 doses, 3 months apart, were administered to 200 healthy adults (18–60 years), from non-endemic areas of the USA. Robust increases in microneutralization titers [MNT<sub>50</sub>] were observed for all 4 serotypes: Day 120:Day 270 geometric mean titer ratios were consistent with those observed in other TAK-003 clinical trials. Seropositivity rates by Day 120 were 99.2%, 100%, 97.7%, and 99.2% for DENV-1, DENV-2, DENV-3, and DENV-4, respectively, and 97% of participants had tetravalent seropositivity. By Day 270, 78.9% and 91% of participants still had tetravalent and at least trivalent seropositivity, respectively. TAK-003 was well-tolerated: solicited local and systemic adverse events (AEs) were mostly mild and transient, and no severe unsolicited AEs or medically attended AEs were observed. None of the serious AEs or AEs leading to TAK-003 withdrawal and/or trial discontinuation was assessed as related to TAK-003 or trial procedure. The immunogenicity and safety data from this trial are consistent with those observed in other TAK-003 trials that involved administration of TAK-003 after shorter storage times, including the DEN-301 efficacy trial (ClinicalTrials.gov NCT02747927) involving >20,000 participants that demonstrated efficacy against dengue infection in endemic regions.

## PHYLDYNAMICS VERSUS EPIDEMIOLOGICAL DYNAMICS OF DENGUE IN BANGKOK, 1994–2014

Bernardo Garcia-Carreras<sup>1</sup>, Angkana T. Huang<sup>1</sup>, Carla Mavian<sup>1</sup>, Henrik Salje<sup>2</sup>, Leah Katzelnick<sup>3</sup>, Ana Coello Escoto<sup>1</sup>, Nayeem Chowdhury<sup>1</sup>, Christian Chávez<sup>1</sup>, Wiriya Rutvisuttinunt<sup>4</sup>, Irina Maljkovic Berry<sup>4</sup>, Chonticha Klungthong<sup>5</sup>, Butsaya Thaisomboonsuk<sup>5</sup>, Ananda Nisalak<sup>5</sup>, Sopon Iamsirithaworn<sup>6</sup>, Pawinee Doung-Ngern<sup>6</sup>, Isabel Rodriguez-Barraquer<sup>7</sup>, Damon W. Ellison<sup>4</sup>, Anthony R. Jones<sup>5</sup>, Stefan Fernandez<sup>5</sup>, Tim Endy<sup>8</sup>, Derek J. Smith<sup>2</sup>, Richard G. Jarman<sup>5</sup>, Stephen S. Whitehead<sup>3</sup>, Derek A. Cummings<sup>1</sup>

<sup>1</sup>University of Florida, Gainesville, FL, United States, <sup>2</sup>University of Cambridge, Cambridge, United Kingdom, <sup>3</sup>National Institutes of Health, Bethesda, MD, United States, <sup>4</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>5</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>6</sup>Ministry of Public Health, Nonthaburi, Thailand, <sup>7</sup>University of California, San Francisco, San Francisco, CA, United States, <sup>8</sup>State University of New York Upstate Medical University, Syracuse, NY, United States

Dengue virus is endemic in Thailand, and all four serotypes have been co-circulating for decades. It constitutes an ideal setting to explore the dynamics of dengue genetic diversity, and how it relates to the epidemiology. In this study, we sequence the whole genomes of 1814

viruses (DENV1: 617; DENV2: 415; DENV3: 424; DENV4: 358) isolated in Bangkok, Thailand between 1994 and 2014. We reconstruct the phylodynamics of each serotype to characterise how their genetic diversity has changed over the two decades and relate these changes to concurrent dynamics in dengue cases by leveraging two other independent sources of data. The first source is the passive surveillance data for Bangkok, which while not serotype-specific, provides the most reliable indicator of the dynamics of dengue cases. The second are case counts from Queen Sirikit National Institute of Child Health (QSNICH), which constitute a subset of the cases reported in the passive surveillance and captured 1.5 to 29.3% of the cases reported during the study period, but are characterised to the serotype-level. Using various schemes, we adjust the QSNICH time series to account for the total number of cases reported in the passive surveillance data. Using time series analyses, we compare and contrast the serotype dynamics of case counts with the genetic diversity time series. In the process, we highlight the strengths and weaknesses of the datasets, their utility, and help build a better understanding of the dynamics of dengue in Thailand.

## CHYMASE AND LIPOPOLYSACCHARIDE BINDING PROTEIN: POTENTIAL BIOMARKERS FOR SEVERE DENGUE

Cynthia Bernal<sup>1</sup>, Fatima Cardozo<sup>2</sup>, Alejandra Rojas<sup>1</sup>, Patricia Langjahr<sup>3</sup>, Oliver Caballero<sup>1</sup>, Patricia Luraschi<sup>4</sup>, Marta Von-Horoch<sup>4</sup>, Sandra Cabral<sup>4</sup>, Cesar Cantero<sup>1</sup>, Maria Eugenia Acosta<sup>1</sup>, Yvalena Aravalo<sup>1</sup>, Malvina Pjez<sup>2</sup>, Laura Mendoza<sup>2</sup>, Jesse J. Waggoner<sup>5</sup>

<sup>1</sup>Universidad Nacional de Asuncion, Instituto de Investigaciones en Ciencias de la Salud, Departamento de Produccion, San Lorenzo, Paraguay, <sup>2</sup>Universidad Nacional de Asuncion, Instituto de Investigaciones en Ciencias de la Salud, Departamento de Salud Publica, San Lorenzo, Paraguay, <sup>3</sup>Universidad Nacional de Asuncion, Facultad de Ciencias Quamicas, Departamento de Biotecnologia, San Lorenzo, Paraguay, <sup>4</sup>Hospital Central del Instituto de Prevision Social, Departamento de Epidemiologia, Asuncion, Paraguay, <sup>5</sup>Emory University School of Medicine, Division of Infectious Diseases, Atlanta, GA, United States

Dengue is the most common vector-borne viral disease worldwide. Most cases are mild, but some will evolve into severe dengue (SD), with high lethality. Therefore, it is important to identify which patients will develop severe disease. The aim of this study was to quantify chymase and lipopolysaccharide binding protein (LBP) levels in serum or plasma from dengue patients with varying degrees of severity and analyze the potential of these molecules as severity biomarkers. A descriptive cross-sectional study was performed. Patients from Paraguay with confirmed dengue (NS1 and/or rRT-PCR positive) and a duration of symptoms ≤8 days were included. Median age was 38 years old (IQR=31,5) and DENV-4 was the predominant serotype. Cases were classified according to 2009 WHO criteria in 3 groups: dengue without warning signs (DWS-), dengue with warning signs (DWS+) and SD. Chymase levels were analyzed in 145 samples and median concentration was significantly higher in patients with SD compared to the DWS- and DWS+ groups (p=0.0003 and p=0.0005, respectively). For LBP analysis, 108 positive dengue patients and 55 healthy controls were included. Mean LBP level were significantly higher when comparing SD with all other groups (p<0.0001 for all comparisons). Mean LBP concentration in DWS+ group was also significantly higher than that of healthy controls (p=0.0004). Levels of chymase and LBP increased according to severity of dengue cases. These results, in accordance with previous studies, indicate that chymase and LBP have potential as severity biomarkers, and their performance as prognostic tests warrants further evaluation.

0165

### NEUTRALIZING AND ENHANCING EFFECTS OF DENGUE ANTIBODIES IN INDIVIDUALS OVER TIME WITH DIFFERENT DISEASE OUTCOMES

**Hoa Thi My Vo**, Vinit Upasani, Heidi Auerswald, Sokchea Lay, Axelle Vanderlinden, Sopheak Sorn, Sowath Ly, Veasna Duong, Philippe Dussart, Tineke Cantaert

*Institut Pasteur du Cambodge, Phnom Penh, Cambodia*

Heterotypic secondary dengue infection is a risk factor for the development of severe dengue. The humoral immune response during heterotypic secondary DENV infection is complex and dynamic and consists of a polyclonal response of pre-existing antibodies against the previous infecting serotype and newly generated antibodies. In order to assess the contribution of the developing humoral immune response to the course of acute infection, we have determined antiDENV antibody titers, neutralizing antibodies, percentages of antibodies binding to DENV-infected cells and *in vitro* antibody-dependent enhancement (ADE) to the infecting serotype in two independent patient cohorts of DENV-infected Cambodian children (n=54). Individuals were either asymptomatic infected (n=10, asymptomatic dengue, ASD) or hospitalized (n=44, clinical dengue, CD) and classified according to WHO classification criteria. The results showed that DENV-IgG titers and neutralizing titers were higher in secondary dengue cases compared to primary dengue cases, but no difference was observed between ASD and CD cases. Percentages of antibodies bound to DENV-infected cells are higher at the time of inclusion in secondary infected cases and are associated with disease outcome after DENV-2 infection and severity in hospitalized patients after DENV-1 infection. ADE-mediating antibodies evolved over time and were highest against the infecting serotype. ADE, IgG titers, and titers of neutralizing antibodies were highly correlated to each other but less to percentages of antibodies binding to DENV-infected cells. Taken together, these data indicate that binding antibodies might contribute to protection or pathogenesis via other mechanisms not related to neutralization or enhancement of infection. These findings are important for the understanding of the measurement of the totality of the humoral response to natural infection and vaccine candidates that may identify novel correlates of protection.

0166

### THE BURDEN OF DENGUE IN LATIN AMERICA AND ASIA -EPIDEMIOLOGICAL DATA FROM A PHASE 3 TRIAL

**Randee Kastner**<sup>1</sup>, John Weil<sup>2</sup>, Mengya Liu<sup>1</sup>, Vianney Tricou<sup>2</sup>, Nicolas Folschweiller<sup>2</sup>, Shibadas Biswal<sup>1</sup>, TIDES Study Group<sup>3</sup>

<sup>1</sup>Takeda Inc, Cambridge, MA, United States, <sup>2</sup>Takeda Pharmaceuticals International AG, Zurich, Switzerland

One of the challenges faced by global dengue disease surveillance is the lack of comparability across surveillance systems. Since September 2016, we have been conducting TIDES (ClinicalTrials.gov NCT02747927), a phase 3 trial of Takeda's tetravalent dengue vaccine candidate (TAK-003) among 20,099 healthy children aged 4-16 years at enrolment across 26 study centers in the Philippines, Sri Lanka, Thailand, Brazil, Colombia, Dominican Republic, Nicaragua and Panama. Here we present data collected over approximately 39 months in the placebo group (n=6,687 as safety population) to provide comparable burden of disease information across countries and regions. During 21,142.5 person-years of active surveillance, there were 8,254 febrile illness cases recorded at study centers (IR=39/100 person-years). Of these, overall, 6% (503/8,254) were virologically confirmed dengue (VCD) using a central laboratory RT-PCR, 7.8% (334/4,287) in Asia and 4.3% (169/3,967) in Latin America. The majority (66.4%) of VCD cases occurred within Asian study sites. The overall incidence of VCD decreased with age group, 3.2/100 Person-Years in those aged 4-5 years at enrolment, 2.5/100 Person-Years in those aged 6-11 years at enrolment, and 1.8/100 Person-Years in those aged 12-16 at enrolment. Overall, 126 VCD cases required hospitalization (IR=0.6/100 person-years), 83% of which were in Asia. Ten VCD cases in Asia and three VCD cases in Latin America met the WHO 1997 Dengue

Hemorrhagic Fever case definition. Overall, DENV-1 was the most prevalent serotype seen among VCD cases (39%), followed by DENV-2 (36%), DENV-3 (22%) and DENV-4 (3%). The data confirms a higher burden of dengue in Asia. We will present more detailed analysis including country-specific data.

0167

### TRENDS AND CHARACTERISTICS OF HUMAN RABIES IN NORTHWESTERN BORNEO ISLAND, 2017 - 2020

**Nur Asheila Abdul Taib**, Jane Labadin, Razitasham Safii

*UNIMAS, Samarahan, Malaysia*

Since 2017, rabies has been an ongoing public health concern in Northwestern Borneo, specifically in the Malaysian state of Sarawak. This investigation provides the first insight into the trend and epidemiological characteristics of human rabies in the region. Data on laboratory-confirmed human rabies from 2017 to 2020 were gathered from official online press statements reported by the Director General of Health Malaysia. A total of 31 cases of human rabies has been admitted for the past four years with an average of 7.75 cases per year and a case-to-fatality rate of 93.5%. Initially clustered in the South, human rabies cases have now spread northwards. Overall, male cases outnumbered the females with a male-to-female ratio of 2.1:1. The human rabies victims were primarily adult males within the age group 45-64. The majority of cases among children and adolescents were from rural areas. In contrast, most adult patients were found to be urban residents. Dogs were responsible for all animal exposures with 60% of them being stray. The rate of rabies post-exposure prophylaxis (PEP) was low with only two victims completed the full regime. The median incubation period for human rabies was 65 days, while the median duration of disease was 12 days. The most common clinical symptoms were weakness in the limbs, hydrophobia, fever and aggressiveness. Interestingly, the only two rabies survivors were both children with history of immediate and complete PEP treatment. All in all, we identified the culture of adopting stray dogs and poor treatment-seeking behaviour as the risk factors for human rabies in Sarawak. Hence, emphasizing awareness, improving PEP accessibility and intensifying mass dog vaccination may help to mitigate rabies in Sarawak.

0168

### GLYCATED CHITOSAN REDUCES MORTALITY IN A LETHAL MOUSE MODEL OF SARS-COV-2

**Christopher M. Weiss**<sup>1</sup>, Hongwei Liu<sup>1</sup>, Erin E. Ball<sup>1</sup>, Samuel Siu Kit Lam<sup>2</sup>, Tomas Hode<sup>2</sup>, Lu Alleruzzo<sup>2</sup>, Richard M. Levenson<sup>3</sup>, Lark L. Coffey<sup>1</sup>

<sup>1</sup>University of California, Davis, Davis, CA, United States,

<sup>2</sup>Immunophotonics, Inc., St. Louis, MO, United States, <sup>3</sup>UC Davis Health, Sacramento, CA, United States

The rapid emergence and global dissemination of the novel coronavirus, SARS-CoV-2, has led to an ongoing global health burden of severe morbidity and mortality, particularly in aged-populations. SARS-CoV-2, which was first detected in late 2019, has infected more than 124 million people worldwide and caused over 2.8 million deaths in a year. While multiple vaccine countermeasures have been approved for emergency use, additional non-specific treatments continue to be needed as a sluggish vaccine rollout, vaccine refusal, and neutralization-escape variants threaten to prolong the pandemic. Immunoadjuvant compounds delivered intranasally can shape non-specific innate immune responses during the critical early stages of viral infection, reducing morbidity and mortality as well as physically interfering with virus-receptor interactions. Glycated chitosan (GC), a polymer of  $\beta$ -D-4-linked N-acetylglucosamine solubilized by the conjugation of galactose glycans, has previously been described as a water-soluble immunoadjuvant for anti-tumor therapy. GC administered intranasally before and after otherwise lethal SARS-CoV-2 exposure diminished morbidity and mortality in humanized ACE2-receptor-expressing mice by up to 75% and reduced infectious virus levels in the upper airway and lungs. Coinciding with lower viral levels in lungs,

a reduction in both the severity of lung lesions and total inflammation was observed in GC-treated compared to mock-inoculated SARS-CoV-2 infected mice. Our findings demonstrate a potential new application for soluble immunoadjuvants such as GC for preventing and possibly treating SARS-CoV-2.

0169

### KNOWLEDGE AND RISK PERCEPTION ABOUT ZIKA AMONG REPRODUCTIVE-AGED WOMEN IN THE ZIKA VIRUS OUTBREAK IN PERU

**Pamela Roxana Chacón-Uscamaita**

*Universidad Peruana Cayetano Heredia, Lima, Peru*

The aim of the study was to identify the knowledge and risk perception about Zika among women of childbearing age in Peru in 2017. Cross-sectional study, in which a secondary database analysis was carried out from three cities in Peru (Lima, Piura and Iquitos). Of the 716 women interviewed, only 85.5% heard of Zika although they were in the Zika virus outbreak, only 72.4% of women identified that they can get Zika in their community and 65.6% properly recognize that all people who can get Zika virus. Knowledge of the different mechanisms of transmission of Zika is greater in the northern of Peru. Women mostly recognized the transmission of mosquitoes (79.9%) in contrast to sexual transmission (30.2%), blood transfusion (36.6%) and vertical transmission (37.0%). Comparing these knowledge according sociodemographic variables, it was found that there were no differences according to the number of children, occupation, number of housemates, or time of residence, only having undergraduate studies increased it ( $p < 0.05$ ). In addition, there were no differences identifying these transmission mechanisms whether they were pregnant or not ( $p \geq 0.05$ ). They obtained the information mostly from television (55.9%) and health workers (33.7%). They identified the following risks: 51.3% for pregnant women (abortion) and 40.6% for the fetus risk (microcephalus). To conclude, there is a need to increase the women's knowledge about the other ways of transmission different from mosquito and the use of television combine with health workers' educational campaigns could be useful in new interventions.

0170

### RANDOMIZED CLINICAL TRIAL, PHASE 2, TO EVALUATE THE EFFICACY OF ARTESUNATE IV ALONE OR COMBINED WITH VITAMIN C IV FOR THE TREATMENT OF COVID-19

**Rianasoambolanoro Rakotosaona**<sup>1</sup>, Sadera Aurelien Mioramalala<sup>1</sup>, Fridolin Maminiana<sup>2</sup>, Fanomezantsoa Rakoto<sup>3</sup>, Willy Ratovondrainy<sup>3</sup>, Antsa Rakotondrandriana<sup>1</sup>, Dominique Razafimandimby<sup>3</sup>, Rabenja Rapelanoro<sup>4</sup>, Zely Randriamanantany<sup>5</sup>, Rivo Rakotoarivelo<sup>5</sup>, Olivat Rakoto<sup>6</sup>, Jhurry Dhanjay<sup>7</sup>, Arsene Claude Ratsimbasoa<sup>1</sup>, Luc Rakotovo<sup>4</sup>, David Ramanitrasimbola<sup>4</sup>

<sup>1</sup>Centre National d'Application de Recherches Pharmaceutiques, Antananarivo, Madagascar, <sup>2</sup>Institut Malgache des Vaccins Vétérinaires, Antananarivo, Madagascar, <sup>3</sup>Military Hospital of Antananarivo, Antananarivo, Madagascar, <sup>4</sup>Faculty of Medicine, University of Antananarivo, Antananarivo, Madagascar, <sup>5</sup>Faculty of Medicine, University of Fianarantsoa, Fianarantsoa, Madagascar, <sup>6</sup>HJRA Hospital, Antananarivo, Antananarivo, Madagascar, <sup>7</sup>University of Mauritius, Moka, Mauritius

There is currently no effective, proven, and safe treatment for severe illness caused by SARS-CoV-2. Artesunate showed its anti-inflammatory and antiviral *in vitro* activity against SARS-CoV-2. Vitamin C, known for its antioxidant propriety is reported to be effective on the immune system response, has antiviral properties and reduces cytokine storm in acute respiratory distress syndrome. A total of seventy (70) patients were screened and forty-four patients (44) with confirmed COVID-19 were enrolled in the study and divided into three groups: artesunate IV ( $n = 15$ ), artesunate IV+Vit C ( $n=14$ ) and control ( $n = 15$ ). The primary outcome was the time taken to reach undetectable levels of severe acute respiratory syndrome-coronavirus-2 (SARS-CoV-2) and the percentage of participants with undetectable SARS-CoV-2 on days 7, 14, 21 and 28.

The computed, adverse events, and abnormal laboratory parameters were corrected interval QT changes the secondary outcomes. The median time to reach undetectable viral RNA was 15 days for the artesunate group, 14 days for artesunate IV plus Vit C and 21 days for the control group. The percentages of patients with undetectable viral RNA on days 7, 14, 21, and 28 were 20%, 6.7%, 13.3%, and 0%, respectively, in the control group; 40%, 33.3%, 13.3%, and 0%, respectively, in the artesunate IV alone group and 21.4%, 21.4%, 14%, and 7.1%, respectively, in the artesunate IV plus VitC group. Electrocardiography adverse events were more common in each group. Premature discontinuation of treatment in placebo occurred because of serious adverse events. No biological failure was noted. In conclusion, there is a trend on the fact that patients in artesunate alone group has a better treatment success. However, a large-scale study should be conducted for evidence based and immunological parameters will be done.

0171

### DETECTION OF SARS-COV-2 IN EXHALED AIR USING NON-INVASIVE EMBEDDED STRIPS IN MASKS

**Emily N. Gallichotte**<sup>1</sup>, William Jon Windsor<sup>2</sup>, Stuart Watts<sup>1</sup>, Elijah Barstis<sup>1</sup>, Charles Henry<sup>1</sup>, Thomas Jaenisch<sup>2</sup>, Molly M. Lamb<sup>2</sup>, Geoffrey Winstanley<sup>2</sup>, May Chu<sup>2</sup>, Gregory Ebel<sup>1</sup>

<sup>1</sup>Colorado State University, Fort Collins, CO, United States, <sup>2</sup>Colorado School of Public Health, Aurora, CO, United States

SARS-CoV-2 emerged in 2019 and resulted in a pandemic causing millions of infections and deaths. Early in the pandemic, testing was severely limited and has only recently caught up with demand. The gold-standard for SARS-CoV-2 detection uses quantitative RT-PCR on respiratory specimens (nasopharyngeal swab, nasal swab, saliva, etc.) to detect viral RNA (vRNA). Acquiring these samples is invasive, can be painful for those with xerostomia and other health conditions, and sample quality varies greatly based on sample source, collection method, and the skill of the collector. Frequently, only symptomatic individuals are tested, despite the fact that asymptomatic individuals can have comparable viral loads and efficiently transmit virus. Therefore, we sought to utilize a non-invasive approach to detect SARS-CoV-2 in individuals regardless of symptom status, using polyvinyl alcohol (PVA) strips embedded in KN95 masks. In laboratory experiments, we show recovery of vRNA, viral protein and infectious virus from virus-spiked PVA strips with detection limits comparable to nasal swab samples. We then recruited 24 individuals from healthcare settings in the Denver area that had recently tested positive for SARS-CoV-2 to wear masks embedded with PVA strips. Seven participants (29%), including both symptomatic and asymptomatic individuals, had detectable SARS-CoV-2 vRNA on their PVA strips. Additionally, we were able to culture infectious virus and sequence vRNA from these PVA strips. Varying levels of human RNA were detected on strips, indicating a range in the amount of material participants exhale. The longer the mask was worn, the more host and vRNA was detected. Participants were surveyed on their activities while wearing the mask. Talking was significantly associated with detecting SARS-CoV-2 on the PVA strip. Together these results demonstrate the feasibility of using masks embedded with PVA strips as a non-invasive platform for detecting SARS-CoV-2 in exhaled air in both symptomatic and asymptomatic individuals. We are expanding this study to a larger cohort of index cases and their contacts to track and evaluate transmission.

0172

### DIRECT DETECTION OF GUAICO CULEX VIRUS IN CULEX SPP. MOSQUITOES OF COSTA RICA

Alejandro Chacón-Chacón<sup>1</sup>, Luis M. Romero-Vega<sup>1</sup>, Eugenia Corrales-Aguilar<sup>1</sup>, Jason T. Ladner<sup>2</sup>, **Adriana Troyo<sup>1</sup>**

<sup>1</sup>Centro de Investigación en Enfermedades Tropicales, Facultad de Microbiología, Universidad de Costa Rica, San Jose, Costa Rica, <sup>2</sup>The Pathogen and Microbiome Institute, Northern Arizona University, Flagstaff, AZ, United States

Guaico Culex Virus (GCXV) is a multicomponent Jingmenvirus that infects mosquitoes. It was isolated in 2014 from *Culex declarator* in Trinidad, and later from *Culex coronator* and/or *Culex interrogator* in Peru, Brazil, and Panama. Considering that all previous detections of GCXV were done after isolation and replication of viruses in cell lines, our aim was to implement a one-step reverse transcriptase PCR (RT-PCT) and a real-time RT-PCR protocol to detect GCXV RNA directly from field-caught mosquitoes in Costa Rica. Before analyzing mosquitoes, both protocols were tested to confirm no unspecific amplification of arboviruses, including dengue (DENV), Zika (ZIKV), and yellow fever (YFV) viruses. A total of 387 *Culex* spp. mosquitoes were collected from different regions of the country using CDC (with CO<sub>2</sub>) and gravid female traps. They were pooled by location, species, and date of collection into 87 pools of up to 10 individual mosquitoes. RNA was extracted and analyzed by RT-PCR and real-time RT-PCR using primers that amplify a 240 bp fragment of genome segment 1 of GCXV. The following controls were included in each PCR run: GCXV cDNA from cell culture isolate, purified GCXV Segment 1, cDNA from uninfected *Aedes aegypti* (laboratory colony), and a reagent control. GCXV was detected by both protocols in only one pool (4 females) of *Cx. coronator* mosquitoes from the Caribbean region of the country. The product obtained was sequenced and it showed 98.9 % (87/88) similarity to sequences of GCXV obtained from *Cx. coronator* in Peru. Of interest, similarity with GCXV sequences from Panama was 93.2 to 95.5 %. Results confirm that GCXV is present in Costa Rica, and that this virus can be detected directly in mosquitoes by one-step and real time RT-PCR. Although GCXV has not been associated with human infection, continuing studies on distribution, ecology and mosquito-virus interactions are necessary to determine possible implications of infection on mosquito fitness and vector competence for pathogenic arboviruses.

0173

### SEROLOGICAL EVIDENCE OF LOW PATHOGENIC AVIAN INFLUENZA SEROTYPE H9 IN LIVE BIRD MARKETS, JOS, PLATEAU STATE NIGERIA

**David A. Abiayi**, Gbeminiyi R. Otolurin, Clement A. Meseko, Asabe D. Emennaa

University of Jos, Plateau State, Nigeria, Jos, Nigeria

Avian influenza is a zoonotic disease that can adversely affect public health and the economy. Nigeria reported outbreak of avian influenza for the first time in 2006. Virological and serological survey thereafter revealed the importance of local birds in live bird markets in the epidemiology of avian influenza in Nigeria. In the present study, 276 serum samples were collected over 5 months from apparently healthy local birds at live bird markets in two Local Government Areas in Plateau State. The Detection of influenza A antibody was carried out using Enzyme linked immunosorbent assay and further tested by haemagglutination inhibition to determine the specific serotype of the influenza A virus. The result showed a prevalence of 30.4% (n=84) of antibody to influenza A, 26% (n=72) of serotype H9, 1.4% (n=4) of serotype H7, and none was confirmed to be H5 serotype. Comparatively Jos-North had higher relative risk of the disease as compared to Jos-South. This study indicated the presence of avian influenza virus in live bird market within the study area with the dominance of antibody to H9. To our knowledge, this is the first serological indication of serotype H9 in Plateau State and Nigeria. Evidence of influenza A/H9 in an ecological niche known for the circulation of subtypes H5Nx may complicate the epidemiology and control of avian

influenza in region and Nigeria at large. Live-bird market operators and poultry farmers should increase or maintain a good level of biosecurity and limit co-mingling with local birds to prevent the transmission of the virus which may have adverse effects on poultry production, national and international trade, the economy and public health.

0174

### CO-CIRCULATION OF CHIKUNGUNYA VIRUS, ALL FOUR DENGUE VIRUSES AND ZIKA VIRUS IN GUERRERO, MEXICO, 2019 AND EVIDENCE OF GROSS UNDER-REPORTING OF ARBOVIRAL DISEASES IN THE REGION

**Daniel Nunez Avellaneda<sup>1</sup>**, Chandra Chandra Tangudu<sup>1</sup>, Jacqueline Barrios-Palacios<sup>2</sup>, Ma. Isabel Salazar<sup>3</sup>, Carlos Machain-Williams<sup>4</sup>, Jonathan Cisneros-Pano<sup>5</sup>, Bradley Blitvich<sup>1</sup>

<sup>1</sup>Iowa State University, Ames, IA, United States, <sup>2</sup>National Institute of Medical Sciences and Nutrition Salvador Zubiraj, Ciudad de México, Mexico, <sup>3</sup>Escuela Nacional de Ciencias Biológicas Instituto Politécnico Nacional, Ciudad de México, Mexico, <sup>4</sup>Universidad Autónoma de Yucatan, Merida, Mexico, <sup>5</sup>Universidad Autónoma de Guerrero, Chilpancingo, Mexico

A clinical investigation was performed to test the hypothesis that arboviral diseases are grossly underreported in Mexico. Sera were collected from human subjects from low-income households in Guerrero, southwest Mexico. Guerrero has a high (66.5%) poverty rate and therefore, many of its residents have restricted access to healthcare and diagnostic testing. We specifically targeted individuals from households poorly represented in the national arbovirus diagnosis and surveillance program. The sample population consisted of 639 patients who developed febrile illness in 2019. Patients were serologically assayed for chikungunya virus (CHIKV) and select flaviviruses, including dengue virus (DENV) and Zika virus (ZIKV). Plaque reduction neutralization test (PRNT) revealed that 181 (28.3%) patients were seropositive for CHIKV. To identify patients with acute CHIKV infections, a subset of sera from seropositive patients were tested for CHIKV-specific IgM. Sera from 21 of 189 (11.1%) patients were positive. These patients met the chikungunya case definition. The number of chikungunya cases identified in this study is over twofold higher than the total number of cases reported across all of Mexico by the public health authorities that same year. To identify patients with acute flavivirus infections, sera from select patients (n = 263) were tested for flavivirus NS1. Sera from 48 (18.3%) patients contained viral antigen. All NS1-positive sera were titrated and tested by PRNT using DENV-1 to -4, St. Louis encephalitis virus, West Nile virus and ZIKV. Seven patients were seropositive for DENV-1, five patients were seropositive for DENV-2, one patient was seropositive for DENV-3 and two patients each were seropositive for DENV-4 and ZIKV. The remainder had secondary flavivirus infections or antibodies to an undetermined flavivirus. In summary, we provide evidence for the concurrent circulation of CHIKV, all four DENV serotypes and ZIKV in Guerrero, Mexico. The public health authorities reported no cases of CHIKV, DENV-3, DENV-4 and ZIKV in Guerrero in 2019 and therefore, we provide evidence of gross under-reporting in the region.

0175

### AN EPIDEMIOLOGICAL STUDY OF A SARS-COV-2 OUTBREAK INVOLVING A RURAL CHURCH SERVICE

**Megan McCarthy<sup>1</sup>**, Shannan Rich<sup>2</sup>, Michaela Gross<sup>3</sup>, Sara Nutley<sup>2</sup>, Brittany Merens<sup>4</sup>, Daniel Chacreton<sup>1</sup>

<sup>1</sup>Florida Department of Health, Bushnell, FL, United States, <sup>2</sup>University of Florida, Gainesville, FL, United States, <sup>3</sup>University of South Florida, Tampa, FL, United States, <sup>4</sup>Florida Department of Health, New Port Richey, FL, United States

We performed an outbreak investigation of SARS-CoV-2 – the virus causing the novel coronavirus disease (COVID-19) – among 57 cases associated with a church service that took place in March 2020 in a rural and predominantly elderly community in Sumter County, Florida. As part

of the investigation, we interviewed 151 church members to identify cases of SARS-CoV-2 associated with a church service. Of the 151 church members interviewed, 90 reported attending the service in question and 46 reported symptoms consistent with SARS-CoV-2 infection within 14 days of attending, corresponding to an attack rate of 51%. Including secondary cases, the investigation uncovered 32 confirmed and 25 probable cases associated with this church service. Of these cases, 46 reported attending the church service and 11 were close contacts of those who attended. Four deaths were linked to this outbreak, revealing a case fatality rate of 5.26%. The estimated attack rate of this church service was higher than previous studies, suggesting that this particular service describes a potential "super-spreading" event. Factors likely contributing to the high attack rate observed in this outbreak included frequent hand shaking, singing, communal meals, and a lack of masks and social distancing. In addition to the high attack rate, this outbreak also had a high case fatality rate likely owing to the high median age (64 years) and prevalence of comorbidities in this population. This study provides important information to help understand the factors contributing to the high SARS-CoV-2 attack rates observed in faith-based settings.

0176

### DO NOROVIRUS AND SAPOVIRUS GASTROENTERITIS EPISODES IN EARLY CHILDHOOD PROTECT AGAINST FUTURE EPISODES?

**Sylvia Becker-Dreps**<sup>1</sup>, Yaoska Reyes<sup>2</sup>, Bryan Blette<sup>1</sup>, Nadja Vielot<sup>1</sup>, Fredman Gonzalez<sup>2</sup>, Christian Toval-Ruiz<sup>2</sup>, Lester Gutierrez<sup>2</sup>, Samuel Vilchez<sup>2</sup>, Marta Diez-Valcarce<sup>3</sup>, Jan Vinje<sup>3</sup>, Filemon Bucardo<sup>2</sup>

<sup>1</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>2</sup>Universidad Nacional Autónoma de Nicaragua, Leon, Leon, Nicaragua, <sup>3</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Human caliciviruses are among the leading causes of acute gastroenteritis (AGE) in children. Little is known about whether natural norovirus and sapovirus episodes evoke protection against future episodes, information needed for vaccine development. We estimated the protective efficacy of first episodes on future episodes using a Nicaraguan population-based birth cohort. Starting in June 2017, 444 children were followed weekly for AGE episodes until 36 months of age; stools collected during AGE episodes were tested by RT-qPCR. As of June 2020, 83, 109, and 97 children experienced a first norovirus GI, norovirus GII, and sapovirus AGE episode, respectively. Of these, 15, 20, and 16 children experienced subsequent norovirus GI, norovirus GII, and sapovirus AGE episodes, respectively. Because children who experience a first episode are likely to have characteristics that place them at higher risk of future episodes, we used two different statistical approaches to estimate hazard ratios (HR), accounting for confounding: 1) an adjusted Andersen-Gill (AG) Model, and 2) a case-only approach comparing the event rates of norovirus and sapovirus episodes to the rates of other AGE episodes with similar risk factors (negative control method). The adjusted AG Model found that first episodes did not protect against future episodes, however, the hazard for future norovirus episodes decreased after second episodes: HR: 0.29 (95% CI: 0.11, 0.78) after two norovirus GI episodes, and HR: 0.11 (95% CI: 0.03, 0.44) after two norovirus GII episodes. In contrast, the negative control method found a lower hazard of subsequent episodes even after the first episode of sapovirus (HR: 0.31, 95% CI: 0.06, 0.83), norovirus GI (HR: 0.67, 95% CI: 0.32, 1.31), and norovirus GII (HR: 0.20, 95% CI: 0.04, 0.44). Although results differed between methods used, these findings suggest that norovirus and sapovirus AGE episodes in early childhood confer some protection against future episodes. Further analyses to include additional confounders in the AG Model and to estimate the protective efficacy against genotype-specific norovirus and sapovirus AGE episodes are underway.

0177

### DETECTION OF ANTIBODIES TO LOKERN, MAIN DRAIN, ST. LOUIS ENCEPHALITIS AND WEST NILE VIRUSES IN VERTEBRATE ANIMALS IN CHIHUAHUA, GUERRERO AND MICHOACÁN, MEXICO

Tangudu<sup>1</sup>, Bradley Blitvich<sup>1</sup>

<sup>1</sup>Iowa State University, Ames, IA, United States, <sup>2</sup>Universidad Autónoma de Ciudad Juárez, Juárez, Mexico, <sup>3</sup>Universidad Autónoma de Chihuahua, Chihuahua, Mexico, <sup>4</sup>Universidad Michoacana de San Nicolás de Hidalgo, Morelia, Mexico, <sup>5</sup>Universidad Autónoma de Ciudad Juárez, Juárez, Mexico

We conducted serologic surveillance for flaviviruses and orthobunyaviruses in vertebrate animals in Mexico in 2018-2019. Sera were collected from 856 vertebrate animals, including 323 dogs, 223 horses and 121 cows, from 16 species. The animals were from three states: Chihuahua in northwest Mexico (704 animals) and Guerrero and Michoacán on the Pacific Coast (27 and 125 animals, respectively). Sera were assayed by plaque reduction neutralization test using four flaviviruses (dengue type 2, St. Louis encephalitis, West Nile and Zika viruses) and six orthobunyaviruses from the Bunyamwera (BUN) serogroup (Cache Valley, Lokern, Main Drain, Northway, Potosi and Tensaw viruses). Antibodies to West Nile virus (WNV) were detected in 154 animals of nine species, including 89 (39.9%) horses, 3 (21.4%) Indian peafowl and 41 (12.7%) dogs. Antibodies to St. Louis encephalitis virus (SLEV) were detected in seven animals, including three (0.9%) dogs. Antibodies to Lokern virus (LOKV) were detected in 22 animals: 19 (8.5%) horses, 2 (1.7%) cows and a dog (0.3%). Antibodies to Main Drain virus (MDV) were detected in three (1.3%) horses. WNV and LOKV activity was detected in all three states, SLEV activity was detected in Chihuahua and Michoacán, and MDV activity was detected in Chihuahua. None of the animals were seropositive for Cache Valley virus, the most common and widely distributed BUN serogroup virus in North America. In conclusion, we provide serologic evidence that select flaviviruses and BUN serogroup viruses infect vertebrate animals in Chihuahua, Guerrero and Michoacán. We also provide the first evidence of LOKV and MDV activity in Mexico.

### DETAILED VIRAL SHEDDING KINETICS PRIOR TO SYMPTOM ONSET IN PATIENTS WITH SARS-COV-2 INFECTION

**Seongman Bae**, Jiwon Jung, Eun Ok Kim, Joon Seo Lim, Heungsung Sung, Sung-Cheol Yun, Sung-Han Kim  
Asan Medical Center, Seoul, Republic of Korea

There are limited data on the detailed kinetics of pre-symptomatic viral shedding of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2). Through the pre-admission screening and epidemiological investigation, we had a unique opportunity to acquire the PCR results of patients with SARS-CoV-2 infection in their pre-symptomatic period. We retrospectively reviewed patients with SARS-CoV-2 infection who were linked with nosocomial clusters in a tertiary referral center (Asan Medical Center, Seoul) in South Korea between March 1, 2020 and December 15, 2020. Patients with a positive PCR result at least 2 days before symptom onset were categorized as pre-symptomatic viral shedders, and those with a negative PCR result at 1 or 2 days before symptom onset were categorized as symptomatic viral shedders. Patients who did not meet either criterion were categorized as indeterminate cases. During the study period, a total of 19 patients who had one or more PCR results within 7 days prior to symptom onset were identified. Of them, 6 patients were classified as pre-symptomatic viral shedders and 10 patients were classified as symptomatic viral shedders; the remaining three patients were classified as indeterminate cases. In the pre-symptomatic shedders, the median duration of viral shedding prior to symptom onset was 3 days (range,

2-5 days). Four of the 6 pre-symptomatic viral shedders were linked to 7 secondary infection cases that they had contact with during the pre-symptomatic phase, whereas none of the 10 symptomatic viral shedders were linked to any secondary cases. While more than half of the patients had no evidence of pre-symptomatic viral shedding prior to symptom onset, about one-third of the patients shed SARS-CoV-2 around 3 days prior to symptom onset and led to secondary infection cases during the pre-symptomatic period. These findings reaffirm the possibility of pre-symptomatic shedding and infectivity of SARS-CoV-2; in contrast, the virus excretion does not precede symptoms in a considerable proportion of the patients.

0179

### RHABDOMYOLYSIS AS PRESENTING FEATURE OF COVID-19: CASE SERIES AND LITERATURE REVIEW

**Hendrik Sy<sup>1</sup>**, Christian Olivo Freitas<sup>2</sup>, Patricia Miguez Arosemana<sup>1</sup>, Gustavo Contreras<sup>3</sup>, Alejandro Prigollini<sup>1</sup>, Georgina Osorio<sup>1</sup>

<sup>1</sup>*Icahn School of Medicine at Mount Sinai, Mount Sinai Morningside - West Hospitals, New York, NY, United States, New York, NY, United States,*  
<sup>2</sup>*University of California Los Angeles, Los Angeles, CA, United States,*  
<sup>3</sup>*Stanford University, Stanford, CA, United States*

Rhabdomyolysis has been increasingly recognized as a complication of COVID-19. We describe four cases of rhabdomyolysis as presenting feature of SARS-CoV-2 infection and conduct a review of the current literature. Four patients between 26 and 80 years were hospitalized with COVID-19 in a New York City Hospital system during March and April 2020. All patients presented with myalgias and had evidence of rhabdomyolysis on admission. Only two patients had respiratory symptoms. Creatinine kinase (CK) ranged from 15,000 to 400,000 U/L. Three patients required renal replacement therapy and died during the hospitalization. We identified 41 case reports with 70 patients and one observational study with 140 patients that were published between June 2020 and March 2021 with a total of 210 cases of rhabdomyolysis in COVID-19. Among those patients, 148 (71%) were male. The majority were Black (45%), followed by Hispanic (16%) and Non-Hispanic White (8%) patients. The most common co-morbidities were hypertension (61%), diabetes mellitus (39%), chronic kidney disease (21%) and dementia (11%). Patients presented most often with dyspnea (59%), fever (54%) and cough (50%). Respiratory symptoms were absent in one third of cases and 20% complained of myalgias. Acute kidney injury developed in 75% of cases and 23% required renal replacement therapy. CK levels differed widely between the observational study and the pooled case reports with a median peak CK of 2,209 U/L and 13,581 U/L, respectively. The most commonly used COVID-19 specific therapies described in the case reports were hydroxychloroquine (30%), azithromycin (24%) and steroids (21%). The in-hospital mortality for all combined cases was 45%. In conclusion, patients with COVID-19 and rhabdomyolysis can present with severe myalgias in the absence of respiratory symptoms. Acute kidney injury is common and may require renal replacement therapy. More research is needed to understand the underlying mechanism.

### MOLECULAR BARRIERS TO SARS-COV-2 REPLICATION IN BAT CELLS

**Sophie-Marie Aicher<sup>1</sup>**, Felix Streicher<sup>1</sup>, Maxime Chazal<sup>1</sup>, Delphine Planas<sup>2</sup>, Dongsheng Luo<sup>3</sup>, Julian Buchrieser<sup>2</sup>, Jordi Serra-Cobo<sup>4</sup>, Dominique Pontier<sup>5</sup>, Olivier Schwartz<sup>2</sup>, Jiri Pikula<sup>6</sup>, Laurent Dacheux<sup>3</sup>, Nolwenn Jouvenet<sup>1</sup>

<sup>1</sup>*Virus Signaling and Sensing Unit, Institut Pasteur Paris, Paris, France,*  
<sup>2</sup>*Virus and Immunity Unit, Institut Pasteur Paris, Paris, France,* <sup>3</sup>*Lyssavirus Epidemiology and Neuropathology Unit, Institut Pasteur Paris, Paris, France,* <sup>4</sup>*Department of Evolutionary Biology, Ecology and Environmental Sciences, Biodiversity Research Institute (IRBIO), University of Barcelona, Barcelona, Spain,* <sup>5</sup>*University Lyon, Universite Lyon 1, CNRS, Laboratoire*

<sup>6</sup>*Department of Ecology and Diseases of Game, Fish and Bees, University of Veterinary and Pharmaceutical Sciences Brno, Brno, Czech Republic*

Bats are natural reservoirs for numerous coronaviruses, including the potential ancestor of SARS-CoV-2. Knowledge concerning the interaction of coronaviruses and bat cells is, however, sparse. There is thus a need to develop bat cellular models to understand cell tropism, viral replication, and virus-induced cell responses. Here, we report the first molecular study of SARS-CoV-2 infection in chiropteran cells. We investigated the susceptibility to SARS-CoV-2 infection of a panel established bat cell lines, belonging to the species *Myotis myotis*, *Eptesicus serotinus* and *Tadarida brasiliensis*, as well as novel *Nyctalus noctula* cells, which was completed with primary cells from *Rhinolophus ferrumequinum* and *Myotis spp.* bats. None of these cells were sensitive to infection, not even the one expressing detectable levels of angiotensin-converting enzyme 2 (ACE2), which serves as the viral receptor in many mammalian species including humans. Following transduction with human ACE2, six bat cell lines expressed comparable or higher level of hACE2 than a permissive human cell line. In three out of these six cell lines, the resistance to infection was overcome by hACE2 expression, suggesting that restriction to viral replication was due to lack of bACE2 expression or absence of bACE2 binding. By contrast, multiple restriction factors to viral replication exist in the three *N. noctula* cells since hACE2 expression was not sufficient to permit infection. Notably, viral replication was efficiently controlled in *E. serotinus* cells and correlated with a potent induction of interferon-stimulated genes. Despite high level of replication, infectious virions were not released from *M. myotis* cells. Together, our data highlight the existence of species-specific molecular barriers to viral replication in bat cells. Our newly developed chiropteran cellular models are useful tools to investigate the interplay between viruses belonging to the SARS-CoV-2 lineage and their natural reservoir, including the identification of factors responsible for viral restriction.

### SEROPREVALENCE OF RIFT VALLEY FEVER VIRUS IN URBAN KENYA: A POTENTIAL PUBLIC HEALTH BURDEN HIDING IN PLAIN SIGHT

**Keli N. Gerken<sup>1</sup>**, Eleonora Migliore<sup>1</sup>, Said Malumbo<sup>2</sup>, Karren N. Shaita<sup>3</sup>, Gladys Agola<sup>3</sup>, Eduardo Fabre<sup>1</sup>, Francis Mutuku<sup>4</sup>, Bryson Ndenga<sup>3</sup>, A. Desiree LaBeaud<sup>1</sup>

<sup>1</sup>*Stanford University School of Medicine, Stanford, CA, United States,*

<sup>3</sup>*Kenya Medical Research Institute (KEMRI), Kisumu, Kenya,* <sup>4</sup>*Technical University of Mombasa, Mombasa, Kenya*

Rift Valley fever virus (RVFV) is a mosquito transmitted bunyavirus that can also transmit directly to humans from animals and can cause severe infections in both. Previous studies have shown that consuming raw milk and preparing meat are risk factors for RVFV exposure, but it is difficult to disentangle those risk factors from other livestock rearing activities. Urban areas have an increased demand for animal source foods, different vector distributions, and various arboviruses are understood to establish localised urban transmission cycles. Thus far, RVFV is an unevaluated public health risk in urban areas. We tested our ongoing urban cohort study on dengue (DENV) and chikungunya (CHIKV) virus for RVFV exposure and found 34/2,779 (1.2%) of adults in two urban areas in Kenya had anti-RVFV antibodies. Higher seroprevalence was seen in the larger western city, Kisumu (1.7%), compared to Ukunda (0.9%) on the coast, and 88% also had co-exposure to DENV, CHIKV, or both. Unlike rural areas, 92% of the cohort did not own animals, but RVFV exposure was significantly associated with seeing goats around the homestead ( $p=.02$ ) which could represent viral amplifiers. Consumption of raw milk ( $p=.05$ ) and not boiling milk ( $p=.002$ ) were also significant risk factors for exposure. To further characterize food-related risk factors, we conducted a nested case-control study and those buy unpasteurized milk, from milk vendors or private purchasing from dairy owners, were three times as likely to have RVFV exposure ( $OR=3.3$ ,  $p=.07$ ). 98% of all participants consumed beef at least

monthly and 2/105 reported tasting the raw beef before cooking and had RVFV exposure. Using animal blood for cooking (OR=3.3,  $p=.08$ ) was also associated with an increased odds of RVFV exposure. None of the seropositive participants knew they had been exposed to or been tested for RVFV, yet were more likely to report occasional sudden decreases in vision compared to seronegative participants (OR=6.25,  $p=.00$ ). Overall this study provided baseline evidence that there may be an urban burden of RVFV tied to food consumption practices and risk factors for disease may differ from rural areas.

0182

### PREVALENCE AND VERTICAL TRANSMISSION OF SARS-COV-2 INFECTION AMONG PARTURIENTS FROM LUANDA, ANGOLA

**Cruz Sebastião<sup>1</sup>**, Paolo Parimbelli<sup>2</sup>, Augusto Bambi<sup>2</sup>, Eden Bernardo<sup>2</sup>, Joaquim Mauito<sup>2</sup>, Mateus Cristovão<sup>2</sup>, Jeffrey Ernesto<sup>2</sup>, Emanuel Junior<sup>2</sup>, Herio Tiberio<sup>2</sup>, Paulo André<sup>2</sup>, Paulo Bumba<sup>2</sup>, Lelo Cambungo<sup>2</sup>, Amadeu Catanha<sup>2</sup>, Anabela Mateus<sup>1</sup>, Janete António<sup>3</sup>, Francisco Manuel<sup>3</sup>, Luzia Quipungo<sup>3</sup>, Manuela Mendes<sup>2</sup>, António Mateus<sup>3</sup>, Zinga David<sup>3</sup>, Joana Morais<sup>3</sup>, Jocelyne Neto de Vasconcelos<sup>1</sup>, Miguel Brito<sup>4</sup>

<sup>1</sup>Centro de Investigação em Saúde de Angola, Caxito, Angola,

<sup>2</sup>Maternidade Lucrecia Paim, Ministério da Saúde, Luanda, Angola, Luanda, Angola, <sup>3</sup>Instituto Nacional de Investigação em Saúde, Luanda, Angola, <sup>4</sup>Health and Technology Research Center, Escola Superior de Tecnologia da Saúde de Lisboa, Instituto Politécnico de Lisboa, 1990-096 Lisboa, Portugal, Lisboa, Portugal

SARS-CoV-2 emerged in China in December 2019. Currently, the infection constitutes the main public health problem. Although some studies have identified SARS-CoV-2 in pregnant women, the possibility of vertical transmission to newborns remains uncertain. In the present study, we investigated the prevalence and vertical transmission of SARS-CoV-2 among 3610 parturients from Luanda, the capital city of Angola. The parturients were screened to SARS-CoV-2 antigen using the COVID-19 Ag Rapid Test Device kit. The age of parturients ranged from 13 to 57 years. A total of 0.3% (10/3610) parturients tested positive on the day of delivery and of these, 2/10 (33.3%) remained positive until the seventh day after the delivery. Moreover, a total of 2 parturients died from the SARS-CoV-2 infection. None of the newborns tested positive in the first 24 hours after birth, however, one of the newborns tested positive seven days after birth. Our results showed a low prevalence of SARS-CoV-2 among the parturients in Luanda. The low rate of transmission observed in this study suggests that the care of the mother infected with SARS-CoV-2 is crucial for continuing breastfeeding. On the other hand, our findings suggest that is necessary to increase SARS-CoV-2 screening in pregnant women, in order to reduce the maternal or newborn mortality rate in Angola.

0183

### KNOWLEDGE, ATTITUDES, AND PRACTICES REGARDING SARS-COV-2 IN A UNIVERSITY COMMUNITY, MASSACHUSETTS, USA AND THE OPTIMIZATION OF COVID-19 RESPONSE PLANNING: A QUALITATIVE STUDY

**Teah R. Snyder**, Johanna Ravenhurst, Kate Wallace, Eva Chow, Sarah Goff, Sheila Pennell, Andrew A. Lover

University of Massachusetts Amherst, Amherst, MA, United States

Mitigation of the spread of SARS-CoV-2 within a population is impacted by the degree to which individuals adhere to recommended infection control measures. An evaluation of individuals' knowledge, attitudes, and practices (KAP) regarding SARS-CoV-2 can provide information regarding the most effective ways to tailor a COVID-19 response program for maximum adherence. Few studies have evaluated knowledge, attitudes, and practices regarding SARS-CoV-2 in university campus communities. We used the information gathered during these interviews to inform COVID-19 response efforts for the Spring 2021 semester. We performed focus groups with undergraduate students, graduate students, faculty members, and staff members at the University of Massachusetts Amherst

to investigate COVID-19-specific KAP. Focus group discussions involved sources of COVID-19 related information, definitions of isolation/quarantine, perceptions of contact tracing, and risk perceptions regarding socialization activities. We asked about experiences in utilizing the campus asymptomatic testing center and gathered any improvement suggestions. Interviews were conducted individually with those who had experienced isolation or quarantine during the Fall 2020 semester. Interview questions included sources of information regarding COVID-19, experiences while in isolation/quarantine, resources utilized or desired while in isolation/quarantine, impacts on academic performance and mental health, and overall perceptions of the contact tracing program. We gathered feedback regarding improvements for the asymptomatic testing center, contact tracing program, and on-campus isolation/quarantine coordinators. Suggestions for improvement were incorporated into Spring 2021 planning efforts as appropriate. Qualitative data analysis will utilize Dedoose software for thematic analysis. Results are expected in August 2021. This study is innovative in being one of the only studies performed in a university community to investigate COVID-19-specific KAP and to incorporate feedback from these studies into future COVID-19 response planning efforts.

### THREE YEARS OF INSECTICIDE RESISTANCE MONITORING IN FIVE SENTINEL SITES IN CAMEROON: CONTRIBUTION TO VECTOR CONTROL DECISION MAKING

**Etienne Fondjo<sup>1</sup>**, Jean-Claude Toto<sup>2</sup>, Magellan Tchouakui<sup>3</sup>, Elysee Ekoko Wolfgang<sup>2</sup>, Salemon Patchoke<sup>4</sup>, Benjamin Menze<sup>5</sup>, Boris Njeambosay<sup>6</sup>, Raymond Tabue<sup>4</sup>, Elysee Mandeng<sup>2</sup>, Emmanuel Elanga<sup>5</sup>, Cyrille Ndo<sup>5</sup>, Billy Tene<sup>3</sup>, Elysee Nchoutpouen<sup>2</sup>, Edmond Kopya<sup>2</sup>, Dorothy Achu<sup>4</sup>, Kelley Ambrose<sup>7</sup>, Judith Hedje<sup>8</sup>, Jose Tchofa<sup>9</sup>, Jenney Carlson<sup>10</sup>, Sarah Zohdy<sup>11</sup>, Joseph Chabi<sup>12</sup>

<sup>1</sup>Vectorlink Cameroon, Yaounde, Cameroon, <sup>2</sup>Organization for the Coordination of Endemic Diseases in Central Africa, Yaounde, Cameroon, <sup>3</sup>Center for Research on Infectious Diseases, Yaounde, Cameroon, <sup>4</sup>National Malaria Control Programme, Yaounde, Cameroon, <sup>5</sup>Centre for Research in Infectious Diseases, Yaounde, Cameroon, <sup>6</sup>Biotechnology Center, Yaounde, Cameroon, <sup>7</sup>Abt associates, Yaounde, Cameroon, <sup>8</sup>Centers for Disease Control and Prevention, Yaounde, Cameroon, <sup>9</sup>President's Malaria Initiative, Agency for International Development, Yaounde, Cameroon, <sup>10</sup>President's Malaria Initiative, Agency for International Development, Washington, DC, United States, <sup>11</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>12</sup>President's Malaria Initiative, Vectorlink project, Abidjan, Côte D'Ivoire

The U.S. President's Malaria Initiative VectorLink Cameroon project has conducted annual insecticide resistance monitoring in five sentinel sites (Bonabéri, Gounougou, Nyabessang, Mangoum, and Simatou) from 2018-2020. Bioassays were carried out using World Health Organization (WHO) susceptibility test kits and CDC bottle bioassays depending on the insecticide. Larvae collected in the field and reared to 2-5-day-old adult female *Anopheles gambiae* s.l. were tested against alpha-cypermethrin (0.05%), deltamethrin (0.05%), permethrin (0.75%), pirimiphos-methyl (0.25%), bendiocarb (0.1%), clothianidin (2%), and chlorfenapyr (100 and 200 µg/bottle). Resistance status was determined using WHO criteria. When pyrethroid resistance was found, resistance intensity (5x and 10x the diagnostic doses) was assessed and synergist assays using 4% piperonyl butoxide (PBO) were done. Following susceptibility testing, a subset of mosquitoes (dead and alive) was also screened for genetic markers of resistance using PCR assays: knock down resistance (*kdr*-west, *kdr*-east, acetylcholinesterase (*Ace-1*) and N1575Y. Results showed persistent pyrethroid resistance and varying susceptibility to chlorfenapyr and clothianidin. *An. gambiae* s.l. were resistant to all pyrethroids in all sites, with an average mortality of less than 78% for alpha-cypermethrin and deltamethrin, and about 29% for permethrin. Pirimiphos-methyl and bendiocarb resistance was recorded only in Mangoum. Susceptibility to clothianidin and chlorfenapyr was recorded in all five sites. High pyrethroid resistance was recorded in all sites except Bonabéri, where moderate permethrin resistance and low alpha-cypermethrin resistance was found.

Pre-exposure of *An. gambiae* s.l. to PBO restored susceptibility to alpha-cypermethrin in Bonabéri and partially restored susceptibility to pyrethroids at all other sites. All four mutations were detected in varying frequency by site. These results can inform the country's vector control decision making, particularly in the selection and strategic deployment of insecticide-treated nets for the planned 2022/23 mass campaign

0185

### BIOMARKERS OF ACUTE KIDNEY INJURY AND PERSISTENT KIDNEY DISEASE IN CHILDREN WITH SEVERE MALARIA

Andrea L. Conroy<sup>1</sup>, Ruth Namazzi<sup>2</sup>, Anthony Batte<sup>2</sup>, Dibadyuti Datta<sup>1</sup>, John Ssenkusu<sup>3</sup>, Robert O. Opoka<sup>2</sup>, Chandy C. John<sup>1</sup>

<sup>1</sup>Indiana University School of Medicine, Indianapolis, IN, United States, <sup>2</sup>Makerere University, Kampala, Uganda, <sup>3</sup>Makerere University School of Public Health, Kampala, Uganda

Acute kidney injury (AKI) is an important complication in children with severe malaria associated with increased mortality and chronic kidney disease (CKD) in survivors. AKI may appear to resolve in the short-term but can lead to acute kidney disease (AKD) or injury may be sub-clinical and result in the gradual development of AKD. The objective of this study was to evaluate established and next-generation biomarkers of AKI (admission) and AKD (1-month). We conducted a prospective observational study enrolling 600 children with severe malaria between 2014 and 2017. Children had AKI defined during the first 24 hours of hospital admission and AKD at 1-month follow-up using the Kidney Disease: Improving Global Outcomes (KDIGO) guidelines. We tested biomarkers (BUN, Cystatin C, NGAL, IL-18, L-FABP, Angpt-2, sICAM-1, sFlt-1, CHI3L1, CXCL10, sTNFR1, sTREM-1) at admission and 1-month follow-up by ELISA or Luminex. Biomarker performance was evaluated using receiver operating characteristic curve analysis and comparing the area under the curve (AUC). On enrollment, 45.3% of children had AKI and 15.6% of survivors had AKD at one month follow-up. All biomarkers were elevated in children with AKI on admission and increased across AKI stages ( $p < 0.001$  for all). To determine whether prolonged increases in biomarkers were related to AKD, we measured 10 of the biomarkers at 1-month follow-up. We found 8 of the 10 biomarkers (Cystatin C, NGAL, Angpt-2, sICAM-1, sFlt-1, CHI3L1, sTNFR1, and sTREM-1) remained elevated in children with AKD ( $p < 0.05$  for all). The top performing biomarkers to identify children with AKD at 1-month follow-up were sTNFR1 (AUC: 0.78, 95% CI 0.73 to 0.83), sTREM-1 (AUC: 0.84, 95% CI 0.78 to 0.89) and NGAL (AUC: 0.76, 95% CI 0.70 to 0.82). These findings suggest that persistent inflammation (sTNFR1, sTREM-1) and tubular injury (NGAL) at one-month follow-up in children with ongoing kidney disease. Future studies need to assess biomarkers of AKI and AKD in urine, as a more direct measure of kidney injury, and to evaluate how markers of AKI and AKD relate to long-term risk of CKD.

0186

### STUDIES OF THE PARASITE-MIDGUT INTERACTION REVEAL PLASMODIUM PROTEINS IMPORTANT FOR MALARIA TRANSMISSION TO MOSQUITOES

Guodong Niu, Yingjun Cui, Xiaohong Wang, Jun Li

Florida International University, Miami, FL, United States

Malaria transmission relies on parasite-mosquito midgut interaction. Targeting on the interactive proteins is hypothesized to block malaria transmission to mosquitoes. We chose 76 genes that contain signal peptide-coding regions and are upregulated and highly abundant at sexual stages. Forty-six of these candidate genes (60%) were cloned and expressed using the baculovirus expression system in insect cells. Six of them, e.g., PF3D7\_0303900, PF3D7\_0406200 (Pfs16), PF3D7\_1204400 (Pfs37), PF3D7\_1214800, PF3D7\_1239400, and PF3D7\_1472800 were discovered to interact with blood-fed mosquito midgut lysate. Among these interactive proteins, previous works showed that knockout the orthologs of Pfs37 or Pfs16 in *Plasmodium berghei* reduced oocysts in mosquitoes. Here we further found that anti-Pfs16 polyclonal antibody

significantly inhibited *P. falciparum* transmission to *Anopheles gambiae*. Investigating these candidate proteins will improve our understanding of malaria transmission and discover new targets to break malaria transmission.

### INCREASED LEVELS OF HYPOXIA INDUCIBLE FACTOR1-ALPHA: IMPLICATIONS FOR THE PATHOGENESIS OF PEDIATRIC SEVERE MALARIAL ANEMIA

Elly O. Munde<sup>1</sup>, Samuel B. Anyona<sup>2</sup>, Caroline Ndege<sup>3</sup>, Perez Kola<sup>3</sup>, Evans Raballah<sup>4</sup>, Benjamin H. McMahon<sup>5</sup>, Kristan Schneider<sup>6</sup>, Qiuying Cheng<sup>7</sup>, Ivy Hurwitz<sup>7</sup>, Christophe G. Lambert<sup>7</sup>, Collins Ouma<sup>8</sup>, Douglas J. Perkins<sup>7</sup>

<sup>1</sup>Department of Clinical Medicine, School of Health Science, Kirinyaga University, Kerugoya, Kenya, <sup>2</sup>Department of Medical Biochemistry, School of Medicine, Maseno University, Maseno, Kenya, <sup>3</sup>University of New Mexico-Kenya Global Health Programs, Kisumu and Siaya, Kenya, <sup>4</sup>Department of Medical Laboratory Sciences, School of Public Health Biomedical Sciences and Technology, Masinde Muliro University of Science and Technology, Kakamega, Kenya, <sup>5</sup>Theoretical Biology and Biophysics Group, Theoretical Division, Los Alamos National Laboratory, Los Alamos, NM, United States, <sup>6</sup>Department Applied Computer and Bio-Sciences, University of Applied Sciences Mittweida, Mittweida, Germany, <sup>7</sup>Center for Global Health, University of New Mexico, Albuquerque, NM, United States, <sup>8</sup>Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Maseno, Kenya

The molecular basis of *Plasmodium falciparum* severe malarial anemia [SMA, hemoglobin (Hb)  $< 5.0 \text{ g dL}^{-1}$  with any parasite density] pathogenesis remains only partially understood. Our previous global gene expression profiling revealed that the microRNA (miRNA), hsa-miR-186, was significantly down-regulated in patients with SMA compared to those with non-SMA. Moreover, *in-silico* analysis revealed that hsa-miR-186 potentially targets the mRNA encoding human hypoxia inducible factor 1-alpha (HIF1 $\alpha$ ) and its consequent expression levels. The current study, therefore, explored this putative pathway. Children of both sexes ( $n=100$ , with *P. falciparum*, based on *a priori* classification into SMA (Hb  $< 5.0 \text{ g/dL}$ ;  $n=26$ ) and non-SMA (Hb  $\geq 5.0 \text{ g/dL}$ ;  $n=74$ ) were recruited at Siaya County Referral Hospital. Peripheral blood samples were obtained for measurement of HIF1 $\alpha$  and hsa-miR-186 using ELISA and qRT-PCR, respectively. Bivariate analysis revealed that plasma HIF1 $\alpha$  levels were higher in children with SMA [(mean  $\pm$  standard error of the mean (SEM));  $3.31 \pm 0.11 \text{ pg mL}^{-1}$ ] compared to the non-SMA group [mean (SEM);  $2.23 \pm 0.08 \text{ pg mL}^{-1}$ ;  $P=2.697^{e-09}$ ]. Levels of HIF1 $\alpha$  were inversely correlated with Hb concentrations ( $r=-0.540$ ,  $P < 0.001$ ). However, hsa-miR-186 transcripts did not differ between the SMA ( $1.09 \pm 0.25$  arbitrary units) and non-SMA ( $0.88 \pm 0.12$  arbitrary units) groups ( $P=0.407$ ) and were not correlated with either HIF1 $\alpha$  levels ( $r=-0.006$ ,  $P=0.954$ ) or Hb levels ( $r=-0.030$ ,  $P=0.766$ ). Collectively, results presented here suggest that HIF1 $\alpha$  may play a role in the pathogenesis of SMA and serve as a correlate of anemia, whereas hsa-miR-186 does not appear to influence either HIF1 $\alpha$  levels or disease.

0188

### IDENTIFICATION OF A LIGAND AND A RECEPTOR THAT MEDIATE PLASMODIUM SPOOROZITE LIVER INFECTION.

Sung-Jae Cha<sup>1</sup>, Min-Sik Kim<sup>2</sup>, Chan Hyun Na<sup>1</sup>, Marcelo Jacobs-Lorena<sup>1,4</sup>

<sup>1</sup>Johns Hopkins University, Baltimore, MD, United States, <sup>2</sup>Daegu Gyeongbuk Institute of Science and Technology, Daegu, Republic of Korea

After inoculation by the bite of an infected mosquito, *Plasmodium* sporozoites enter the blood stream and infect the liver, where each infected cell produces thousands of merozoites. These in turn, infect red blood cells and cause malaria symptoms. To initiate a productive infection, sporozoites must exit the circulation by traversing the blood lining of the liver vessels after which they infect hepatocytes with unique specificity. We screened a phage display library for peptides that structurally mimic

(mimotope) a sporozoite ligand for hepatocyte recognition. We identified HP1 (hepatocyte-binding peptide 1) that mimics a ~50 kDa sporozoite ligand (identified as phospholipid scramblase). Further, we determined that HP1 interacts with a ~160 kDa hepatocyte membrane putative receptor (identified as carbamoyl-phosphate synthetase 1). Importantly, immunization of mice with the HP1 peptide protects them from infection by the rodent parasite *P. berghei*. Moreover, an antibody to the HP1 mimotope inhibits human parasite *P. falciparum* infection of human hepatocytes in culture. The sporozoite ligand for hepatocyte invasion is a novel pre-erythrocytic vaccine candidate.

0189

### CHARACTERIZATION OF PLASMODIUM MALARIAE RETICULOCYTE BINDING PROTEIN 1A

Harry Danwonno<sup>1</sup>, Kwadwo Asamoah Kusi<sup>2</sup>, Gordon Awandare<sup>1</sup>, Yaw Aniweh<sup>1</sup>

<sup>1</sup>West Africa Centre for Cell Biology of Infectious Pathogens, Legon, Ghana, <sup>2</sup>Noguch Memorial Institute of Medical Research, Legon, Ghana

The advent of highly sensitive molecular diagnostic methods has demonstrated *Plasmodium malariae* infection is more prevalent than previously thought. Although it is considered to cause mild malaria, it has been implicated in nephrotic syndrome, inflammation of the gall bladder and anaemia-related deaths. These complications are because of its unique biology of a relatively longer life cycle, typical low parasitemia and chronic-promoting factor(s) which allows its persistence in the human host. Furthermore, the current neglect by malaria elimination programmes could lead to the persistence and expansion of *P. malariae* population. With the publication of *P. malariae* reference genome, Rutledge et al. (2017) also found *P. malariae* reticulocyte binding protein 1a (*PmRBP1a*) to be the most divergent among the *PmRBP*s. With computational analysis, nucleotide-binding and erythrocyte-binding domains of *PmRBP1a* were identified which suggests it is involved in both sensing and anchorage to erythrocytes during erythrocyte invasion. The predicted tertiary structure of *PmRBP1a*'s erythrocyte-binding domain is structurally similar to *P. falciparum* reticulocyte binding-like homologue 5 (*PfRh5*) and *P. vivax* reticulocyte binding homologue 2b (*PvRBP2b*). *PmRBP*s genetic analysis revealed limited genetic sequence variation in the sampled strains with evidence of the genes under purifying selection. Relatively high titre of naturally acquired antibodies specific to the N-terminus of *PmRBP1a* was quantified, a region that overlaps with the erythrocyte-binding domain. The measured anti-*PmRBP1a* positively correlated with increasing age and exposure levels.

The sickle-cell trait hemoglobin genotype (HbAS) protects against severe *Plasmodium falciparum* malaria. However, the biological mechanisms behind this protection are not well understood. A comparative

transcriptomics study of asexual *P. falciparum* parasites found cyclophilin 19B (*PfCyP-19B*) to be significantly downregulated in HbAS red blood cells (RBCs) compared to normal hemoglobin (HbAA) RBCs. *PfCyP-19B* is a parasitic gene that produces the protein cyclophilin 19B, a member of the unfolded protein response that is important in parasitic protein folding and trafficking. A separate study in Southeast Asia found *PfCyP-19B* to be up-regulated in artemisinin resistant *P. falciparum* parasites, posing a threat to malaria elimination efforts there. We measured the transcript expression level of *PfCyP-19B* to investigate its potential role in the mechanisms that confer protection for HbAS individuals. RNA was extracted from both *in vivo* samples collected from Malian children with *P. falciparum* malaria as well as *in vitro* samples of parasite strain 3D7 collected throughout a 48-hour life cycle. RNA extracts were reverse transcribed and transcript expression was measured via qPCR. Wilcoxon rank sum and bootstrapping methods were used to compare transcript units between parasites grown in HbAA and HbAS RBCs. *In vitro* time series results showed no significant difference in *PfCyP-19B* transcript expression levels between genotypes but did display a 24-hour pattern of peak expression for both HbAA and HbAS genotypes. The results from our *in vivo* data revealed a reduction in expression of *PfCyP-19B* among individuals with the HbAS genotype compared to those with the HbAA genotype (Wilcoxon rank sum  $p=0.006$ ). The under expression of *PfCyP-19B* among HbAS individuals could be linked to impaired protein trafficking, interfering with the parasite's ability to display surface proteins vital for cytoadherence and severe disease manifestation. The differential expression of *PfCyP-19B* observed in HbAS RBCs highlights further need for *PfCyP-19B* research to understand its diverse role within the parasite and in relation to artemisinin resistance.

### GENETIC VALIDATION OF THE FUNCTION OF PFEMP1 IN PLASMODIUM FALCIPARUM ROSETTE FORMATION

Stanley E. Otoboh<sup>1</sup>, Alex J. Rowe<sup>1</sup>, Hussein M. Abkallo<sup>2</sup>

<sup>1</sup>University of Edinburgh, Edinburgh, United Kingdom, <sup>2</sup>International Livestock Research Institute, Nairobi, Kenya

Malaria is a disease of global concern, responsible for a significant burden of mortality and morbidity, especially in developing countries of tropical and sub-tropical regions. Rosetting, the binding of *Plasmodium falciparum* infected erythrocytes (IEs) to uninfected erythrocytes to form clusters (rosettes), is thought to contribute to severe malaria. Rosetting phenotypes are mediated through the adhesive properties of *P. falciparum* Erythrocyte Membrane Protein 1 (PfEMP1), encoded by the *var* gene family (~60 distinct copies per parasite genome). Two *var* genes "IT4var60" and "IT4var09" have been identified as encoding rosette-mediating PfEMP1 variants in the well-characterised culture-adapted *P. falciparum* line IT4. However, the role of PfEMP1 in adhesion in live IEs remains poorly understood, mainly due to the difficulty in genetically manipulating *P. falciparum*. We aim to investigate the hypothesis that specific motifs within PfEMP1 mediate rosetting, utilizing CRISPR-Cas9 genome editing technology. This will contribute to the rational design of anti-rosetting interventions with the ultimate goal of reducing deaths from severe malaria. So far, we have successfully constructed CRISPR-Cas9/mutant plasmids for the mutagenesis of rosetting *var* genes and currently in the process of generating transgenic parasites.

### AXONAL INJURY MARKER TAU IN PLASMA IS ELEVATED IN ALL FORMS OF PEDIATRIC SEVERE MALARIA AND ASSOCIATED WITH IN-HOSPITAL MORTALITY AND COGNITIVE IMPAIRMENT AT 12-MONTH FOLLOW-UP

Dibyadyuti Datta<sup>1</sup>, Adnan Gopinadhan<sup>1</sup>, Ruth Namazzi<sup>2</sup>, Andrea L. Conroy<sup>1</sup>, Paul Bangirana<sup>3</sup>, Robert O. Opoka<sup>2</sup>, Keisuke Kawata<sup>4</sup>, Andrew J. Saykin<sup>5</sup>, Chandy C. John<sup>1</sup>

<sup>1</sup>Ryan White Center for Pediatric Infectious Diseases and Global Health, Indiana University School of Medicine, Indianapolis, IN, United States,

<sup>2</sup>Department of Paediatrics and Child Health, Makerere University College of Health Sciences, Kampala, Uganda, <sup>3</sup>Department of Psychiatry, Makerere University College of Health Sciences, Kampala, Uganda, <sup>4</sup>Department of Kinesiology, Indiana University School of Public Health-Bloomington, Bloomington, IN, United States, <sup>5</sup>Indiana Alzheimer's Disease Research Center and Department of Radiology and Imaging Sciences, Indiana University School of Medicine, Indianapolis, IN, United States

The axon microtubule binding protein tau is predominantly expressed by neurons. Increased tau concentrations in circulation are a well validated marker of diffused axonal injury and disease progression in several neurodegenerative disorders. We previously reported elevated levels of tau in cerebrospinal fluid and plasma from Ugandan children with cerebral malaria (CM), compared to community children (CC). In children with CM, who present in coma, elevated cerebrospinal fluid and plasma tau concentrations on admission predict long-term neurocognitive impairment (NCI). In the present study, we assessed whether plasma tau concentrations are elevated in other forms of severe malaria, including those without overt neurologic symptoms, and if they are associated with NCI in these children. Plasma tau concentrations were measured in a single molecule, highly sensitive assay. The study cohort consisted of children 6 months to 4 years of age with one or more of the 5 most common forms of severe malaria: 1) CM; 2) respiratory distress (RDS); 3) severe malarial anemia (SMA); 4) malaria with multiple seizures (M/S); and 5) prostration (PRS). Plasma tau concentrations in children with severe malaria (n=383) were elevated when compared to CC (n=123) (median [95% confidence interval (CI)], 7.51 pg/mL [4.67, 11.59 vs. 2.63 [1.44, 3.96], p<0.001). Plasma tau concentrations on admission were significantly higher in children who died than in survivors (median [95% CI], 13.55 [7.62, 42.45], vs. 7.30 [4.59, 11.26], p<0.001), and in children with malaria retinopathy compared to those without retinopathy (median [95% CI] 9.28 [6.39, 15.11] vs. 7.12 [4.63, 11.4], p=0.02). Elevated plasma tau concentrations among children with severe malaria were associated with a lower z-score for overall cognition at 12-month follow-up ( $\beta$  -0.34 [-0.67, -0.004], p=0.05). Plasma tau shows promise as a reliable, minimally invasive biomarker of brain injury associated complications in survivors of all forms of severe malaria that could be used to identify children susceptible to long-term neurocognitive impairment.

0193

#### DIFFERENCES BETWEEN ORTHOLOGOUS GENES OF RODENT AND HUMAN MALARIA PARASITES IN THEIR ROLE DURING SPOOROZITE FORMATION

Catherin Y. Marin Mogollon<sup>1</sup>, Shinya Miyazaki<sup>2</sup>, Magali Roques<sup>3</sup>, Yukiko Miyazaki<sup>4</sup>, Fiona J. Geurten<sup>1</sup>, Severine Chevalley-Maurel<sup>1</sup>, Hans Kroeze<sup>1</sup>, Jai Ramesar<sup>1</sup>, Volker Heussler<sup>3</sup>, Chris J. Janse<sup>1</sup>, Blandine MD Franke-Fayard<sup>1</sup>

Genes that are only essential for late liver stage development during the complete life cycle of malaria are considered target genes for generation of genetically attenuated parasites (GAP) that arrest growth in late liver (LL) stages. These genes can therefore be used to improve GAP-vaccination approaches. Rodent parasites have been used for screening for essential LL-stage genes in gene-deletion studies. These screens resulted in identification of several genes that play a critical role in LL-stage development, including several genes involved in the FAS-II fatty acid (FA) synthesis pathway, such as *Fabi*, *Fabb/f*. However, the use of these FA-synthesis genes for generation of human *P. falciparum* GAP have proven to be impossible because of their essential role for sporozoite formation. Based on published rodent parasite gene-deletion studies, we have selected three other genes with a role in LL-stage development for deletion of the orthologous *P. falciparum* genes using CRISPR/Cas9 gene-editing. These genes were *palm*, a gene with unknown metabolic function and two genes encoding enzymes; NADH-cytochrome b5 reductase (*cbr*),

that has multiple functions including in fatty acid elongation and biological oxidation-reduction processes, and biotin-protein ligase 1 (*hcs1*), with a role in biotin metabolism. We will report on the generation of the three *P. falciparum* gene-deletion mutants and their phenotype characterization throughout the life cycle, revealing i) their essential role in *P. falciparum* life cycle ii) differences between the rodent and human malaria orthologs and iii) insights into their (metabolic) functions.

0194

#### MARKED REDUCTION OF MALARIA TRANSMISSION WITH SEASONAL MALARIA CHEMOPREVENTION IN CHILDREN UNDER FIVE YEARS OF AGE DURING TES IN SÉLINGUÉ, MALI

Lansana Brehima Sangare<sup>1</sup>, Lassina Doumbia<sup>1</sup>, Youssouf Diarra<sup>1</sup>, Oumar Koné<sup>2</sup>, Dade Ben Sidi Ben Bouillé Haidara<sup>3</sup>, Ousmane Koita<sup>1</sup>

<sup>1</sup>University of Sciences, Techniques and Technology of Bamako, Bamako, Mali, <sup>2</sup>National Malaria Control Program, Ministry of Health and Public Hygiene, Bamako, Mali, <sup>3</sup>Referral Health Center of Sélingué, Ministry of Health and Public Hygiene, Sélingué, Mali

The seasonal malaria chemoprevention (SMC) is a WHO recommendation to reduce the burden of malaria infection in children of 3 to 59 months of age with sulfadoxine-pyrimethamine plus amodiaquine (SP-AQ) treatment during the malaria transmission season. Therapeutic efficacy studies (TES) are performed bi-annually to monitor the efficacy of antimalaria drugs. The objective of this study was to assess the impact of SMC on malaria incidence rates in children under five years of age before and during SMC campaign. Data were collected in the health district of Sélingué between July and December in 2016 during the malaria season, one year before SMC was initiated in Selingue, as a baseline and between July 2017 and January 2018 while SMC was implemented. *Plasmodium falciparum* genotypes were examined using *Msp-1*, *Msp-2*, and *Glurp* markers. The impact of SMC was assessed by comparing malaria incidence in children enrolled in the TES before and after SMC was initiated. The proportion of confirmed malaria cases enrolled in the TES study at baseline, 15.22% (449/2951) was higher than the year when SMC was initiated, 4.12% (180/4370). The reduction rate was 59.91% with an Odds ratio = 0.24, 95% CI (0.20 - 0.29), p-value < 0.0001. The PCR corrected reinfection rate at baseline without SMC was 15.49% (66/426) and with SMC campaign, 8.52% (15/176). The odds ratio = 0.50 (0.28 - 0.91) the difference between these two reinfection rates was statistically significant, p-value = 0.025. Our results indicate that SMC may have contributed to reductions in malaria incidence and malaria reinfections in Sélingué.

The emergence and spread of drug resistance to current antimalarial therapies remains a pressing concern, escalating the need for compounds that demonstrate novel modes of action and overcome the development of drug-resistance. We are characterizing the acyl Co-A synthetase (ACS) enzyme family as new potential drug targets. Mutations in ACS10 and ACS11 were identified from selections of two structurally unrelated

compounds (MMV665924 and MMV019719) by the Malaria Drug Accelerator (MalDA) consortium, which has adopted a chemogenomic approach to identify targets of the most promising compounds from chemically diverse libraries. ACSs activate fatty acids (FA) scavenged from the host, which can then be used for protein modification, phospholipid biosynthesis, and FA elongation. By introducing the observed mutations into the 3D7 parental line using CRISPR/Cas9, we demonstrated that the mutations in ACS10 and ACS11 are indeed sufficient to phenocopy the resistance phenotype of the selected lines. We generated conditional knock-down lines and confirmed that ACS10 is essential while ACS11 is non-essential in asexual growth *in vitro*. Reducing the protein levels of ACS10 and ACS11 lead to changes in the FA composition of the parasites confirming their role in FA metabolism. Thermal-shift assays followed by Western blot did not show a direct interaction between the compounds and ACS11. Thermal-shift assays followed by mass spectrometry are on the way to determine potential interaction partners for the two compounds. This will further our understanding if ACS10 and ACS11 are the direct targets of the compounds or are part of a resistance mechanism. ACS genes are highly polymorphic and surprisingly, the ACS10 M300I mutation identified here was present at 78% in a Malawi parasite population. We obtained Malawian isolates and found that an isolate containing the M300I polymorphism was five-fold more resistant to MMV665924 than a matched ACS10 wild type Malawi isolate. Regardless, if ACS10 and ACS11 are the target or involved in a resistance mechanism, natural occurring polymorphisms might reduce the efficacy of these compounds.

#### DECREASED SUSCEPTIBILITY TO PFDHFR INHIBITORS ASSOCIATED WITH GENETIC POLYMORPHISMS IN UGANDAN PLASMODIUM FALCIPARUM ISOLATES

**Oriana Kreutzfeld**<sup>1</sup>, Patrick Tumwebaze<sup>2</sup>, Oswald Byaruhanga<sup>2</sup>, Thomas Katairo<sup>2</sup>, Martin Okitwi<sup>2</sup>, Stephen Orena<sup>2</sup>, Stephanie A. Rasmussen<sup>3</sup>, Jennifer Legac<sup>1</sup>, Melissa D. Conrad<sup>1</sup>, Samuel L. Nsoby<sup>2</sup>, Ozkan Aydemir<sup>4</sup>, Jeff Bailey<sup>4</sup>, Maelle Duffey<sup>5</sup>, Brett R. Bayles<sup>3</sup>, Philip J. Rosenthal<sup>1</sup>, Roland A. Cooper<sup>3</sup>

<sup>1</sup>UCSF, San Francisco, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>Dominican University of California, San Rafael, CA, United States, <sup>4</sup>Brown University, Providence, RI, United States, <sup>5</sup>Medicines for Malaria Venture, Geneva, Switzerland

The *Plasmodium falciparum* dihydrofolate reductase (PfdHFR) inhibitor pyrimethamine is combined with sulfadoxine for malaria chemoprevention, and proguanil, which is metabolized to the PfdHFR inhibitor cycloguanil, is combined with atovaquone for chemoprophylaxis in travelers. However, drug resistance, mediated by PfdHFR mutations, challenges the efficacies of these inhibitors. P218 is a novel PfdHFR inhibitor designed to overcome this challenge. However, data are available only for a small number of *P. falciparum* laboratory strains. We studied *ex vivo* susceptibilities to P218 and other PfdHFR inhibitors of 559 *P. falciparum* isolates collected in Tororo and Busia districts, Uganda from 2016-2020. Median IC<sub>50</sub>s were 42,100 nM for pyrimethamine, 1,200 nM for cycloguanil, 13,000 nM for proguanil, and 0.6 nM for P218. Among 383 isolates, three PfdHFR mutations, 51I (100%), 59R (93.7%), and 108N (100%), were very common, as previously seen in Uganda, and another mutation, 164L (12.8%), had moderate prevalence. Increasing numbers of mutations were associated with decreasing susceptibility to pyrimethamine, cycloguanil, and P218, but not to proguanil, which does not directly inhibit PfdHFR. Importantly, differences in P218 susceptibilities between haplotypes were modest, with susceptibility to quadruple mutant (51I/59R/108N/164L) parasites (median IC<sub>50</sub> 1.4 nM for mixed isolates and 5.7 nM for pure mutants at position 164) at a level expected to maintain excellent treatment or preventive efficacy for the compound. Previous studies reported duplication of the GTP cyclohydrolyse I (*pfghl*) gene in mutant (particularly 164L) parasites. For 58 Ugandan isolates with various genotypes and drug susceptibilities, associations were not seen between *pfghl* copy number and 164L genotype or susceptibility to PfdHFR inhibitors. Overall, PfdHFR mutations associated with high level resistance

to pyrimethamine and cycloguanil were common in Ugandan isolates; activity of P218 decreased with increasing mutations, but the compound retained potent activity against all Ugandan isolates, warranting continued research on PfdHFR inhibitors.

0197

#### VARIED SUSCEPTIBILITY TO PROTEASOME INHIBITORS AND ASSOCIATIONS WITH GENETIC POLYMORPHISMS IN PLASMODIUM FALCIPARUM ISOLATES FROM UGANDA

**Shreeya Garg**<sup>1</sup>, Oriana Kreutzfeld<sup>1</sup>, Sevil Chelebieva<sup>2</sup>, Patrick K. Tumwebaze<sup>3</sup>, Oswald Byaruhanga<sup>3</sup>, Martin Okitwi<sup>3</sup>, Stephen Orena<sup>3</sup>, Thomas Katairo<sup>3</sup>, Samuel L. Nsoby<sup>3</sup>, Melissa D. Conrad<sup>1</sup>, Ozkan Aydemir<sup>4</sup>, Jeffrey A. Bailey<sup>4</sup>, Gang Lin<sup>5</sup>, Laura A. Kirkman<sup>5</sup>, Roland A. Cooper<sup>2</sup>, Philip J. Rosenthal<sup>1</sup>

<sup>1</sup>Dept. of Medicine, UCSF, San Francisco, CA, United States, <sup>2</sup>Dominican University, San Rafael, CA, United States, <sup>3</sup>Infectious Disease Research Collaboration, Kampala, Uganda, <sup>4</sup>Brown University, Providence, RI, United States, <sup>5</sup>Department of Medicine, Weill Cornell Medical College, New York, NY, United States

The proteasome is a multi-protein complex responsible for protein degradation in eukaryotes. Proteasome components are promising targets for antimalarial chemotherapy. In considering these targets, it is important to characterize naturally occurring variation in sensitivity of *P. falciparum* from malaria-endemic regions to proteasome inhibitors under study. We assessed *ex vivo* susceptibilities of fresh clinical isolates of *P. falciparum* collected in Tororo and Busia districts in Uganda from 2017-2020 to nine asparagine ethylenediamine and three macrocyclic peptide proteasome inhibitors. IC<sub>50</sub> values were determined using a 72-h microplate growth inhibition assay with SYBR Green. We observed a range of proteasome inhibitor potencies, with median IC<sub>50</sub>s from 1.1 - 1942 nM (28 - 170 isolates tested per compound), with 10 of the compounds having median IC<sub>50</sub>s < 100 nM. TDI8304, a lead compound with drug-like properties, had a median IC<sub>50</sub> of 16 nM (range 3.0 - 50 nM). Positive associations ( $r = 0.36 - 0.94$ ) were seen between IC<sub>50</sub> values for all asparagine ethylenediamine compounds. We sequenced the  $\beta 5$  (catalytic) proteasome subunit, which is the target of these inhibitors, and the  $\beta 6$  (structural) proteasome subunit, in Ugandan isolates. We observed two mutations in the  $\beta 5$  subunit, A142S and D150E, in two isolates. We observed no mutations in the  $\beta 6$  subunit. Considering the  $\beta 2$  (catalytic) subunit, we observed two mutations, I204T and S214F, in three isolates. Mutations in the  $\beta 2$  and  $\beta 5$  subunits were not associated with decreased susceptibility to the twelve proteasome inhibitors tested. *In vitro* screening of susceptibilities to the peptide proteasome inhibitors WLW and WLL, which target the  $\beta 2$  subunit and  $\beta 2$  and  $\beta 5$  subunits, respectively, demonstrated low nM activity, and did not show decreased susceptibilities to  $\beta 2$  S214F mutant parasites. Our results showed that a number of proteasome inhibitors had potent activity against *P. falciparum* isolates circulating in Uganda. Genetic variation in presumed proteasome targets was uncommon, and this variation was not clearly associated with changes in inhibitor susceptibility.

0198

#### ASSESSMENT OF PLASMODIUM FALCIPARUM RESISTANCE TO PIPERAQUINE IN WESTERN KENYA USING PIPERAQUINE SURVIVAL ASSAY AND MOLECULAR MARKER ANALYSES

Army Medical Research Directorate-Africa, Department of Biochemistry Egerton University, Kisumu, Kenya, <sup>4</sup>US Army Medical Research Directorate-Africa, Kisumu, Kenya

Malaria is a significant public health burden, especially in sub-Saharan Africa (SSA). Chemotherapy is central in the control of malaria. Dihydroartemisinin-piperazine (DHA-PPQ) is the recommended second-line antimalarial in Kenya. The shift to this regimen was driven by increased reports of quinine resistance & declining artemether-lumefantrine (AL) efficacy, a first line drug. However, the widespread use of DHA-PPQ in Kenya may be a short-lived solution if PPQ resistance, such as that observed in South Eastern Asia (SEA) spreads to Kenya. It is therefore important to establish PPQ susceptibility in Kenya using piperazine survival assay (PSA) & molecular marker analyses. Clinical isolates collected from *Plasmodium falciparum* naturally infected individuals were tested for *ex-vivo* & *in-vitro* PPQ susceptibility using PSA. A subset of the isolates was analyzed for *in-vitro* susceptibility using SYBR Green 1 method. Further, each isolate was genotyped for piperazine resistance markers in *Pfcr1*, *Pfmdr1*, *Pfpm2*, *Pfpm3*, *Pfdhps* *Pfexo* & *Pfk13* genes using qPCR & MassARRAY platform. A total of 40 clinical isolates showed PSA median (interquartile range) of 0% (0-11.02%), n=40, at 95% CI, of these, 34/40 clinical isolates had PSA <10% depicting sensitivity to PPQ. Six isolates had PSA >10% consistent with PPQ resistance. PPQ median IC<sub>50</sub> (interquartile range) for the subset of clinical isolates *in-vitro* was 20.81 nM (17.33-42.26), n=20. A statistically significant positive association was observed between PPQ IC<sub>50</sub> and *Pfcr1* K76T ( $p=0.0007$ ), *Pfdhps* A437G ( $p=0.0167$ ) and A613S ( $p=0.0043$ ) respectively. Re-culture for *in-vitro* testing & analyses of polymorphisms in PPQ resistance genes for these samples are underway. These findings show that circulating Kenyan malarial parasites are sensitive to PPQ. PPQ resistance putative markers finding provide baseline status for continued monitoring of PPQ susceptibility as DHA-PPQ continues to be widely embraced in the country. Our previous studies showing extensive genotype changes in this region herald the need for genetic studies focusing on samples with PSA survival rate >10% for timely detection of changes.

### SANGER SEQUENCING AND DECONVOLUTION OF POLYCLONAL INFECTIONS: A QUANTITATIVE APPROACH TO MONITOR DRUG-RESISTANT PLASMODIUM FALCIPARUM

Hamma Maiga<sup>1</sup>, Robert Morrison<sup>2</sup>, Jillian Neal<sup>2</sup>, Zaidi Irfan<sup>2</sup>, Patrick E. Duffy<sup>2</sup>

<sup>1</sup>Institut National de Sante Publique, Bamako, Mali, <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology, National Institute of Allergy and Infectious Diseases, National Institutes of Health, Bethesda, MD, United States

Molecular markers are used in epidemiological surveillance of drug-resistant pathogens to monitor their emergence and spread. Molecular markers are constituted of either single nucleotide substitution (SNP) or concatenated SNPs in microbial genes that interact with drugs. Although various technical improvements in current sequencing methods have been introduced to identify SNPs, current tools commonly used for the measurement of molecular markers of antimalarial resistance do not allow discrimination of mixed infections and need to be improved for more sensitive surveillance of antimalarial resistance and improved control strategies. We developed a new method to quantify molecular markers of drug resistance in *PfDHPS* and *PfDHFR* genes by standard sequencing of amplicons and bioinformatic estimation of the proportions of different genotypes in individual samples. The method is based on Sanger sequencing of resistance gene fragments and deconvolution of chromatograms to quantify the molecular marker variants. This computational approach uses a combination of R scripts and the DuffyTools package on GitHub. We assessed the performance of our sequencing and computational approach in a pilot study, using mixtures of FCR3 and V1/S parasites at varying proportions between 0-100%. Our results demonstrated quantitative discrimination of varying proportions of wild-type versus mutant-type *PfDHPS* and *PfDHFR* alleles. We are now applying this method to field samples and will report changes in mean

levels of drug-resistant parasites. We will compare this new approach to the standard approach that assigns a binary call to each parasite sample (resistant vs. sensitive). In conclusion, this new method is a cost-effective sequencing approach for population-based surveys that characterize infections at the individual level and thereby provide an earlier signal so that public health officials might sooner plan and implement treatment policy changes.

### THE INFLUENCE OF BIOLOGICAL, EPIDEMIOLOGICAL, AND TREATMENT FACTORS ON THE ESTABLISHMENT AND SPREAD OF DRUG-RESISTANT PLASMODIUM FALCIPARUM

Thiery Masserey<sup>1</sup>, Tamsin Lee<sup>1</sup>, Andrew James Shattock<sup>1</sup>, Monica Golumbeanu<sup>1</sup>, Ian Hastings<sup>2</sup>, Melissa Penny<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The evolution of *Plasmodium falciparum* parasites less susceptible to artemisinin derivatives and their partner drugs threatens the effectiveness of Artemisinin Combination Therapies (ACTs). Identifying the factors that promote the establishment and spread of drug-resistant malaria parasites is essential to delay these processes and develop more sustainable therapies. We adapted a stochastic, individual-based model of malaria epidemiology and transmission dynamics to systematically quantify the influence of biological, transmission settings, health systems, and pharmacokinetics/pharmacodynamics factors on the establishment and spread of drug-resistant parasites. We did this via a global sensitivity analysis by exploring a range of drug properties of artemisinin derivatives and partner drugs for various epidemiological settings and treatment levels. Our analysis confirms that the establishment and spread of drug-resistant parasites is more likely in low, seasonal transmission settings due to the reduced level of human immunity and the lower level of within-host competition between genotypes. Furthermore, our study demonstrates that the spread of partially artemisinin-resistant parasites greatly accelerates when the efficacy of the partner drug decreases. Therefore, proper adherence to treatments should be ensured, alongside molecular surveillance to detect the emergence of resistance to partner drugs and change first-line treatments accordingly. In addition, we found that prolonged exposure to artemisinin during treatments reduced the spread of partially artemisinin-resistant parasites. Consequently, future ACTs should optimize or increase parasites exposure to artemisinin. Finally, the spread of parasites resistant to a partner drug depended strongly on the length of the selection window of the partner drug. To minimize this selection window, future ACTs should include an additional long-acting drug. This would reduce the risk of resistance evolution to each of the long-acting partner drugs and thereby further protect artemisinin derivatives.

0201

### THE THERAPEUTIC EFFICACIES OF ARTEMETHER-LUMEFANTRINE AND CHLOROQUINE FOR THE TREATMENT OF UNCOMPLICATED PLASMODIUM FALCIPARUM AND P. VIVAX INFECTIONS, RESPECTIVELY IN TWO SENTINEL, ETHIOPIA 2021

Ashenafi Assefa Bahita, Hussein Mohanne, Heven Sime<sup>1</sup>, Henock H/giorgis, Ebba Abate

Ethiopian Public Health Institute, Addis Ababa, Ethiopia

Regular monitoring of antimalarial drugs is recommended for early detection of drug resistance and to maintain effective national malaria treatment guidelines. In Ethiopia, the national malaria diagnosis and treatment guidelines employ a species-specific approach for malaria treatment. Artemether-lumefantrine (AL) and chloroquine (CQ) are the first-line schizonticidal treatments for *Plasmodium falciparum* (Pf) and *P. vivax* (Pv), respectively. AL is used for mixed infection treatment. In this study, we report the clinical and parasitological efficacy of AL against uncomplicated *P. falciparum* and CQ against uncomplicated *P. vivax*

infections. The WHO guideline, Surveillance of antimalarial drug efficacy protocol with 28 days follow up was followed. The study was conducted between December 2020 and March, 2021 in two sentinel sites. A total of 348 patients were followed for 28 days in two arms (n = 152 in the AL/Pf arm, n = 232 in the CQ/Pv arm). High cure rate was observed for the 28 day follow up (PCR uncorrected): AL/Pf 97.7% (95% CI: 93.5-99.5), CQ/Pv 95.2% (95% CI: 95.2-97.7). In both arms 100% of patients cleared parasites on the third day. No early treatment failure was detected in all arms. Three late clinical failures (LTF) were detected on the AL/Pf arm and a total of 10 failures (6 late clinical failures (LTF) and 4 late parasitological failures (LPF)) were detected on CQ/Pv arm before the 28 days follow up. Our study on progress is showing similar results for Pyramax (Artesunate-pyronaridine) against uncomplicated *P. falciparum* and *P. vivax* on patients above 18 years and 42 days follow up, full data collection is not completed for reporting. The study showed the current anti-malaria drugs used by the malaria control program in Ethiopia are efficacious. In addition, the Pyramax (Artesunate-pyronaridine) study on progress showing promising results.

0202

### ASSESSING THE REAL-WORLD STABILITY OF ARTESUNATE RECTAL CAPSULES

Andrew Slade<sup>1</sup>, Andy Baxter<sup>1</sup>, Stephan Duparc<sup>1</sup>, Hans Rietveld<sup>1</sup>, Eliza Walwyn-Jones<sup>2</sup>, Theodoor Visser<sup>2</sup>

<sup>1</sup>Medicines for Malaria Venture, Geneva, Switzerland, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States

Artesunate rectal capsules (ARC) were first developed and tested in large-scale clinical trials by WHO-TDR. They comprise 100mg of artesunate in an inert lipid fill, encapsulated in a soft gel capsule. Two manufacturers, Cipla and Strides, supported by MMV, have developed products which were prequalified in 2018 and now play a vital part in the pre-referral management of severe malaria in over 15 African countries. As part of routine product development, the stability of ARC under controlled storage conditions (25°C/60%RH, 30°C/75%RH, 40°C/75%RH) has been rigorously assessed. Globally, the data indicate that ARC is a reasonably robust product, but specifically, the data do not support a 24-month shelf life under Zone IVb (30°C/75%RH) conditions. In the absence of any additional data, the shelf-life is set at 24-month under Zone II (25°C/60%RH) conditions. For clinical use, WHO-PQ recommends a cautious approach, whereby stocks of ARC should remain in the field on a short-term basis, for between 4 and 6 months. The need for frequent discard and resupply of ARC has proven to be logistically difficult. It risks stock-outs at the community health worker level, affects trust in the product and wastes limited resources. Encouraged by the data from the controlled storage studies, we will retrieve and test ARC that has been in field storage in the DRC, Nigeria and Uganda for defined periods, including between 9 and 12 months. Although the storage conditions in these settings are not controlled, they are not unknown. Site-specific temperature logger values, as well as local and regional maximum, minimum and average temperatures provide a comprehensive dataset against which to interpret the results of the testing. The testing itself will be done by an independent laboratory in Switzerland, using the same tests and acceptance specifications as the original capsule suppliers. The data from the testing of these real-world samples will complement the existing data from the controlled storage studies and may allow end-users and regulatory agencies to make more informed decisions regarding the appropriate intervals for product replacement in the field.

0203

### INHIBITION MECHANISMS AND STRUCTURES OF PLASMODIUM-SELECTIVE PROTEASOME INHIBITORS DETERMINE IN VITRO RESISTANCE PROFILES

Recent research has identified the *Plasmodium falciparum* proteasome as a promising new antimalarial drug target. This multi-subunit proteolytic enzyme complex is essential for maintaining cellular homeostasis, regulating diverse processes such as cell cycle progression and removal of damaged proteins. Large-scale screening efforts combined with the elucidation of differences in substrate preferences and the *Plasmodium* proteasome structure, relative to its human counterpart, have enabled the design of highly selective inhibitors. These inhibitors differ substantially in their binding properties (covalent vs. noncovalent, reversible vs. irreversible) and chemotypes. We assessed the resistance liabilities of a panel of inhibitors comprising boronates, epoxyketones, vinyl sulfones, asparagine ethylenediamines and N,C-capped peptides. We screened these compounds against *P. falciparum* lines harboring mutations in the 20S proteasome core particle or in the 19S regulatory particle, and performed selection experiments to determine the minimum parasite inoculum required to yield *in vitro* resistance. Vinyl sulfones (covalent, irreversible peptide inhibitors) exhibit minor shifts in their half-maximal effective concentrations (EC50 values) when tested against proteasome mutant parasites, while asparagine ethylenediamines (noncovalent, reversible binders) exhibit the largest changes in EC50 values. Several classes of *Plasmodium* proteasome inhibitors do not readily select for resistance *in vitro*, with select epoxyketone and vinyl sulfone inhibitors yielding no resistance even with large starting inocula (1E8 parasites). Moreover, we observe infrequent cross-resistance between compounds; in fact, partial resistance to one compound can yield hypersensitivity to another, suggesting that resistance to *Plasmodium* proteasome inhibitors is largely mechanism- and occasionally compound-dependent. These data underscore the potential of targeting the *P. falciparum* proteasome with small-molecule inhibitors to treat multidrug-resistant parasites.

### NOVEL MOLECULES TO OVERCOME EXISTING RESISTANCE AND PREVENT THE EMERGENCE OF RESISTANCE TO ARTEMISININ AND INHIBITORS OF PROTEIN DEGRADATION PATHWAYS

Gang Lin<sup>1</sup>, Wenhu Zhan<sup>1</sup>, Yi Jing Liu<sup>1</sup>, Changmei Yang<sup>2</sup>, Hao Zhang<sup>1</sup>, Jacob Harris<sup>1</sup>, Rong Wang<sup>3</sup>, Songbiao Zhu<sup>2</sup>, George Sukenick<sup>3</sup>, Haiteng Deng<sup>2</sup>, Carl Nathan<sup>1</sup>, Laura Kirkman<sup>1</sup>

<sup>1</sup>Weill Cornell Medicine, New York, NY, United States, <sup>2</sup>Tsinghua University, Beijing, China, <sup>3</sup>Memorial Sloan Kettering Cancer Center, New York, NY, United States

Malaria, an ancient infection that still causes 200 million cases and nearly half million deaths globally. Worldwide emergence and spread of *Plasmodium falciparum* resistance to first-line artemisinins and artemisinin-combination therapies has created an urgent need of therapeutics with novel mechanisms that suppress the ability of parasites to develop resistance. We will be presenting novel molecules that overcome existing artemisinin resistance and prevent the emergence of the resistance to artemisinin and protein degradation pathways. These molecules exert a novel mode of action that differs between each individual parasite cells. We propose that this aspect of parasite killing will increase selectivity of our compounds over human cells. We also identify that our novel

compounds can overcome mechanisms of resistances and retain potency against a variety of global isolates with varied background resistance patterns.

0205

### TRACKING ANTIMALARIAL DRUG RESISTANCE USING MOSQUITO BLOOD MEALS

Bei<sup>2</sup>, Brian D. Foy<sup>4</sup>, Roch K. Dabiré<sup>3</sup>, Jean-Bosco Oudraogo<sup>3</sup>, Sunil Parikh<sup>2</sup>

<sup>1</sup>Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, <sup>2</sup>Yale University, New Haven, CT, United States, <sup>3</sup>Institut de Recherche en Sciences de la Santé, Bobo Dioulasso, Burkina Faso, <sup>4</sup>Colorado State University, Fort Collins, CO, United States

Strong surveillance systems are needed to monitor the emergence and spread of antimalarial drug resistance. Yet approaches are often limited by costly infrastructure, regulatory oversight, and significant reporting delays. In this study, we hypothesized that mosquito blood meals could be used as an efficient method to monitor antimalarial resistance in *Plasmodium* populations and also provide data on vector metrics relating to malaria transmission. We conducted a series of cross-sectional surveys to compare resistance-associated molecular markers in humans and mosquitos in Bama, Burkina Faso. We surveyed in two high-transmission seasons (10/2018, 09/2019) and one low-transmission season (03/2019). Household clusters in six village sub-sectors were sampled proportionately to sector size. Following consent, we obtained 1,481 dried blood spots via capillary finger-prick. We simultaneously collected 2,349 blood-fed mosquitos via vacuum aspiration from the same households and then pressed abdominal contents onto FTA cards. Parasite DNA was extracted with the KingFisher Flex System and *P. falciparum* (*Pf*) infections were detected with qPCR for *varATS*. Drug resistance-associated mutations were identified in *pfmdr1* N86Y, D1246Y, and *pfcr1* K76T using High Resolution Melting. Over the three surveys, we found that 54, 43 and 34% of humans were infected, respectively, and 22, 17, and 21% of mosquito blood meals were *Pf+*. In the first survey, humans and mosquito midguts exhibited statistically equivalent rates of *pfmdr1* 86Y and 1246Y mutations. However, we observed significantly more mixed infections at *pfcr1* K76T in blood meals compared to human blood sampling. We will present full statistical comparisons of the prevalence of all alleles in humans and mosquito blood meals for each survey, at household and community cluster spatial scales, as well as comparative frequency data on multiplicity of infection. Our study is sufficiently powered to validate or invalidate the use of mosquito blood meals as a low-cost and rapidly deployable tool to monitor changes in the distribution of antimalarial resistance.

0206

### THE EFFECT OF COVID-19 PANDEMIC ON THE PERFORMANCE OF ESSENTIAL MALARIA CONTROL INTERVENTIONS IN UGANDA: A CASE STUDY OF AMURU, AGAGO, DOKOLO AND OTUKE DISTRICTS OF NORTHERN UGANDA

Geofrey Beinomugisha<sup>1</sup>, Anthony Nuwa<sup>1</sup>, Shirah Karungi<sup>1</sup>, Acio Harriet<sup>1</sup>, Irene Ayaa<sup>1</sup>, Godfrey Magumba<sup>1</sup>, Francis Abwaimo<sup>1</sup>, Jimmy Opigo<sup>2</sup>, Maureen Amutuhaire<sup>2</sup>, James Tibenderana<sup>3</sup>, Joseph Ocitti<sup>4</sup>, Patrick Odongo<sup>5</sup>

<sup>1</sup>Malaria Consortium Uganda, Kampala, Uganda, <sup>2</sup>Ministry of Health Uganda, Kampala, Uganda, <sup>3</sup>Malaria Consortium United Kingdom, London, United Kingdom, <sup>4</sup>Agago District Local Government, Gulu, Uganda, <sup>5</sup>Amuru District Local Government, Gulu, Uganda

Uganda confirmed her first COVID 19 case in March 2020 and the government acted quickly to institute total lockdown in the same month. This study was conducted to assess the effect of COVID-19 on performance of essential malaria control services in four high malaria endemic districts. Eight district health team (DHT) members, 40 health

workers, 160 village health teams (VHTs) and 618 households (HHs) participated. DHIS 2 data was analyzed and significance tests performed at 5% to establish significance of the observed change. Data from interviews was also analyzed. Outpatient attendance decreased from 187,737 before COVID-19 to 164,132 during lockdown. Confirmed malaria cases significantly (Fisher's value=0.038<5%) increased from 70,369 before COVID-19 to 80,924 during lockdown and to 110,716 when the lockdown was eased. VHTs and HHs also reported a significant increase of malaria cases in the communities during COVID-19 lockdown (p-value=0.000<5%). Malaria in pregnancy significantly (Fisher's value=0.040<5%) increased from 1,936 before COVID-19 to 2,220 during lockdown and then to 3,045 when the lockdown was eased. VHTs also reported a significant increase of malaria in pregnancy during COVID-19 fear and lockdown in place (p-value=0.013 and 0.001, <5% respectively). Malaria deaths increased from zero before COVID-19 to six during COVID-19 scare, dropped to five and to four deaths during lockdown easing. VHTs also reported a significant decrease during and after lockdown (p-value=0.035<5% and p-value=0.044<5% respectively). IPT3+ coverage significantly (Fisher's exact=0.000<5%) increased from 24.8% before COVID-19 to 63.2% during lockdown easing. The study confirmed that COVID-19 significantly affected malaria service delivery as shown by indicator performance. The Ministry of health and districts should strengthen health education systems on malaria and COVID-19 prevention and environmental management. Health facilities should ensure adherence to standard operating procedures (SOPs) and distinctively separate COVID-19 patients and suspects from other patients and effectively deliver adequate services.

0207

### EFFECT OF COVID-19 ON TREATMENT-SEEKING AMONG PEOPLE LIVING IN A MALARIA-ENDEMIC AREA OF COASTAL KENYA

Donal Bisanzio<sup>1</sup>, Francis Mutuku<sup>2</sup>, Bryson Ndenga<sup>3</sup>, Charles N'ang'a<sup>4</sup>, Said Malumbo<sup>4</sup>, Gladys Agola<sup>4</sup>, A. Desiree LaBeaud<sup>5</sup>

<sup>1</sup>RTI International, Washington, DC, United States, <sup>2</sup>Department of Environment and Health Sciences, Technical University of Mombasa, Mombasa, Kenya, <sup>3</sup>Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, <sup>4</sup>Vector Borne Disease Control Unit, Msambweni, Kenya, <sup>5</sup>Department of Pediatrics, Division of Infectious Diseases, Stanford University, Stanford, CA, United States

In malaria-endemic countries, prompt testing of fevers and treatment of positive individuals are the main pillars of interventions to reduce the malaria burden. However, COVID-19 has affected people's treatment-seeking behavior due to reduced mobility and fear of attending health facilities. This study aimed to evaluate the impact of COVID-19 on hospital visits and malaria burden in coastal Kenya during 2020. We gathered data of fever cases tested for malaria at Msambweni sub-County Referral Hospital, Kwale County, Kenya, from January 2014 to December 2020. Per each visit, gender, age, the village of residence, and malaria test results were recorded. Trend analysis of hospital visits and malaria positive rate among tested people were performed using generalized additive mixed models (GAMMs). Spatial analyses were performed to identify the heterogeneity of changes in treatment-seeking behavior among villages during the year 2020. Among the 84,607 tested febrile cases, 24.4% were positive for *Plasmodium* infection. Malaria positivity rates showed a marked reduction from 2014 to 2019, followed by an increase of positive fevers during 2020. The total number of tested fevers in 2020 (9,685) was 20.8% lower compared to 2019 (12,238). A higher reduction of tested fevers was recorded among males (-28.1%) compared to females (-15.8%). However, only children under five years (U5) of age recorded an evident reduction of tested fevers with 43.5% fewer tested fevers in 2020 (3,426) compared to 2019 (6,064). The time trend analyses estimated that 290 (95% CI: 283-315) U5 malaria cases could have missed treatment at the hospital during 2020. The reduction of tested fevers showed a marked spatial heterogeneity associated with the distance from the hospital. This study showed that during the COVID-19 epidemic, malaria cases have increased in coastal Kenya. Furthermore, treatment was not sought for

a high fraction of U5 children. Our results highlight the importance of adapting malaria interventions during COVID-19 epidemics to mitigate its effect on malaria burden and protect highly vulnerable age groups.

0208

### THE RELATIONSHIP BETWEEN COVID-19 AND PERCEIVED ACCESS TO MALARIA CARE IN UGANDA

**Anna Passaniti**<sup>1</sup>, Judith Nalukwago<sup>1</sup>, Bolanle Olapeju<sup>1</sup>, Isaac Musoke<sup>1</sup>, Musa Kimbowa<sup>1</sup>, Pallen Mugabe<sup>1</sup>, Emmanuel Kayongo<sup>1</sup>, Ruth Musekura<sup>1</sup>, Lyndsey Mitchum<sup>1</sup>, Arzum Ciloglu<sup>1</sup>, Leanne Wolfe<sup>1</sup>, Glory Mkandawire<sup>1</sup>, Richard Nabanda<sup>2</sup>, Joel Kisubi<sup>3</sup>, Sheila Nyakwezi<sup>1</sup>, Douglas Storey<sup>1</sup>, Mariam Nabukenya<sup>2</sup>

<sup>1</sup>Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, <sup>2</sup>Ministry of Health, Uganda, Kampala, Uganda, <sup>3</sup>US President's Malaria Initiative, United States Agency for International Development (USAID), Uganda, Kampala, Uganda

During the COVID-19 pandemic, malaria remained the leading cause of death among all ages (13.3%) in Uganda. The USAID Social and Behavior Change Activity explored the relationship between COVID-19 and perceived access to malaria care in Uganda. A nationally representative mobile phone survey was conducted among 1,400 men and women aged 18-49 years. Multivariable regressions explored the relationship between the perception that the COVID-19 pandemic affected access to malaria services and sociodemographic factors. More respondents reported the COVID-19 pandemic influenced access to malaria services (65%) compared to HIV (51%) and maternal health (56%). Perceived access to malaria care was significantly different among residents of Eastern (AOR=2.5, 95% CI 1.8, 3.5) and Western (AOR=2.1, 95% CI 1.5, 3.0) regions, educated (AOR=1.6, 95% CI 1.2, 2.2), those with 5 or more children (OR=1.9, 95% CI 1.2, 3.0), and those exposed to two or more COVID-19 prevention messages (AOR=1.6, 95% CI 1.1, 2.3). Community members who perceive barriers to accessing malaria care due to the COVID-19 pandemic may be less likely to seek care when they have symptoms. The impact of COVID-19 on access to malaria services may be due to restrictions on travel to health facilities, risks of exposure to COVID-19, overlapping symptoms, and potentially perceptions of low quality of care. Interventions are needed to promote COVID and malaria preventive measures, uptake of non-pandemic health services, and address challenges to health services access.

0209

### IMPACT OF COVID-19 PANDEMIC ON SEASONAL MALARIA CHEMOPREVENTION 2020 CAMPAIGN IN WEST AND CENTRAL AFRICA

<sup>1</sup>La Cooperativa Humanitaria, Barcelona, Spain, <sup>2</sup>University of Thies, Thies, Senegal, <sup>3</sup>National Malaria Programme, Conakry, Guinea, <sup>4</sup>National Malaria control Programme, Cotonou, Benin, <sup>5</sup>National Malaria control Programme, Ouagadougou, Burkina Faso, <sup>6</sup>National Malaria control Programme, Yaounde, Cameroon, <sup>7</sup>National Malaria control Programme, Ndjamen, Chad, <sup>8</sup>National Malaria control Programme, Accra, Ghana, <sup>9</sup>National Malaria control Programme, Bissau, Guinea-Bissau, <sup>10</sup>National Malaria control Programme, Bamako, Mali, <sup>11</sup>National Malaria control Programme, Niamey, Niger, <sup>12</sup>National Malaria control Programme, Abuja, Switzerland, <sup>13</sup>National Malaria control Programme, Abuja,

Nigeria, <sup>14</sup>National Malaria control Programme, Dakar, Senegal, <sup>15</sup>National Malaria control Programme, Banjul, Gambia, <sup>16</sup>National Malaria control Programme, Lome, Togo, <sup>17</sup>MMV, Geneva, Switzerland, <sup>18</sup>LSHTM, London, United Kingdom, <sup>19</sup>WHO, Geneva, Switzerland

As the world came together to tackle the COVID-19 pandemic, it was important to ensure access to core malaria preventive measures such as Seasonal Malaria Chemoprevention (SMC). It was anticipated that COVID-19 pandemic could create disruptions during 2020 SMC campaign for which countries would need to put in place new strategies to mitigate its impact. Through the OPT-SMC project, a cross sectional survey using mixed methods (qualitative and quantitative) measurements was conducted to evaluate the level of disruptions due to COVID-19 on 2020 SMC planning and delivery activities, and to document mitigation strategies put in place by the countries. An evaluation tool was developed using a systematic approach with risk assessment of disruption because of COVID-19 for each SMC activity and definition of adequate indicators to measure disruptions. Additional information was gathered through interviews of partners supporting National Malaria Programmes and during the 2021 SMC working group meeting. Twelve out of 13 countries implementing SMC participated in the survey. Half of the countries had to adapt their micro-planning activities and nine faced transport and supply chain management disruptions. All countries adapted their training methods either in increasing the number of training sessions for smaller groups or with using virtual platform. Social mobilisation was disrupted in all countries with challenges to reach houses due to rumours and fear of community drug distributors wearing masks. The use of digital technology for training, supervision and coordination activities was instrumental. Despite COVID-19 pandemic, countries didn't scale back their SMC implementation plan for 2020 and over 33 million children were reached with SMC. Only some activities were partially disrupted by the COVID-19 pandemic and none were cancelled. This is because of mitigation strategies put in place by countries since the preparatory phase and thanks to the substantial financial and technical support provided by partners and WHO. Lessons learned from this survey should inform 2021 SMC preparation phase.

0210

### IMPACT OF THE COVID-19 PANDEMIC ON ACCESS TO OUTPATIENT MALARIA CARE IN UGANDA: AN INTERRUPTED TIME SERIES ANALYSIS

**Jane F. Namuganga**<sup>1</sup>, Jessica Briggs<sup>2</sup>, Asadu Sserwanga<sup>1</sup>, Chris Ebong<sup>1</sup>, James A. Kapisi<sup>1</sup>, Grant Dorsey<sup>2</sup>, Jaffer Okiring<sup>1</sup>, Catherine M. Sebuguzi<sup>1</sup>, Emmanuel Arinaitwe<sup>1</sup>, Moses R. Kanya<sup>1</sup>, Bayo S. Fatunmbi<sup>3</sup>, Michelle E. Roh<sup>2</sup>, Joaniter I. Nankabirwa<sup>1</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>University of California San Francisco, San Francisco, CA, United States, <sup>3</sup>World Health Organisation, Kampala, Uganda

In March 2020, the Ugandan government implemented several policy measures to prevent the spread of COVID-19. The effect of these interventions on outpatient malaria care is not well documented. We assessed the impact of the COVID-19 outbreak and corresponding government-mandated restrictions on indicators of routine malaria care at 17 public health facilities in rural Uganda. We analyzed routine health management information system (HMIS) data from outpatients seen at 17 facilities as part of an enhanced malaria sentinel site surveillance network from March 2017 to February 2021. Interrupted time series analyses (ITSA) were conducted to quantify the impact of COVID-19 lockdown policies on counts of outpatient visits, non-malaria visits, and malaria cases. We extrapolated the pre-policy trend, estimated using Poisson regression with generalized estimating equations, into the post-policy period and compared this counterfactual trend to the observed post-policy trend. Incidence rate ratios were calculated by summing the outcomes across the one-year post policy period and dividing the observed by predicted values. A total of 1,438,517 patients visited the 17 facilities over the 4-year observation period. More than half (55%) of the patients were suspected to have malaria, of which 98.7% had a malaria diagnostic

test performed; there was no change in these measures pre- and post-lockdown. ITSA showed no difference between observed and predicted total outpatient visits (IRR=0.96, 95%CI=0.86,1.07), non-malarial visits (IRR=1.01, 95%CI=0.92,1.11), or number of malaria cases (IRR=1.02, 95%CI=0.69,1.51) in the post-lockdown period. In conclusion, despite restrictions to public transit, closure of non-essential businesses, and diversion of personnel/resources to support response to the pandemic, the number of patients seeking care at these 17 health facilities was unaffected. Additionally, there were no significant differences in number of malaria cases diagnosed or measures of malaria case management in the pre- versus post-lockdown period.

0211

### THE IMPACT OF COVID-19 PANDEMIC ON OUTPATIENT AND MALARIA SERVICES: EXPERIENCE FROM EIGHT STATES IN NIGERIA

**Aderonke Omokhapse**<sup>1</sup>, Abimbola Olayemi<sup>1</sup>, Uchenna Nwokenna<sup>1</sup>, Kazeem Ayankola<sup>1</sup>, Yakubu Cherima<sup>1</sup>, Paul Waibale<sup>2</sup>, Abba Umar<sup>1</sup>, Perpetua Uhomobhi<sup>3</sup>, Nnenna Ogbulafor<sup>3</sup>, Emmanuel Shekarau<sup>3</sup>, Thomas Hall<sup>4</sup>, Ratha Loganathan<sup>4</sup>

<sup>1</sup>Management Sciences for Health, Abuja, Nigeria, <sup>2</sup>Management Sciences for Health, Kampala, Uganda, <sup>3</sup>National Malaria Elimination Programme, Abuja, Nigeria, <sup>4</sup>Management Sciences for Health, Arlington, VA, United States

While health systems are being challenged by increasing demand for care of COVID-19 patients, it is critical to maintain basic health services, especially for the most vulnerable populations (WHO 2020). In Nigeria, the government instituted a total lockdown (with the exception of health service delivery) between April-May 2020. An analysis of routine national health management information systems (NHMIS) data was conducted in eight states for uptake of outpatient services including malaria. Data for March - August 2020 was compared with the same period for the previous year. COVID-19 incidence data was also analyzed for 2020. Seven states reported a decline in the number of patients who visited the health facilities for general outpatient services. Nasarawa and Oyo reported the largest declines, 45% and 31%, respectively, while Ebonyi reported <1% decline. Uptake of malaria services also declined in six states. The analysis showed that as COVID-19 cases increased, uptake of services declined. This pattern was particularly evident in Oyo, which had the highest number of COVID-19 cases among the eight states, and the largest percentage decline of outpatient and malaria services uptake. Health facility services utilization began to increase after the lockdown was eased across the states and reached pre-COVID-19 figures by August 2020. While the decline in care seeking could have been due to physical restrictions associated with the lockdown, fear and uncertainties brought about by the pandemic, along with possible stock out of some medicines due to supply chain effects may have also contributed. Access to health facilities was never restricted during the lockdown, revealing a pattern of changed health seeking behavior and concerns around sources of treatment for malaria and other febrile diseases during the period.

0212

### FUNGAL METABOLITE ASPERACULANE B INHIBITS MALARIA INFECTION AND TRANSMISSION

**Guodong Niu**<sup>1</sup>, Yue Hao<sup>2</sup>, Xiaohong Wang<sup>1</sup>, Jin-Ming Gao<sup>3</sup>, Jun Li<sup>1</sup>

<sup>1</sup>Florida International University, Miami, FL, United States, <sup>2</sup>South China University, Hengyang, China, <sup>3</sup>Northwest A&F University, Yangling, China

Mosquito-transmitted *Plasmodium* parasites cause millions of people worldwide to suffer malaria every year. Drug-resistant *Plasmodium* parasites and insecticide-resistant mosquitoes make malaria hard to control. Thus, the next generation of antimalarial drugs that inhibit malaria infection and transmission are needed. We screened our Global Fungal Extract Library (GFEL) and obtained a candidate that completely inhibited *Plasmodium falciparum* transmission to *Anopheles gambiae*.

The candidate fungal strain was determined as *Aspergillus aculeatus*. The bioactive compound was purified and identified as asperaculane B. The concentration of 50% inhibition on *P. falciparum* transmission (IC50) is 7.89  $\mu$ M. Notably, asperaculane B also inhibited the development of asexual *P. falciparum* with IC50 of 3  $\mu$ M, and it is nontoxic to human cells. Therefore, asperaculane B is a new dual-functional antimalarial lead that has the potential to treat malaria and block malaria transmission.

### CLINICAL PHARMACOLOGY OF EXTENDED DURATION ARTEMETHER-LUMEFANTRINE FOR THE TREATMENT OF PLASMODIUM FALCIPARUM MALARIA IN EFAVIRENZ-TREATED HIV-INFECTED CHILDREN IN UGANDA

Meghan Whalen<sup>1</sup>, Richard Kajubi<sup>2</sup>, Justin Goodwin<sup>3</sup>, Francis Orukan<sup>2</sup>, McKenzie Colt<sup>3</sup>, Kacey Richards<sup>3</sup>, Moses Were<sup>2</sup>, Martina Wade<sup>3</sup>, Liusheng Huang<sup>1</sup>, **Sunil Parikh**<sup>3</sup>, Francesca Aweeka<sup>1</sup>, Norah Mwebaza<sup>2</sup>

<sup>1</sup>University of California - San Francisco, San Francisco, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>Yale School of Public Health, New Haven, CT, United States

There is substantial overlap of HIV and malaria infections in sub-Saharan Africa. Efavirenz (EFV)-based antiretroviral therapy (ART) is a recommended first-line ART for HIV-infected children >3 years and amongst the most widely used ART in malaria-endemic regions. For malaria, artemether-lumefantrine (AL) is the most widely used ACT. Previous studies have shown significant drug interactions between EFV and AL, with EFV reducing exposure to artemether (ARM), dihydroartemisinin (DHA), and lumefantrine (LUM) in children. To compensate for the effect of EFV on AL exposure, we conducted a prospective PK/PD study to see if an extended 5-day regimen could improve AL exposure in children on EFV, compared to a 3-day regimen. We also enrolled HIV-uninfected children for comparison (n=100). Children ages 3-17 years were randomized to 5-day (10-dose) or 3-day (6-dose) AL in a high transmission setting in Uganda. PK sampling for ARM, DHA, and LUM was performed for 21 days with 42 day follow-up. HIV-infected children were randomized into 5-day (n=37) or 3-day (n=39) AL. Day 28 treatment outcomes for 5-day vs 3-day were: ACPR (71% vs 62%), LPF (26% vs 26%), and LCF (3% vs 12%). Day 42 treatment outcomes were: ACPR (36% vs 32%), LPF (44% vs 44%), and LCF (19% vs 24%). Total ARM exposure (AUC<sub>0-8hr</sub>) post-last dose indicates a geometric mean AUC<sub>0-8hr</sub> of 70 and 63 ng-hr/mL for the 5-day and 3-day regimens, respectively. Total DHA exposure indicates a geometric mean AUC<sub>0-8hr</sub> of 99 and 112 ng-hr/mL for the 5-day and 3-day regimens, respectively. Total LUM exposure measured from the time of the last dose over 21 days indicates a geometric mean AUC<sub>0-21d</sub> of 216 and 149 ug-hr/mL, for the 5-day and 3-day regimens, respectively. Terminal LUM concentrations were significantly increased in the 5-day vs 3-day regimen on days 8 and 14 for HIV-infected children (460, 130 ng/mL vs 150, 68 ng/mL, respectively; all p-values <0.005), and similar to the day 8 and 14 LUM concentrations in HIV-uninfected children on 3-day AL (330, 131 ng/mL). In HIV-infected children, extended duration AL compensates for the EFV-induced reduction of LUM. Data is preliminary but final PK/PD analysis will be presented.

Persistent malaria transmission and increasing cases of drug resistance to current antimalarials necessitates the urgent development of new antimalarial drugs. In this study we employed a chemogenomics target-similarity approach to prioritize drugs with antimalarial activity. Protein targets of drugs with potential for repurposing were searched for and retrieved from Drugbank and Therapeutic Target Database (TTD). Using the Basic Alignment Local Search Tool (BLAST), we searched *Plasmodium falciparum* proteome for similar proteins (orthologs) using protein sequences of the known drug targets. We analysed for similarity in functional amino acids between known drug targets and predicted *P. falciparum* protein targets (for protein pairs that were at least 30% identical in the BLAST analysis). We performed molecular docking using Autodock to compare binding orientation and binding affinities of the drug compounds to the known targets and to the predicted *P. falciparum* protein targets. We retrieved essentiality and druggability indices of the predicted *P. falciparum* protein targets from Tropical Disease Research (TDR) database. Currently, we are assessing the association between the similarity of known drug targets and corresponding predicted *P. falciparum* proteins target (BLAST percentage similarity, BLAST bit score and functional amino acid similarity) with *in vitro* antimalarial activity (EC50s). BLAST search revealed 735 *P. falciparum* proteins that are likely targets to 143 drugs. A total of 161 *P. falciparum* proteins (out of 308 with data) had druggability indices above 0.5, and 251 (out of 545 with data) were essential for the survival of the parasite. Preliminary results indicate that the target similarity approach used in this study can be successfully used to prioritize compounds for antimalarial drug discovery and development.

### CONSENSUS LIGAND AND STRUCTURE-BASED SCREENING FOR IDENTIFICATION OF PFDXR INHIBITORS

**Bakary N. Diallo**, Azlem T. Bishop, Kevin A. Lobb  
Rhodes University, Grahamstown, South Africa

The malaria parasite *Plasmodium falciparum* is a life-threatening pathogen that incurs a high death and economic burden, especially in Africa and Southeast Asia. Chemotherapy is the most effective strategy in disease burden reduction. Despite a trend toward elimination in the last decade, malaria still remains a health concern with the parasite developing resistance to drugs. Virtual screening is both time and cost-effective in the early stages of drug discovery. In this study, 3 million leads from the ZINC database were screened against *P. falciparum* 1-deoxy-D-xylulose-5-phosphate reductoisomerase using a combined ligand and structure-based approach, combined with consensus scoring. Multiple molecular fingerprints were used to compare ZINC compounds to 17 known DXR inhibitors and to select 50000 compounds. These were docked to the receptor using Qvina-w and rescored using 11 scoring functions. Further, Molecular Mechanics Poisson-Boltzmann Surface Area (MM-PBSA), steered molecular dynamic (SMD) and umbrella sampling (US) were performed to select final hits. Four compounds outperformed the potent 280 nM PfDXR inhibitor LC5 in US. ZINC000050633276 showed a promising -20.43 kcal/mol binding free energy corresponding to  $K_i$  of 1.934 fM. Comparing the methods ranking correlations, in both LVBS and SBVS, some techniques remained uncorrelated while others agreed. In LBVS, two main clusters (ES, USR, USRCAT, OBSPEC) and (MHFP, RDKit\_3dpharm) are noted. In SBVS (Vina, Idock, and Smina), (AutoDock, DSX, Cyscore, Xscore) and the Rf-score group (Rf-score\_V1 to V4) formed distinct clusters. At the residue level, GLU233, CYS268, SER270, TRP296, and HIS341 had a significant contribution to binding free energy in MM-PBSA. Breaking of interactions with these residues in steered MD correlated with higher values of rupture force.

Prodiginines are a family of intriguing pyrrolypyrromethane alkaloid antibiotics produced by actinomycetes and other eubacteria. Our investigations of the antimalarial activity of prodiginines were inspired by previous reports, dating back to 1967. The intriguing structural and antimalarial properties of the prodiginines motivated us to reassess the activity of the natural prodiginines and encouraging preliminary results led us to expand the structural and functional diversity toward the development of prodiginines as potent antimalarials. In our study, a number of the natural and synthetic prodiginines were equally effective at low nanomolar ( $IC_{50} < 10$  nM) concentrations against a panel of multidrug-resistant (MDR) *Plasmodium falciparum* strains. Several of these prodiginines exhibited excellent oral efficacy in erythrocytic *Plasmodium yoelii* murine model without any evident weight loss or overt clinical toxicity. These prodiginine analogues also exhibited optimal metabolic stability and PK profiles. Significantly, prodiginines displayed antimalarial activity in two *in vitro* liver-stage assays: schizonticidal assay using luciferase-expressing *Plasmodium berghei* sporozoite infected human hepatocyte HepG2 cells and hypnozoitocidal assay using non-human primate *Plasmodium cynomolgi*. Our compounds also demonstrated the transmission blocking potential against sexual blood-stage parasite. Moreover, the prodiginines likely operate by a novel mechanism(s) of action given the pan-sensitivity against a large panel of MDR malaria parasites. Detailed structural optimization, multiple-stage antimalarial activities, safety, and metabolic stability studies will be presented.

Malaria remains one of the deadliest diseases in the world today and accounts for over 200 million clinical cases worldwide each year along with roughly half a million deaths, mostly children under the age of five and pregnant women. With increasing multi-drug resistance (MDR) and absence of a clinically proven vaccine, there is an urgent need and continuous search for novel, effective, affordable and safe antimalarial drugs for both treatment of active bloodstream infections as well as preventing the disease at the liver stage. Recently, we have developed a novel antimalarial acridone chemotype with dual stage activity against both liver stage and blood stage malaria, as well as single-dose cure ability and potential to prevent relapsing infections. Here, we disclose the detailed late lead optimization and structure-activity relationships of the second-generation novel antimalarial acridones.

<sup>1</sup>Medicines for Malaria Venture, Geneva, Switzerland, <sup>2</sup>The Art of Discovery, Derio, Spain

New antimalarial medicines are urgently needed to counter the emergence of resistance and contribute to malaria's global elimination. These medicines should be developed as fixed-dose combinations of at least two drugs, each with different mechanisms of action and compatible PK profiles. Unlike in the past, these medicines are now deliberately developed as fixed-dose combinations of two or more agents, where at least one of the agents is novel. However, the selection and ranking of optimal combination candidates is a complex scientific challenge because of the high number of biological, pharmacological and pharmacodynamics variables involved. Moreover, there is a high number of potential drug combinations of the set of antimalarials currently in preclinical development. In our current drug development model, new drug combinations are prioritized based on their efficacy in the *P. falciparum* infected humanized mouse model (NODscidIL2R<sup>ynull</sup>, NSG) in which mice are engrafted with human erythrocytes. This model allows *in vivo* growth of human *Plasmodium* providing a means of assessing the efficacy of novel agents to kill the human parasite. *In vivo* drug combination studies are conducted to investigate, understand, and gauge the individual contribution and mechanistic interactions of the partner drugs. So far, thirty combinations have been studied using this animal model. Our results indicate that the data generated in the *P. falciparum* infected NSG model effectively translates to the human volunteer infection study model. Therefore, the development of humanized mouse models has emerged as a powerful enabling technology to assess new candidate drug combinations.

The World Health Organization (WHO) recommends regular surveillance of efficacy and safety of artemisinin-based combination therapies (ACT) for the treatment of uncomplicated malaria, which are the currently recommended antimalarial drugs. A prospective one-arm study was conducted to assess the efficacy and safety of artemether-lumefantrine (AL), the first line ACT for uncomplicated malaria in Tanzania at four outpatient health facilities in Bagamoyo, Kigoma, Kilombero, and Muheza

districts. This study was conducted from June to December 2020 and recruited children aged 6 months to 10 years with microscopy confirmed uncomplicated *P. falciparum* malaria who met the inclusion criteria. The inclusion and exclusion criteria was based on WHO protocol. Children were treated with AL twice daily for three days and followed-up on days 3, 7, 14, 21, and 28, and on any day of recurrent illness for clinical and parasitological assessments. Blood was also collected on Whatman filter paper on day 0 and at the time of recurrent infection for polymerase chain reaction (PCR) analysis. The primary outcome measure was PCR-corrected adequate clinical and parasitological response (ACPR) on day 28. A total of 672 children were screened; among these, 356 (53.0%) were enrolled, and 350 (98.3%) completed 28 days of follow-up or attained the treatment outcomes according to the protocol. There was no early treatment failure; late clinical failure occurred in 20 (5.6%) patients, and late parasitological failure occurred in 36 (10.1%) patients. The day 28 PCR-uncorrected ACPR ranged from 82.7% at Muheza district to 94.8% at Kilombero district. The overall PCR-corrected cure rate was high (98.3%). There were 56 (15.7%) recurrent infections, with the majority (32.5%) occurring in Muheza district. The drug was well tolerated, and no serious adverse events were reported. The most commonly reported adverse event was cough in 13.7% of enrolled patients. The findings show that AL is still highly efficacious and was well tolerated with minimal adverse events in Tanzania. The high proportion of Recurrent infections were seen in a district with high transmission rate.

0220

### DEVELOPMENT OF AN ECTOPIC HULIVER MODEL FOR PLASMODIUM LIVER STAGE INFECTION

**Gabriela Samayoa Reyes**<sup>1</sup>, Siobhan Flaherty<sup>1</sup>, Kristina Wickham<sup>2</sup>, Sara Viera<sup>3</sup>, Pamela Strauch<sup>1</sup>, Laura Padrón<sup>3</sup>, Conner Jackson<sup>1</sup>, Patricia Meireles<sup>3</sup>, David Calvo<sup>3</sup>, Wanlapa Roobsoong<sup>4</sup>, Niwat Kangwanrangsan<sup>4</sup>, Jetsumon Sattabongkot<sup>4</sup>, Gregory Reichard<sup>2</sup>, Maria José Lafuente-Monasterio<sup>3</sup>, Rosemary Rochford<sup>1</sup>

<sup>1</sup>Department of Immunology and Microbiology, University of Colorado School of Medicine, Aurora, CO, United States, <sup>2</sup>Department of Drug Discovery, Experimental Therapeutics Branch, Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>3</sup>Diseases of the Developing World, Infectious Diseases-Centre for Excellence in Drug Discovery (ID CEDD), GlaxoSmithKline, Madrid, Spain, <sup>4</sup>Mahidol Vivax Research Unit, Faculty of Tropical Medicine, Mahidol University, Bangkok, Thailand

The first stage of *Plasmodium falciparum* and *P. vivax* infection involves parasite replication within the host hepatocytes, and is referred to as the liver stage (LS). Current knowledge regarding human LS infection dynamics is limited due to species-specificity challenges. Here we report a moderate-throughput, moderate-cost, and reproducible *in vivo* model to study *P. falciparum* and *P. vivax* LS using NOD/SCID/IL2R<sup>gnull</sup> mice, herein referred to as the ectopic huLiver model. In this model, ectopic huLiver tumors were generated following subcutaneous injection of HC-04 cells. HuLivers were highly vascularized and expressed essential hepatic receptors, including the hepatic asialoglycoprotein receptor 1 (ASGPR1)—an essential receptor for targeted delivery of therapeutics. After investigating various methods of delivery, inoculation with infected *P. falciparum* sporozoites via mosquito bite was determined to be the most effective. The ectopic huLiver model was shown to support complete LS development and to allow for subsequent transition to blood-stage infection in mice repopulated with human red blood cells. Blood stage infection was quantified by measuring *P. falciparum* 18S expression levels using qRT-PCR. The ability of the model to enable testing of compounds for malaria chemoprophylaxis was demonstrated with primaquine, which was able to penetrate the ectopic liver and act as an effective prophylactic in this model. Furthermore, we established that our ectopic huLivers could be infected with *Plasmodium vivax* sporozoites isolated from infected mosquitoes suggesting the utility of this model for other *Plasmodium* species. As such, the ectopic huLiver model presented here provides an additional system for studies of human *Plasmodium* to elucidate parasite biology and aid in the development of anti-malarial therapeutics.

## INHIBITION OF THE PLASMODIUM FALCIPARUM ACETYL-CoA SYNTHETASE BY MULTIPLE CHEMOTYPES DISRUPTS PROTEIN ACETYLATION AND EPIGENETIC REGULATION IN BLOOD STAGE PARASITES

Robert Summers<sup>1</sup>, Charisse Pasaje<sup>2</sup>, Joao Pisco<sup>3</sup>, Manu Vanaerschot<sup>4</sup>, James Murithi<sup>4</sup>, Madeline Luth<sup>5</sup>, Justin Munro<sup>6</sup>, Emma Carpenter<sup>7</sup>, Avinash Puneekar<sup>3</sup>, Sabine Otilie<sup>5</sup>, Manuel Llinás<sup>6</sup>, Marcus Lee<sup>7</sup>, Elizabeth Winzeler<sup>5</sup>, David Fidock<sup>4</sup>, Ian Gilbert<sup>3</sup>, Dyann Wirth<sup>1</sup>, Jacquin Niles<sup>2</sup>, Beatriz Baragaña<sup>3</sup>, Amanda Lukens<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Massachusetts Institute of Technology, Cambridge, MA, United States, <sup>3</sup>University of Dundee, Dundee, United Kingdom, <sup>4</sup>Columbia University Medical Center, New York, NY, United States, <sup>5</sup>University of California San Diego School of Medicine, La Jolla, CA, United States, <sup>6</sup>The Pennsylvania State University, University Park, PA, United States, <sup>7</sup>Wellcome Sanger Institute, Hinxton, United Kingdom

Global malaria control and elimination efforts rely on new generations of antimalarial drugs with novel modes of action against the malaria parasite *Plasmodium falciparum*. Using *in vitro* resistance evolution experiments, we previously identified mutations in the parasite's Acetyl-CoA Synthetase (PF3D7\_0627800; PfAcAS) that confer resistance to structurally distinct compounds, including MMV084978 and MMV019721. Allelic exchange using the CRISPR/Cas9 system confirmed that the A597V or T648M mutations in PfAcAS phenocopied the resistance phenotype. Conditional knockdown using the Tet-DOZI-RNA-aptamer system demonstrated that PfAcAS is essential for parasite growth, and partial knockdown sensitized parasites to both compounds. MMV019721 and MMV084978 directly inhibited recombinant PfAcAS activity in a substrate-competitive manner, with Ki values of 73 and 369 nM respectively, and the A597V mutation reduced inhibitor affinities by >90-fold. Orthologues of PfAcAS in eukaryotes catalyze the formation of the central metabolite acetyl-CoA from acetate, coenzyme A and ATP, and participate in a range of essential processes including epigenetic regulation. Metabolomic analyses revealed that exposure of trophozoite parasites to PfAcAS inhibitors reduced cellular acetyl-CoA levels by ~4-fold. To examine the biological implications of PfAcAS disruption further, we have explored the effects of PfAcAS inhibition on histone acetylation throughout the blood stage of the parasite. Together these findings suggest that PfAcAS may play a role in maintaining nucleo-cytosolic acetyl-CoA pools that are necessary for epigenetic regulation of parasite gene expression. These findings highlight PfAcAS as a promising drug target with inhibitors that exert their effects on the parasite via a unique mode of action.

## COLLATERAL SENSITIVITY AS A STRATEGY TO SUPPRESS THE EVOLUTION OF RESISTANCE IN IN VITRO AND IN VIVO CONTEXTS

Maria Jose Lafuente-Monasterio<sup>1</sup>, Rebecca E.K. Mandt<sup>2</sup>, Amanda K. Lukens<sup>3</sup>, Madeline R. Luth<sup>4</sup>, Sabine Otilie<sup>4</sup>, Laura Padrón<sup>1</sup>, Delfina Segura-Carro<sup>1</sup>, Helena María Garuti-Rodríguez<sup>1</sup>, María del Carmen Cuevas<sup>1</sup>, Sara Viera-Morilla<sup>1</sup>, Elizabeth A. <sup>1</sup>GlaxoSmithKline, Tres Cantos, Spain, <sup>2</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>3</sup>The Broad Institute, Cambridge, MA, United States, <sup>4</sup>University of California, San Diego, La Jolla, CA, United States

Resistance has emerged to frontline antimalarial combination therapies, making the development of new treatment strategies for malaria a public health priority. In addition to safety and efficacy, a key target profile for novel therapeutics is a reduced probability of resistance emergence. Previously, we characterized the rapid evolution of resistance both *in vivo* and *in vitro* to the clinical antimalarial candidate DSM265, a *Plasmodium* dihydroorotate dehydrogenase (DHODH) inhibitor. Interestingly, we found

that mutant lines resistant to DSM265 showed increased sensitivity to other DHODH inhibitors, a phenomenon known as 'collateral sensitivity'. Here we explore the potential of using collateral sensitivity to develop a combination therapy that would suppress the evolution of resistance. We report that parasites resistant to DSM265 display collateral sensitivity to the structurally-distinct DHODH inhibitor Genz669178. Work in other systems has shown that when two compounds confer collateral sensitivity to each other, resistance to combination treatment with both compounds is less likely to emerge. This led to the hypothesis that a combination treatment of DSM265 and Genz669178 would suppress the emergence of resistant parasites. We test this hypothesis using both an *in vitro* cell culture system and an *in vivo* mouse model of resistance selection. We find that while resistance to DSM265 + Genz669178 arises rapidly *in vitro*, cross-resistant parasites do not emerge *in vivo*. The different results from our *in vitro* and *in vivo* models highlight the importance of the *in vivo* environment, including the pharmacokinetics of drug exposure, on the evolution of resistance. Our findings also suggest that combination strategies based on collateral sensitivity may be effective in an *in vivo* context. The human biological samples were sourced ethically and their research use was in accord with the terms of the informed consents. All animal studies were ethically reviewed and carried out in accordance with European Directive 2010/63/EEC and the GSK Policy on the Care, Welfare and Treatment of Animals.

## MALARIA TRANSMISSION DYNAMICS IN A HUMANITARIAN CRISIS IN SOUTHERN VENEZUELA, 2016-2020

Leopoldo Villegas<sup>1</sup>, Jorge Moreno<sup>2</sup>, Maria Villegas<sup>1</sup>, Erika Wetzler<sup>3</sup>, Sara Canavati<sup>3</sup>, Maria E. Guevara<sup>1</sup>, Paola Marchesini<sup>4</sup>

<sup>1</sup>ASOCIS, Tumeremo, Bolivar, Bolivarian Republic of Venezuela, <sup>2</sup>Centro de Investigación de Campo "Francesco Vitanza", Instituto de Altos Estudios "Dr. Arnoldo Gabaldon", Tumeremo, Bolivar, Bolivarian Republic of Venezuela, <sup>3</sup>World Vision, Washington, DC, United States, <sup>4</sup>Ministry of Health Brazil, Brasília, Brazil

Since 2010, malaria transmission has increased significantly in Venezuela, and currently more than 50% of cases in all the Americas region being reported by Venezuela. Health data has been censored by the Venezuelan government since 2016, hence civil society organizations have played an important role in monitoring malaria data. This study aims to describe the changes in malaria transmission, geo-distribution, and the impact of COVID-19 on malaria transmission in Bolivar state, Venezuela from 2016 to 2020. During this period, Bolivar state reported on average 64% of the malaria cases in the country. A total of 2,754,606 blood samples were taken with 1,047,437 reported malaria cases. Overall, 40% of those tested for malaria were positive with test positivity rates ranging from 31% in 2016 to 67% in 2018 with a significant decrease (28%) in 2020. Annual parasite incidence (API) declined 41% overall with a high API from 2016 to 2019 (102-147 per 1000 population at risk) and sharply declined to 60 per 1000 par in 2020. Key and vulnerable populations included mainly young adults and indigenous groups. Illegal mining remains the main occupational risk factor. The causes of this malaria resurgence were multifactorial and, occurred as part of the complex humanitarian emergency: internal/external migration, illegal mining, limited funding for operations, and inadequate implementation of interventions. Stock-outs of antimalarial drugs were common in 2016. At the beginning of 2018; supplies of all antimalarials drugs were widely distributed. LLINs have been distributed in main hotspots since late 2018 with high coverage (>98%). The COVID-19 pandemic has hit Venezuela hard with >390 deaths among health workers. Gasoline shortages and strict quarantine rules have shrunk domestic activities. Venezuela has been driving Latin America severely off track in meeting WHO's 2016-2030 milestones. Venezuela lacks resilient infrastructure and is clearly ill-equipped for effective COVID-19 and malaria national responses. The consequences of Venezuela's crisis spillover will be also presented.

0224

### HIGH PREVALENCE OF ASYMPTOMATIC MALARIAL ANEMIA AND ASSOCIATION WITH EARLY CLINICAL CONVERSION IN A PLASMODIUM FALCIPARUM HYPER-ENDEMIC SETTING IN CAMEROON

**Balotin Fogang**<sup>1</sup>, Marie Florence Biabi<sup>2</sup>, Rosette Megnekou<sup>3</sup>, Franklin Maloba<sup>4</sup>, Estelle Essangui<sup>2</sup>, Christiane Donkeu<sup>1</sup>, Glwadys Cheteug<sup>2</sup>, Marie kapen<sup>2</sup>, Rodrigue Keumoe<sup>1</sup>, Sylvie Kemleu<sup>2</sup>, Sandrine Nsango<sup>2</sup>, Carole Eboumbou<sup>2</sup>, Tracey Lamb<sup>4</sup>, Lawrence Ayong<sup>2</sup>

<sup>1</sup>University of Yaounde II/Centre Pasteur Cameroon, Yaounde, Cameroon, <sup>2</sup>Centre Pasteur Cameroon, Yaounde, Cameroon, <sup>3</sup>University of Yaounde I, Yaounde, Cameroon, <sup>4</sup>University of Utah, Yaounde, UT, United States

Asymptomatic malaria is highly prevalent in *Plasmodium falciparum* endemic areas and often associated with increased prevalence of mild-to-moderate anemia. The aim of this study was to assess the prevalence of anemia during asymptomatic malaria parasite carriage and the interplay with persistent infection in highly exposed malaria-endemic residents. A household-based longitudinal survey was undertaken in a malaria hyper-endemic area in Cameroon using multiplex nested PCR for malaria diagnosis. Residents with *P. falciparum* asymptomatic parasitemia were monitored over a three-week period with the aid of structured questionnaires and weekly measurements of axillary temperatures. Of the 353 individuals included in the study (median age: 26 years, range 2-86 years, male/female sex ratio 0.9), 328 (92.9%) were positive for malaria parasitemia of whom 266 (81.1 %) were asymptomatic carriers. The prevalence of anemia in the study population was 38.6%, of which 69.2% were asymptomatic for *P. falciparum* infections. Multivariate analyses identified elevated blood parasitemia and female gender as associated risk factors of asymptomatic malarial anemia in the population. 15.4% of the asymptomatic participants reported with a fever before the end of the study. Furthermore, risk analyses revealed anemia at the time of enrolment as a key predictor of early development of febrile illness in the population. Together, the data reveal an extremely high prevalence of asymptomatic malaria parasitemia and anemia in the study area, unveiling for the first time the association of asymptomatic malarial anemia with early clinical conversion. These findings underscore the negative impact of asymptomatic malaria parasitemia on individual health, necessitating the development of adequate control and preventive measures.

### MALARIA INFECTION BURDEN AND ASSOCIATED RISK FACTORS IN AREA OF PYRETHROID-RESISTANT VECTORS TO LONG-LASTING INSECTICIDAL NETS IN BENIN

**Manfred Accrombessi**<sup>1</sup>, Martin Akogbeto<sup>2</sup>, Edouard Dangbenon<sup>2</sup>, Hilaire Akpovi<sup>2</sup>, Arthur Sovi<sup>1</sup>, Boulais Yovogan<sup>2</sup>, Aurore Ogouyemi-Hounto<sup>3</sup>, Corine Ngufor<sup>1</sup>, Mark Rowland<sup>1</sup>, Natacha Protopopoff<sup>1</sup>, Jackie Cook<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, <sup>3</sup>National Malaria Control Program, Ministry of Health, Cotonou, Benin

Recent reductions in the malaria burden, mainly due to long-lasting insecticidal nets (LLINs), are currently threatened by the wide-scale selection of insecticide-resistant malaria vectors. In the present study, we aimed to determine the overall burden of malaria and its associated factors in a rural area of Benin with high pyrethroid-resistant vectors. As part of the pre-intervention activities of the New Nets project, a cluster randomised controlled trial assessing the efficacy of two dual-active ingredients LLINs, a community-based cross-sectional survey was conducted in three districts in southern Benin. More than 4,320 participants all ages were randomly selected using two-stage cluster sampling. Malaria rapid diagnostic tests were performed on consented participants. Risk factors for malaria infection were evaluated using multi-level mixed logistic regression adjusted within clusters. LLIN possession and the population net use were very high in the population (97% and 96%,

respectively). However, malaria infection prevalence was 43.5% (cluster range: 15.1-72.7%). High household density, low socioeconomic status, young age (<5y; 5-10y; 10-15y), high education level, poor LLIN condition, fever in the past 48 hours and at the time of the survey were the risk factors significantly associated with malaria infection. Despite important population net use, malaria prevalence remain high in this area of intense pyrethroid-resistance. New classes of LLINs effective against resistant vectors are therefore crucial to sustain malaria reduction.

0226

### THE EFFECTS OF METEOROLOGICAL FACTORS AND GEOGRAPHICAL ELEVATION ON MALARIA INCIDENCE IN ELIMINATION TARGETED DISTRICT OF ETHIOPIA

**Desalegn Dabaro**<sup>1</sup>, Zewdie Birhanu<sup>2</sup>, Abiyot Negash<sup>2</sup>, Dawit Hawaria<sup>1</sup>, Delenasaw Yewhalaw<sup>2</sup>

<sup>1</sup>Yirgalem Hospital Medical College, Yirgalem, Ethiopia, <sup>2</sup>Jimma University, Jimma, Ethiopia

Ethiopia has made significant strides in the fight against malaria. The country has now adopted & is implementing the global malaria elimination program, which is expected to be completed by 2030. The success of the elimination attempt, on the other hand, can be influenced by multiple factors. Climate & environmental conditions can be one of the most significant factors affecting the progress of elimination. As a result, the study aimed to investigate the burden & transmission drivers of malaria in one of the country's elimination targeted districts. From 2010 to 2017, all febrile patients in the district's health facilities were diagnosed for malaria using a microscope & Rapid Diagnostic Test. The malaria data were collected from the malaria registers, the meteorological data from the country's National Meteorological Agency, & the geographic coordinates from each village. The data were entered using EpiData 3.1, & analyzed by R version 4.0.0. During the study period, a total of 135,607 patients were diagnosed, with 29,554 (21.8%) of them being confirmed malaria cases. Only two species, *Plasmodium falciparum* & *Plasmodium vivax*, were identified, with 56.3 % & 38.4 %, respectively. The rest 5.2 % was a mixed infection. A time series plot revealed a significant reduction of malaria, with a clear downward trend in case numbers. In a Negative Binomial Regression, the transmission season, rainfall, temperature, elevation, & the patient's sex & age were found to be predictors of disease incidence & spatial distribution. An ARIMA (2, 1, 2), the best fit model for point prediction of potential malaria incidence in 2030, the target year for elimination, projected that the monthly incidence will fluctuate around 88 cases. Finally, the results showed a significant reduction in malaria morbidity in the district. The results of the predictive model, on the other hand, raised doubts about whether the elimination goal will be reached within the time frame. Thus, achieving the elimination goal would necessitate an equitable distribution & efficient use of current interventions, as well as the development of evidence-based interventions.

### MALARIA PARASITEMIA AND ANEMIA AMONG PREGNANT WOMEN ATTENDING GENERAL HOSPITAL, ENUGWU UKWU, ANAMBRA STATE, NIGERIA

**Pauline U. Umeanaeto**<sup>1</sup>, Chukwujindu Odagwe<sup>1</sup>, Ifenna C. Onwuagana<sup>1</sup>, Kindness C. Irikannu<sup>1</sup>, Chukwudinma C. Okoli<sup>2</sup>, Justina C. Akulue<sup>3</sup>, Stella C. Afulukwe<sup>4</sup>

<sup>1</sup>Department of Parasitology and Entomology, Nnamdi Azikiwe University, Awka Anambra State, Nigeria, <sup>2</sup>Hospital Management Board, Laboratory Unit, Kuje General Hospital, FCT, Abuja, Nigeria, <sup>3</sup>Department of Medical Laboratory Sciences, Nnamdi Azikiwe University, Nnewi, Anambra State, Nigeria, <sup>4</sup>Department of Anatomy, Chukwuemeka Odumegwu Ojukwu University, Uli, Anambra State, Nigeria

The physiological changes associated with pregnancy make women more susceptible to malaria infection. Malaria infection is a cause of severe anemia in pregnancy which is an important contributor to maternal morbidity and mortality, in addition to low birth weight in many parts of

the world including Nigeria. A study to determine malaria parasitemia and hemoglobin concentration among pregnant women attending General hospital Enugwu-Ukwu, Anambra State, Nigeria, was conducted between July and December, 2019. Two milliliter of venous blood was collected from 408 pregnant women during antenatal visits. Thick and thin blood films were prepared, stained with 10% Giemsa stain and examined microscopically for malaria parasites. Hemoglobin (Hb) concentration was estimated using cyanmethemoglobin method. Hemoglobin concentration below 11.0g/dl was regarded as anemia in pregnancy. Of 408 blood samples collected, 112 (27.5%) were positive for malaria parasites. The age group 15–20 years had the highest prevalence 8 (40%) while the age group 36–40 years had the least 24 (23.1%). The primigravidae had the highest malaria prevalence 72 (36%), while the multigravidae had the least 40(19.2%). Malaria prevalence among the pregnant women in relation to gravidity was not statistically significant ( $P>0.01$ ). The pregnant women in their first trimester had the highest malaria prevalence 48 (50%), while those in third trimester had the least 24 (16.7%). Malaria parasitemia in relation to trimester was statistically significant ( $P<0.01$ ). A total of 248 (60.8%) pregnant women had Hb value less than 11g/dl. The multigravidae 128(61.5%) had an average Hb of 9g/dl, while the primigravidae 120(60.0%) had an average Hb of 10g/dl. Health education and proper administration of Intermittent Preventive Therapy (IPT) during pregnancy is recommended for malaria prevention and control in pregnancy.

0228

#### A QUICK LOOK INTO MALARIA AMONG THE AMERINDIAN PEOPLE OF VENEZUELA

Juan Carlos Gabaldon<sup>1</sup>, Carlos Chaccour<sup>2</sup>, Jorge E. Moreno<sup>3</sup>, Maria Villegas<sup>4</sup>, Leopoldo Villegas<sup>4</sup>

<sup>1</sup>Clinica Universidad de Navarra, Pamplona, Spain, <sup>2</sup>Instituto de Salud Global de Barcelona, Barcelona, Spain, <sup>3</sup>Instituto de Altos Estudios Arnoldo Gabaldon, Tumeremo, Bolivarian Republic of Venezuela, <sup>4</sup>Asociación Civil Impacto Social, Tumeremo, Bolivarian Republic of Venezuela

Venezuela accounts for more than half the cases of malaria in the Americas, most of which occur in mining areas south of the Orinoco river, and the north-east shore of the country, where several Amerindian groups live. These communities have traditionally had limited access to healthcare, and the real magnitude of their malaria burden is unknown. We reviewed published and unpublished epidemiological records collected by field workers to determine the risk of contracting malaria among Amerindian patients of Amazonas, Bolivar, and Sucre, three states that accumulate 90% of all cases registered in the country. We determined the geographic distribution of cases, and the risk factors associated to infection with *Plasmodium falciparum*. We registered 116,097 cases of malaria among Amerindian patients between 2014 and 2018. Despite an increased incidence between 2014 and 2016, the risk of contracting malaria among Amerindian patients compared to the general population has reduced in later years. Hot spots were identified in municipalities of the three states, although more clearly in Bolivar. Two groups, the Yanomami, and the Hoti, showed higher odds for infection with *P. falciparum*. Cases of malaria among Amerindian patients in Venezuela increased between 2014 and 2018, although not as quickly as in the rest of the population. These cases are clustered in different geographic regions than those in the general population, and their control will likely require tailored approaches. Interventions should initially prioritize the Yanomami and the Hoti, given their increased risk of infection with *P. falciparum*, associated to cases of severe malaria.

0229

#### AGE AND SEASONAL DISTRIBUTION OF MALARIA HOSPITAL ADMISSIONS IN THE CONTEXT OF SEASONAL MALARIA CHEMOPREVENTION IN OUELESSEBOUGOU, MALI

Djibrilla Issiaka

Malaria Research & Training Center, Faculty of Medicine, Pharmacy and Dentistry, University of Bamako, Bamako, Mali

Seasonal Malaria Chemoprevention (SMC) was approved as a policy for malaria control in children under the age of 5 years by WHO in 2012. Nationwide implementation in Mali was achieved in 2016 including the health district of Ouelessebouguou. This study assessed age and seasonal distributions of malaria hospital admissions to the district hospital of Ouelessebouguou in 2018 after SMC was fully deployed. A total of 943 children aged 0-15 years were admitted for malaria disease confirmed by rapid diagnostic test or blood smear microscopy. Of these, 453 had severe malaria according to WHO criteria. Children under 5 years of age represented 77.9% (735/943) of laboratory confirmed malaria admissions and 83.2% (377/453) of severe malaria admissions. 89.4% (843/943) of the laboratory confirmed malaria admissions and 90.3% (409/453) of severe malaria admissions occurred during the malaria transmission season between July and December. Despite the wide implementation of SMC, malaria remained the major cause of the hospital admissions especially in children under 5 years of age. Most of the cases are concentrated over a six-month period from July to December. Additional tools are needed to reduce the burden of malaria especially in children under 5 years of age.

#### ENHANCING COUNCIL HEALTH TEAMS ON USING MALARIA RISK MAPS FOR SUPPORTING DECENTRALISED MALARIA CONTROL PLANNING IN MAINLAND TANZANIA

Sumaiyya G. Thawer<sup>1</sup>, Ally Mohamed<sup>2</sup>, Samwel Lazaro<sup>2</sup>, Sijenuu Aaron<sup>2</sup>, Frank Chacky<sup>2</sup>, Khalifa Munisi<sup>2</sup>, Joanna Lyimo<sup>2</sup>, Stanslaus Henry<sup>2</sup>, Sigsbert Mkude<sup>3</sup>, Victor Alegana<sup>4</sup>, Peter Macharia<sup>5</sup>, Robert Snow<sup>6</sup>, Noela Kisoka<sup>1</sup>, Christian Lengeler<sup>7</sup>, Amanda Ross<sup>7</sup>, Fabrizio Molteni<sup>1</sup>, Emilie Pothin<sup>8</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute/ University of Basel, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>National Malaria Control Program, Ministry of Health, Community Development, Gender, Elderly and Children, Dodoma, Tanzania, Dodoma, United Republic of Tanzania, <sup>3</sup>PMI Impact Malaria, USAID, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>Population Health Unit, KEMRI-Welcome Trust Research Programme, Nairobi, Kenya, Nairobi, Kenya, <sup>5</sup>Population Health Unit, KEMRI-Welcome Trust Research Programme, Nairobi, Kenya / CHICAS, Lancaster Medical School, Lancaster University, Lancaster, UK, Nairobi, Kenya, <sup>6</sup>Population Health Unit, KEMRI-Welcome Trust Research Programme/Centre for Tropical Medicine and Global Health, Nuffield Department of Clinical Medicine, University of Oxford, Nairobi, Kenya, <sup>7</sup>Swiss Tropical and Public Health Institute/ University of Basel, Basel, Switzerland, <sup>8</sup>Swiss Tropical and Public Health Institute/ University of Basel/Clinton Health Access Initiative, Basel, Switzerland

Control efforts in mainland Tanzania have led to a decline in the prevalence of malaria infection ( $PfPR_{6-59mo}$ ) from 18.1% (DHS/MIS-2008) to 7.5% (MIS-2017). This decrease in transmission was accompanied by an increasing trend in the heterogeneity of transmission. Hence, the country recognized that a more strategic allocation of resources to the sub-national epidemiological context was needed. In line with the World Health Organization High Burden to High Impact initiative, mainland Tanzania employed a country-led data-driven approach to develop a national malaria risk stratification. This approach was originally developed during the revision of the previous national malaria strategic plan. The current plan (2021-2025) makes use of available evidence and advocates for tailored interventions. As the country moves towards implementation of targeted intervention, a more granular micro-stratification of malaria risk becomes valuable for even further targeting of community-based interventions. The country's routine health management information

system provides numerous data that can be used to define the risk strata of each ward within a council. As a first step, combinations of survey and routine indicators were collated at ward level for the period 2017-2019. The council prevalence estimated through school surveys served as a guide to set appropriate cut-offs for the routine indicators through a sensitivity analysis. This allowed for allocating the 3,311 wards to one of four risk groups: very low, low, moderate and high. As a next step, capacitating council health teams to translate the risk map for micro-planning of suitable intervention strategies becomes crucial in the process towards decentralization. To this end, the country is currently employing a top-down approach, whereby trained national malaria program staff are enabling the council teams to take charge of community-case management and focal vector control initiatives such as indoor residual spraying and larviciding down to ward level. Such a detailed and dynamic framework can lead to better allocation efficiency to maximize future impacts on disease burden.

### SYSTEMATIC REVIEW OF PLASMODIUM FALCIPARUM AND P. VIVAX POLYCLONAL INFECTIONS: IMPACT OF PREVALENCE, STUDY POPULATION CHARACTERISTICS, AND LABORATORY PROCEDURES

Luis Lopez, Cristian Koepfli

University of Notre Dame, Notre Dame, IN, United States

Multiple infections of genetically distinct clones of the same *Plasmodium* species are common in many malaria endemic settings. Mean multiplicity of infection (MOI) and the proportion of polyclonal infections are often reported as surrogate marker of transmission intensity, yet the relationship with traditional measures such as parasite prevalence is not well understood. We screened published articles and assessed the impact of population prevalence, genotyping method, number of genotyping markers, method for diagnosis (microscopy/RDT vs. PCR), presence of clinical symptoms, age, geographic region, and year of sample collection on multiplicity indices. For *P. falciparum* (275 data points, 33526 genotyped individuals) the proportion of polyclonal infections ranged from 0-96%, and mean MOI from 1-6.1. For *P. vivax* (115 data points, 13325 genotyped individuals) the proportion of polyclonal infections ranged from 0-100%, and mean MOI from 1-3.8. A weak correlation between prevalence and the proportion of polyclonal infections was observed (Pf: 0.34% increase per percentage increase in prevalence,  $P < 0.001$ ; Pv: 0.78% increase per percentage increase in prevalence,  $P < 0.001$ ). In multivariable analysis, higher prevalence, typing multiple markers, diagnosis of infections by PCR, and sampling in Africa were found to result in a higher proportion of *P. falciparum* polyclonal infections. For *P. vivax*, prevalence, year of study, typing multiple markers, and geographic region were significant predictors. In conclusion, polyclonal infections are frequently present in all settings, but the association between multiplicity and prevalence is weak.

0232

### LOW PREVALENCE OF PLASMODIUM MALARIAE AND P. VIVAX, AND HIGH PREVALENCE OF P. OVALE DETECTED AMONG TANZANIAN SCHOOL CHILDREN WITHIN THE 2017 SCHOOL MALARIA PARASITEMIA SURVEY (SMPS)

Mhamilawa<sup>3</sup>, Fabrizio Molteni<sup>4</sup>, Ssanyu Nyinondi<sup>3</sup>, Bilali Kabula<sup>5</sup>, Erik Reaves<sup>6</sup>, Naomi Serbantez<sup>6</sup>, Chonge Kitojo<sup>6</sup>, Twilumba Makene<sup>3</sup>, Thwai Kyaw<sup>1</sup>, Jonathan B. Parr<sup>1</sup>, Billy Ngasala<sup>3</sup>, Jonathan J. Juliano<sup>1</sup>

<sup>1</sup>University of North Carolina, Chapel Hill, Chapel Hill, NC, United States,

<sup>2</sup>National Malaria Control Programme, Dodoma, United Republic of Tanzania, <sup>3</sup>Muhimbili University of Health and Allied Sciences, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>Swiss Tropical and Public Health

Institute, Basel, Switzerland, <sup>5</sup>RTI International, Dar es Salaam, United Republic of Tanzania, <sup>6</sup>US President's Malaria Initiative, Dar es Salaam, United Republic of Tanzania

Characterization of non-*falciparum* malaria species across Tanzania is necessary for informing national control efforts toward elimination. Evidence from large-scale studies is currently limited, and non-*falciparum* malaria is thought to be under-diagnosed due to lower accuracy of rapid diagnostics for these species. We leveraged dried blood spots from a large, cross-sectional survey encompassing 8 geographically diverse regions and 198 primary schools across Tanzania to quantify prevalence of non-*falciparum* infections among school children in 2017. A sub-population was selected via stratified random sampling by region for real-time PCR to identify species and estimate prevalence and parasitemia levels. Mapping was performed by school district to assess geographic distribution of non-*falciparum* infections. Among 3,456 school children, 23.6% (n=814) were infected with *Plasmodium ovale* spp., 3.9% (n=136) with *P. malariae*, and 0.3% (n=11) with *P. vivax*, including single and mixed species infections; *P. falciparum* infection was detected in 18.8% (n=651) of children as single or co-infections. Single-species infections were identified in 67.3% (n=548), 24.3% (n=33), and 36.4% (n=4) of all *P. ovale*, *malariae*, and *vivax* infections, respectively. The majority of infections were low parasitemia (*P. ovale*: median [IQR] 1.8 [0.3 - 6.2] p/μL; *P. malariae*: 2.9 [0.7 - 13.7] p/μL; *P. vivax*: 0.1 [0.1 - 0.2] p/μL). *P. ovale* spp. infections were detected in all 8 regions, and *P. malariae* was detected in all but 2 regions (northern and central). *P. vivax* infections were predominately clustered near the northern-western border (54.5%, n=6). Findings confirm non-*falciparum* species are prevalent across Tanzania among school children, with *P. ovale* prevalence considerably higher than *P. malariae*. *P. ovale* and *P. malariae* infections are widely distributed across Tanzania, and would generally be detected as malaria due to co-infection with *P. falciparum*. As malaria control continues and *P. falciparum* parasitemia is reduced, testing specific to non-*falciparum* species will become increasingly important for supporting further malaria elimination efforts.

0233

### USE OF A CONTINUOUS MALARIA INDICATOR SURVEY (CMIS) FOR EVALUATION OF MALARIA INDICES AND INTERVENTION COVERAGE IN WESTERN KENYA, 2015-2020

Julia Janssen<sup>1</sup>, Ryan Wiegand<sup>1</sup>, Brian Seda<sup>2</sup>, Kelvin Onoka<sup>2</sup>, Oliver Towett<sup>2</sup>, Titus Kwambai<sup>3</sup>, Simon Kariuki<sup>2</sup>, Feiko ter Kuile<sup>4</sup>, Aaron Samuels<sup>1</sup>

<sup>1</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Kisumu, Kenya, <sup>4</sup>Department of Clinical Sciences, Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Cross-sectional Malaria Indicator Surveys are timed to occur every 2-5 years during peak prevalence seasons to provide discrete snapshots of malaria indices. However, these indices vary greatly by month and year, and survey timing may result in inaccurate estimates of intervention coverage and impact. In 2015, we began a continuous malaria indicator survey (cMIS) in western Kenya. Following a sub-county-wide census, households were randomly selected yearly for inclusion. Each working day, staff administered questionnaires and malaria rapid diagnostic tests (RDTs) to consented, eligible household members. A total of 21,754 surveys were administered from April 07, 2015 to March 20, 2020 across 3,753 households. Using a negative binomial model, we found that malaria prevalence increased at a rate of 1.13 times (95% CI: 1.07-1.20) annually, insecticide-treated net (ITN) ownership decreased at a rate of 0.97 times (95% CI: 0.95-0.98) annually, and ITN use decreased at a rate of 0.93 times (95% CI: 0.91-0.95) annually. Annual peak malaria prevalence varied between June and September, ranging from 34% (95% CI: 27-41%) to 51% (95% CI: 43-58%). Annual malaria prevalence troughs occurred in April, May, October, or December, ranging from 17% (95% CI: 12-23%) to 40% (95% CI: 32-48%). Monthly ITN ownership ranged from 80%

(95% CI: 70-87%) to 99% (95% CI: 95-100%) and use ranged from 62% (95% CI: 53-71%) to 95% (95% CI: 90-97%). In July 2017, prior to an ITN campaign, ITN ownership was 90% (95% CI: 83-95%), ITN use was 77% (95% CI: 69-84%), and malaria prevalence was 48% (95% CI: 42-54%). After the campaign, in September 2017, ITN ownership rose to 98% (95% CI: 94-100%), ITN use rose to 91% (95% CI: 86-95%) and malaria prevalence fell to 33% (95% CI: 27-39%). In 2018, malaria prevalence was 34% (95% CI: 28-40%) in July and peaked at 40% (95% CI: 34-46%) in September; an MIS done in 2018, a year after the mid-2017 ITN campaign, may have inaccurately estimated the impact of the campaign. In 3 of the 5 years, a traditional MIS in July would have missed the annual peak. Data from these analyses will be used to inform National Malaria Control Program intervention and evaluation timing.

## 0234

### RISK FACTORS FOR ASYMPTOMATIC MALARIA INFECTIONS IN THE PERUVIAN AMAZON

**Stefano Garcia**<sup>1</sup>, Joaquin Gomez<sup>1</sup>, Caroline Abanto<sup>1</sup>, Elizabeth Villasis<sup>2</sup>, Mitchel Guzman<sup>3</sup>, Christopher Delgado-Ratto<sup>4</sup>, Joseph Vinetz<sup>5</sup>, Katherine Torres<sup>2</sup>, Dionicia Gamboa<sup>6</sup>

<sup>1</sup>Laboratorio de Malaria: Parasitos y Vectores, Laboratorios de Investigacion y Desarrollo, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Laboratorio de Malaria, Laboratorios de Investigacion y Desarrollo, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>Laboratorio ICEMRAmazonia, Laboratorios de Investigacion y Desarrollo, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>4</sup>Global Health Institute, Faculty of Medicine, University of Antwerp, Antwerp, Belgium, <sup>5</sup>Section of Infectious Diseases, Department of Internal Medicine, Yale School of Medicine, New Haven, CT, United States, <sup>6</sup>Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

The Peruvian Amazon reflects a challenging scenario of malaria elimination. The high proportion of asymptomatic infections, only identified by active case detection, obscures the actual number of cases. Infected individuals who do not experience any symptoms are ignored, and if left untreated, could transmit the disease. In response to the burden of asymptomatic infections, it is necessary to know the epidemiology and the risk factors intrinsic to the hosts and the environment. From 2018 to 2020, population screenings were done in 11 communities around the Loreto region. The individuals answered a survey related to socio-demographics, malaria antecedents, and household conditions. Participants also provided blood samples for malaria diagnosis. Asymptomatic malaria infection was defined as an infection with the presence of fever, headache, or shaking chill. A univariate logistic regression analysis was performed to test the association of the potential risk factors with asymptomatic infection. For the multivariate logistic regression analysis, factors with p-values <0.2 for the likelihood ratio test in the univariate analysis were considered for further analysis. Of 3,839 surveyed individuals, 13.57% (N=521) were infected by *Plasmodium* spp. Among the malaria cases, 70% were asymptomatic infections. Seasonality, age, previous malaria infection, fumigation, and wooden households, were associated with asymptomatic malaria in the univariate analysis. The multivariate analysis showed a strong association between experience of previous malaria infection and an asymptomatic infection (AOR=0.06, 95%CI 0.01-0.18). During the wet season, individuals were 43.4% less likely to develop an asymptomatic infection (AOR = 0.57, 95%CI 0.37-0.88). Interestingly, patients over 46 years old have decreased odds of developing an asymptomatic infection (AOR=0.42, 95%CI 0.19-0.86). Our study contributes to the knowledge on transmission dynamics of asymptomatic malaria in the Peruvian Amazon by listing the risk factors that need to be considered by the National Malaria Control Program during the formulation of elimination strategies.

## 0235

### CLOSING THE KNOWLEDGE GAP IN HUMAN MOBILITY AND CONNECTEDNESS BETWEEN RURAL VILLAGES ENDEMIC TO MALARIA IN THE PERUVIAN AMAZON

**Joaquin Gomez**<sup>1</sup>, Stefano Garcia<sup>1</sup>, Caroline Abanto<sup>1</sup>, Mitchel Guzman<sup>2</sup>, Roberson Ramirez<sup>2</sup>, Christopher Delgado-Ratto<sup>3</sup>, Joseph Vinetz<sup>4</sup>, Dionicia Gamboa<sup>5</sup>

<sup>1</sup>Laboratorio de Malaria: Parasitos y Vectores, Laboratorios de Investigacion y Desarrollo, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Laboratorio ICEMRAmazonia, Laboratorios de Investigacion y Desarrollo, Facultad de Ciencias y Filosofia, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>Global Health Institute, Faculty of Medicine, University of Antwerp, Antwerp, Belgium, <sup>4</sup>Section of Infectious Diseases, Department of Internal Medicine, Yale School of Medicine, New Haven, CT, United States, <sup>5</sup>Instituto de Medicina Tropical Alexander von Humboldt, Universidad Peruana Cayetano Heredia, Lima, Peru

Malaria exacts a massive toll on human health worldwide, with more than 229 million cases and 400 thousand deaths reported in 2019. In Peru, the disease mainly affects vulnerable populations from the Amazon. These are rural riverine villages that lack access to primary health care services. In recent years, human mobility has been associated with malaria transmission; yet, national malaria control plans do not include it in their control measures. Furthermore, population genetics analyses in these regions signal human mobility as a relevant factor in transmitting and maintaining the disease. However, few studies address precisely the travel profile of the inhabitants and the connectivity between these villages. Here, we characterized the travel profile of inhabitants from an Amazonian malaria endemic district in Peru and assessed the connectivity of their villages through social network analysis. We surveyed 2,378 persons from the Mazan district, an Amazonian region divided in the Napo and Mazan basin, during the 2018 dry season (July and October). Participants answered a sociodemographic survey, including questions about recent travels. Through non-parametrical statistical testing, we found that the Mazan basin inhabitants showed significantly higher travel mobility than those from the Napo basin, both in travel record proportion and total travel time. Additionally, we estimated the travellers' profile through multivariate logistic regression. Our results showed that people older than 16 years, currently studying, earning a salary in the last month and belonging to the Mazan basin are prone to show a travel record in the previous 30 days. Finally, our social network analysis proved that communities from the Mazan basin were strongly connected compared to villages from the Napo basin. Still, connectedness between basins was recorded. All in all, we described the villages' connectivity profile in Mazan and Napo basins, both inside the malaria-endemic district of Mazan. Our results provide more detailed connectivity than previous works done in the region.

## 0236

### SPATIAL DISTRIBUTION OF PLASMODIUM FALCIPARUM AND P. VIVAX IN NORTHERN ETHIOPIA THROUGH MICROSCOPY, RAPID DIAGNOSTIC TEST, ANTIBODY AND ANTIGEN DETECTION DATA

**Colleen Leonard**<sup>1</sup>, Ashenafi Assefa<sup>2</sup>, Heven Sime<sup>2</sup>, Hussein Mohammed<sup>2</sup>, Amha Kebede<sup>3</sup>, Hiwot Solomon<sup>4</sup>, Chris Drakeley<sup>5</sup>, Matthew Murphy<sup>6</sup>, Jimmie Hwang<sup>6</sup>, Eric Rogier<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Ethiopian Public Health Institute, Addis Ababa, Ethiopia, <sup>3</sup>African Society for Laboratory Medicine, Addis Ababa, Ethiopia, <sup>4</sup>Ethiopian Federal Ministry of Health, Addis Ababa, Ethiopia, <sup>5</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>6</sup>US. President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

There are challenges to identifying areas of active malaria transmission within regions of low, heterogenous prevalence. Different tests provide different information including acute diagnosis (rapid diagnostic tests

(RDTs) and microscopy) or prior infection (IgG antibody data). This study describes the concordance of multiple field and laboratory-based malaria tests using data from the 2015 Ethiopian Malaria Indicator Survey. Blood samples were collected for microscopy and RDTs, and dried blood spot samples (n=2,279) from three regions in northern Ethiopia (Afar, Amhara and Tigray) were also analyzed by multiplex bead assay for antigen detection and IgG detection against 10 *Plasmodium* antigens (seven *P. falciparum* and three *P. vivax*). Geospatial analysis was conducted using spatial scan statistics and kernel density estimation to identify hotspots (spatial clusters) of malaria by the different tests. Prevalence of current or recent malaria infection was low (1.4% by RDT, 1.0% by microscopy, and 1.8% by sensitive bead antigen assay, which can detect lingering HRP2 antigens even after parasite clearance). Evidence for prior malaria infection found 38.1% seroprevalence for long-lived IgG against *P. falciparum* antigens and 39.9% seroprevalence for *P. vivax*. For *P. falciparum*, overlapping spatial clusters were identified for all four tests. Five *P. falciparum* antibody clusters were also found that had no overlap with clusters found by any other test, possibly indicating very low transmission areas. For *P. vivax*, three clusters identified based on bead antigen assay, microscopy and IgG antibodies partially overlapped. There were an additional two *P. vivax* antibody clusters identified with no overlap with other clusters. The abundance of antibody clusters detected indicate that in areas of low-transmission, IgG antibody data are a sensitive marker to assess malaria transmission in a population. As countries strengthen their routine surveillance system, assessing the geographic distribution of malaria infection and exposure using multiple metrics can help improve the understanding of malaria transmission dynamics in a region.

0237

#### STRONG CLUSTERING OF ASYMPTOMATIC PLASMODIUM FALCIPARUM AND P. VIVAX INFECTIONS AMONG ETHNIC GROUPS BUT ABSENCE OF POPULATION STRUCTURE IN CHITTAGONG HILL TRACTS, BANGLADESH

**Tiffany Huwe**<sup>1</sup>, Mohammad Golam Kibria<sup>2</sup>, Fatema Tuj Johora<sup>2</sup>, Ching Swe Phru<sup>2</sup>, Nusrat Jahan<sup>2</sup>, Mohammad Sharif Hossain<sup>2</sup>, Wasif Ali Khan<sup>2</sup>, Ric N. Price<sup>3</sup>, Benedikt Ley<sup>3</sup>, Mohammad Shafiqul Alam<sup>2</sup>, Cristian Koepfli<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>International Centre for Diarrheal Disease Research Bangladesh, Dhaka, Bangladesh, <sup>3</sup>Menzies School of Health Research and Charles Darwin University, Darwin, Australia

Malaria remains endemic in eastern Bangladesh, with the most cases in the forested, mountainous region in the southeast called the Chittagong Hill Tracts (CHT). This area is home to Bengali settlers and diverse groups of indigenous people residing largely in mono-ethnic villages. We purposively selected the 10 most prominent ethnicities of the CHT and then randomly selected similar numbers of afebrile individuals from each ethnicity. All 1002 enrolled participants were screened for malaria by RDT and qPCR. The prevalence of *Plasmodium falciparum* and *P. vivax* infection was 0.7% by RDT (*Pf*: 6/1002; *Pv*: 0/1002, mixed: 1/1002) and 4% by qPCR (*Pf*: 21/1002; *Pv*: 16/1002, mixed: 5/1002). Infections were highly clustered, with 60% (30/50) occurring in only two ethnic groups, the Khumi and Mro. To investigate whether transmission occurs primarily within ethnic groups, parasites were genotyped. Twenty-one *P. falciparum* isolates were typed by *msp2* and deep sequencing of 5 amplicons (*ama1-D3*, *cpmp*, *cpp*, *csp*, and *msp7*), and 21 *P. vivax* infections by microsatellite (MS) typing of ten loci and amplicon sequencing of *msp1*. Diversity was high with 5-15 alleles per marker. Expected heterozygosity was 0.93 for *P. falciparum* and 0.81 for *P. vivax*. In total 85.7% (18/21) of *P. vivax* and 23.8% (5/21) of *P. falciparum* infections were polyclonal. No population structure was evident for either species, suggesting high transmission and gene flow among ethnic groups. However, MS pairwise relatedness of *P. vivax* among the Mro was higher than in other ethnicities. Identity-by-state (IBS) for *Plasmodium spp.* among samples from the Mro ethnicity was greater (*Pf*: 0.50; *Pv*: 0.25) than for all samples (*Pf*: 0.11; *Pv*: 0.22). This suggests that the Mro may be isolated from transmission from other ethnicities, perhaps due to geographic distance or some Mro-specific

behavior. High asymptomatic and subpatent infection prevalence and high genetic diversity suggest sustained ongoing transmission in CHT. Control activities should be specifically directed to ethnicities at high risk.

0238

#### DIFFERENTIAL PATTERNS OF NATURALLY ACQUIRED IMMUNE RESPONSES TO 28 PLASMODIUM FALCIPARUM VACCINE ANTIGENS WITH VARIOUS LEVELS OF GENETIC DIVERSITY

**Myo Thet Naung**<sup>1</sup>, Ramin Mazhari<sup>1</sup>, Wilson Wong<sup>1</sup>, Eizo Takashima<sup>2</sup>, Takafumi Tsuboi<sup>2</sup>, Ivo Mueller<sup>1</sup>, Alyssa E. Barry<sup>3</sup>

<sup>1</sup>Walter Eliza Hall Medical Institute, Melbourne, Australia, <sup>2</sup>Division of Malaria Research, Proteo-Science Center, Ehime University, Japan, Ehime, Japan, <sup>3</sup>School of Medicine, Deakin University, Geelong, Australia

The study of antigenic targets of naturally acquired immunity (NAI) is essential to identify and prioritize antigens for effective vaccine development. NAI to *Plasmodium falciparum* malaria is mainly mediated by IgG antibodies but acquisition of protective antibody responses in relation to genetic diversity and signatures of immune selection of each antigen is largely unexplored. Using partial or full-length expressed recombinant proteins (3D7 allele), we measured total IgG responses to 28 *Plasmodium falciparum* antigens from more than 700 Papua New Guinean school-aged children (5 - 14 years old) at the first and last timepoints of two longitudinal cohorts from high and moderate transmission settings (n = 1500). We then measured correlations between antibodies, genetic diversity and immune selection (defined using MalariaGEN Pf3K sequences), and protective efficacy against malaria in the two transmission settings. Acquisition of total IgG was associated with repeated exposure to infection, genetic diversity, balancing selection, and antigen function. In the high transmission setting, high antibody levels were associated with protection from malaria; in contrast, in the moderate transmission setting they were typically associated with an increased risk of malaria. Among antigens with the highest total IgG at high transmission were rhoptry (e.g., RALP1), microneme (e.g., AMA1) or conserved antigens (e.g., CyRPA, TRAMP, Pfs25). Whilst, antigens with expected balancing selection hotspots such as AMA1, MSP3, MSP9, DBLMSP1, and RH5 were most frequently identified as the highest total IgG acquisition at moderate transmission setting, indicating allele-specific immune responses which can increase the chance of breakthrough infection. This study highlights different mechanisms of immunity at different transmission levels which enhances further understanding of naturally acquired antibody acquisition to different vaccine candidate antigens.

0239

#### POST-DISCHARGE BURDEN OF MORBIDITY AND MORTALITY IN CHILDREN ADMITTED WITH SEVERE ANEMIA OR OTHER SYNDROMES IN MALARIA-ENDEMIC SETTINGS IN AFRICA: A SYSTEMATIC REVIEW AND META-ANALYSIS

**Titus Kwambai**<sup>1</sup>, Amani T. Mori<sup>2</sup>, Sarah Nevitt<sup>3</sup>, Anna Maria van Eijk<sup>4</sup>, Aaron M. Samuels<sup>1</sup>, Bjarne Robberstad<sup>2</sup>, Kamija S. Phiri<sup>5</sup>, Feiko O. ter Kuile<sup>4</sup>

<sup>1</sup>Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Kisumu, Kenya and Atlanta, GA, United States of America, Kisumu, Kenya, <sup>2</sup>Section for Ethics and Health Economics and Centre for International Health, Department of Global Public Health and Primary Care, University of Bergen, Bergen, Norway, Bergen, Norway, <sup>3</sup>Department of Health Data Science, University of Liverpool, Liverpool, Merseyside, United Kingdom, Liverpool, United Kingdom, <sup>4</sup>Department of Clinical Sciences, Liverpool School of Tropical Medicine (LSTM), Liverpool, United Kingdom, Liverpool, United Kingdom, <sup>5</sup>School of Public Health and Family Medicine, College of Medicine, University of Malawi, Blantyre, Malawi, Blantyre, Malawi

Severe anemia (SA), hemoglobin <5.0 g/dL, is associated with high in-hospital mortality among young children. In malaria-endemic areas surviving children remain at increased risk of mortality or readmission for

at least six months post-discharge. We conducted a systematic review and performed random-effects meta-analyses to determine the risks of morbidity and mortality in the post-discharge period among children aged <15 years admitted with SA versus other syndromes in malaria-endemic Africa. Mantel-Haenszel odds ratios (MHOR) were used for paired binary outcomes. Pooled effect estimates were generated using DerSimonian and Laird random-effects model to obtain relative risks (RR) or hazard ratios (HR). Heterogeneity was expressed using the  $I^2$  statistic. The primary outcomes were all-cause death and readmission within six months post-discharge. Twenty-four studies (N=24) including prospective and retrospective cohort studies and randomised-controlled trials were included. For children previously admitted with SA, mortality by six months post-discharge was higher than during the in-hospital period (studies N=5, MHOR=1.72, 95% CI 1.22-2.44,  $p=0.002$ ,  $I^2=51.5\%$ ) and almost three-times higher compared to children previously admitted without SA (N=4, RR=2.80, 95% CI 1.614-86,  $p<0.0001$ ,  $I^2=73.1\%$ ). Readmissions were also more common in children admitted with SA (N=1, RR=3.05, 1.12-8.35,  $p<0.0001$ ,  $I^2=0.0\%$ ). Children admitted with severe acute malnutrition also had a higher 6-month post-discharge mortality than those admitted for other reasons (N=2, RR=3.45, 1.89-6.31,  $p<0.0001$ ,  $I^2=81.3\%$ ). In malaria-endemic Africa, children hospitalised with SA and severe acute malnutrition are at increased risk of mortality in the first six months post-discharge. Improved strategies are needed for the post-discharge management in these high-risk groups.

## 0240

### EPIDEMIOLOGICAL IMPACT OF PIPERONYL BUTOXIDE (PBO) LONG-LASTING INSECTICIDAL NETS AFTER A NATIONAL NET DISTRIBUTION CAMPAIGN IN RWANDA, 2020

**Michee S. Kabera**<sup>1</sup>, Aline Uwimana<sup>1</sup>, Yvette Muyirikazi<sup>1</sup>, Jean Louis Mangala<sup>1</sup>, Aimable Mbituyumuremyi<sup>1</sup>, Pauline Saida Sebatunzi<sup>1</sup>, Noella Umulisa<sup>2</sup>

<sup>1</sup>Rwanda Biomedical Center, Kigali, Rwanda, <sup>2</sup>JHPIEGO/Impact Malaria, Kigali, Rwanda

Rwanda is making progress in malaria control with the incidence of malaria reducing from 321 per 1,000 person per year in 2018-2019 to 198 per 1,000 in 2019/2020. The use of long-lasting insecticidal nets (LLINs) is a key malaria prevention tool used in Rwanda. However, pyrethroid resistance threatens gains made in malaria control. Rwanda has adapted a multi-pronged vector control strategy including the use of Indoor Residual Spraying (IRS) in high malaria burden districts and the distributions of LLINs in other districts. In 2018, the National Malaria Control Program strategic approach changed to include the use of newer types of LLINs such as Piperonyl butoxide (PBO) nets and Interceptor G2 to counter pyrethroid resistance. PBO nets have a synergist that partially restores pyrethroid susceptibility in mosquito vectors and were first distributed in Rwanda in 2019. In 2019-2020 Rwanda distributed 5,566,006 rectangular LLINs through a mass campaign in 24 districts. These included 1,399,528 PBO nets distributed between February to March 2020, in five medium malaria burden districts: Rulindo, Gicumbi, Kicukiro, Gasabo and Nyarugenge. Data on malaria cases were collected monthly through the Rwanda Health Information Management System (R-HMIS). We compared malaria cases reported during a period of 12 months before and after the mass distribution of the PBO nets. Data analysis showed a reduction in malaria cases in all five districts. In Gasabo district, malaria cases decreased by 71% from 292,431 to 85,454. In addition, malaria incidence in the same district reduced from 469 to 134 cases per 1,000. In Gicumbi, Kicukiro and Nyarugege districts, malaria cases reduced by 72%, 61% and 62% respectively. The highest reduction of 83% in malaria cases was observed in Rulindo district. Notwithstanding that other additional malaria control interventions such as larviciding and the weather during the study period may affect the incidence malaria, initial results from our evaluation indicate that PBO nets can reduce malaria incidence dramatically, making them a promising new tool to combat pyrethroid resistance on malaria control in Rwanda

## 0241

### THE FIGHT AGAINST MALARIA: THE CASE OF THE US PRESIDENT'S MALARIA INITIATIVE (PMI) MALARIA ACTION PROGRAM FOR DISTRICTS

**Sam S. Gudo**<sup>1</sup>, Emily Goodwin<sup>1</sup>, Daniella Busharizi<sup>1</sup>, John Baptist Bwanika<sup>1</sup>, Ruth Kigozi<sup>1</sup>, Jimmy Opigo<sup>1</sup>, Mame Niang<sup>2</sup>, Kassahun Belay<sup>3</sup>, Gloria Sebikaari<sup>3</sup>, Godfrey Magumba<sup>1</sup>, James Tibenderana<sup>4</sup>

<sup>1</sup>Malaria Consortium, Kampala, Uganda, <sup>2</sup>US President's Malaria Initiative, Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>US President's Malaria Initiative, US Agency for International Development, Kampala, Uganda, <sup>4</sup>Malaria Consortium, London, United Kingdom

The PMI Malaria Action Program for Districts (MAPD) project was implemented from 2016 to 2021 to reduce malaria related morbidity and mortality in Uganda, in collaboration with the National Malaria Control Division (NMCD). All 52 project districts signed a memorandum of understanding to commit to support the implementation of effective malaria interventions in line with the national malaria strategy, and to build the capacity of the NMCD and districts to effectively manage malaria programs. Key activities included the development of annual district malaria plans; the routine distribution of long lasting insecticidal treated nets (LLINs) and intermittent preventive treatment in pregnancy (IPTp); technical assistance for malaria case management with regular health facility support supervision; surveillance, monitoring, and evaluation including performance reviews; social behavior change; and gender and youth interventions. Comparing first to fourth project year, health facility data in project areas showed great progress in malaria health service delivery, mortality, and morbidity indicators. The proportion of women receiving three or more doses of IPTp increased from 1.9% (95% CI 1.8% - 1.9%) to 72.9% (95% CI 72.8% - 73.1%), the proportion of pregnant women receiving LLINs increased from 48.7% (CI 48.5% - 48.8%) to 78.8% (95% CI, 78.6% - 78.9%), the proportion of suspected malaria cases tested increased from 76.0% (95% CI 75.9% - 76.0%) to 98% (95% CI 97.9% - 98.1%), and the proportion of patients with a negative malaria test who were treated with an antimalarial decreased from 46.8% (95% CI 46.7% - 46.8%) to 1.4% (95% CI; 1.47% - 1.51%). Moreover, a 49% reduction in annual reported malaria deaths (from 2142 to 1098) and a 15% reduction in annual parasite incidence (API) (from 109 to 92 per 1000 population) was seen. Analysis of non-MAPD district data showed a 7% reduction in malaria deaths (from 3178 to 2943), but API data lacks reliability for analysis. These results suggest that PMI support and collaboration with the Uganda NMCD, through MAPD and districts, were successful in considerably reducing malaria morbidity and mortality in Uganda.

## 0242

### ASSESSING THE DIRECT EFFECT OF INDOOR RESIDUAL SPRAYING WITH FLUDORA® FUSION IN NCHELENGE DISTRICT, ZAMBIA

**Ellen Ferriss**<sup>1</sup>, Mike Chaponda<sup>2</sup>, Mbanga Muleba<sup>2</sup>, Jean-Bertin Kabuya<sup>2</sup>, Lawrence H. Moulton<sup>1</sup>, Douglas E. Norris<sup>1</sup>, William J. Moss<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Tropical Diseases Research Centre, Ndola, Zambia

In 2019, the National Malaria Elimination Program of Zambia transitioned to a novel insecticide, Fludora® Fusion, for its annual targeted indoor residual spraying campaign in Nchelenge District, an area with high year-round transmission. Monthly cross-sectional active surveillance data from 2014-2020 were used to determine the impact of the transition from Actellic to Fludora® Fusion in indoor residual spraying on parasite prevalence using Poisson regression models with robust variance estimation. Annual and rainy season models were adjusted for annual population coverage with indoor residual spraying in the sprayed area, weeks since annual spraying began, participant age, net use, population density, and distance to the nearest health facility, stream, and

lake. Fludora® Fusion use was not associated with decreased parasite prevalence in sprayed homes compared to unsprayed homes relative to Actellic use (relative risk ratio = 1.11, 95% confidence interval = 0.94, 1.30). However, household indoor residual spraying receipt in the past six months was only borderline statistically significantly associated with parasite prevalence under Actellic (relative risk = 0.91, 95% confidence interval = 0.82, 1.01). Further, increasing year-over-year indoor residual spraying coverage was not associated with malaria risk (relative risk = 1.00, 95% confidence interval = 1.00, 1.00), suggesting that, in addition to household benefit, community benefit was limited or absent. Self-reported bed net use was associated with a 19% decrease in risk (95% confidence interval = 0.75, 0.87). These findings indicate indoor residual spraying with neither Actellic nor Fludora® Fusion have sufficiently controlled malaria in Nchelenge District and should be supplemented with alternative strategies, such as housing improvements or universal long-lasting insecticide-treated net coverage.

0243

### UNDERSTANDING CROSS BORDER MALARIA IN SAUDI ARABIA

Shaymaa A. Abdalal<sup>1</sup>, Joseph Keating<sup>1</sup>, Mohammad A. Shammaky<sup>2</sup>

<sup>1</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>2</sup>Saudi Arabia Ministry of Health, Jazan, Saudi Arabia

Border malaria is a major obstacle to malaria elimination in Saudi Arabia. Today malaria on the southern border of Saudi Arabia, a region where malaria cases are resurging, and elimination efforts are stalled mainly due to humanitarian crisis and the Conflict in Yemen. This study analyzes the current border malaria epidemiology in the southern border of Saudi Arabia from 2015 to 2018. All reported cases maintained by the malaria elimination centers in Aledabi and Baish, Jazan Province, Saudi Arabia, from 2015 to 2018 were analyzed to examine the epidemiological changes over time. Pearson's Chi-Square test of differences was utilized to assess differences between characteristics of imported and local causes and between border cases. A logistic regression model was used to predict imported status was related to living in the border area. A total of 3,210 malaria cases were reported in Baish, and Aledabi malaria centers between 2015 and 2018, of which 170 were classified as local cases and 3,040 were classified as imported cases. The majority of cases are male and residents of the border areas. Given the complexity of cross-border malaria, creating a malaria buffer zone that covers a certain margin from both sides of the border would allow for a joint force, cross-border malaria control operation. To conduct malaria elimination activity and cases reported as belonging to this zone, rather than being pushed from one country to the other, would allow malaria elimination staff to work collaboratively with local borderland residents and other stakeholders to come up with innovative solutions to combat malaria and reach malaria-free borders.

0244

### CHARACTERIZING MOBILITY PATTERNS OF FOREST GOERS IN SOUTHERN LAO PDR USING GPS LOGGERS

Francois Rerolle<sup>1</sup>, Emily Dantzer<sup>1</sup>, Toula Phimmakong<sup>2</sup>, Rattanaxy Phetsouvanh<sup>2</sup>, Bouasy Hongvanthong<sup>2</sup>, John Marshall<sup>3</sup>, Hugh Sturrock<sup>1</sup>, Adam Bennett<sup>1</sup>

<sup>1</sup>UCSF, San Francisco, CA, United States, <sup>2</sup>CMPE, Vientiane, Lao People's Democratic Republic, <sup>3</sup>UC Berkeley, Berkeley, CA, United States

In the Greater Mekong Sub-region (GMS), engaging in forest activities is a major risk factor for malaria. As countries focus their malaria control and elimination efforts on forest-going populations, a better understanding of their mobility patterns and risk associated with specific types of forest-going trips, is essential. In 2018, we conducted a focal test and treat intervention (FTAT) in Champasak Province, southern Lao PDR, and recruited 2904 forest-goers in our study. A subset of them were offered to carry a "i-Got-U" GPS logger for roughly two months, collecting GPS

coordinates every 15 to 30 minutes. The utilization distribution (UD) surface around each GPS trajectory was used to extract trips to the forest or forest-fringes. A hierarchical clustering algorithm identified trips with shared mobility patterns characteristics in terms of duration, timing of the trip and forest penetration further enabling classification of high-risk trips because of an increased exposure to dominant malaria vectors in the region. Finally, we used gradient boosting trees to assess which of the forest-goers' socio-demographic and behavioral characteristics predicted the best their likelihood to engage in trips at higher-risk for malaria. A total of 122 forest-goers accepted to carry a GPS logger resulting in the collection of 803 trips to the forest or forest-fringes. Six clusters of trips emerged, helping to identify 240 trips at higher-risk for malaria based on high forest penetration and whether the trip happened overnight. Age, size of traveling group, outdoor sleeping structures and number of children were the best predictors of forest-goers' probability to engage in high-risk trips. This study characterized the heterogeneity within the mobility patterns of forest-goers and further segmented their role in malaria transmission in the GMS. These results are key for national control programs across the region to assess and meet their 2030 malaria elimination goals.

### VEUPATHDB: COMPREHENSIVE INFORMATICS SUPPORT FOR YOUR RESEARCH NEEDS

Susanne Warrenfeltz<sup>1</sup>, Brian Brunk<sup>2</sup>, Gloria I. Giraldo-Calderon<sup>3</sup>, Omar Harb<sup>2</sup>, Mark Hickman<sup>2</sup>, Jessica C. Kissinger<sup>1</sup>, Mary Ann McDowell<sup>4</sup>, David Roos<sup>2</sup>, Samuel Rund<sup>3</sup>, For the VEuPathDB Team<sup>1</sup>

<sup>1</sup>University of Georgia, Athens, GA, United States, <sup>2</sup>University of Pennsylvania, Philadelphia, PA, United States, <sup>3</sup>University of Notre Dame, South Bend, IN, United States, <sup>4</sup>University of Notre Dame, South Bend, IN, United States

VEuPathDB is a free, online, NIAID-funded bioinformatics resource center focused on eukaryotic pathogens, vectors, fungal and host informatics. It represents the merger of VectorBase and EuPathDB and supports over 400 organisms. VEuPathDB empowers users to leverage omics data without the need for computational programming. VEuPathDB analyzes a wide variety of omics data and couples the analysis results to advanced search capabilities, data visualizations and custom tools to facilitate the discovery of meaningful relationships from large volumes of data. Available data range from basic sequence and annotation to transcript and protein expression, variation, domains, orthology, phenotypes, pathways, epigenomics and host-pathogen interactions. Data mining strategies include: records that compile all data for a single feature like a gene, a genome browser, a search strategy system, a Galaxy interface, and a geovisualization tool to observe population biology data. Users might begin at a gene page to view tables and graphs of that gene's behaviour in an RNA-Seq experiment, then transition to the genome browser for a dynamic view of the RNA-Seq data aligned to the genome, as well as the opportunity to view nearby gene models or other data types. The search strategy system allows users to query from a genome-wide perspective, easily merge evidence from diverse data and across species, and ask questions such as 'Find genes in these 4 species that are expressed in the first half of the organism's life cycle'. Users with their own omics data can use Galaxy to privately analyze and port their results to VEuPathDB for comparison. The MapVEu geovisualization tool facilitates mining of population data for traits such as insecticide resistance and infection status. Our active user support offers an email help desk, social media, tutorials, webinars, and workshops. Email us at help@veupathdb.org with questions or suggestions.

## EXPANDING THE UTILITY OF PLASMODIUM GENETIC CROSSES USING NANOPORE LONG-READ GENOME ASSEMBLIES FOR PARENTAL PARASITES

Xue Li<sup>1</sup>, Marina McDew-White<sup>1</sup>, Shalini Nair<sup>1</sup>, Ann Reyes<sup>1</sup>, Lisa Checkley<sup>2</sup>, Sudhir Kumar<sup>3</sup>, Katie Button-Simons<sup>2</sup>, Stefan Kappe<sup>4</sup>, Francois Nosten<sup>5</sup>, Ashley Vaughan<sup>3</sup>, Michael Ferdig<sup>2</sup>, Ian Cheeseman<sup>1</sup>, Tim Anderson<sup>1</sup>

<sup>1</sup>Texas Biomedical Research Institute, San Antonio, TX, United States,

<sup>2</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>3</sup>Seattle Children's Research Institute, Seattle, WA, United States, <sup>4</sup>University of Washington, Seattle, WA, United States, <sup>5</sup>Mahidol-Oxford Tropical Medicine Research Unit, Mae Sot, Thailand

Illumina short-read sequencing of parents and progeny from genetic crosses provides a useful approach to characterize malaria genetic crosses, but is limited to the core genome regions, and cannot resolve rearrangements and complex structural variants. *Plasmodium falciparum* has an AT-rich, haploid genome, with highly variable subtelomeric regions that contain polymorphic gene families involved in immune evasion and pathogenesis. These regions cannot be efficiently sequenced with short read Illumina methods, because it is not possible to map reads to the 3D7 reference sequence. To help resolve this issue, we used long-read technology (Oxford Nanopore Technologies, ONT) to sequence 6 parental parasites from three genetic crosses. We performed *de novo* assembly to generate highly contiguous, cross-specific reference sequences. By comparing the assembly of these parental parasites with the 3D7 reference genome, we uncovered a number of structural variants and rearrangements, as well as genes that are not present in the 3D7 reference. Furthermore, by mapping Illumina short read sequencing from the progeny to parental reference sequences, we were able to expand the percentage of genome sequenced and improve resolution of QTL peaks. This approach allowed us to identify a novel candidate gene (merozoite-associated tryptophan-rich antigen 2) that is not present in the 3D7 reference or NF54 nanopore assembly but is segregating (either present or absent) in the progeny of a cross (NF54×NHP4026) and falls under a prominent QTL for differential growth in serum or AlbuMAX based culture. These results demonstrate the value of high-quality cross-specific reference genomes for malaria linkage analysis.

0247

## PIGGYBAC MUTAGENESIS APPLIED TO PLASMODIUM KNOWLESII

Shulin Xu, Min Zhang, Jenna Oberstaller, Marris Thomas, John H. Adams

Center for Global Health and Infectious Diseases Research, University of South Florida, Tampa, FL, United States

*Plasmodium vivax* is the second most prevalent type of malaria worldwide and the most common cause outside of Africa. Unfortunately, an inability to maintain blood-stage parasites in the lab has severely limited experimental studies on this parasite. The adaptation of *Plasmodium knowlesi* (PkA1-H.1) to continuous *in vitro* culture in human RBCs now provides an important breakthrough to support a laboratory model for analysis of vivax-like malaria parasites. Using this culture system, we have successfully adapted the *piggyBac* transposon mutagenesis method for pursuing forward genetic screens and gene functional analysis at genome scale in *P. knowlesi*. To establish the *piggyBac* system for *P. knowlesi*, the 5' UTR of *pkef1a* was amplified from genomic DNA and inserted as the 5' regulatory element in the *piggyBac* transposase helper plasmid PfDCTH, replacing the original promoter. This helper plasmid PkETH was designed to drive transposase expression to mobilize and integrate the *piggyBac* transposon in *P. knowlesi*. In parallel, the 5'UTR of *pkhsp70* was inserted in the drug selection cassette carried by the transposon to drive expression of hDHFR-GFP in *P. knowlesi*. The two plasmids were co-transfected into cultured *P. knowlesi* schizont-infected human RBCs by direct electroporation using an Amaxa 4D-Nucleofector. Anti-folate

resistant clones of transfected PkA1-H.1 were isolated by limiting dilution and *piggyBac* genome integration by sequence analysis. Consistent with results for random integration at TTAA-target insertion sites observed in other *Plasmodium* spp. insertions were widely distributed in different chromosomes throughout the genome in UTRs and CDS of genes. These preliminary results indicate that *piggyBac* transposable system is feasible for functional genomic analyses of *P. knowlesi* it has achieved in *P. falciparum*.

0248

## UNDERSTANDING RESIDUAL PLASMODIUM FALCIPARUM TRANSMISSION IN ZANZIBAR THROUGH MULTIPLEXED AMPLICON DEEP SEQUENCING

Aurel Holzschuh<sup>1</sup>, Anita Lerch<sup>1</sup>, Bakar S. Fakhri<sup>2</sup>, Logan Stuck<sup>3</sup>, Abdul-wahid H. Al-mafazy<sup>4</sup>, Abdullah Ali<sup>5</sup>, Manuel W. Hetzel<sup>6</sup>, Joshua Yukich<sup>3</sup>, Cristian Koepfli<sup>1</sup>

<sup>1</sup>University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Tulane University, New Orleans, LA, United States, <sup>4</sup>Research Triangle Institute (RTI) International, Zanzibar, United Republic of Tanzania, <sup>5</sup>Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, <sup>6</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland

Over the past 15 years, Zanzibar has achieved substantial reductions in the burden of malaria, but case numbers have recently increased again. Reactive case detection (RCD) using RDTs is routinely conducted by the Zanzibar Malaria Elimination Program (ZAMEP). To better understand residual *Plasmodium falciparum* transmission dynamics in Zanzibar, we characterized the genetic diversity of parasites circulating within 5 districts on both islands. We have developed a novel droplet digital PCR (ddPCR) based high-throughput method for highly multiplexed amplicon deep sequencing from dried blood spots (DBS). 518 samples were typed by a panel of 28 highly diverse microhaplotypes (median expected heterozygosity = 0.74) and 7 drug-resistance loci. The method was highly sensitive, genotyping data was obtained for >80% of markers in 80% of samples at densities of ≥5 parasites/μL. The parasite population in Zanzibar was highly diverse (mean heterozygosity = 0.71; mean allelic richness = 9.6). The majority of infections (75%) were polyclonal, with a mean multiplicity of infection (MOI) of 2.2. We found that index cases had significantly lower MOI than secondary cases (1.98 vs. 2.33, p=0.007), but no differences in MOI between travelers and non-travelers were observed. Low spatial and temporal genetic differentiation was observed, indicating frequent gene-flow between the two islands. Fine-scale population structure was detectable, with frequent clustering of highly related infections (IBS ≥0.5) within households. No *kelch13* mutations were observed, but mutations were found in drug-resistance genes *Pfdhfr*, *Pfdhps*, *Pfmdr1*, and *Pfmdr2*. No *hrp2/hrp3* deletions were observed. In conclusion, a highly diverse parasite population indicates sustained transmission. Closely related parasites within households point to clinical cases as important sources of onward transmission.

0249

## SINGLE CELL ANALYSIS REVEALS TRANSCRIPTIONAL HETEROGENEITY AND CHANGES ACCOMPANYING PLASMODIUM SPOROZOITE DEVELOPMENT

Haikel N. Bogale

University of Maryland, Baltimore, Baltimore, MD, United States

Sporozoites, the infective stage of the malaria parasite, develop in oocysts on the mosquito midgut and make their way to the mosquito salivary glands where they wait to be inoculated into the mammalian host. Despite their critical role in malaria transmission, little is known about the mechanisms underlying the maturation of *Plasmodium* sporozoites in mosquitoes. Here, we use single-cell RNA sequencing to characterize the gene expression profiles of 16,038 *P. berghei* sporozoites derived from 12 independent collections and isolated throughout their development: 614 sporozoites collected from punctured late-stage oocysts, 2,147 isolated

from mosquito hemolymph, 5,979 isolated from the salivary glands and 7,298 obtained from forced salivation experiments. Our single cell data reveal extensive transcriptional heterogeneity among parasites isolated from the same anatomical site, suggesting that *Plasmodium* development in mosquitoes is asynchronous and might be regulated by intrinsic as well as environmental factors. In addition, we describe a succession of tightly regulated changes in gene expression occurring during the maturation of sporozoites and highlight novel candidate genes that could play important roles in oocyst egress, sporozoite motility, and the mechanisms underlying the invasion of mosquito salivary glands and mammalian hepatocytes. Lastly, our analyses show a general decrease in transcriptional activity preceding the translational repression observed in mature sporozoites and associated with their quiescent state in salivary glands, followed by a rapid reactivation of the entire transcriptional machinery immediately upon salivation. This study provides a valuable resource and lays the foundation to characterize the role of novel genes required for sporozoite development and transmission, thus identifying new targets for the development of malaria control strategies.

The majority of severe and fatal malaria infections affect young children in sub-Saharan Africa. Most severe malaria cases are due to infection with *Plasmodium falciparum*. Variant surface antigens mediate cytoadhesion and rosetting, thereby enabling sequestration in the microvasculature, preventing clearance of infected cells by the spleen, and contributing to endothelial activation that increases vascular permeability and an inflammatory response that can be detrimental to the host if unregulated. The most well-known variant surface antigens, *Plasmodium falciparum* erythrocyte membrane protein-1 (PfEMP1s), are encoded by *var* genes and mediate adhesion to host cell receptors such as endothelial protein C receptor (EPCR) and intercellular adhesion molecule 1 (ICAM1). Expression of particular PfEMP1s binding to EPCR and ICAM1 is associated with severe malaria syndromes, including cerebral malaria and severe malarial anemia. To identify PfEMP1 variants associated with cerebral malaria and severe malarial anemia, we conducted a case-control study of severe malaria cases matched to uncomplicated cases of malaria in Mali, West Africa from 2014-2018 that included children aged six months to five years. We report results from assembly of full-length PfEMP1 transcripts from specific severe malaria syndromes in comparison to uncomplicated malaria controls. We sequenced RNA extracted from whole blood, after enrichment for parasite RNA (and *vars* in particular) using a custom capture-based approach. Transcripts from malaria cases were *de novo* assembled, and those corresponding to PfEMP1 domain sub-classifications were determined to identify potential host cell receptor targets. We determined PfEMP1 transcripts in 14 cases of cerebral malaria, 11 cases of severe malarial anemia, and seven cases of cerebral malaria and severe malarial anemia compared to uncomplicated malaria matched controls. Our results have the potential to provide insight into the pathogenesis of specific syndromes of severe malaria and may inform drug and vaccine development efforts to prevent severe malarial disease.

*Plasmodium falciparum* malaria infection continues to be among the principal causes of childhood morbidity and mortality worldwide. Ubiquitination is essential for regulating physiological processes, including innate and adaptive immunity. Our recent studies in children from a *P. falciparum* holoendemic region of Kenya with either uncomplicated (Hb $\geq$ 9.0 g/dL) or complicated (Hb $<$ 6.0 g/dL) malaria (any density parasitemia) showed differential expression of genes involved in the human ubiquitination process. We and others have shown that treatment of peripheral blood mononuclear cells (PBMCs) from healthy, malaria-naïve donors with a physiological concentration (10  $\mu$ g/mL) of *P. falciparum* hemozoin (PfHz) can serve as an *in vitro* model for severe malaria. As such, PBMCs from such donors (n=3) were cultured in the absence or presence of PfHz (10  $\mu$ g/mL) for 3, 9, and 24 hrs. RNA from the samples were isolated (Qiagen RNeasy Mini Kit) and cDNA was synthesized (Qiagen RT<sup>2</sup> First Stand Kit). Gene expression profiles for a panel of 84 key ubiquitination genes were quantified (Qiagen Human Ubiquitylation Pathway RT<sup>2</sup> Profiler PCR Array). Although PBMCs treated with PfHz for 3 hrs showed no significant alterations in mRNA levels, stimulation for 9 hrs elicited significant transcriptional changes for 6 genes: 4 were down-regulated (*FBXO4*, *NEDD8*, *UBE2E3*, and *UBE2W*), whereas 2 were up-regulated (*HERC5* and *UBE2J1*). Moreover, PfHz treatment for 24hrs significantly altered mRNA levels of 14 genes: 12 being down-regulated (*ANAPC11*, *BRCC3*, *CUL4B*, *FBXO4*, *MIB1*, *SKP2*, *TP53*, *UBA2*, *UBA3*, *UBE2G1*, *UBE2G2*, and *WWP1*) and 2 being up-regulated (*UBE2J1* and *UBE2Z*). Collectively, these studies demonstrate temporal differential regulation of ubiquitylation genes and suggest a potential role for this process in the pathogenesis of severe malaria.

## COMPLEMENT COMPONENT 5 (C5) MISSENSE MUTATIONS ALTER THE LONGITUDINAL RISK OF MALARIA AND SEVERE MALARIAL ANEMIA IN CHILDREN RESIDING IN A HOLENDEMIC REGION OF PLASMODIUM FALCIPARUM TRANSMISSION

Severe malarial anemia (SMA) is a leading cause of childhood morbidity and mortality in holoendemic *Plasmodium falciparum* transmission regions. To gain an enhanced understanding of predisposing factors for SMA (Hb<5.0g/dL), we explored the relationship between complement component 5 (C5) missense mutations [rs17216529 (433C>T, Val>Ile<sup>145</sup>) and rs17610 (3929C>T, Ser>Asn<sup>1310</sup>)], malaria, and SMA in a cohort of children (n=1,487) over 36-months of follow-up in western Kenya. C5 variants were selected based on their ability to impart amino acid substitutions that can alter the structure and function of C5. We explored the relationship between C5 genotypes/haplotypes and the number of malaria and SMA episodes over the 3-year follow-up period by fitting a Poisson regression (R glm function, family=Poisson; model selection: forward-backward search based on AIC). Potential confounding risk factors, such as age at enrollment, sex, HIV, bacteremia, sickle cell trait status, G6PD deficiency, and  $\alpha$ -thalassemia, were included as independent variables in the model selection. After adjusting for multiple comparisons, longitudinal analyses revealed that inheritance of the homozygous mutant (TT) at locus 433 enhanced the risk of malaria (RR=1.144, 95%CI: 1.059-1.236,  $P=0.001$ ). The CT haplotype also enhanced the risk of malaria (RR=1.068, 95%CI: 1.017-1.122,  $P=0.009$ ). Consistently, the TT genotype at locus 433 that increased the risk of malaria also increased the risk of SMA (RR=1.627, 95%CI: 1.201-2.204,  $P=0.002$ ). The haplotype containing both wild-type alleles (CC) decreased the longitudinal risk of SMA (RR=0.679, 95%CI: 0.542-0.850,  $P=0.001$ ). Collectively, inheritance of the investigated C5 missense mutations influence the longitudinal risk of malaria and SMA in immune-naïve children exposed to intense *P. falciparum* transmission.

## OPTIMIZATION OF PLASMODIUM FALCIPARUM WHOLE GENOME CAPTURE FOR MULTIPLEX SEQUENCING OF LOW PARASITEMIA DRIED BLOOD SPOTS

**Matthew Adams**, Zalak Shah, Emily M. Stucke, Sandra H. Ott, Biraj Shrestha, Mark A. Travassos, Joana C. Silva, Shannon Takala-Harrison

University of Maryland School of Medicine, Baltimore, MD, United States

Generation of high-quality *Plasmodium falciparum* whole genome sequencing data from low parasitemia dried blood spots (DBS) will increase our capacity to conduct population genomic studies and genomic surveillance. Generation of sequencing data with high breadth of coverage requires isolation or enrichment of parasite DNA from the predominating host DNA. Previous methods of parasite DNA enrichment have included leukocyte depletion, selective whole genome amplification, enzymatic digestion of host DNA, and to a more limited extent, hybrid capture. In this study, we designed a whole genome capture approach, using Roche's SeqCap EZ platform, for generation of whole genome sequencing data from *P. falciparum*, and evaluated the extent to which capture reactions can be multiplexed to increase throughput, avoid non-specific hybridization, and reduce costs. Laboratory-created DBS from NF54 cultured parasites diluted in whole blood resulting in final parasitemias of 500, 1200 and 10000 parasites/ $\mu$ L were generated. DNA extracted from DBS underwent library preparation and barcode labeling. Individually labeled samples were combined into multiplex mixtures, captured, and sequenced using an Illumina NovaSeq S1. Genome coverage statistics, including the percent of parasite reads and proportion of the genome with at least 5x depth of coverage, were compared between multiplexed and non-multiplexed samples and across parasitemias. The average percentage of the *P. falciparum* genome covered by  $\geq 5x$  reads in 8-plexed samples was 88.2%, 74.1%, and 59.7% for 10000, 1200, and 500 parasites/ $\mu$ L, respectively, which is equivalent or better coverage than in 4-plex samples (Wilcoxon RS, 10000 p/ $\mu$ L  $p=0.030$ , 1200 p/ $\mu$ L  $p=0.059$ , 500 p/ $\mu$ L  $p=0.478$ ). In addition, we are evaluating the distribution of genome coverage and the potential for differential capture of varied parasite strains. Our results indicate that multiplexing did not decrease genome coverage, and in some instances, improved coverage at different parasitemias, suggesting increased multiplexing may be possible.

## GENETIC EPIDEMIOLOGY OF SÉNÉGAL MALARIA INFECTIONS REVEALS PARASITE CONNECTIVITY AND CORRELATION WITH MALARIA INCIDENCE

<sup>7</sup>Harvard University, Cambridge, MA, United States

Genetic epidemiology of *Plasmodium falciparum* in Sénégal, utilizing identical-by-descent analysis of sequencing data, detects patterns of outcrossing and inbreeding that inform transmission dynamics and parasite connectivity across time and space. Parasite relatedness reveals transmission dynamics in Thiès, Sénégal from 2006 to 2020, including persisting clonal lineages across multiple transmission seasons and  $R_0$  declines and rebounds. Working with the Sénégal National Malaria Control

Program, we identified distinct patterns of relatedness to guide decision-making about intervention use. Genetic relatedness among parasites collected at 26 health-posts with incidence from  $< 1/1000$  to  $> 450/1000$  reveals distinct within- and between-site patterns that provide actionable data toward intervention use. Parasite relatedness patterns suggest human mobility contributes to malaria infections, including sites with little local transmission but many shared infections (Koutal), and distant that share genetically related parasites sites (Kafountine to Dakar). Distinct parasite genetic relatedness patterns are observed in sites with similar incidence, including Diourbel, with large residential schools characterized by a highly clonal parasite population structure consistent with local transmission that may be amenable to vector-based interventions; and Touba, a pilgrimage site characterized by partially-related infections shared within Touba and across Senegal. Epidemiological modeling of population genetic parasite data correlate with transmission (i.e.,  $R_0$ ) and with epidemiological indicators (i.e., incidence). Key modeling parameters include complexity of infection or proportion polyclonal and measures of clonality or genetic identity among the parasite populations. Integration of genetic epidemiology into ongoing surveillance is being used to understand how parasite infections in a population are derived, shared, and maintained and to reveal otherwise undetected patterns of relatedness among infections that can help gauge transmission and guide appropriate intervention targeting and selection.

Laurens<sup>1</sup>, Youssouf Tolo<sup>2</sup>, Bourema Kouriba<sup>2</sup>, Ogobara K. Doumbo<sup>2</sup>, Abdoulaye Djimde<sup>2</sup>, Mahamadou A. Thera<sup>2</sup>

<sup>1</sup>Center for Vaccine Development and Global Health, University of Maryland Baltimore, Baltimore, MD, United States, <sup>2</sup>Malaria Research and Training Center, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali

Although the overall malaria incidence has decreased sharply over the past decade, there has been a plateau in the past three years. Vaccination is a control strategy that could limit malaria burden. While multiple malaria vaccines have been tested in phase 2/3 trials, and one undergoing a phase 4 trial, none has induced an overall clinical efficacy greater than 50%. Understanding the parasite genetic factors playing a role in malaria pathogenesis could help identify essential proteins and design an effective malaria vaccine. We hypothesize that clinical phenotypes are a function of parasite density, parasite and human genetic makeup and potentially parasite and host epigenetics factors. To identify a relationship between parasite genetics and clinical phenotypes, here we have focused on the relation between the AMA1, an antigen involved in parasite invasion into the red blood cells and the clinical phenotype of resulting malaria clinical disease. Using *ama1* gene sequences generated from samples collected from 425 children in an incidence study conducted in Bandiagara, Mali over three consecutive years, we assessed the relationship between individual haplotypes and malaria clinical symptoms and disease. The dynamic of AMA1 haplotypes showed a gene under balancing selection during the three years of follow-up. After adjusting for study participants' sample collection location, we found a significantly greater proportion of most frequent c1L haplotypes in male participants compared to female. ( $p=0.01$ ). Also, the distributions of AMA1 haplotypes indicates a clustering of all major variants in study participants with splenomegaly and diarrhea together ( $p=0.01$ ). Finally, none of the most frequent haplotypes were linked to malaria defined as any temperature greater than 37.5°C and a parasitemia greater or equal to 2500 parasites/mcl. Our findings suggest a lack of association between AMA1 haplotypes and all malaria symptoms highlighting the role of multiple factors in malaria symptomatology.

#### GENETIC DIVERSITY AND DEMOGRAPHICS OF PLASMODIUM SPECIES ON BIKO ISLAND, EQUATORIAL GUINEA

Thomas C. Stabler<sup>1</sup>, Ankit Dwivedi<sup>2</sup>, Biraj Shrestha<sup>3</sup>, Sudhaunshu Joshi<sup>3</sup>, Olivier Tresor Donfack<sup>4</sup>, Carlos A. Guerra<sup>5</sup>, Guillermo A. García<sup>5</sup>, Joana C. Silva<sup>6</sup>, Claudia Daubenberger<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute; University of Basel, Basel, Switzerland, <sup>2</sup>Institute for Genomic Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Malaria Research Program, Center for Vaccine Development and Global Health, University of Maryland Baltimore, Baltimore, MD, United States, <sup>4</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>5</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>6</sup>Institute for Genomic Sciences, University of Maryland School of Medicine; Department of Microbiology and Immunology, University of Maryland School of Medicine, Baltimore, MD, United States

Since 2004, the Bioko Island Malaria Elimination Project (BIMEP) has been conducting annual malaria indicator surveys (MIS). Starting in 2014, the Equatorial Guinea Malaria Vaccine Initiative (EGMVI) conducted a series of clinical trials examining safety and protective efficacy of the attenuated whole-sporozoite malaria vaccine candidate, PfSPZ Vaccine of Sanaria Inc. A large-scale phase III study is planned for 2022-2023 to demonstrate the protective efficacy against *P. falciparum* field exposure. Despite continuous monitoring, the diversity and genotypes of *Plasmodium* spp. infections on Bioko Island are unknown. Determining the baseline population of *P. falciparum* will help to understand its evolution under sustained control interventions and illuminate potential targets of vaccine-induced immunity. During the 2019 MIS, ~8,000 dried blood samples collected by finger pricking were stored on Whatman filter papers. DNA was extracted using a high-throughput method developed at the Malaria Research Program, at the University of Maryland Baltimore. A multiplex PCR assay confirmed the presence and species identify of *Plasmodium* spp. A subset of samples based on geographic location and age group on Bioko, will undergo selective whole genome amplification (sWGA) and Illumina sequencing. Travel history, pregnancy status, and gender will be examined. Genetic diversity will be measured by genome-wide nucleotide diversity (average pairwise sequence divergence) based on single nucleotide polymorphisms (SNPs). Major allele frequency per site, in each sample, will be assigned when read support is greater than 70%. Results from our investigation will describe characteristics of circulating infections, including *Plasmodium* species, complexity of infection and parasite population structure. Travel history will enable potential differentiation between local strains on Bioko Island and imported malaria cases from mainland Equatorial Guinea. By establishing baseline characteristics, the impact of future interventions can more effectively be measured by following their consequence on *P. falciparum* population over time.

0257

#### SEASONAL RISK ASSOCIATED WITH FIXATION OF ANTIMALARIAL RESISTANCE THROUGH IMPORTATION

Robert Zupko, Thu Tran, Trần Đăng Nguyễn, Maciej Boni  
Pennsylvania State University, State College, PA, United States

The introduction of artemisinin combination therapies (ACTs) has been instrumental in the global effort to reduce the public health burden due to *P. falciparum* malaria. However, the use of ACTs is also associated with an increased risk of the emergence and evolution of antimalarial resistance. While *de novo* acquisition through mutation is one mechanism by which antimalarial resistance can arise, another is through the importation of a resistant genotype though mechanisms such as human movement and migration. Despite awareness of the role that importation may play in the regional emergence of antimalarial resistance, knowledge of how the risk of antimalarial genotype fixation fluctuates with the seasonal patterns in malarial prevalence remains limited. To address this gap, we utilized a national-scale, individually-based stochastic model of malaria; previously calibrated for the prevalence and seasonality patterns in Burkina Faso; and

introduced individuals carrying resistant genotypes at defined intervals in order to observe possible fixation patterns. We show under what conditions importation events may lead to regional anti-malarial resistance, independent of any *de novo* mutation events.

0258

### CAN SELECTION ON HISTIDINE-RICH PROTEIN 2/3 GENE DELETIONS BE DETECTED BY TRACES OF SELECTION?

Pierre Marie Ngougoue Ngougoue, Kristan Alexander Schneider

Hochschule Mittweida, University of Applied Sciences, Mittweida, Germany

Efficient malaria control requires access to antimalarials and appropriate diagnostics, especially in remote areas. Rapid diagnostic tests (RDTs), being as sensitive as light microscopy, are most appropriate for these settings. Confirming infections by RDTs is also recommended by the WHO before treatment with artemisinin in an effort to contain resistance. The antigens targeted by widely used *P. falciparum* RDTs are histidine-rich proteins 2 and 3 (pfrp2 and pfrp3). So far hrp-based tests showed the best performance. However, *P. falciparum* variants having deletions at pfrp2 and/or pfrp3 are increasingly being observed, leading to false-negative RDT results and hence jeopardize reliable malaria diagnostics. We introduce a population genetic framework to investigate potential mechanisms driving the spread of pfrp2/3 deletions. Particularly, delays in chemotherapy due to false-negative RDT results are a potential mechanism driving the pfrp2/3 deletions. We show how this mechanism - unlike the mechanism driving antimalarial drug resistance - is linked to transmission intensities as reflected by multiplicity of infection (MOI). Namely, selection in a low-transmission setting is more efficient. Moreover, we show how traces of selection as reflected by genetic hitchhiking manifest for selection for pfrp2/3 deletions vs. drug resistance. The population genetic models sustaining our framework can be employed to study the combined effect of drug resistance evolution and the spread of hrp2/3 deletions and be readily adapted to estimate frequencies and prevalences of pfrp2/3.

### ESTIMATING THE RETROSPECTIVE IMPACT OF MALARIA INTERVENTIONS USING MODELLING: AN EVALUATION OF IRS IN SOUTHERN MOZAMBIQUE

Tatiana Alonso Amor<sup>1</sup>, Elise Smith<sup>2</sup>, Carl Schutte<sup>2</sup>, James Colborn<sup>3</sup>, Baltazar Candrinho<sup>4</sup>, Emilie Pothin<sup>5</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Genesis Analytics, Johannesburg, South Africa, <sup>3</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>4</sup>National Malaria Control Programme, Maputo, Mozambique, <sup>5</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland/ Clinton Health Access Initiative, Boston, MA, United States

As malaria strategies are scaling up, there is an increasing need to assess their retrospective epidemiological impact in order to optimize scarce resources in future. Interventions aimed at reducing malaria transmission are chosen based on the impact shown in trials, however, often lack of context-specific pre-implementation assessment due to funding and/or operational constraints. Evaluations of interventions therefore often need to be conducted in the absence of a control group or baseline. The use of transmission models can facilitate these evaluations by reconstructing a possible counterfactual to what would have happened in absence of intervention. In this work, we present the steps taken, from exploratory data analysis to the calibration and simulation of a malaria transmission model, for the ongoing impact evaluation of indoor residual spraying (IRS) in districts in South Mozambique for the period 2017-2019. We collated routine surveillance and operational data to understand the malaria situation and the implementation of IRS during the evaluation time and before. Additional data was also collated to investigate other possible drivers of malaria transmission, including data on climate, other malaria interventions and insecticide resistance. Intermittent time series analyses were performed to understand malaria trends following IRS

implementation. We found a statistically significant decrease in incidence after the intervention for children under the age of five, but not for adults. OpenMalaria, a malaria transmission model, was calibrated and used to disentangle the impact of IRS from any other potential drivers and represent the situation in each district. The impact of IRS was quantified by estimating the number of cases averted when compared to the counterfactual. These analyses were complemented by detailed district-level costing of interventions, to explore return on investment and support further economic evaluations. The framework presented here is a novel method for impact evaluations and highlights the additional value modelling can bring for estimating past impact of malaria programs.

### AN ENSEMBLE MODEL FOR URBAN MALARIA INTERVENTION MICROSTRATIFICATION IN NIGERIA

Ifeoma D. Ozodiegwu<sup>1</sup>, Chilochibi Chiziba<sup>1</sup>, Ousmane Diallo<sup>1</sup>, Fernando Hidalgo<sup>2</sup>, Jaline Gerardin<sup>1</sup>

<sup>1</sup>Northwestern University, Chicago, IL, United States, <sup>2</sup>General Assembly, Chicago, NJ, United States

Malaria is a leading cause of childhood mortality in Nigeria, accounting for an estimated 30% of all deaths between the ages of 1-59 months from 2008 - 2013. Intervention strategies that account for spatial variation in malaria transmission intensity both within and across urban areas, to target areas with the greatest burden will lead to cost-savings and potentially improve intervention effectiveness. We developed an ensemble model for predicting areas of high malaria transmission in urban Nigeria using data from Malaria Indicator Surveys (2010, 2015), Demographic and Health Surveys (2018), and geospatial covariates. Covariates and individual-level malaria microscopy results were aggregated to an area level by computing cluster-level proportions, where clusters are defined by a geographic boundary and consist of sampled households with children under the age of five tested for malaria. Cluster-level malaria prevalence was stratified into areas of low (<10%) and high (≥10%) transmission to create a balanced binary target variable. Twenty-three features were used in the prediction. Eighty percent of the data was used to train a random forest model to classify clusters by transmission status. Model performance was evaluated with a test set comprising 20% of the overall dataset. Model hyperparameters were tuned to optimize performance using both a random search and grid search algorithm. Classification accuracy, the number of correct predictions divided by the total predictions, was 74% for the training set and 71% for the test set. The strongest prediction feature was the proportion of individuals in the highest wealth quintiles followed by the proportion of women with secondary or higher education suggesting the strong influence of socio-economic drivers on malaria transmission in urban areas. Our model outputs can be used by regional malaria control programs to inform decisions on where to concentrate malaria interventions in urban areas.

0261

### CHALLENGES IN DEVELOPING STATISTICAL MODELS TO UNDERSTAND FACTORS DRIVING URBAN MALARIA TRANSMISSION IN NIGERIA.

Chilochibi Chiziba, Jaline Gerardin, Ifeoma D. Ozodiegwu  
Northwestern University, Evanston, IL, United States

Nigeria is the largest contributor to the global malaria burden, accounting for 27% of global malaria cases and 23% of global malaria deaths. Malaria transmission in urban Nigeria is highly spatially variable. Understanding drivers of transmission in urban settings can provide insight into how interventions can be allocated most efficiently. We describe data quality issues and their impact on our ability to identify and describe factors that drive malaria transmission in urban Nigeria. We used cluster-level data from the Demographic Health Survey in Nigeria (2010, 2015, 2018) and publicly available socioeconomic and climate data. Hierarchical clustering was performed with population density, housing quality, and building density data to assess cluster-sampling heterogeneity. Cluster-level

estimates of malaria parasite prevalence in children under the age of five were categorized into low (<10%) and high ( $\geq$ 10%) prevalence groups. A Bayesian multilevel model was used to evaluate each explanatory variable's effect on the log-odds of a cluster being in the high prevalence group, and state-level variation was modeled with a random intercept. The clustering analysis suggested inadequate heterogeneity: very high population and building density areas were underrepresented in the analysis dataset. Density plots of individual covariates showed a skewness towards zeros and ones, suggesting that most were improper. Educational attainment and wealth index were the only statistically significant variables, and each showed a negative correlation with parasite prevalence. We interpret the lack of a statistically significant relationship between potential confounders and mediators of the relationship between socioeconomic variables and parasite prevalence as due to their improper data distribution rather than the absence of a link. Data quality issues and low-resolution data hinder models from identifying malaria transmission drivers. Acceleration of malaria control and elimination efforts in urban areas require more resources to be invested in urban subnational malaria data collection.

### MODELING THE POTENTIAL IMPACT OF ANTIMALARIAL INTERVENTIONS IN HIGH-BURDEN AREAS OF ETHIOPIA

Amir Siraj<sup>1</sup>, Mebrahtom H. Zeweli<sup>2</sup>, Asefaw Getachew<sup>3</sup>, Gezahegn Biratu<sup>3</sup>, Duncan Earle<sup>4</sup>, Laurence Slutsker<sup>1</sup>, John Miller<sup>5</sup>, Hannah Slater<sup>1</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>Ministry of Health, Addis Ababa, Ethiopia, <sup>3</sup>PATH, Addis Ababa, Ethiopia, <sup>4</sup>PATH, Geneva, Switzerland, <sup>5</sup>PATH, Lusaka, Zambia

Over the last decade, Ethiopia launched a major scale-up of malaria control interventions following a renewed interest to further reduce morbidity and mortality and eventually eliminate the disease. High coverage of these interventions coupled with the extensive deployment of health extension workers at the lowest administrative unit, have led to a large reduction in malaria morbidity and mortality across the country. Motivated by the gains made, the country embarked on a sub-national malaria elimination in 2017. However, there remain pockets of relatively high disease burden, where large population movements and seasonal workforces have complicated efforts to reduce transmission in these areas. By focusing on the high-burden areas of the country and using a previously developed dynamic malaria transmission model, this study, conducted in partnership with the FMOH, quantified the potential impact of new malaria control interventions including seasonal malaria chemoprevention (SMC), mass drug administration (MDA), and use of Piperonyl Butoxide (PBO) nets in 74 high-risk districts that represent 50% of the malaria burden nationally. A combination of PBO nets and MDA was estimated to yield the highest reduction in annual clinical incidence (28% all ages and 24% for children under five [U5s]), followed by a scenario that combines PBO nets and SMC (25% for all ages and 46% for U5s). Our results also demonstrated an 18% greater incidence reduction for PBO nets compared to standard long-lasting insecticidal nets (LLINs), highlighting the importance of pyrethroid resistance profile in Ethiopia. With effective mix of interventions targeting the highest incidence areas, Ethiopia can further reduce malaria burden not only in those regions, but also nationally, bringing elimination closer. A national malaria strategy incorporating modelling based on local data could help to guide sub-national tailoring of malaria intervention mixes for optimal burden reduction and accelerate progress towards elimination.

### SAME BUDGET, MORE IMPACT: USING MATHEMATICAL MODELLING TO OPTIMIZE CAMEROON'S MALARIA PROGRAM

Branwen Nia Owen<sup>1</sup>, Katya Galactionova<sup>2</sup>, Munir Winkel<sup>1</sup>, Sophie Diarra<sup>1</sup>, Dorothy Achu<sup>3</sup>, Florentine Tchounga<sup>3</sup>, Magloire Kuetche<sup>3</sup>, Emilie Pothin<sup>4</sup>

<sup>1</sup>Swiss TPH / University of Basel, Basel, Switzerland, <sup>2</sup>University of Basel, Basel, Switzerland, <sup>3</sup>National Malaria Control Programme, Yaoundé, Cameroon, <sup>4</sup>Swiss TPH / University of Basel / Clinton Health Access Initiative, Basel, Switzerland

National intervention plans are designed in the context of heterogeneous risks, multiple available tools, and non-linear disease dynamics. Coupling mathematical modelling of malaria dynamics with economic tools is a powerful way to explore trade-offs between strategies. We aim to identify two stratification plans that minimize all-age malaria cases and deaths within the program budget. Firstly, we developed a list of interventions considered under the national strategy; these reflect global guidelines. Second, we calibrated an established malaria microsimulation platform to historical prevalence. We used the model to predict the district-level impact (number of cases or deaths averted compared to the current national plan) and the cost of each possible combination of interventions. Using a linear optimization algorithm, we selected stratifications that maximise i. cases averted and ii. deaths averted, at a cost within the available budget. Piperonyl butoxide bednets were selected over standard long-lasting insecticidal nets for near blanket coverage both when optimizing for cases and deaths (in >90% of 189 districts). Indoor-residual spraying was rarely selected (<10% districts). Intermittent preventive treatment for infants was selected in fewer districts when optimizing to avert cases (~50% districts), than to avert deaths (~70% districts), with seasonal malaria chemoprevention selection following the same pattern (in ~9% and ~20% of 45 eligible districts, when averting cases and deaths, respectively). Enhanced case management was selected for blanket coverage for both targets. Both optimized strategies were projected to reduce the number of cases and deaths by 16-18% over the current plan. Our analysis combines information on malaria ecology, burden and intervention costs within a unified framework. Such analyses provide a valuable additional source of information for decision-makers when designing national strategies. Faced with competing health priorities and stagnating malaria funding, we must find ways to make money go further: optimized intervention stratification offers an exploration of possible paths.

0264

### ESTIMATING THE IMPACT OF SINGLE LOW DOSE PRIMAQUINE ON REDUCING MALARIA TRANSMISSION IN NKOMAZI SUBDISTRICT, SOUTH AFRICA

Jared M. Norman, Sheetal Silal

Modelling and Simulation Hub, Africa (MASHA), University of Cape Town, Cape Town, South Africa

Single Low-Dose (SLD) Primaquine may be used successfully to decrease transmission of the *Plasmodium falciparum* parasite. In South Africa, a modelling study was conducted to estimate the community benefit of widescale distribution of SLD Primaquine in combination with Artemether / Lumefantrine in the Nkomazi sub-district in Mpumalanga Province. A nonlinear ordinary differential equation compartmental model was developed to simulate malaria transmission and estimate the intervention's impact on reported malaria incidence. The model was developed to capture the *in vitro* gametocyte stage of the parasite life cycle by accounting for sequestration and maturity of gametocytes. In order to quantify the contribution of SLD Primaquine in reducing transmission, it was also necessary to estimate the impact of supporting interventions like indoor residual spraying activities, active case detection, importation of malaria and the seasonality of transmission. The model was validated with local and imported case and intervention data from the Mpumalanga Malaria Control Programme (MMCP) in order to estimate the cases averted

due to the SLD Primaquine intervention. The impact of intervention at various coverage levels within the malaria season was also explored. The modelling study is currently being extended to other endemic subdistricts in South Africa where SLD Primaquine was introduced.

0265

### ESTIMATING THE VARIABILITY OF ANOPHELES BIONOMICS AND ITS IMPACT ON TRANSMISSION WITH A HIERARCHICAL BAYESIAN MODEL

Jeanne Lemant<sup>1</sup>, Barnabas Zogo<sup>2</sup>, Thomas A. Smith<sup>1</sup>, Clara Champagne<sup>1</sup>, Monica Golumbeanu<sup>1</sup>, Emilie Pothin<sup>3</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute / University of Basel, Basel, Switzerland, <sup>2</sup>University of Montpellier, Montpellier, France, <sup>3</sup>CHAI, Clinton Health Access Initiative / Swiss Tropical and Public Health Institute, Boston, USA / Basel, Switzerland

Locality-specific information is generally unavailable on how the bionomics of *Anopheles* mosquitoes affect the vectorial capacity for malaria, or on the vulnerability of local vectors to different vector control methods. To address this, we estimated geography-, time- and species-specific survival and behavioral parameters of *Anopheles* mosquitoes using an augmented version of the Malaria Atlas Project's global database of bionomics data. A sensitivity analysis using an existing mathematical model of the impact of vector control was used to determine which bionomics parameters are most influential. We then applied inclusion and exclusion criteria to select subsets of studies with relevant experimental designs that minimize bias from collection methods for parous, endophagy, and endophily rates. For informing the human blood index, we separated data from indoor and outdoor collections. We performed a meta-analysis by fitting a Bayesian hierarchical model with levels based on *Anopheles* taxonomy. The resulting algorithm can be applied automatically to select relevant data for a specific country and/or time span. Using 26 studies, we found a mean endophagy rate of  $40 \pm 4\%$  with high inter-species variability: on average,  $23 \pm 2\%$  of *Anopheles albimanus* and  $66 \pm 0.5\%$  of *Anopheles arabiensis* mosquitoes bite indoors. Location is also highly influential:  $67 \pm 0.5\%$  of *Anopheles arabiensis* bite indoors in East Africa, but only  $39 \pm 3\%$  in West Africa. We selected 61 studies for estimating the parous rate and observed it is highly species-variable, with averages ranging from  $29 \pm 2\%$  for the *Nuneztovari* complex to  $76 \pm 0.8\%$  for *Anopheles funestus sensu stricto*. There is little intra-continent variation, with the parous rate of *Anopheles gambiae sensu stricto* varying between  $61 \pm 0.4\%$  in West Africa and  $65 \pm 2\%$  in East Africa. The model allows extrapolation of knowledge on *Anopheles* bionomics and quantification of variability between species and geographies. The dataset can be readily augmented with additional data, but there is still a need for more frequent and standardized entomological data collections to understand local behaviors of malaria vectors.

0266

### MODELING THE DIFFERENTIAL IMPACT OF IMPROVED EFFECTIVE COVERAGE FOR MALARIA CASE MANAGEMENT ACROSS TRANSMISSION SETTINGS

Laura Skrip<sup>1</sup>, Clara Champagne<sup>1</sup>, Arnaud Le Menach<sup>2</sup>, Justin Cohen<sup>2</sup>, Theodoor Visser<sup>2</sup>, Emilie Pothin<sup>3</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>3</sup>Swiss Tropical and Public Health Institute/Clinton Health Access Initiative, Basel, Switzerland

Effective treatment of symptomatic malaria is a critical component of control efforts due to its role in reducing not only morbidity and mortality but also the transmission potential of detected cases. Directly measuring the impact of routine case management is challenging due to underreporting and the concurrent deployment of other interventions. Mathematical models can be applied to capture transmission events under pre-specified scenarios while accounting for underlying immunological profiles. Using an agent-based simulation model of *Plasmodium falciparum* malaria dynamics, we aimed to evaluate the impact of case management services at programmatically attainable effective coverage levels and

in varying transmission contexts. Specifically, we estimated the impact on incidence, prevalence, and mortality of increasing realistic levels of baseline effective coverage (15%, 25%, or 50% cure rates of symptomatic malaria) by 10%, 30%, or 50% points in three hypothetical transmission settings: low (15% under 5 prevalence at baseline), moderate (25%), and high (50%). Across transmission settings, operationally feasible increases in effective coverage resulted in reductions in incidence, prevalence, and most notably mortality. For instance, increasing coverage by 30% pts—as might be achieved by preventing stockouts—was associated with reductions of ~0-23% in incidence, ~7-29% in prevalence, and ~16-38% in deaths. Impact was greatest among children and in low transmission settings. For example, given a low baseline coverage of 15%, increasing coverage by 30% pts was associated with 51% and 22% reductions in prevalence among children under five for low and high transmission settings, respectively. The same scenario was associated with 29% and 7% reductions in population-level prevalence. By isolating the impact of case management on malaria outcomes, we identified that, regardless of baseline coverage, even modest coverage increases have transmission and mortality burden impact, not only in low endemic areas but also in high endemic settings characterized by greater immunity and thus lower proportions of cases with symptoms.

0267

### ESTIMATION OF MULTIPLICITY OF INFECTION IN MALARIA ASSUMING OVER-DISPersed MOSQUITO BITING RATES

Kwamou Ngaha Sandy Frank<sup>1</sup>, Kristan A. Schneider<sup>2</sup>

<sup>1</sup>African Institute for Mathematical Sciences (AIMS), Limbe, Cameroon, <sup>2</sup>University of Applied Sciences, Mittweida, Germany

In areas of high transmission, individuals are typically infected with multiple genetically distinct malaria lineages (haplotypes) due to multiple infective contacts (super-infections) during one disease episode. The number of (super-)infections is referred to as multiplicity of infection (MOI), which is considered an essential metric in malaria control. MOI correlates with transmission intensity, mediates recombination and hence affects the parasite's genetic diversity. MOI also impacts the spread of multidrug resistance characterized by point mutations in different genes. MOI estimates from heuristic methods are inferior to those from formal statistical frameworks. Maximum-likelihood (ML) frameworks to estimate MOI typically have desirable properties but are based on the assumptions made by the underlying model. A standard assumption is that of rare and independent infective events, leading to a Poisson distribution. ML methods to estimate MOI have been criticized because of the Poisson assumption. Namely, it implicitly reflects that the number of mosquito bites within a given time interval is also Poisson distributed - which is not supported by empirical evidence. The distribution of mosquito bites is typically overdispersed and accurately modelled by a negative binomial distribution. Here, we introduce a maximum likelihood framework under the assumption that MOI follows a negative binomial distribution. We show that this model is degenerate and always yields the same estimate as the corresponding Poisson model. This shows that the Poisson model is more generally applicable than previously thought and implies that the effect of overdispersion can only be accounted for if sustained by the data, e.g., by providing additional information on the risk of exposure of certain patients.

0268

### PREDICTING THE EPIDEMIOLOGICAL IMPACT OF LARGE-SCALE IMPLEMENTATION OF INTERMITTENT PREVENTIVE THERAPY IN INFANTS IN SOUTHERN NIGERIA

Manuela Runge<sup>1</sup>, Ifeoma D. Ozodiegwu<sup>1</sup>, Brie Falkard<sup>2</sup>, Jaline Gerardiin<sup>1</sup>

<sup>1</sup>Department of Preventive Medicine and Institute for Global Health, Northwestern University, Chicago, IL, United States, <sup>2</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States

Intermittent preventive therapy in infants (IPTi) aims to reduce clinical malaria episodes and deaths by administering sulfadoxine-pyrimethamine (SP) at three time-points during infancy. The World Health Organization (WHO) recommends IPTi in moderate to high, non-seasonal malaria transmission areas. Although recommended since 2010, only one country has adopted the strategy. Delaying IPTi may miss the opportunity to reduce adverse malaria outcomes in infants and young children and to accelerate policy adoption, but stronger evidence on IPTi effectiveness as well as a re-assessment of its deployment schedule are urgently needed. This study estimates the likely impact of large-scale implementation of IPTi when administered as recommended at 2, 3, and 9 months of age or with additional doses during infancy and extended into the second year of life. We adapt an existing malaria transmission model (EMOD) to model the impact of IPTi in 365 eligible local government areas (LGAs) in Nigeria. The model was calibrated to capture the transmission intensity and seasonality in each LGA and parameterized using Demographic Health Survey (DHS) and Malaria Indicator Survey data for insecticide treated bednet coverage and case management. IPTi coverage was informed using pentavalent 2, 3, and measles vaccine coverage from the DHS in 2019. We use IPTi-SP efficacy estimates from a systematic review of IPTi trials to inform the model. We estimate the reduction in malaria infections and clinical cases in infants at 21.5% (range across LGAs 6.8-34%) and 15% (4.2-21.0%) respectively. Results further suggest that an additional dose during the second year of life would be more impactful than an additional dose during infancy. Although relative reductions are small, absolute cases averted may be high and the results favor an extension of IPTi doses into the second year. Our modeling study provides IPTi impact estimates for different deployment schemes across various transmission settings in Southern Nigeria and contributes to strengthening evidence for informing national IPTi policy in high malaria burden countries.

0269

### TRANSMISSION-BLOCKING INTERVENTIONS: FROM LABORATORY TO THE FIELD

Joseph D. Challenger<sup>1</sup>, Dari F. Da<sup>2</sup>, Teun Bousema<sup>3</sup>, Thomas S. Churcher<sup>1</sup>

<sup>1</sup>Imperial College London, London, United Kingdom, <sup>2</sup>Institut de Recherche en Sciences de la Santé, Bobo-Dioulasso, Burkina Faso, <sup>3</sup>Radboud University Medical Centre, Nijmegen, Netherlands

Transmission-blocking interventions (TBIs), designed to block transmission of malaria parasites from an infected human to a feeding mosquito, have been proposed as a potential tool in the fight against malaria. Interest in TBIs is increasing, as candidates are now being evaluated in malaria-endemic settings, rather than purely in the laboratory. It is important to understand how effective these vaccines are in the field, compared to in the laboratory, and how best to deploy them as a public health tool. Building on recent work, an established model of malaria transmission is used to provide insight into how potential candidate TBIs could be combined with existing control interventions to support malaria control and elimination. The work is illustrated using monoclonal antibodies with transmission-blocking properties. It is particularly important to identify which age groups within a population should be targeted with a TBI, and how these novel tools could be utilised alongside existing interventions. The composition of the infectious reservoir in a malaria-endemic setting will be influenced by the current intensity of malaria transmission but will also depend on how transmission intensity has changed in recent years.

Model predictions are compared to evidence on the reservoir of infection from direct membrane feeding assays. The framework is used to predict the public health impact of different monoclonal antibody use cases in areas with different malaria endemicity and seasonality of transmission and investigate how these novel interventions could be evaluated in large scale clinical trials.

0270

### EFFECT OF SOCIAL AND BEHAVIOUR CHANGE INTERVENTIONS ON MALARIA HEALTH BEHAVIOUR - LLIN USE AND TREATMENT SEEKING IN ETHIOPIA

Habtamu Tamene Temesgen<sup>1</sup>, Bolanle Olapeju<sup>2</sup>, Simon Heliso Kuka<sup>1</sup>, Nandita Kapadia-Kundu<sup>2</sup>, Tsegahiwot Berhanu Zerihun<sup>1</sup>, Guda Alemayehu<sup>3</sup>, Jon Eric Tongren<sup>3</sup>

<sup>1</sup>Johns Hopkins Center for Communication Programs, Addis Ababa, Ethiopia, <sup>2</sup>Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, <sup>3</sup>U.S. President's Malaria Initiative, Addis Ababa, Ethiopia

The Johns Hopkins Centre for Communication Programs (CCP) aims to improve malaria behaviours in Ethiopia. The project's baseline research included 2770 women in rural Ethiopia in 2016 and evaluated knowledge on malaria prevention and women's gender equitable norms as predictors for LLIN use; and self-efficacy a predictor for woman's treatment seeking behaviour for fever. Consequently, the program designed and implemented gender sensitive multi-channel social and behaviour change (SBC) interventions including roadshow community events, a mobile app, maternal and child health videos and weekly radio programs. Endline data were collected from 1773 randomly sampled rural women from intervention areas in 2019. Regression analysis suggests that program exposure significantly increased women's knowledge of malaria prevention methods (aOR: 3.21, 95% CI: 1.34-7.67), positive attitude towards gender equitable norms (aOR: 1.33; 95% CI: 1.07-1.670), and self-efficacy on treatment seeking for fever (aOR: 3.50; 95% CI: 1.70-7.46). These behavioural antecedents also were significantly associated with LLIN use and treatment seeking for fever. Treatment seeking for children with fever under five improved from 66.9% to 70.5% between baseline and endline, respectively (P<0.05). Women exposed to the interventions were 2.5 times (95% CI: 1.15-5.42) more likely to seek treatment than those unexposed. Significant dose-response relationships were also seen between the women's LLIN use by level of exposure (none, some, high) to the SBC interventions: LLIN use was 55.9%, 62.1% and 75.8%. The results support that well-designed "community and gender sensitive" SBC interventions can improve malaria prevention and treatment seeking behaviour.

0271

### RE-INTRODUCED MALARIA IN QUEENSLAND, AUSTRALIA DURING THE SECOND WORLD WAR

G Dennis Shanks

Australian Defence Force Malaria and Infectious Disease Institute, Enoggera, Australia

Once malaria has been eliminated from an area, it is difficult re-introduce it despite the continued presence of competent *Anophelines*. One of the greatest tests of this principle occurred during the Second World War when thousands of soldiers with malaria infections from New Guinea were stationed in Queensland. A *P. vivax* epidemic arose in 1942 in Cairns which was the evacuation point for many military and civilians from the Imperial Japanese Army's offensive in New Guinea. Malaria in Cairns was noted from May 1942 especially in outer areas (Bungalow) where brackish water creeks promoted mosquito breeding. The epidemic of nearly 700 total cases peaked at mid-year which are the cooler months (average 17-26° C) and then fell rapidly in September. Sporozoite positive mosquitoes (1.5% positive out of 1891 dissected) were first documented in Australia during the Cairns epidemic from *Anopheles farauti* (known then as *An. punctulatus moluccensis*). Thus warned, public health authorities made

great efforts to suppress parasites in transiting soldiers and to position them south of 19° S latitude away from most vectors. Only two distinct outbreaks other than Cairns were recorded in Queensland during the war. Pamaquine, an old 8-aminoquinoline, was extensively used in combined treatment regimens killing most gametocytes. Queensland experienced some scattered locally transmitted epidemics in 1943-44 but by 1945 malaria transmission had largely been eliminated. Improved 8-aminoquinoline regimens such as tafenoquine could assist blocking future re-introductions of malaria into eliminated areas.

0272

### IMPACT OF COMMUNITY DELIVERY ON COVERAGE OF INTERMITTENT PREVENTIVE TREATMENT FOR MALARIA IN PREGNANCY IN MALAWI

Jobiba Chinkhumba<sup>1</sup>, **Beth L. Rubenstein**<sup>2</sup>, Ethel Chilima<sup>3</sup>, Collins Kwizombe<sup>4</sup>, Shelby Cash<sup>5</sup>, Katherine Wright<sup>6</sup>, Peter Troell<sup>7</sup>, Humphrey Msona<sup>8</sup>, Fannie Kachale<sup>8</sup>, Doreen Ali<sup>9</sup>, Michael Kayange<sup>8</sup>, Don Mathanga<sup>1</sup>, John Munthali<sup>9</sup>, Julie Gutman<sup>2</sup>

<sup>1</sup>University of Malawi College of Medicine, Malaria Alert Centre, Blantyre, Malawi, <sup>2</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention (CDC), Atlanta, GA, United States, <sup>3</sup>Management Sciences for Health, Lilongwe, Malawi, <sup>4</sup>U.S. President's Malaria Initiative, United States Agency for International Development (USAID), Lilongwe, Malawi, <sup>5</sup>U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>6</sup>Management Sciences for Health, Medford, MA, United States, <sup>7</sup>U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Lilongwe, Malawi, <sup>8</sup>Ministry of Health, Lilongwe, Malawi, <sup>9</sup>Population Services International, Blantyre, Malawi

Increasing coverage of at least three doses of sulfadoxine-pyrimethamine (SP) for intermittent preventive treatment in pregnancy (IPTp3) is a priority to prevent malaria in moderate to high transmission areas. In 2020, only 30% of pregnant women across sub-Saharan Africa received IPTp3. Coverage of IPTp3 in Malawi was higher (41%, 2017 MIS), but still low. From February 2019-August 2020, we implemented a cluster randomized controlled trial in 20 health facilities (HF) in two districts in Malawi. The purpose of the trial was to assess whether community IPTp delivery (cIPTp) by Health Surveillance Assistants (HSAs) can increase IPTp3 coverage, compared with IPTp delivery at antenatal clinics (ANC) alone. Potential adverse effects of cIPTp on ANC attendance were also evaluated. HFs were randomly assigned 1:1 to control or intervention. All HSAs affiliated with a HF were assigned to the same group. Household surveys were conducted at baseline (Dec 2017) and endline (Aug 2020) among women who had completed a pregnancy in preceding 12 months. Effects were estimated using a difference-in-difference regression analysis, accounting for clustering by HF. Surveys were conducted with 370 women at baseline, and 687 at endline. Half of those surveyed at both timepoints were from intervention areas. Median age was 24 years; 35% of women were primigravid. Socio-demographic features were similar between intervention and control areas. Compared with controls, IPTp1, IPTp2 and IPTp3 in intervention areas changed by 13.5 (95% CI: 4.7, 22.3), -2.5 (95% CI: -16.3, 11.4) and 6.9 (95% CI: -5.9, 19.6) percentage points, respectively, while ANC2, ANC3 and ANC4 in intervention areas compared with controls changed by -0.3 (95% CI: -8.4, 7.8), 17.7 (95% CI: 0.9, 34.4) and 25.3 (95% CI: 1.3, 49.3) percentage points, respectively. Women initiated ANC on average 2.5 weeks earlier in intervention versus control areas (95% CI: 1.4, 3.7). In a setting with above average baseline coverage of IPTp3, cIPTp failed to significantly increase coverage of IPTp. cIPTp was associated with earlier initiation of ANC and may have prevented a decrease in IPTp coverage during COVID lockdowns.

0273

### THE CONTRIBUTION OF COMMUNITY DELIVERY TO THE UPTAKE OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY WITH SULFADOXINE-PYRIMETHAMINE IN THREE DISTRICTS OF THE DEMOCRATIC REPUBLIC OF THE CONGO

**Cibinda Ntale Deogratias**<sup>1</sup>, Fernand Ketembwe<sup>1</sup>, Joseph Ekanjji<sup>1</sup>, Sarah Nsiangani Nsiangani<sup>1</sup>, Christina Maly<sup>2</sup>

<sup>1</sup>Jhpiego, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Jhpiego, Baltimore, MD, United States

According to the 2017-2018 Multiple Indicator Cluster Survey (MICS), 56.0% of pregnant women in the Democratic Republic of Congo initiated intermittent preventive treatment of malaria in pregnancy (IPTp) with quality-assured Sulfadoxine-Pyrimethamine (QA SP). However, only 13.4% of pregnant women received the minimum three doses recommended by the WHO. To help close this gap, community-based distribution of QA SP (C-IPTp) by community health workers (CHWs) was introduced as a pilot in 88 health facilities across three districts. C-IPTp was launched in Kenge district in August 2018 followed by Bulungu and Kunda districts in November 2019. Community selected CHWs were trained and deployed to identify pregnant women and refer them to ANC, as well as to screen them for eligibility to receive QA SP and administer QA SP to those eligible. Another key part of this intervention is focused social and behavior communication change activities and ANC outreach promotion. Health facility service delivery data from the National Health Management Information System, coupled with supplementary data from CHW activities were analyzed to examine trends in ANC and IPTp uptake. We used estimated number of pregnant women as a denominator in our analysis. Across the three districts, the IPTp uptake trend showed clear progress. In Kenge, 37% of pregnant women received IPTp3 in 2017 prior to introduction of C-IPTp which increased to 90% in 2020 with 30% of doses given by CHWs. In Bulungu and Kunda, 48% of pregnant women received IPTp3 in 2017, which increased to 72% in 2020 with 12% of doses given by CHWs. In addition, pilot districts experienced improvements in ANC attendance. The percentage of pregnant women attending at least 4 ANC visits increased from 41% in 2017 to 64% in 2020. In Kenge district, early ANC initiation (before 16 weeks) increased from 36% to 67% over the same time period. These data suggest that complementing ANC distribution of QA SP for IPTp with CHW distribution can contribute to overall increases in IPTp uptake as well as improvements ANC attendance.

0274

### IDENTIFICATION OF NATIVE SECRETED PROTEINS WITH ASAIA BOGORENSIS FOR PARATRANSGENIC MODIFICATION

**Marisa Guido**, David J. Lampe

Duquesne University, Pittsburgh, PA, United States

Malaria is a major global health concern, responsible for 229 million cases and over 400,000 deaths in 2020. This disease is caused by parasites of the genus *Plasmodium* and spread through the bite of infected female *Anopheles* mosquitoes. While preventative measures such as bednet usage, and indoor spraying of insecticides have reduced the global incidence, it is obvious that new measures are desperately needed to combat the spread of this disease. Paratransgenesis is one such technique, and refers to engineering a native symbiont of mosquitoes to produce antiparasitoid molecules and ultimately prevent parasite transmission. *Asaia bogorensis* is a native symbiont of *Anopheles* mosquitoes, and an ideal candidate for paratransgenic modification. However, little is known about the native secretion systems present in *A. bogorensis* and how to harness them for use. Through the use of an online prediction tool called BastionHub, we have identified over 300 predicted Type I and Type II secreted proteins. We have narrowed these down to the top 30 most likely candidates and used qPCR analysis to determine which, if any, of these candidates were upregulated in the presence of bloodmeal-like conditions. Upregulation in bloodmeal-like conditions may improve a

paratransgenic system by narrowing the production of antiparasitoids to when *Plasmodium* is present. The candidates identified through qPCR were then tested for secretion, by directly inserting an epitope tag into the chromosome of *A. bogorensis*. These strains were analyzed for secretion in minimal and bloodmeal-like conditions. This identified the first confirmed secreted proteins within the *A. bogorensis* proteome and can be targeted for paratransgenic modification with antiparasitoid effectors.

0275

### IMPACT OF THREE MONTHS OF MALARIA CHEMOPROPHYLAXIS AFTER SEVERE FLOODING IN WESTERN UGANDA: A PRAGMATIC TRIAL IN A HUMANITARIAN CONTEXT

Erin Xu<sup>1</sup>, Brandon Hollingsworth<sup>1</sup>, Varun Goel<sup>1</sup>, Emmanuel Baguma<sup>2</sup>, Amanda Brown Marusiak<sup>1</sup>, Rabbison Muhindo<sup>2</sup>, Raquel Reyes<sup>1</sup>, Edgar Mulogo<sup>2</sup>, **Ross Mathew Boyce<sup>1</sup>**

<sup>1</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States,

<sup>2</sup>Mbarara University of Science and Technology, Mbarara, Uganda

Nearly half of global disasters over the past two decades were attributable to extreme precipitation and flooding, including 64% of events in the Africa region, where malaria is endemic. Unlike the immediate impacts of flooding, however, epidemics of malaria emerge months after flooding and cause substantial excess morbidity and mortality. We conducted a pragmatic, quasi-experimental trial of malaria chemoprophylaxis in response to severe flooding that occurred in the Kasese District of western Uganda in May 2020. All children 12 years of age and younger in one village were eligible to receive monthly rounds of dihydroartemisinin-piperazine (DP) in the three months following flooding. During each round, field staff geolocated households with a handheld GPS, administered a brief questionnaire. And performed a rapid diagnostic test. Tablets of DP were provided according to weight-based dosing guidelines. To assess the impact of the program, we selected two neighboring villages where no malaria-specific interventions were undertaken to serve as controls. We abstracted routine clinical information from registers at the five nearest health facilities to measure the incidence of clinical malaria. A total of 554 children completed at least one round with 413 (74.6%) completing at least two rounds. Compared to control villages, we estimated a 30.1% ( $p = .03$ ) and a 55.0% reduction ( $p < .001$ ) in test positivity and incidence, respectively. Using differences in the observed incidence between the intervention and control villages, we estimate that the chemoprophylaxis intervention resulted in 318 cases averted (95% CI 294 - 342) among a population of 1,188 residents. While eligible represent the largest share of averted cases (217, 68.2%), the model also predicted a substantial decrease in cases among older individuals who were not eligible for the intervention. Total program costs were \$3.89 per course of DP delivered or \$15.87 (95% CI \$14.75 - \$17.16) per case averted. Our study adds to evidence base of opportunities where targeted, relatively short periods of malaria chemoprophylaxis may be used to reduce excess disease burden.

0276

### MALARIA CARE-SEEKING AND TREATMENT IDEATION AMONG GOLD MINERS IN GUYANA

**Bolanle Olapeju<sup>1</sup>**, Camille Adams<sup>2</sup>, Sean Wilson<sup>2</sup>, Joann Simpson<sup>2</sup>, Gabrielle Hunter<sup>1</sup>, TrishAnn Davis<sup>1</sup>, Lyndsey Mitchum<sup>1</sup>, Horace Cox<sup>3</sup>, Neil Trotman<sup>3</sup>, Helen Imhoff<sup>3</sup>, Jennifer Orkis<sup>1</sup>, Douglas J. Storey<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Breakthrough ACTION Guyana, Georgetown, Guyana, <sup>3</sup>Guyana National Malaria Program, Georgetown, Guyana

Guyana hinterland regions 1, 7, 8, and 9 have the country's highest malaria transmission rates, particularly among remote mobile gold miners. The USAID-funded Breakthrough ACTION project, in collaboration with the Guyana National Malaria Program (NMP), sought to understand how gold miners' malaria-related ideation - knowledge, beliefs, attitudes, and

feelings - influence the adoption and maintenance of malaria care-seeking/treatment behaviors. 1685 miners from 233 mining camps in project focal areas in Regions 1, 7 and 8 were surveyed. Malaria care-seeking and treatment ideation was defined as a composite additive score consisting of general malaria knowledge, perceived susceptibility, perceived severity, and interpersonal communication in addition to specific care-seeking/treatment beliefs, perceived self-efficacy, norms, and response efficacy. Higher scores indicate more positive ideation. Logistic regressions assessed the relationship between ideation score and care-seeking/treatment behavior. Overall, miners' care-seeking/treatment ideation score ranged from 0 to 8 with a mean (SD) of 3.8 (1.7), and scores were higher among miners who were in Region 7, Christian, older than 35 years, more educated, or had prior episodes of malaria. Higher levels of ideation were associated with higher rates of any care-seeking (aOR: 1.19, 95%: 1.04 - 1.36), but not prompt care-seeking; with higher rates of malaria testing (aOR: 1.22; 95% CI: 1.07 - 1.38); and with lower rates of self-medication (aOR: 0.80, 95% CI: 0.77 - 0.99). Miners' care-seeking/treatment ideation was linked with improved malaria behavior outcomes. The NMP is implementing a community case management (CCM) initiative using trained volunteers to test and treat uncomplicated malaria in mining camps. Breakthrough ACTION Guyana is implementing a mass media campaign to address miners' ideation related to care-seeking and treatment; distributing counseling materials to ensure high quality of testing and treatment services; and branding of malaria testing and treatment locations and testers with flags and certificates to increase the visibility of the CCM program.

### ASSESSING SEASONAL MALARIA CHEMOPREVENTION ADHERENCE IN NIGER THROUGH AN INDEPENDENT MONITORING SURVEY USING A RANDOMIZED CLUSTER DESIGN

**Daniel Koko<sup>1</sup>**, Djibrilla Maiga<sup>1</sup>, Aminata Maazou<sup>1</sup>, Charlotte Eddis<sup>2</sup>, Ibrahim Ouba<sup>3</sup>, Hadiza Jakou<sup>3</sup>

<sup>1</sup>PMI Impact Malaria Project, PSI, Niamey, Niger, <sup>2</sup>PMI Impact Malaria Project, PSI, Washington, DC, United States, <sup>3</sup>National Malaria Control Program, MOH, Niamey, Niger

In Niger, community distributors give Seasonal Malaria Chemoprevention (SMC) medication through home visits to children aged 3 -59 months at monthly intervals for four months during the rainy season. Despite the scale-up of SMC since 2016 to all eligible districts and high administrative coverage (>85%), the reduction in child morbidity due to malaria remained below the expectations of the Niger National Malaria Control Program (NMCP). To assess adherence to the full SMC treatment regimen, the NMCP instituted monitoring surveys after each cycle of SMC campaign. In 2020, an independent monitoring survey using randomized cluster sampling was conducted to collect quantitative data from caregivers using an electronic tool (KoBoCollect) in the 17 health districts (HD) (eight in the Dosso region and nine in the Tahoua region) supported by President's Malaria Initiative Impact Malaria (IM) project. For each of the four cycles, two to three HDs per region were surveyed, covering each district once. In each HD, one urban and two rural health areas were selected; in each health area, three villages were selected and 20 households per village. All the sampling was done through systematic sampling. A total of 153 villages in 17 districts were sampled and 3,059 households were visited with caregivers of 5,130 children assessed on the medication's adherence. According to parent declaration, 99.6% of children (5,107/5,130) received at least one dose and among them, 99.2% (5,064/5,107) could show proof (filled SMC card or empty blister pack); 90.6% of children (4,180/4,616) received the second dose and 84% (2,008/2,392) the third dose according to parent report; parents could show proof of administering medicines to 80% (3,306/4,180) of children on the second day and 77.6% (1,558/2,008) on the third day. Loss or damage to cards were cited as the primary reason for not being able to show proof. Independent monitoring surveys (using the randomized

cluster sampling approach) implemented over each SMC cycle suggest that the less than expected reductions in morbidity are unlikely to be the result only of a lack of adherence to the full treatment regimen.

### **INCREASED INTERMITTENT PREVENTIVE TREATMENT (IPTP) WITH SULFADOXINE PYRIMETHAMINE IN PREGNANT WOMEN THROUGH THE USE OF A MONITORING REGISTER: EXPERIENCE FROM THE STOPPALU+ PROJECT IN 19 DISTRICTS IN GUINEA**

**Aissata Fofana**<sup>1</sup>, Eugene Kaman Lama<sup>2</sup>, Alioune Camara<sup>2</sup>, Nouman Diakit<sup>2</sup>, Mohamed Saran Condé<sup>1</sup>, Souleymane Béréte<sup>1</sup>, Daouda NDiaye<sup>1</sup>, Mamadou Sitan Kéita<sup>1</sup>, Hamidou Barry<sup>1</sup>, Hadja Fanta Camara<sup>1</sup>, Amadou Tidiane Diallo<sup>1</sup>, Djénabou Barry<sup>1</sup>, Mamadou Aliou<sup>1</sup>

<sup>1</sup>Stop Palu+ Guinea, Conakry, Guinea, <sup>2</sup>NMCP Guinea, Conakry, Guinea

Malaria infection in pregnancy is associated with anemia, low birth weight and neonatal mortality. The WHO recommends using intermittent preventive treatment in pregnancy (IPTp) to reduce the risk of malaria, giving at least three doses of sulfadoxine-pyrimethamine (SP) at scheduled antenatal care (ANC) visits. IPTp in pregnant women remains low in Guinea. According to national health information system (HIS) data, in 2018, 58% of pregnant women received three doses of SP and only 53% received four doses. While IPTp can be measured using survey data, coverage estimates from surveys represent a retrospective time period of up to 2 years. Routine data from ANC can be used to provide a more current estimate of IPTp coverage; however, there are challenges such as nonstandard ANC registers across health facilities and calculation methods that are aggregate instead of individually-based and are therefore less accurate. It is within this framework that the StopPalu+ project funded by the President's Malaria Initiative (PMI) supported the ministry of health to develop ANC monitoring registers. The objective was to document the actual level of IPTp coverage and design methods to improve coverage in areas that were lagging in the 19 districts supported by the project. Pregnant women who came for their first ANC visit in HCs from April 1, 2019 to March 31, 2020 were entered in the cohort register and followed until delivery. IPTp coverage with three doses increased over the monitoring period from 62% in the Apr-June 2019 cohort to 78% for Jan-March 2020 cohort. Documenting and following pregnant women using the cohort registers allowed for closer

### **MALARIA IN PREGNANCY AND ANTENATAL CARE KNOWLEDGE, ATTITUDES AND INTERVENTION COVERAGE IN ATLANTIQUE DEPARTMENT, BENIN**

**Katherine Wolf**<sup>1</sup>, Manzidatou Alao<sup>2</sup>, Alexandre Binazon<sup>2</sup>, Faustin Onikpo<sup>2</sup>, Stephanie Suhowatsky<sup>1</sup>, Ahmed Saadani<sup>2</sup>, Julie Buekens<sup>4</sup>, Julie Niemczura de Carvalho<sup>5</sup>, Aurore Ogouyemi-Hounto<sup>6</sup>, Julie Gutman<sup>7</sup>

<sup>1</sup>Jhpiego/PMI Impact Malaria, Washington, DC, United States, <sup>2</sup>MCDI/PMI Impact Malaria, Cotonou, Benin, <sup>3</sup>US President's Malaria Initiative, Centers for Disease Control and Prevention, Cotonou, Benin, <sup>4</sup>MCDI/PMI Impact Malaria, Washington, DC, United States, <sup>5</sup>MCDI/PMI Impact Malaria, Silver Spring, MD, United States, <sup>6</sup>Ministry of Health, Cotonou, Benin, <sup>7</sup>US President's Malaria Initiative, Centers for Disease Control and Prevention, Atlanta, GA, United States

PMI Impact Malaria, in collaboration with the Benin National Malaria Control Program, is conducting a cluster randomized controlled trial in 40 health facilities (HF) comparing the impact of group antenatal care (gANC) versus standard (individual) ANC on uptake of malaria in pregnancy (MiP) interventions and quality of antenatal care. From November to December of 2020, we conducted a baseline cross-sectional household survey to assess coverage of MiP interventions, birth outcomes, knowledge and attitudes about ANC, role of gender in decision-making around ANC attendance, and behavior differences between those attending and not

attending ANC among women who had completed a pregnancy in the last 12 months. One enumeration area (EA) per HF catchment was selected population proportional to size, and 33 women were randomly selected per EA. Analyses were done in SAS V9.4 and accounted for clustering at the HF level. Of 1259 women included, 21% were primigravid, 23% were secundigravid; 94% attended ANC1 but only 58% attended ANC4+. Of those who did not attend any ANC, 29% stated the facility was too far and 36% stated care was too expensive. Women initiated ANC at a mean of 3.3 months. Half reported that their husband had accompanied them to ANC. While 88% of women received at least 1 dose of intermittent preventive treatment in pregnancy (IPTp), 69% received 2 doses, and 40% received 3 doses. A total of 97% of pregnant women had their blood pressure taken, 96% had urinalysis, and 82% were dewormed. Most women (89%) reported using long-lasting insecticide-treated nets (LLIN). The group ANC intervention began in March 2021 and will continue for 18 months. The baseline data, as well as findings from the trial, may be used to improve ANC quality and better tailor and target malaria in pregnancy interventions for pregnant women in Benin, and throughout the region. Results may also be used to refine messaging and communication to promote early and continued ANC attendance.

0280

### **INTRODUCING FIELD DIGITAL DATA COLLECTION SYSTEMS INTO SEASONAL MALARIA CHEMOPREVENTION CAMPAIGNS - LESSONS LEARNT AND OPPORTUNITIES FOR ROBUST EVIDENCE DEVELOPMENT**

**Abena Poku-Awuku**, André-Marie Tchouatieu  
*Medicines for Malaria Venture, Vernier, Switzerland*

Data management has been cited as one of the challenges hindering the development of evidence generation for health interventions in Africa. To address these challenges, field digital data collection tools were introduced to support data management for health interventions, including malaria. Investigating the impact of the use of digital data collection tools in Seasonal Malaria Chemoprevention, a multi-dose health intervention that requires eligibility verification and follow-up for compliance, could benefit other multi-step health interventions that experience compliance challenges. Recently, Benin, the Gambia, Ghana, and Nigeria introduced digital android mobile data collection systems into their SMC campaigns. Based on qualitative evidence provided, this presentation shows the benefits, challenges and lessons learnt from the incorporation of digital data collection tools in the implementation of SMC. It discusses the challenges, and opportunities of linking field digital data collection tools into routine healthcare data management. Digital data collection systems were instrumental in the enumeration, satellite mapping and registration of children for SMC as well as in tracking the coverage of SMC. They were also useful in tracking dose compliance and monitoring of adverse drug reactions. Countries, however, cited that internet connectivity issues as well as limited resources to scale up the use of digital data collection systems were limiting the effective use and scale up of digital data collection tools, respectively. While all countries recognized the benefits of linking the data from digital collection tools with routine healthcare data collection systems none had implemented this till date due to resource constraints. The authors encourage that field data collection tools be scaled up for use in SMC campaigns. They advocate those solutions that can effectively link field data collection tools to routine health management systems be pursued to support robust evidence generation for policy development and innovation.

0281

### SOCIAL NORMS, SOCIAL SUPPORT AND AVAILABILITY ARE CRITICAL DETERMINANTS OF CONSISTENT ITN USE BY FOREST-GOERS IN CAMBODIA: IMPLICATIONS FOR SBC PROGRAMMING FROM A RESPONDENT-DRIVEN SAMPLING STUDY

Po Ly<sup>1</sup>, Boukheng Thavrin<sup>1</sup>, Sochea Phok<sup>2</sup>, Mahesh Paudel<sup>3</sup>, Shwetha Srinivasan<sup>4</sup>, Huy Rekol<sup>1</sup>, Siv Sovannaroth<sup>1</sup>, Saad Hassan<sup>5</sup>, Stephen Poyer<sup>3</sup>, Andy Tompsett<sup>3</sup>, Jim Malster<sup>3</sup>

<sup>1</sup>National Center for Malaria Control, Parasitology and Entomology, Phnom Penh, Cambodia, <sup>2</sup>Population Services International Cambodia, Phnom Penh, Cambodia, <sup>3</sup>Population Services International, Washington, DC, United States, <sup>4</sup>Population Services International Laos, Vientiane, Lao People's Democratic Republic, <sup>5</sup>U.S. President's Malaria Initiative/United States Agency for International Development, Phnom Penh, Cambodia

Malaria transmission in Cambodia is highly localized to forests and forest fringes. Forest-goers are a hard-to-reach population at heightened risk of malaria infection and rely on repellents, coils, clothing and mosquito nets (ITNs) and hammock nets for prevention. However, ITNs are an imperfect tool in this context and insights into determinants of use can improve targeted SBC activities. We used respondent-driven sampling to conduct a survey of 654 forest-goers in 2020 to understand determinants of ITN use. One seed from each of 16 villages in Kampong Chhnang and Pursat provinces was recruited and referred up to three forest-goer contacts. Eligible participants reported spending at least one night in the forest in the past month. Recruitment continued until the required sample was reached, yielding up to 9 waves for some seeds. Multivariate logistic regression analysis was conducted using sleeping under ITN as the dependent variable. Three-fourths (75%) of forest-goers reported sleeping under an ITN every night during their last forest visit ("users"). The most common reasons for not consistently using an ITN were "too hot to use net" (51%), "no net available for use in forest" (21%) and "net available but wasn't brought" (19%). ITN users were more likely to own one or more ITNs that could be brought to the forest compared to non-users (96% vs 66%,  $p < 0.0001$ ) and were more likely to report prevalent social norms on ITN use within their community when in the forest than non-users (95% vs 65%,  $p < 0.0001$ ). ITN users also reported stronger social support than non-users, agreeing that their family and friends support the use of ITNs (79% vs 21%,  $p < 0.0001$ ). Finally, ITN users were less likely than non-users to believe that ITN use carried adverse health effects than non-users (40% vs 50%,  $p = 0.03$ ). This study revealed that social norms and social support for forest ITN use and perceived adverse effects were strongest behavioral determinants of consistent ITN use by forest-goers in these sites. Future SBC activities should target these levers to support ITN use, while complementary activities will be required to ensure adequate ITN availability for forest use.

0282

### LESSONS FROM DIGITIZING MASS DRUG ADMINISTRATION CAMPAIGN FOR MALARIA DURING A COMPLEX EMERGENCY — CABO DELGADO, MOZAMBIQUE, 2021

Samira Sibindy<sup>1</sup>, Andrea Rowan<sup>2</sup>, Baltazar Candrinho<sup>1</sup>, Júlia Montañã Lopes<sup>3</sup>, Guidion Mathe<sup>1</sup>, Amber Dismar<sup>4</sup>, Dominic Lucero<sup>2</sup>, Bradley Didier<sup>2</sup>, Rita Chico<sup>2</sup>, Pedro Aide<sup>3</sup>, Eva de Carvalho<sup>5</sup>, James Colborn<sup>2</sup>, Mércia Dimene<sup>1</sup>, Leonildo Nhampossa<sup>6</sup>, Anastacio Cardoso<sup>6</sup>, Aníbal Nhazime<sup>6</sup>, Júlio Genésio Nikhotope<sup>6</sup>, Dalito Samuel Dala<sup>6</sup>, John Rossow<sup>4</sup>

<sup>1</sup>National Malaria Control Program, Ministry of Health, Maputo, Mozambique, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>3</sup>Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, <sup>4</sup>Division of Global Health Protection, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>5</sup>World Health Organization, Maputo, Mozambique, <sup>6</sup>Ministry of Health, Cabo Delgado, Mozambique

In February-May 2021, a malaria mass drug administration (MDA) campaign using dihydroartemisinin-piperazine was conducted in two

districts of Cabo Delgado province, Mozambique amidst a complex humanitarian emergency that could increase mortality due to limited access to care. Limited information on the impact of MDAs in these settings underscores the importance of coverage monitoring. Data was collected on size, geolocation, treatment eligibility, and acceptance from each household and institution visited. This data was monitored daily via Google Sheets and then Power BI Desktop. Dashboards summarized coverage, absences, ineligibility, refusals, and team performance. Daily data quality reviews were conducted, and data error reports were provided to field teams. Daily monitoring and clear feedback loops with field teams strengthened campaign activities. Supervisors used team-specific daily reports on coverage and data quality issues to provide tailored supervision to teams and adapt coverage strategies. Google Sheets was not suited to process the volume of data reaching capacity after one day. The dashboard built in Power BI was able to effectively process and display large data volumes in digestible visuals that were updated daily. Direct use of the Power BI dashboard by supervisors was initially impeded by lack of familiarity with Power BI and software access. In one district, lack of connectivity prevented daily data uploads, so teams could not benefit from dashboard use during Round 1. Changes based on lessons learned from Round 1 included offline data collection and monitoring capacity for areas with no connectivity via ODK Briefcase and Power BI Desktop; one-step monitoring for supervisors via online dashboards; and adapting data collection and workflow to improve coverage estimates. In areas with connectivity, daily monitoring effectively identified coverage issues, informed mop-up efforts, and corrected data quality concerns. Flexible and proactive monitoring allowed for strengthening of systems during MDA implementation and highlight good practices for dashboards in low connectivity settings.

0283

### MODELLING MALARIA ELIMINATION STRATEGIES IN ZANZIBAR, TANZANIA

Aatreyee M. Das<sup>1</sup>, Manuel W. Hetzel<sup>1</sup>, Joshua Yukich<sup>2</sup>, Logan Stuck<sup>3</sup>, Bakar S. Fasih<sup>1</sup>, Abdul-wahid H. Al-mafazy<sup>4</sup>, Abdullah Ali<sup>4</sup>, Nakul Chitnis<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>3</sup>Amsterdam Institute for Global Health and Development, Amsterdam, Netherlands, <sup>4</sup>Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania

Despite the implementation of vector control interventions, use of artemisinin-based combination therapies, and reactive case detection, malaria continues to persist at a low prevalence on the island archipelago of Zanzibar. Human movement between mainland Tanzania and Zanzibar is hypothesized to be a significant contributor to disease persistence, as prevalence is substantially higher in some areas of the mainland than on the islands. Studies have previously shown that repeated importation of infections can allow for disease persistence in areas where the disease would otherwise become extinct. In this study, we developed a metapopulation model of malaria transmission on the two main islands of Zanzibar and mainland Tanzania to provide insights into the local reproduction number in the absence of human movement. Then, we calibrated the transmission and human movement rates between the islands and the mainland to data on malaria prevalence and travel history collected during a cross-sectional survey, and data from the reactive case detection programme carried out in Zanzibar. We explored potential improvements to reactive case detection, with the aim of finding strategies that would substantially lower the infection prevalence on the islands. We found that human movement between the islands and the mainland played a pivotal role in disease persistence on Zanzibar, with the local reproductive number being below one on both islands in the absence of human movement. Tackling the issue of imported cases is crucial, as improvements to reactive case detection were projected to have only a small impact on prevalence. Shifting from reactive case detection to a reactive focal mass drug administration programme also showed substantial reductions, as patients with sub-patent infections, who would

typically be missed by screen-and-treat programmes, would also receive treatment. Additionally, we found that treating imported infections could lead to a large reduction in prevalence, but only if the majority of imported cases are successfully treated.

0284

### ASSESSING THE CONTRIBUTION OF ACTIVE CASE DETECTION TO MALARIA ELIMINATION IN THAILAND

**Suravadee Kitchakarn**<sup>1</sup>, Sathapana Naowarat<sup>2</sup>, Prayuth Sudathip<sup>1</sup>, Chalita Suttiwong<sup>1</sup>, Darin Areechokchai<sup>1</sup>, Chantana Padungtod<sup>1</sup>, Deyer Gopinath<sup>3</sup>, Niparueradee Pinyajeerapat<sup>4</sup>, David Sintasath<sup>4</sup>, Jui A. Shah<sup>2</sup>

<sup>1</sup>Division of Vector Borne Diseases, Ministry of Public Health, Nonthaburi, Thailand, <sup>2</sup>Inform Asia: USAID's Health Research Program, RTI International, Bangkok, Thailand, <sup>3</sup>World Health Organization, Nonthaburi, Thailand, <sup>4</sup>U.S. President's Malaria Initiative, United States Agency for International Development (USAID), Regional Development Mission for Asia, Bangkok, Thailand

Thailand's malaria surveillance system complements passive case detection in health facilities with several methods of active case detection (ACD). ACD comprises both proactive methods (PACD) that seek new cases in high-risk areas and reactive methods (RACD) that target community members near index cases. As Thailand approaches elimination, with just 4,474 cases in fiscal year 2020 (FY20), it is unclear if these resource-intensive surveillance strategies are yielding the same output as in the past. This study used routine data to examine achievements and trends in ACD among all 9,833,506 patients tested from FY15-20. ACD accounted for 42.3% of blood tests and 5.4% of confirmed cases, which was consistent over the study period (range = 4.3%-6.0%). As expected in an elimination setting, test positivity was low for both ACD (0.09%) and passive case detection (1.12%) and declined over time (from 0.14% to 0.05% for ACD). Whereas PACD and RACD contributed nearly equal proportions of confirmed cases at the start of the study period, by FY20, PACD accounted for just 29.7% of ACD cases, with 0.02% test positivity. Fixed-schedule malaria clinics (PACD) were the lowest-yielding ACD method, and case investigation surveys (RACD) were the highest ( $p < 0.05$ ). Both PACD and RACD contributions were significantly higher among active foci than other foci with a confirmed index case ( $p < 0.05$ ). ACD enhances surveillance by capturing cases that would not be discovered in health facilities but could spark indigenous transmission. The results of this study can be used to optimize ACD deployment as incidence continues to drop. For example, Thailand may consider reducing the frequency or radius of PACD screenings, and revised focus investigation protocols could restrict RACD screenings to only the highest-risk individuals or to active foci. Strategically targeting ACD could release resources for emerging priorities, such as prevention of reintroduction, and complementary modeling analyses could quantify potential risks of undetected cases. The results may also be useful to other countries aiming to strengthen surveillance for elimination.

0285

### PROGRESS TOWARD PLASMODIUM FALCIPARUM ELIMINATION IN THAILAND

**Prayuth Sudathip**<sup>1</sup>, Donal Bisanzio<sup>2</sup>, Suravadee Kitchakarn<sup>1</sup>, Deyer Gopinath<sup>3</sup>, Niparueradee Pinyajeerapat<sup>4</sup>, David Sintasath<sup>4</sup>, Jui A. Shah<sup>2</sup>

<sup>1</sup>Division of Vector Borne Diseases, Department of Disease Control, Ministry of Public Health, Nonthaburi, Thailand, <sup>2</sup>Inform Asia: USAID's Health Research Program, RTI International, Bangkok, Thailand, <sup>3</sup>World Health Organization, Nonthaburi, Thailand, <sup>4</sup>U.S. President's Malaria Initiative, United States Agency for International Development (USAID), Regional Development Mission for Asia, Bangkok, Thailand

The evolution of multidrug-resistant parasites has made the Greater Mekong Subregion's goal of eliminating *Plasmodium falciparum* (Pf) by 2023 increasingly urgent. Thailand's program includes the 1-3-7 strategy: notification within 1 day, case investigation within 3 days, and response

within 7 days. This study used national surveillance data and logistic regressions to assess the program's progress and identify characteristics of remaining Pf cases and foci. A panel vector autoregression with a Granger causality Wald test assessed the effects and causality of historical values of variables (time lags) on current values. From fiscal year 2013 through 2020 (FY13-20), Pf infections dropped from 11,991 cases among 1,943 foci to 250 among 125 foci; mean cases per focus declined from 6.2 to 2.0. Although incidence of other malaria species also declined, the proportion of Pf among all cases dropped from 43.4% to 5.8%, and the proportion of active foci with Pf infections dropped from 53.3% to 11.3%. A spatial-temporal analysis showed that Pf foci are increasingly clustered in high-burden provinces at the Myanmar border. Among 23,113 cases from FY17-20, after new elimination strategies were launched, increased odds of Pf were significantly associated ( $p < 0.05$ ) with Thai citizenship, male sex, and historical values in the proportion of Pf cases, the proportion of imported cases, and foci classification. Granger test results suggest that historical values of model variables have a causal relationship with the presence of Pf in a given year. Among active foci for all species, presence of Pf infections was associated with adherence to 1-3-7 protocols ( $p < 0.05$ ). These results highlight Thailand's progress and reveal unique factors of Pf infections. Although malaria epidemiology is heavily influenced by the matrix of Thai and migrant workers in border areas, Pf cases are concentrated among Thai men, suggesting that elimination may require more targeted approaches. Foci with Pf infections may be better implementing surveillance policies; further analyses could clarify whether this association is explained by programmatic or other health system factors.

0286

### ROLE OF RURAL PRIVATE SECTOR PROVIDERS IN MALARIA SURVEILLANCE AND CASE MANAGEMENT DURING COVID-19 PANDEMIC IN MYANMAR

**May Me Thet**, Kyaw Zaya, Si Thu Thein

Population Services International Myanmar, Yangon, Myanmar

During COVID-19 pandemic in Myanmar, essential health services were disrupted including malaria case management. Population Services International Myanmar (PSI/Myanmar) provided malaria testing with rapid diagnostic tests (RDT) and case management through its networks such as private medical doctors (Sun Quality Health clinics, SQH) in urban areas, community volunteers (Community Health Services Providers, CHSP) and private non-formal providers (Private Outlets, PO) in rural areas. We explored their performance and service quality prior and during the pandemic. As the first COVID-19 case was found in March 2020, we compared 9-month data of 2020 (Apr-Dec) with that from 2019 using program data. The data for comparison was confined to the providers present in both periods. Service quality assessments were done via a standard electronic checklist where scores above 80 points were considered satisfactory. Statistical significance was determined as  $p < 0.05$ . The data came from 783 SQH (30.3%), 1163 CHSP (45%), and 637 PO (24.7%) providers. A total of 384971 and 346725 patients were tested with RDT and 3413 and 3543 were found to be positive in 2019 and 2020 (positivity rates 0.9% and 1.0%). The mean number of fever patients tested per provider per month were CHSP (16.3 vs. 15.7,  $p = 0.11$ ), PO (10.3 vs. 12.3,  $p = 0.02$ ), SQH (6.8 vs. 4.1,  $p < 0.001$ ). The mean number of RDT positive patients per provider per month were CHSP (0.1 vs. 0.1,  $p = 0.51$ ), PO (0.1 vs. 0.5,  $p = 0.005$ ), SQH (0.6 vs. 0.5,  $p = 0.44$ ). Positivity rates were CHSP (0.8% vs. 0.7%), PO (1.2% vs. 1.0%) and SQH (0.9% vs. 2.7%). The mean quality scores were CHSP (76.4 vs. 83.4,  $p < 0.001$ ), PO (87.9 vs. 86.6,  $p = 0.01$ ) and SQH (94.5 vs. 96.7,  $p < 0.001$ ). During the COVID-19 pandemic, malaria testing dropped among private medical doctors in urban clinics but rural private sector providers continued malaria services as before, at similar levels to traditional volunteers, maintaining adequate service quality. Thus, their role in malaria surveillance and case management was important and they could be one of the promising channels for providing such services during crisis situations in Myanmar and similar settings.

0287

### CROSS-BORDER MOVEMENT AS A KEY CHALLENGE IN MALARIA ELIMINATION EFFORTS IN THE GUIANA SHIELD: ASSESSMENT OF MOBILE MIGRANT POPULATION CHARACTERISTICS

Pierre Pratley<sup>1</sup>, Marieke Heemskerck<sup>2</sup>, Eelco Jacobs<sup>1</sup>, François-Michel Le Tourneau<sup>3</sup>, Oscar Mesones Lapouble<sup>4</sup>, Helene Hiwat<sup>5</sup>

<sup>1</sup>*KIT Royal Tropical Institute, Amsterdam, Netherlands*, <sup>2</sup>*Social Solutions, Paramaribo, Suriname*, <sup>3</sup>*CNRS/University of Arizona, Tucson, AZ, United States*, <sup>4</sup>*PAHO, Paramaribo, Suriname*, <sup>5</sup>*Malaria Program Suriname, Paramaribo, Suriname*

Migration along the porous borders of Suriname with French Guiana, a European Territory, and Brazil, represents a continuous challenge to the national elimination goal in Suriname. A key population that engages in this migration are Artisanal Small-Scale Gold miners (ASM) that work throughout the Guiana Shield. This study focused on understanding the size, characteristics, migration patterns and health-related perceptions on risk of disease, health needs and access to care among mobile migrant ASM communities in Suriname. Mobile Migrants' population characteristics were examined using a mixed methods approach combining document review, a quantitative survey and qualitative in-depth interviews with the target population and experts. The total ASM population was estimated at around 31,000 individuals, of which 20,000 active in Suriname and 11,000 in French Guiana. Turnover was estimated to be 10,5% of which 95%, or some 2,000 persons annually are newcomers to the sector. International migration patterns were mapped from Brazil, but also from Venezuela, Dominican Republic, Cuba and China. In terms of perceived health risks, we find that most ASM workers are somewhat concerned with malaria, leishmaniasis and COVID-19. The improved understanding of the size, characteristics, migration patterns and health needs of ASM communities carries important implications for targeting the health needs of these vulnerable and hard-to-reach mobile communities in the Guiana shield. Recommendations include 1) using data to target most vulnerable subgroups 2) Increasing efforts to communicate risks, preventive measures and treatment options 3) Scaling up support by increasing service delivery, specifically for most at-risk subgroups to implement prevention and treatment options for malaria elimination and 4) Prioritization by the Surinamese government to work with the French government and regional institutions to guarantee access to diagnosis and treatment for ASM workers in remote areas in French Guiana

0288

### IDENTIFYING AND ADDRESSING GAPS IN THE MALARIA ELIMINATION STRATEGY: ACTIVE CASE DETECTION IN MADAGASCAR, 2020

Fanomezana Andriamamonjy<sup>1</sup>, Maurice Ye<sup>2</sup>, Sandy Ralisata<sup>3</sup>, Jean Marie N'Gbichi<sup>4</sup>, Sabas Rabesahala<sup>1</sup>, Urbain Rabibizaka<sup>1</sup>, Saraha Rabeherisoa<sup>1</sup>, Brune Ramiranirina<sup>1</sup>, Celestin Razafinjato<sup>1</sup>, Laurent Kapesa<sup>5</sup>, Brittany S. Iskarpatyoti<sup>6</sup>, Yazoume Ye<sup>4</sup>

<sup>1</sup>*National Malaria Control Program, Antananarivo, Madagascar*, <sup>2</sup>*U.S. President's Malaria Initiative Measure Malaria, University of North Carolina at Chapel Hill/ICF, Chapel Hill, NC, United States*, <sup>3</sup>*PMI Impact Malaria, Antananarivo, Madagascar*, <sup>4</sup>*U.S. President's Malaria Initiative Measure Malaria, University of North Carolina at Chapel Hill/ICF, Chapel Hill, NC, United States*, <sup>5</sup>*U.S. President's Malaria Initiative, Antananarivo, Madagascar*, <sup>6</sup>*U.S. President's Malaria Initiative Measure Malaria, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Progressive malaria elimination is a goal of Madagascar's National Malaria Control Program (NMCP). In 2020, 13 (11.4%) of 114 districts met the NMCP's malaria elimination criterion (incidence <1 case per 1,000 inhabitants). To support these 13 districts, the U.S. President's Malaria Initiative (PMI) Measure Malaria and Impact Malaria projects implemented elimination strategies in Madagascar, including training health workers at the community level in surveillance, active case detection, investigation, and electronic case reporting. From December 1, 2020 to February

28, 2021, the NCMP conducted three rounds of active case detection, investigating, and screening of all household members where an index case (a passively identified confirmed malaria case) was reported, as well as the 10 surrounding households, in 18 rural communities in the health district of Antsirabe II. A malaria rapid diagnostic test was done on every individual, and real-time polymerase chain reaction was performed. Data from the screened individuals were recorded in a digitalized tool running on the District Health Information Software 2 (DHIS2) platform. The team screened 913 individuals based on 40 index cases reported from 18 communities in 20 health centers. Of the 913 individuals screened, 31 (3.4%) had a positive malaria rapid diagnostic test and were locally transmitted infection. Real-time polymerase chain reaction was performed on 507 of the 913 individuals due to limited stock on reagent. During the February round of foci investigation, a stock-out of primaquine, the recommended national treatment protocol (single-dose primaquine plus artemisinin-based combination therapy to treat a positive case), was reported in 11 health centers (55%). Active case detection and integrated vector management will only be as strong as the treatment supply chain that supports it (procurement system for primaquine and other malaria commodities) is well functioning to ensure adequate stock availability.

### ACCELERATE EFFORTS TOWARDS MALARIA ELIMINATION TO ACHIEVE ACTIVE FOCI FREE STATUS IN RAMREE TOWNSHIP, RAKHINE STATE OF MYANMAR

Day Naing Aung<sup>1</sup>, Aung Thi<sup>2</sup>, Nu Nu Khin<sup>3</sup>, Hala J. AlMossawi<sup>4</sup>, Thant Zin Aung<sup>1</sup>, Arkar Htet<sup>1</sup>, Ye Thu Aung<sup>1</sup>, Khin Than Win<sup>5</sup>, Khin Mon Mon<sup>5</sup>, Ye Hein Naing<sup>5</sup>, Kyaw Myint Tun<sup>5</sup>

<sup>1</sup>*University Research Co., LLC, Toungup, Myanmar*, <sup>2</sup>*National Malaria Control Programme, Ministry of Health and Sports, Nay Pyi Taw, Myanmar*, <sup>3</sup>*PMI/USAID, Yangon, Myanmar*, <sup>4</sup>*University Research Co., LLC, Chevy Chase, MD, United States*, <sup>5</sup>*University Research Co., LLC, Yangon, Myanmar*

Ramree, the largest island in Rakhine State, has two more islands within the township territory. About 98,097 people reside in the 6 wards and 222 villages which contribute a total of 228 malaria reporting units as a whole township. Pilot malaria elimination activities were started in 2018 by the National Malaria Control Programme in collaboration with Defeat Malaria project of the University Research Co. with the support of the U.S. President's Malaria Initiative. After three years of implementing activities, 198 out of 228 villages (87% of total) achieved Annual Blood Examination Rate (ABER) of at least 10%. Out of 198 villages with adequate ABER, the villages were classified as 197 residual non-active foci and one active focus. Htauk Kyant Taw village, surrounded by mountainous forest and has 42 households with a population of 202, was classified as an active focus at the end of 2020 due to the occurrence of 1 indigenous, 1 imported, and 3 introduced cases. A village Malaria Worker (VMW) provides community-based malaria elimination activities. An entomological survey conducted in 2019 found primary vectors *An. dirus* and *An. minimus*. The index case (Pv) was detected on 4<sup>th</sup> November 2021 and immediately notified by the VMW and was classified as imported after conducting a case investigation in the next day by township response team. Foci investigation and response activities were initiated by the township response team within 7 days of case detection. An additional 3 Pv cases were detected on 19<sup>th</sup>, 22<sup>nd</sup>, and 23<sup>rd</sup> of November 2020 during reactive case detection (RACD). The last indigenous case was found in on 16<sup>th</sup> December 2020. Based on foci investigation, the accelerated efforts to interrupt the local transmission in the village comprised of RACD, filling the gaps after bed-nets coverage and utilization assessment, larval source management, mobility monitoring and provision of mosquito repellents to night-time forest goers. Building on this, it should be explored how Pv transmission dynamics would potentially impact the existing surveillance and response strategy for effective intervention of onward malaria transmission.

## ADAPTATION OF RAPID MULTI-OBJECTIVE LOT QUALITY ASSURANCE SAMPLING (LQAS) SURVEYS AS PART OF SEASONAL MALARIA CHEMOPREVENTION PROGRAMS IN BURKINA FASO, CHAD, NIGERIA AND MOZAMBIQUE FOR IDENTIFYING ISSUES AND DRIVING IMPROVEMENTS IN SMC DELIVERY

Sol Richardson<sup>1</sup>, Azoukalne Moukenet<sup>2</sup>, Taiwo Ibinaiye<sup>3</sup>, Adaeze Aidenagbon<sup>3</sup>, Benoit Sawadogo<sup>4</sup>, Cheick Compaore<sup>4</sup>, Junica M. De Macedo Alface<sup>5</sup>, Albertino Zunza<sup>5</sup>, Pedro Aide<sup>6</sup>, Kevin Baker<sup>1</sup>, Christian Rassi<sup>1</sup>, Helen Counihan<sup>1</sup>, Arantxa Roca-Feltrer<sup>7</sup>

<sup>1</sup>Malaria Consortium, London, United Kingdom, <sup>2</sup>Cheikh Anta Diop University, Dakar, Senegal, <sup>3</sup>Malaria Consortium, Abuja, Nigeria, <sup>4</sup>Malaria Consortium, Ouagadougou, Burkina Faso, <sup>5</sup>Malaria Consortium, Nampula, Mozambique, <sup>6</sup>The Manhiça Health Research Centre, Manhiça, Mozambique, <sup>7</sup>Malaria Consortium, Maputo, Mozambique

Malaria Consortium supports delivery of seasonal malaria chemoprevention (SMC) to children aged 3-59 months as monthly doses of sulfadoxine-pyrimethamine plus amodiaquine against *Plasmodium falciparum* malaria during the rainy season in several countries where transmission is highly seasonal, typically in four monthly cycles. In 2020, Malaria Consortium adapted the lot quality assurance sampling (LQAS) method for its end-of-cycle SMC monitoring surveys in Burkina Faso, Chad, Nigeria and Mozambique to measure quality of delivery across 16 indicators pertaining to SMC coverage, use of SMC Record Cards, dissemination of information on SMC to caregivers, and safe SMC implementation during the COVID-19 pandemic. LQAS data facilitated local assessment of program performance at the supervision area (SA) level using hypothesis tests to determine whether standards for one or more indicators were met. Targets and decision values were defined for each indicator. Districts were divided into SAs based on groups of health facility catchments, from which lots of 25 households were sampled; when numbers of households fell below the decision value for an indicator an issue was identified at the SA level. In all countries LQAS surveys were completed within two weeks of each of the first three cycles, giving time to process data, identify and prioritize issues, communicate issues to local stakeholders involved in SMC delivery, and engage them to implement improvements in distributor training and SMC delivery in the subsequent month's cycle. While overall programme coverage was high, coverage in some SAs was below the 80% target (e.g., in Chad cycle 3, coverage was 95% but the target was not met in 21/98 SAs). We compiled results for each indicator and attainment of targets; engaged with national, regional and local stakeholders; and noted changes to SMC delivery in some SAs. Results contributed to continuous improvement of SMC delivery. There were challenges in interpreting results and attributing causes of issues identified, identifying stakeholders in each country, and optimizing messaging to motivate further improvements to SMC delivery.

## COMMUNITY HEALTH COUNCILS FOR MALARIA ELIMINATION IN HAITI: LESSONS FROM A PILOT PROJECT IN GRAND ANSE DEPARTMENT

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>The Carter Center, Atlanta, GA, United States, <sup>3</sup>The Carter Center, Atlanta, GA, United States, <sup>4</sup>Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti, <sup>5</sup>Ministère de la Santé Publique et de la Population, Port au Prince, Haiti

Community engagement (CE) in vector-borne disease control and elimination, including malaria, is often more experimental, messy and adaptive than we anticipate. This paper examines the social construction and micro-politics of program design and implementation, focused on a volunteer-based CE model developed in Haiti as part of the Malaria Zero

Initiative. The study draws on quantitative and qualitative data collected from 23 Community Health Councils (CHCs) from 2018-2021 in Grand Anse, a malaria hotspot region in Haiti. Project plans were disrupted by political crisis, a severe weather event, administrative hurdles and COVID-19; this conspired to create a "natural experiment" where greater emphasis was placed on self-organization than intensive facilitation. Despite this, none of the 23 CHCs ceased functioning over a two-year period, and an average of 0.86 monthly meetings were held with a 78% attendance rate. A high degree of transparency and diversity in membership helped create strong micro-planning and involvement. CHCs conducted an average of 1.8 community-based activities per month, with high levels of fluctuation indicative of local ownership. This included school and church sensitization, environmental sanitation campaigns, mass education, support for case referrals and community mobilization during Mass Drug Administration and Indoor Residual Spraying. The nature of volunteerism and incentives were a constant topic of negotiation; members drew on the tradition of *konbit* (mutual self-help), local histories of health and development campaigns and a lexicon of "solidarity" in difficult times. Small incentives played both symbolic and supportive roles and some level of politicization was viewed as inevitable, even beneficial. Rumors about financial and political profiteering of CHC volunteers took time to dispel while the tendency towards vertical planning in malaria control created conditions to exclude CHCs from some activities. With the end of Malaria Zero in 2020, there is now an opportunity to monitor the continued self-sufficiency of CHCs in promoting anti-malaria activities within their communities.

## DEVELOPMENT OF A SECOND-GENERATION GENETICALLY ATTENUATED MALARIA VACCINE: EN ROUTE TO A FIRST CLINICAL TRIAL

Among different approaches to developing an effective malaria vaccine, immunisation with live, attenuated *Plasmodium falciparum* (Pf) sporozoites has so far induced the highest protective efficacy (>90%) in clinical trials. There are several approaches to immunisation with whole sporozoites (Wsp); the currently most advanced Wsp vaccine consists of sporozoites that have been attenuated by radiation (RAS). As an alternative to radiation attenuation, Wsp vaccine approaches are being developed based on the use of genetically attenuated sporozoites (GAP). The first generation of GAP, so-called early-arresting GAP (EA-GAP), abort their development within 2-3 days after invading liver cells and as such have a similar attenuation phenotype to RAS. We recently completed the world's first clinical safety and efficacy assessment of an EA-GAP malaria vaccine (GA1 vaccine). The GA1 was immunogenic and showed protective efficacy comparable to RAS immunization, although protective efficacy of both RAS and the EA-GAP in malaria-naïve Dutch individuals was lower than desired<sup>1</sup>. Thus, despite theoretical advantages, Wsp vaccines still require substantial improvement in order to further enhance their efficacy. One way to increase the immunogenicity and thus efficacy of Wsp vaccines is to broaden the array of antigens displayed to the immune system by extending the duration of parasite exposure to the immune system. In rodent malaria models it has been shown that GAP that arrest late during liver stage development (LA-GAP) induce significantly higher protective immune responses as compared to both RAS and EA-GAP, most likely resulting from increased antigen breadth and biomass of LA-GAP. We have therefore created an equivalent PflA-GAP that arrests late during liver stage development. We will report on the generation and pre-clinical testing of this PflA-GAP parasite and plans for the first clinical

trial to evaluate the safety and protective efficacy of a second-generation LA-GAP vaccine (GA2 vaccine) that arrest growth late during liver stage development. <sup>1</sup>Roestenberg, M. *et al. Science translational medicine* (2020)

PfSPZ Vaccine is comprised of radiation-attenuated, aseptic, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ). Clinical trials of PfSPZ Vaccine in >1700 5-month to 61-year-olds in the USA, Europe, and six African countries, including three trials in Equatorial Guinea (EG), have shown PfSPZ Vaccine to be safe and well-tolerated including in infants, children, adolescent, and HIV- and HIV+ adults. The vaccine has shown sustained (6-18 month) protection against naturally transmitted Pf in 4 separate field trials. We are now planning to demonstrate safety and vaccine efficacy (VE) in a Phase III randomized, double-blind, placebo-controlled trial of 2100, 2- to 50-year-olds living on Bioko Island, EG. Preparatory work for implementation is ongoing and has included a recently completed trial for down selection of an optimal regimen to be used for Phase III testing and licensure. The selected regimen, 3 doses of  $9.0 \times 10^5$  PfSPZ administered on days 1, 8 and 29, has given the best VE against homologous controlled human malaria infection (CHMI) and is practical for deployment as compared to longer 16-20 week regimens tested in earlier trials. Two epidemiological studies have been conducted to assess local (Bioko Island) malaria incidence and risk factors (EGMALEP) and to pilot recruitment and screening procedures while creating a registry of potential participants for the upcoming trial (EGRESPAR). The clinical protocol for this trial - EGSPZV4, has gone through ethical and regulatory reviews in the USA, Europe, and two African countries with positive opinion and approvals. EGSPZV4 is expected to begin during first or second quarter of 2022. Details of the design, follow-up schedule for safety and efficacy endpoints as well as implementation plan in the post COVID-19 era and milestones will be presented. In addition, critical issues related to development pathway, study endpoints in malaria pre-exposed volunteers, ethical and regulatory review will be discussed.

0294

### PHASE 2 SAFETY AND EFFICACY EVALUATION OF RADIATION ATTENUATED PLASMODIUM FALCIPARUM SPOOROZOITE (PFSPZ) VACCINE IN HEALTHY AFRICAN ADULT WOMEN OF CHILDBEARING POTENTIAL IN OUELESSÉBOUGOU, MALI

Halimatou Diawara

Icermal, Bamako, Mali

Sanaria® PfSPZ Vaccine, composed of radiation-attenuated, aseptic, purified, cryopreserved, *Plasmodium falciparum* (Pf) sporozoites (SPZ), is an advanced malaria vaccine candidate being developed for use in Africa, including in pregnant women. Previous studies of PfSPZ Vaccine in African infants, children and adults demonstrated an excellent safety profile with no differences in frequency or severity of adverse events (AEs) compared to normal saline (NS) controls. Vaccine efficacy (VE) over 6 months against naturally transmitted Pf infection calculated as 1 minus the hazard ratio in 3 studies was 48%, 51% and 52% in fully vaccinated adults. Accelerated regimens offer an advantage to pregnant women as they could confer protection earlier in pregnancy. This double blind NS placebo-controlled trial assessed safety and VE of  $9.0 \times 10^5$  or  $1.8 \times 10^6$  PfSPZ administered on accelerated 1, 8 and 29 day schedule. Women of childbearing potential were immunized before pregnancy, discontinued birth control following immunization and were followed for two years including during any subsequent pregnancies. 407 volunteers were screened June-July 2019, 324 enrolled and 300 were equally randomized to  $9 \times 10^5$  PfSPZ,  $1.8 \times 10^6$  PfSPZ or NS injected via direct venous inoculation (DVI). All were administered artemether/lumefantrine 2 weeks prior to 1<sup>st</sup> and 3<sup>rd</sup> vaccinations to clear any existing parasitemias. Vaccinations were well tolerated, with the majority of AEs classified as mild (Grade 1). There were no statistically significant differences between vaccines and controls for total AEs, related AEs, solicited AEs (local, systemic, individual), laboratory abnormalities, or vital sign changes. VE against Pf infection of fully vaccinated individuals per protocol was, was 41% (95% CI 14%-59%  $p=0.005$ ), in  $9 \times 10^5$  PfSPZ arm and 57% (95% CI 37%-71%,  $p<0.001$ ) in  $1.8 \times 10^6$  PfSPZ arm. Durability of VE was assessed during the 2020-2021 malaria transmission season, without further study product administered, and will be presented. These promising results set the stage for immunization during pregnancy to reduce the risk and deleterious consequences of pregnancy malaria.

0295

### PRODUCTION OF PFSPZ FOR MALARIA VACCINES IN A BIOREACTOR WITHOUT MOSQUITOES

**Abraham G. Eappen**, Peter F. Billingsley, Poojan Pyakurel, Tao Li, MingLin Li, Ayyappan Rathakrishnan, Alemtaye Yossef, Sumana Chakravarty, Christiane Tran, Yonas Abebe, Asha Patil, Lixin Gao, B. Kim Lee Sim, Stephen L. Hoffman

Sanaria Inc., Rockville, MD, United States

Sanaria has developed methods to produce *Plasmodium falciparum* (Pf) sporozoites (SPZ) *in vitro* (iPfSPZ) without mosquitoes to eventually replace mosquito-produced PfSPZ (mPfSPZ) in our PfSPZ-based vaccines. We produced hundreds of millions of iPfSPZ without mosquitoes in 12-well culture plates. iPfSPZ invade and develop *in vitro* to late liver stage parasites expressing Pf merozoite surface protein 1 (PfMSP1) in the 6-day hepatocyte potency assay using HC-04 cells and human primary hepatocytes as well, if not better than mPfSPZ, and to late liver stage parasites expressing PfMSP1 when injected into FRG mice with humanized livers at ~50% the efficiency of mPfSPZ. We have now progressed to a bioreactor system for producing iPfSPZ. Using a mini-bioreactor, we produced up to  $2.3 \times 10^8$  iPfSPZ per culture, and in a medium bioreactor that was 6.25 times larger, we produced up to  $1.5 \times 10^9$  iPfSPZ per culture. iPfSPZ expressed Pf circumsporozoite protein (PfCSP). Bioreactor-produced iPfSPZ were equal or better in potency compared to mPfSPZ in the 6-day *in vitro* hepatocyte potency assay. Importantly, for the first time, ~20% of the iPfSPZ were free in the supernatant of the culture harvest and not contaminated with the *Drosophila* S2 feeder cells used in the cultures.

We harvested up to  $1.58 \times 10^8$  free iPfSPZ from a mini-bioreactor in three independent experiments. These free iPfSPZ were PfCSP positive. This is an extremely important step forward which will facilitate the use of larger capacity bioreactors for mass production of free iPfSPZ and subsequent optimization of purification and cryopreservation of iPfSPZ for use in PfSPZ vaccines. By eliminating the need for mosquitoes and dissectors from manufacturing, the transition from mPfSPZ to iPfSPZ will dramatically increase the efficiency and consistency of production of PfSPZ vaccines, and reduce cost of goods by more than 90%.

0296

### PARASITE TARGETS OF PROTECTION INDUCED BY PfSPZ VACCINE: A WHOLE ORGANISM-BASED VACCINE AGAINST MALARIA

Ankit Dwiwedi<sup>1</sup>, Biraj Shrestha<sup>1</sup>, Kephaz Otieno<sup>2</sup>, Reuben Yego<sup>2</sup>, Simon Kariuki<sup>2</sup>, Andrea A. Berry<sup>1</sup>, Kirsten E. Lyke<sup>1</sup>, Shannon Takala-Harrison<sup>1</sup>, B. Kim Lee Sim<sup>3</sup>, Thomas L. Richie<sup>3</sup>, Stephen L. Hoffman<sup>1</sup>, Robert Seder<sup>4</sup>, Martina Oneko<sup>2</sup>, **Joana C. Silva<sup>1</sup>**

<sup>1</sup>Univ Maryland School Medicine, Baltimore, MD, United States, <sup>2</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>3</sup>Sanaria Inc, Rockville, MD, United States, <sup>4</sup>Vaccine Research Center, National Institutes of Health, Bethesda, MD, United States

A placebo-controlled efficacy study of Sanaria® PfSPZ Vaccine, composed of radiation attenuated, *Plasmodium falciparum* (Pf) sporozoites (SPZ), was conducted in 5-12 month olds in Western Kenya. This pre-erythrocytic vaccine did not induce detectable T cell responses and while there was 41% vaccine efficacy (VE) at 3 months in infants receiving the highest PfSPZ dose, no VE remained at 6 months. We were interested in determining if the genotype distribution of infecting Pf strains was identical in controls and vaccinees or if, instead, Pf genotypes observed differed between study arms. The former would be consistent with the absent T cell responses and lack of durable VE in these infants, while the latter would suggest genotype-specific vaccine-induced protection in a setting with high parasite genetic diversity and attack rate, enabling vaccine evasion. Isolates analyzed correspond to first infections in each infant, starting at 3 weeks post last immunization. Illumina short read data was generated from DNA extracted from leukocyte-depleted blood, and SNPs called according to best practices. Allele frequency distribution differences between Pf isolated from vaccinees in the high dose group (n=44) and controls (n=56) were estimated using  $F_{ST}$ . Of 21,738 bi-allelic, non-synonymous SNPs, 442 differed significantly between study arms ( $p < 0.05$ , permutation test, 5,000 replicates). They mapped to 338 genes, which were significantly enriched for membrane-associated cellular localization, as expected of antigens, and consistent with a sieve effect imparted by vaccine-induced protection. Unexpectedly, among these genes are several blood stage antigens, including apical membrane antigen-1 and rhoptry-associated membrane antigen. Although the results are partly consistent with genotype-specific PfSPZ Vaccine-induced protection, they could be confounded by factors such as variable previous exposure or the presence of maternal antibodies. To determine the main driver(s) of the patterns observed, bioinformatics analyses and immunological experiments are ongoing to characterize host responses to antigens/variants of interest.

0297

### PfSPZ VACCINE EFFICACY WITH AND WITHOUT ANTIMALARIAL PRE-TREATMENT-COMPARISON BETWEEN STUDIES

**Aye Sousa**

NIH/NIIAID, Bethesda, MD, United States

Sanaria® PfSPZ Vaccine, composed of aseptic, purified, radiation-attenuated *Plasmodium falciparum* (Pf) sporozoite (SPZ) of the NF54 strain, is an advanced malaria vaccine candidate used in multiple studies conducted in Mali. The vaccine has shown an excellent safety profile and significant vaccine efficacy (VE) at different dosages and schedules administered by direct venous inoculation (DVI). We previously reported

100% VE against controlled human infection with homologous NF54 parasites in individuals who did or did not receive antimalarial treatment with artesunate/amodiaquine (ASAQ) before PfSPZ Vaccine ( $1.8 \times 10^6$  PfSPZ at 0, 8 and 16 weeks) in Mali. A phase 1 study ("Study 1") in healthy adults investigated two PfSPZ Vaccine regimens ( $0.9 \times 10^6$  PfSPZ at 0, 1, 4 weeks versus  $0.9 \times 10^6$  PfSPZ at 0, 1, 4 weeks, with 2<sup>nd</sup> year booster doses); subjects received antimalarial treatment with artemether/lumefantrine (AL) pre-treatment before 3<sup>rd</sup> but not 1<sup>st</sup> or 2<sup>nd</sup> doses in Year 1 (2018) and before 4<sup>th</sup> dose in Year 2 (2019). A phase 2 study ("Study 2") in healthy adult women of childbearing potential investigated two PfSPZ Vaccine regimens ( $0.9 \times 10^6$  PfSPZ versus  $1.8 \times 10^6$  PfSPZ at 0, 1, 4 weeks) and subjects received AL pre-treatment before 1<sup>st</sup> and 3<sup>rd</sup> doses in Year 1 (2019). Follow-up for Pf infection in both studies for 24 weeks started immediately after 3<sup>rd</sup> dose. PfSPZ Vaccine was well-tolerated in all study arms, with no significant differences in AE profiles compared to placebo study arms. In Study 1, VE was not significant for either regimen versus normal saline (NS) placebo control group. In Study 2, VE was significant for both regimens versus NS group: VE 42% (95%CI 16-59,  $p=0.003$ ) after  $0.9 \times 10^6$  PfSPZ Vaccine; VE 56% (95%CI 36-70,  $p < 0.001$ ) after  $1.8 \times 10^6$  PfSPZ Vaccine. Notably, the regimen of  $0.9 \times 10^6$  PfSPZ Vaccine given at 0, 1, 4 weeks achieved significant VE in Study 2 but not Study 1. Taken together, these studies indicate that antimalarial pretreatment before initial doses of PfSPZ Vaccine is required to maximize protective immunity.

0298

### GIVING MALARIA VACCINATIONS THE ALL CLEAR: THE IMPORTANCE OF CLEARING ASEQUAL ERYTHROCYTIC STAGE PARASITEMIA BEFORE ADMINISTRATION OF PfSPZ VACCINES

**Peter F. Billingsley<sup>1</sup>**, On behalf of International PfSPZ Consortium<sup>2</sup>

<sup>1</sup>Sanaria Inc., Rockville, MD, United States, <sup>2</sup>International PfSPZ Consortium, Rockville, MD, United States

Symptomatic and asymptomatic malaria have been associated with decreased antibody responses to multiple vaccines; asexual erythrocytic stages of *Plasmodium falciparum* (Pf) are immunosuppressive. Results of controlled human malaria infection (CHMI) assessment of PfSPZ-CVac vaccine efficacy (VE) and field trial assessment of PfSPZ Vaccine and PfSPZ-CVac VE indicate that the presence of blood stage Pf at the time of immunization can eliminate vaccine-induced protection. When doses of  $5 \times 10^4$  PfSPZ of PfSPZ-CVac were administered at 5-day intervals, the 1<sup>st</sup> and 2<sup>nd</sup> doses were administered before development of blood stage parasitemia, and the 3<sup>rd</sup> dose was administered at the nadir of blood stage parasitemia from the 1<sup>st</sup> dose and before blood stage parasitemia from the 2<sup>nd</sup> dose; VE against CHMI 10 weeks later was 63%. When the same dosage was administered at 7-day intervals, the 2<sup>nd</sup> and 3<sup>rd</sup> doses were administered at the peak of blood stage parasitemia from the preceding dose and VE against CHMI 10 weeks later was 0. The mean peak parasitemias recorded by qPCR in this group with no protection were 1.7 and 1.6 parasites/ $\mu$ L after doses 1 and 2. In Africa, we have results of 8 clinical trials of PfSPZ Vaccine or PfSPZ-CVac in infants to adults. In 5 of these trials in Mali and Burkina Faso, blood stage parasitemia was cleared presumptively before the first immunization; in all 5 of these clinical trials there was statistically significant VE against field transmission of Pf during the next 6 months (42% to 56% VE). In 3 trials in Mali and Kenya, blood stage parasitemia was not cleared presumptively and VE against Pf infection during the next 6 months was not statistically significant. Results from a clinical trial in Gabonese children who did not receive presumptive treatment before dose 1 are still blinded. These data indicate immunosuppression caused by asexual erythrocytic stage infection, even at submicroscopic levels, significantly reduces the VE of PfSPZ vaccines, and provide a compelling imperative for the clearing of blood stage Pf parasitemia in study subjects prior to the start of clinical trials of any PfSPZ vaccine, and potentially any malaria vaccine.

0299

### SAFETY AND PROTECTIVE EFFICACY OF PfSPZ-CVAC (PYR) VACCINATION AGAINST PLASMODIUM FALCIPARUM INFECTION IN HEALTHY ADULTS IN BANCOUNAMA, MALI

**Maiga Mahamadoun H. Assadou<sup>1</sup>**, David Cook<sup>2</sup>, Issaka Sagara<sup>1</sup>, Kourane Sissoko<sup>1</sup>, Sibiri Sissoko<sup>1</sup>, John Woodford<sup>2</sup>, Amatigue Ziguime<sup>1</sup>, Seydou Sankare<sup>1</sup>, Sadio Koni Diarra<sup>1</sup>, Mamady Kone<sup>1</sup>, Sintry Sanogo<sup>1</sup>, Moussa Bamaba Kanoute<sup>1</sup>, Sara Anne Healy<sup>2</sup>, Imeru Alemush<sup>2</sup>, Emily Higbee<sup>2</sup>, Mahamadou Soumana Sissoko<sup>1</sup>, Jacquelyn Lane<sup>2</sup>, B Kim Lee Sim<sup>3</sup>, Thomas L. Richie<sup>4</sup>, Stephen L. Hoffman<sup>4</sup>, Patrick Duffy<sup>2</sup>

<sup>1</sup>International Center for Excellence in Research (ICER), Mali, Bamako, Mali, <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology (LMIV), Bethesda, MD, United States, <sup>3</sup>Protein Potential, LLC, Rockville, MD, United States, <sup>4</sup>Sanaria Inc, Rockville, MD, United States

We assessed safety and vaccine efficacy (VE) of Chemoprophylaxis Vaccination (CVac) against naturally transmitted *Plasmodium falciparum* (Pf) infection in a Phase 2 randomized double blind placebo-controlled study in Mali. PfSPZ-CVAc comprised 3 doses of 4.0x10<sup>5</sup> PfSPZ Challenge [NF54] (aseptic, purified, cryopreserved, infectious Pf sporozoites [SPZ]) administered by direct venous inoculation (DVI) at 0, 4, and 8 weeks combined with oral pyrimethamine (PYR) and, pending an interim analysis of Year 1 efficacy, of a 4<sup>th</sup> (booster) dose given in Year 2. In 2019, we randomized 240 adults to 4 arms to receive artemether/lumefantrine pre-treatment and then PfSPZ Challenge (V) or normal saline placebo (P) DVI: Arms V<sub>0</sub> (n=90) and P<sub>0</sub> (n=54) received 75mg of oral PYR on day of DVI (day 0) while Arms V<sub>2+3</sub> (n=60) and P<sub>2+3</sub> (n=36) received 75mg of oral PYR on days 2 and 3 post-DVI. After 3<sup>rd</sup> vaccination, participants were monitored for Pf by thick blood smear (TBS) every two weeks for 24 weeks. As previously reported, PfSPZ-CVAc was safe and well tolerated, with two SAEs unrelated to study procedures (intestinal volvulus and death by rifle injury). Of 1651 adverse events (AEs), 1.2% (19/1651) were grade 3, and 3 of these (all neutropenia) were considered possibly related. Grade 1 and 2 AEs frequencies were respectively 35.01% (578/1651) and 63.8% (1053/1651), mostly lab abnormalities or episodes of rhinitis that were unrelated. In an interim analysis, significant VE was observed in at least one of interventional main phase arms, which allowed the booster phase in 2020. After 4<sup>th</sup> vaccination, participants were again monitored for Pf by thick blood smear every two weeks for 24 weeks. The booster phase is now complete and final VE analyses are underway. We will present safety and VE results as well as immunology data. Sanaria PfSPZ CVAc (PYR) dosed at 4.0x10<sup>5</sup> was safe and well-tolerated and at least one dosing regimen of PYR or both showed protective efficacy against Pf infection in adults in Bancoumana, Mali. This is the first demonstration of VE in a field trial of PfSPZ-CVAc.

### IMPACT OF COVID-19 ON PLANNED AND ONGOING PfSPZ VACCINE CLINICAL RESEARCH AND SITE MITIGATION STRATEGIES IN BIKO ISLAND, EQUATORIAL GUINEA IN 2020

**Marta Alene Owono Eyang<sup>1</sup>**, Vicente Urbano Ndong<sup>1</sup>, Maria Silvia Angue Mikie<sup>1</sup>, Wonder P. Phiri<sup>2</sup>, Raul Chuquiyauro Haro<sup>2</sup>, Juan Carlos Momo<sup>2</sup>, L.W. Preston Church<sup>3</sup>, Laurence Lemiale<sup>4</sup>, Thomas Richie<sup>4</sup>, Guillermo A. Garcia<sup>5</sup>, Peter Billingsley<sup>6</sup>, Claudia Daubenberger<sup>7</sup>, Kamaka Kassim<sup>8</sup>, Stephen L. Hoffman<sup>4</sup>, Said Jongu<sup>8</sup>

<sup>1</sup>Ministry of Health and Social Welfare, Malabo, Equatorial Guinea, <sup>2</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>3</sup>Sanaria Inc., Rockville, MD, United States, <sup>4</sup>Sanaria Inc, Rockville, MD, United States, <sup>5</sup>Medical Care Development International, Silver Spring, MD,

United States, <sup>6</sup>Sanaria Inc., Rockville, MD, United States, <sup>7</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>8</sup>Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania

The world has been impacted by the 2019 novel coronavirus SARS-CoV-2 and the resulting disease, "COVID-19". The current containment efforts in Equatorial Guinea and the world at large have disrupted the implementation of ongoing and planned clinical research of the Bioko Island Malaria Elimination Program (BIMEP). BIMEP executes the study entitled "Pilot Study to Optimize Recruitment and Screening Procedures for Future Clinical Trials and to Create a Registry of Potential Research Participants on Bioko Island, Equatorial Guinea" (EGRESPAR) and plans to conduct a Phase 3 clinical trial of Sanaria® PfSPZ Vaccine on Bioko Island, initially planned to start in 2020 with enrolment of 2100 research subjects, aged 2 to 50 years. Clinical trial execution during the pandemic could significantly increase risk to study participants and study staff by creating opportunities for SARS-CoV-2 transmission, thereby seeding communities with infected individuals. Therefore, we continue to document how the COVID-19 pandemic has impacted upon BIMEP and the mitigation strategies to minimize this effect. We will use qualitative techniques to analyse study documents and reports to gain a broad understanding of the situation. The impact of the COVID-19 pandemic will be described in terms of the financial impact on the program, monitoring of participant safety and willingness to participate, potential loss of experienced staff, and the delays to the clinical trial schedule.

### PfSPZ-LARC1 VACCINE, A PLASMODIUM FALCIPARUM SPOOROZITE VACCINE GENETICALLY ATTENUATED TO ARREST AT THE LATE LIVER STAGE

**B. Kim Lee Sim<sup>1</sup>**, Tao Li<sup>1</sup>, Debashree Goswami<sup>2</sup>, Nelly Camargo<sup>2</sup>, Asha Patil<sup>1</sup>, Yonas Abebe<sup>1</sup>, Janna Armstrong<sup>2</sup>, Will Betz<sup>2</sup>, Ayyappan Rathakrishnan<sup>1</sup>, Donald Ward<sup>1</sup>, Christiane Urgena<sup>1</sup>, Ashley Vaughan<sup>2</sup>, Stephen L. Hoffman<sup>1</sup>, Stefan Kappe<sup>2</sup>

<sup>1</sup>Sanaria Inc., Rockville, MD, United States, <sup>2</sup>Seattle Children's Research Institute, Seattle, WA, United States

There has been little to no change in the numbers of cases and deaths caused by malaria in the past 5 years. A vaccine is needed. An ideal vaccine would prevent infection, thereby preventing all clinical manifestations and transmission of malaria. 100% vaccine efficacy (VE) against heterologous controlled human malaria infection (CHMI) 12 weeks after last dose has been achieved by immunizing subjects taking chloroquine (CQ) chemoprophylaxis with 3 doses of 2x10<sup>5</sup> aseptic, purified, cryopreserved Pf sporozoites (SPZ) (Sanaria® PfSPZ Challenge). This is the best VE ever achieved against heterologous CHMI. This vaccine, known as PfSPZ-CVAc, is limited because there is 1) full development of the liver stage and transient parasitemia after the 1st dose which can cause malaria-like symptoms and 2) risk of uncontrolled infection if CQ is not properly taken or absorbed. To produce a vaccine with the strengths, but not the drawbacks of PfSPZ-CVAc, we have genetically engineered PfNF54 parasites so that PfSPZ invade hepatocytes and develop to the late liver stage normally, and then arrest in development. This was done by deletion of the gene encoding Plasmei2, an essential protein exclusively expressed in the late liver stage. Challenge with these late arresting replication competent (LARC) PfSPZ in FRG mice containing humanized livers showed complete attenuation. We now report that we have robustly produced this PfSPZ-LARC1 vaccine in aseptic mosquitoes. The fresh PfSPZ-LARC1 had a viability of 98%, and in a 6-day *in vitro* human hepatocyte assay, aseptic, purified, cryopreserved PfSPZ-LARC1 invaded and developed as expected to late liver stage parasites expressing PfMSP1 comparably to wild-type PfSPZ. All GMP manufacturing process steps previously used are suitable for manufacture of PfSPZ-LARC1. We will report on our IND-directed activities, production of a GMP clinical lot, quality control release of the lot, and design of and plans for clinical trials in the US and Germany to assess safety, immunogenicity and VE of PfSPZ-LARC1 Vaccine.

### TOWARDS HUMAN USE OF A GLYCOLIPID ADJUVANT FOR PLASMODIUM FALCIPARUM SPOOROZITE (SPZ)-BASED VACCINES AGAINST MALARIA

Sumana Chakravarty<sup>1</sup>, Natasha KC<sup>1</sup>, Urvashi Rai<sup>1</sup>, Moriya Tsuji<sup>2</sup>, Sean C. Murphy<sup>3</sup>, B. Kim Lee Sim<sup>1</sup>, Anita B. Manoj<sup>1</sup>, Stephen L. Hoffman<sup>1</sup>

<sup>1</sup>Sanaria Inc., Rockville, MD, United States, <sup>2</sup>Aaron Diamond AIDS Research Center, Department of Medicine, Columbia University Irving Medical Center, New York, NY, United States, <sup>3</sup>Department of Laboratory Medicine, University of Washington, Seattle, WA, United States

We are working to further enhance *Plasmodium falciparum* (Pf) sporozoite (SPZ)-based vaccines against malaria. In malaria naïve individuals, PfSPZ Vaccine demonstrated 100% vaccine efficacy (VE) at 12 weeks after last vaccine dose against controlled human malaria infection (CHMI) with heterologous Pf and 46% to 56% VE lasting 6 to 18 months in adults in Africa against intense transmission of heterogeneous Pf. Using a unique glycolipid adjuvant 7DW8-5, our goal has been to prolong the duration of VE and to increase efficacy in endemic settings. In a mouse model using *P. yoelii* (Py) SPZ, we had achieved greater than 80% protection at 16 weeks with 2 dose and 4 dose accelerated regimens of irradiated (irr) PySPZ plus 7DW8-5 adjuvant administered by direct venous inoculation (DVI) representing a 2-fold enhancement over irr PySPZ without adjuvant. The adjuvant can be mixed with irr PySPZ. High level (>80%) protection of mice persisted at 16 weeks with irr PySPZ administered by DVI, in the presence of 7DW8-5, but not by non-DVI routes. Manufacturing of 7DW8-5 under cGMPs was completed and in a pilot study with *P. knowlesi* (Pk) SPZ, irr PkSPZ we achieved 50% VE, but no improvement with the adjuvant, likely attributable to sub-optimal comparative dose or dosing regimens, or the short-term infectious challenge design. However, we demonstrated an excellent safety profile of the combined PkSPZ-adjuvant vaccine in NHPs. Body weights remained constant throughout the study with no changes in physical, or behavioral patterns indicating pain or distress in animals injected with the adjuvant. In addition, a 58-parameter chemistry panel was assessed at baseline and after the 2<sup>nd</sup> and 3<sup>rd</sup> vaccination, and no abnormalities were noted. With regard to functionality, in a co-culture system with human iNKT cells *in vitro*, the GMP adjuvant exhibited comparable bioactivity with research grade product, paving the way for further confirmatory studies in animal models. Our efforts represent steps toward the first development of an adjuvant for a live eukaryotic parasite vaccine.

### ASSESSING THE BEHAVIOURAL AND PHYSIOLOGICAL EFFECTS OF PIPERONYL BUTOXIDE (PBO) EXPOSURE ON ANOPHELES GAMBIAE

Rhosheen S. Mthawanji<sup>1</sup>, Hilary Ranson<sup>2</sup>, Geraldine Foster<sup>2</sup>, Themba Mzilahowa<sup>3</sup>, Christopher Jones<sup>1</sup>

<sup>1</sup>Malawi Liverpool Wellcome Trust, Blantyre, Malawi, <sup>2</sup>Liverpool School of Tropical medicine, Liverpool, United Kingdom, <sup>3</sup>MAC Communicable Diseases Action Centre, College of Medicine, Blantyre, Malawi, Blantyre, Malawi

Long lasting insecticidal nets (LLINs) remain one of the frontline tools in malaria vector control, however due to insecticide resistance, Piperonyl butoxide (PBO) has been incorporated into LLINs. These LLINs have been deployed around Africa and have proven to be efficient in areas that have resistant vectors. However, a knowledge gap exists when it comes to the interactions between the vectors and PBO LLINs. This project assessed the impacts of exposure to PBO-LLINs and PBO-alone on *Anopheles gambiae* s.l. with focus on longevity, host-seeking behaviour, and reproductive capacity in a laboratory environment. A baited-box video assay was used to assess the behavioural responses of susceptible lab reared *Anopheles gambiae* to three different net types: untreated, deltamethrin only and PBO- deltamethrin. The mosquitoes were then observed post assay for longevity. The sublethal effects of PBO alone on both male and female

mosquitoes was observed using the WHO tube assay. The effects of PBO on blood-feeding and longevity were characterized. An Olfactometer was then used to quantify host-seeking behavior. There were significant differences between the time spent blood-feeding on both the strains. However, no differences were seen for the time taken before the mosquito appears in the box. For both the Kisumu and Banfora strains, longevity significantly differed between the net types (Kisumu,  $X^2=128.0$ ,  $df=2$ ,  $P < 0.0001$ ; Banfora  $X^2=114.3$ ,  $df=2$ ,  $P < 0.0001$ ). WHO tube assay results showed that where blood-feeding was allowed immediately after exposure there was a significant reduction in feeding ( $X^2=429.0$ ,  $df=7$ ,  $P < 0.0001$ ). Male mosquitoes lived nearly three times as long if exposed to control papers rather than those treated with PBO ( $\chi^2 = 66.1$ ,  $df = 1$ ,  $p = 0.0001$ ). The Olfactometer assay confirmed that mosquitoes that are exposed to PBO are less likely to seek a host successfully. In conclusion, the PBO LLINs show efficacy against both resistant and susceptible mosquitoes in lab-based assays. This study highlights that PBO remains an important compound in the fight against resistance in malaria vectors

### EFFECT OF MASS-DISTRIBUTION CAMPAIGN OF INSECTICIDE-TREATED NETS AND INDOOR RESIDUAL SPRAYING ON ENTOMOLOGICAL MEASURE OF MALARIA TRANSMISSION IN BURUNDI

Virgile Gnanguenon<sup>1</sup>, Denis Sinzinkayo<sup>2</sup>, Louise Mahana<sup>3</sup>, Jeanne d'Arc Ntiranyibagira<sup>3</sup>, Jenny Carlson<sup>4</sup>, Akililu Seyoum<sup>5</sup>

<sup>1</sup>U.S President's Malaria Initiative, VectorLink project, Bujumbura, Burundi, <sup>2</sup>University of Burundi and National Malaria Control Program, Bujumbura, Burundi, <sup>3</sup>U.S President's malaria Initiative, Bujumbura, Burundi, <sup>4</sup>U.S President's malaria Initiative, United States Agency for International Development, Bureau for Global Health, Bujumbura, NC, United States, <sup>5</sup>PMI VectorLink Project, Abt Associates, Washington, CA, United States

Malaria is the main public health challenge in Burundi with a high incidence of the disease. Insecticide treated nets (ITNs) and indoor residual spraying (IRS) are the main vector control interventions in the country. *Anopheles gambiae* s.l. and *An. funestus* s.l. represented the major malaria vectors in the country. In December 2019, a mass-distribution campaign of ITNs was conducted in all the eighteen provinces of the country. All provinces received a standard deltamethrin-based ITN (Yorkkool), except Kirundo province where piperonyl butoxyde (PBO) ITNs (Permanent 3.0) were distributed. IRS was only conducted in Ngozi and Muyinga provinces in October 2019. Monthly entomological surveys were conducted before (October 2018-September 2019) and after the implementation of vector control interventions (October 2019-September 2020) in eight sentinel sites (including one which received both IRS and ITNs) using human landing catches (HLC). The highest Entomological Inoculation Rate (EIR) based on HLC was observed in December 2020 just before the distribution of ITNs with 11.32 infective bites/person/month, while the highest EIR after the ITN mass campaign was 2.81 infective bites/person/month and observed in March 2020. In general, in most of the sentinel sites EIR was reduced after the implementation of vector control interventions with an average EIR of 8.88 infective bites/person/month before the ITN mass campaign versus 1.09 infective bites/person/month after the campaign ( $p < 0.0001$ ). The average parous rates were 79.34% (95% CI: 77.47-81.10) for *An. gambiae* s.l. populations and 76.75% (95% CI: 72.53-80.60) for *An. funestus* s.l. Parity was significantly lower as compared to the rate in 2019 before the ITN mass campaign with 84.31% for *An. gambiae* s.l. ( $p < 0.0001$ ) and 83.27% ( $p = 0.013$ ) for *An. funestus* s.l., suggesting impact on the older population of the malaria vectors that would potentially transmit malaria in the community. The results demonstrated a reduction in malaria transmission risk after the implementation of the two vector control interventions.

### TARGETING STRONGLY INSECTICIDE RESISTANT ANOPHELES FUNESTUS BY USING IVERMECTIN BASED ATTRACTIVE TOXIC SUGAR BAITS IN THE SEMIFIELD SYSTEM

**Felician Clement Meza**<sup>1</sup>, Letus L. Muyaga<sup>1</sup>, Polius G. Pinda<sup>1</sup>, Nuru S. Nchimbi<sup>1</sup>, Frederic Tripet<sup>2</sup>, Sarah J. Moore<sup>3</sup>, Fredros O. Okumu<sup>1</sup>  
<sup>1</sup>Ifakara Health Institute, Ifakara, Morogoro, United Republic of Tanzania, <sup>2</sup>Keele University, Centre for Applied Entomology and Parasitology, ST5 5BG, Staffordshire, United Kingdom, <sup>3</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania

Vector control strategies are crucial for malaria elimination. Each current vector control tool has its own set of limitations and additional new tools with novel active ingredients (AI) or modes of action to work synergistically with current tools are required. Attractive Toxic Sugar Baits (ATSBs) which exploit mosquito sugar feeding behavior to lure individuals into a bait station treated with a killing agent have proven to be effective in controlling malaria vectors. But little is known if ATSB can control *Anopheles funestus*. Here we evaluated the efficacy of a cost-effective ivermectin-based ATSB as an intervention for controlling *An. funestus* in the semi-field. A 3x3x2 m cage was constructed with 4 separate chambers. Four ATSB containers with only sugar meals were put at each corner on the ground floor, inside the chambers. 100 female *An. funestus* were released in each chamber and left there for 7 days, while only given sugar meal, scoring fed and dead mosquitoes daily. After 7 days, two chambers were used as treatment and the other two chambers remained as control with the addition of 100 female *An. funestus* to each chamber. The number of mosquitoes sugar-fed or dead was recorded daily. The survival rate of *An. funestus* were similar in all chambers before the introduction of 0.01% ATSB container on day 7 and lower in the treatment chamber shortly after the introduction of ATSB container, suggesting an impact of ATSB on the survival rate of *An. funestus*. A significant difference in *An. funestus* survival between the control and treatment chambers was observed ( $P = 0.0025$ ). The feeding success was 61% in both chambers within 24 hrs. *An. funestus* were susceptible to pirimiphos-methyl, but resistant to all pyrethroids commonly used on LLINs. In conclusion, *An. funestus* can feed on ivermectin-based ATSB, and subsequently affects their survival rate in the semi-field. Therefore, targeting this strongly insecticide-resistant and endophilic *An. funestus* using ivermectin-based ATSB indoor is very crucial towards malaria control and elimination, and further field trials are necessary to assess its efficacy in a real environment.

0306

### THE TRIPARTITE RELATIONSHIP BETWEEN ANOPHELES ARABIENSIS' GUT MICROBIOME, 20-HYDROXYECDYSONE (20E) SIGNALING, AND VECTORIAL CAPACITY

**Elodie Ekoka**<sup>1</sup>, Luisa Nardini<sup>1</sup>, Yael Dahan-Moss<sup>2</sup>, Lizette Leonie Koekemoer<sup>1</sup>

<sup>1</sup>University of the Witwatersrand, Johannesburg, South Africa, <sup>2</sup>National Institute for Communicable Diseases, Johannesburg, South Africa

20-hydroxyecdysone (20E) agonists have emerged as promising insecticides to target malaria vectors. Indeed, they can reduce *Anopheles* mosquitoes numbers even in areas with high levels of pyrethroid resistance. These agonists bind to *EcR*, mosquitoes' 20E receptor, and activate 20E signaling. Whether 20E agonists can target mosquitoes that have fed on antibiotics-containing blood is still unknown. Addressing this question is essential since antibiotic-fed *An. gambiae* females are more fertile. Therefore, the over-prescription of antibiotics observed in African countries may contribute to their high number of mosquitoes and malaria transmission. Here, we explored the relationship between *An. arabiensis*' 20E signaling, gut bacteria, and reproductivity. First, we tested if *EcR* levels and the gut bacterial load are linked. For this purpose, we (i) measured *EcR* expression post-blood meal, a time where the gut bacteria proliferates, (ii) quantified the gut bacteria after depleting *EcR* with RNA interference, and (iii) assessed if antibiotic-fed mosquitoes have fewer *EcR* transcripts. We found that *EcR* expression is significantly induced post-blood meal, and *EcR*

transcript levels correlate with gut bacterial load, notably bacteria of the Enterobacteriaceae and Acetobacteriaceae family. Next, we investigated how 20E titers regulate gut bacteria. Mosquitoes were injected with 20E, and the expression of ten *Imm* pathway-related immune genes was measured at different time points post-injection. Strikingly, 20E injection initially decreased the expression of these genes but later increased their expression, probably to maintain bacteria homeostasis. Our last objective explored if the gut bacteria affect how 20E signaling regulates mosquitoes' reproductivity. We thus compared the reproductivity of *EcR*-depleted aseptically and septic mosquitoes. Both fecundity and fertility were equally affected by *EcR*-depletion, regardless of mosquitoes' gut bacteria load. Altogether, *EcR*'s ability to regulate *An. arabiensis*' reproductivity suggests that 20E agonists could effectively control malaria vectors in Africa.

0307

### LONG-ACTING IVERMECTIN AGAINST MALARIA: A ONE-HEALTH APPROACH CONSIDERING ECOLOGICAL SIDE-EFFECTS OF TREATED PERIDOMESTIC ANIMALS

**Andre Patrick Heinrich**<sup>1</sup>, Alexandra Schinzel<sup>1</sup>, Si Hermann Pooda<sup>2</sup>, Lamidi Zela<sup>2</sup>, Christophe Roberge<sup>3</sup>, Karine Mouline<sup>4</sup>, Rolf-Alexander Düring<sup>1</sup>

<sup>1</sup>Institute of Soil Science and Soil Conservation, Research Center for Biosystems, Land Use and Nutrition, Justus Liebig University (JLU) Giessen, Giessen, Germany, <sup>2</sup>Centre International de Recherche-Developpement sur Elevage en zone Subhumide (CIRDES) - University de Adougou, Bobo-Dioulasso, Burkina Faso, <sup>3</sup>MedinCell, Jacou, France, <sup>4</sup>Institut de Recherche pour le Developpement (IRD), Montpellier, France

In Burkina Faso, the ANIVERMATE project investigates the treatment of peridomestic animals (cattle) with ivermectin (IVM) as complementary malaria vector control. However, excreted veterinary drugs can enter the environment and burden ecosystems. Therefore, we consider ecological consequences of excreted residues. We monitored IVM concentrations in dung of Zebu cattle, treated with either an innovative injectable long-acting depot (MedinCell's Bepo® technology, see companion abstract by Pooda *et al.*) or monthly injections of a commercial IVM formulation (Ivomec®). IVM treatments were designed to last six months. In addition to residues in fresh dung, we studied the environmental fate of IVM in stored dung and conducted sorption studies with soil samples from local villages. The Bepo® depot resulted in significantly lower IVM peak concentrations in cattle dung. Excreted IVM showed a bimodal curve with moderate fluctuations over the trial period. Monthly injections of Ivomec® peaked within 7 days after each injection, followed by exponential decline. Ecotoxicological effects of excreted IVM on dung-dependent organisms are common. For adult species of Coleoptera and Diptera, IVM in dung appears to be of lower toxicity. Due to uniformly moderate IVM dung concentrations with the depot formulation compared to fluctuating concentrations with Ivomec® injections, the depot induces less toxicity for larvae of dung organisms that can tolerate concentrations in a medium range. However, for more sensitive larvae, the prolonged exposure to toxic IVM concentrations in fresh dung warrants further ecotoxicological investigation. More knowledge on local dung/soil fauna is desirable. After 3 months of dung storage, IVM displayed low degradation. Soil sorption studies revealed strong sorption, indicating high hydrophobicity of IVM. ANIVERMATE highlights the importance of integrating ecological risk assessment with regards to a One-Health approach. A long-acting depot administered in cattle may provide a complementary and reliable mosquito control with manageable ecological side-effects to reduce impacts on agricultural production.

## BIOEFFICACY OF CLOTHIANIDIN AND PIRIMIPHOS METHYL IN NORTH WESTERN LAKE ZONE REGIONS IN TANZANIA TO CONTROL PYRETHROID RESISTANT MALARIA VECTORS

**Karen Nelwin Zablon**<sup>1</sup>, Charles Kakilla<sup>1</sup>, Jackline Martine<sup>1</sup>, Safari Kinung'hi<sup>1</sup>, Eric Lyimo<sup>1</sup>, Coleman Kishamawe<sup>1</sup>, Doris Mangalu<sup>1</sup>, Lucy Bernard<sup>1</sup>, Chonge Kitojo<sup>2</sup>, Naomi Serbantez<sup>2</sup>, Erik Reaves<sup>2</sup>, Dismas Mwalimu<sup>3</sup>, Shabbir Lalji<sup>4</sup>, Humphrey Mkali<sup>4</sup>, Joseph J. Joseph<sup>4</sup>, Adeline Chan<sup>5</sup>, Bilali Kabula<sup>4</sup>, Ssanyu Nyinondi<sup>4</sup>, Erin Eckert<sup>6</sup>, Richard Reithinger<sup>6</sup>, Alphaxard Manjurano<sup>1</sup>

<sup>1</sup>National Institute for Medical Research, Mwanza, United Republic of Tanzania, <sup>2</sup>US President's Malaria Initiative, CDC, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>National Malaria Control Program, Ministry of Health, Community Development, Gender, Elderly and Children, Dodoma, United Republic of Tanzania, <sup>4</sup>USAID-Okoa Maisha Dhibiti Malaria Project, RTI International, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>President's Malaria Initiative and Centers for Disease Control and Prevention, CDC, Atlanta, GA, United States, <sup>6</sup>RTI International, Washington, DC, United States

The aim of this study was to assess the residual efficacy of clothianidin and pirimiphos-methyl (p-methyl) used as indoor residual spray (IRS) on different wall surfaces inside houses and their effectiveness in controlling malaria vectors in Tanzania from October 2019 to September 2020. WHO wall cone and fumigant bioassays were conducted monthly for 12 months with laboratory susceptible *An. gambiae* s.s. Kisumu strain on different wall surface types sprayed with either clothianidin or p-methyl. The walls were mud, oil or water painted, lime washed, unplastered cement and burnt bricks. Claypots, CDC light traps, Prokopack aspirators and collection bottle rotators with CDC light traps were used during monthly entomological surveillance conducted in 10 districts (6 IRS and 4 without IRS as control). Collected mosquitoes were identified morphologically and sibling species identified by PCR. Mean mortality on all wall surface types was above the 80% WHO threshold for eleven months post-IRS with clothianidin. All p-methyl-sprayed wall surfaces had a mean mortality above 80% post-IRS for seven consecutive months. There was no significant variation among different wall surfaces ( $p > 0.05$ ). A total of 39,686 female *Anopheles* mosquitoes were collected and morphologically identified as *An. gambiae* s.l. (71.9%), *An. funestus* s.l. (21.7%), *An. coustani* (3.7%), *An. pharoensis* (1.8%) and *An. rufipes* (0.9%). Molecular identification conducted on 23,961 mosquitoes revealed the local malaria vector population was predominated by *An. funestus* s.s. (40.9%), *An. arabiensis* (37.6%), *An. gambiae* s.s. (15.7%) and *An. parensis* (1.1%). In sprayed sites, *An. funestus* were predominant before IRS and *An. arabiensis* after IRS. *An. funestus* s.s. was predominant in unsprayed control sites. The average pre-IRS sporozoite rate was 1.6 and reduced to 0.9 after spraying. The sporozoite rate remained higher (1.8%) in unsprayed sites ( $p < 0.01$ ). Clothianidin and p-methyl remained efficacious on all types of sprayed wall surfaces post-IRS during peak transmission season. IRS with these insecticides has significantly reduced sporozoite rates in *Anopheles* vectors.

## TWO-YEAR ENTOMOLOGICAL SURVEILLANCE RESULTS FROM A CLUSTER-RANDOMIZED CONTROLLED TRIAL ASSESSING THE EFFICACY OF DUAL ACTIVE INGREDIENTS LONG-LASTING INSECTICIDAL NETS (LLINS) IN MISSUNGWI DISTRICT, SOUTH-WESTERN TANZANIA

**Dr. Nancy S. Matowo**<sup>1</sup>, Dr. Louisa A. Messenger<sup>1</sup>, Dr. Manisha A. Kulkarni<sup>2</sup>, Mohamed Jumanne<sup>3</sup>, Jackline Martin<sup>3</sup>, Jacklin F. Mosha<sup>3</sup>, Gladness Isaya<sup>4</sup>, Boniface Shirima<sup>4</sup>, Dr. Robert Kaaya<sup>4</sup>, Dr. Mark Rowland<sup>1</sup>, Dr. Alphaxard Manjurano<sup>3</sup>, Dr. Franklin W. Mosha<sup>4</sup>, Dr. Natacha Protopopoff<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, London, United Kingdom, <sup>2</sup>University of Ottawa, Ottawa, ON, Canada, <sup>3</sup>National Institute for Medical Research, Mwanza, United Republic of Tanzania, <sup>4</sup>Kilimanjaro Christian Medical University College, Moshi, United Republic of Tanzania

The effectiveness of current malaria vector control tools mainly pyrethroids-based long-lasting insecticidal nets (LLINs) and indoor residual spraying (IRS) is threatened by the widespread pyrethroid resistance in malaria vectors. Next-generation LLINs with two novel active ingredients of different mode of actions were evaluated against malaria transmitted by pyrethroid-resistant vector mosquitoes in Missungwi district, North-western Tanzania. A 2-year single-blind, four arm cluster-randomized controlled trial was conducted to evaluate the efficacy of dual-active LLINs compared to the standard pyrethroid-LLIN on density, and entomological inoculation rates of malaria vectors across 84 study clusters. Indoor light trap collections were carried out quarterly in eight houses in each cluster that received study interventions, between February 2019 and December 2020. Dual-active LLINs deployed included Royal Guard®, a mixture LLIN combining pyriproxyfen and the pyrethroid alpha-cypermethrin; Olyset® Plus, a mixture LLIN combining the synergist piperonyl butoxide and the pyrethroid permethrin; Interceptor® G2, a mixture LLIN contains chlorfenapyr and alpha-cypermethrin in comparison with a standard LLIN that contains alpha-cypermethrin alone. All *Anopheles* mosquitoes sampled were morphologically identified to species or species group, and a subset of malaria vectors were further tested for *Plasmodium falciparum* circumsporozoite protein and identified to sibling species using polymerase chain reaction. Analysis of mosquito's outcomes by interventions and dual active LLINs will be presented. Together with the epidemiological outcomes, the findings will provide the first body of evidence on the efficacy of Royal Guard and Interceptor G2 in a RCT against pyrethroid-resistant malaria vectors.

## ENTOMOLOGICAL IMPACT OF PIPERONYL BUTOXIDE (PBO) NET DEPLOYMENT ON PYRETHROID-RESISTANT ANOPHELES GAMBIAE S.L. MOSQUITOES IN EBONYI STATE, SOUTHEASTERN NIGERIA

**Adedayo O. Oduola**<sup>1</sup>, Lazarus M. Samdi<sup>1</sup>, Petrus U. Inyama<sup>1</sup>, Ifeanyi Okeke<sup>1</sup>, Jesse C. Uneke<sup>2</sup>, Lawrence Nwankwo<sup>3</sup>, Perpetua Uhomoibhi<sup>4</sup>, Adedapo Adeogun<sup>5</sup>, Okefu O. Oyale<sup>4</sup>, Kelley Ambrose<sup>6</sup>, Uwem Inyang<sup>7</sup>, Melissa Yoshimizu<sup>8</sup>, Aklilu Seyoum<sup>6</sup>

<sup>1</sup>U.S. President's Malaria Initiative VectorLink Project, Abt Associates,, Abuja, Nigeria, <sup>2</sup>Ebonyi State University, Abakaliki, Nigeria, <sup>3</sup>Ebonyi State Ministry of Health, Abakaliki, Nigeria, <sup>4</sup>National Malaria Elimination Programme, Abuja, Nigeria, <sup>5</sup>Nigerian Institute of Medical Research, Lagos, Nigeria, <sup>6</sup>PMI VectorLink Project, Abt Associates, Rockville, MD, United States, <sup>7</sup>PMI U.S. Agency for International Development (USAID), Abuja, Nigeria, <sup>8</sup>U.S. PMI, USAID,, Washington, WA, United States

Pyrethroid insecticide resistance has been widely reported in 20 of the 36 states in Nigeria, where insecticide-treated nets (ITNs) are the main malaria prevention method. Insecticide susceptibility data helps inform which ITNs will be most effective for local mosquito populations. Susceptibility data generated in Ebonyi by the President's Malaria Initiative VectorLink project guided the deployment of deltamethrin+piperonyl butoxide (PBO) ITNs in November 2019. VectorLink assessed the entomological impact of

these nets in three Local Government Areas (LGAs): Ezza North, Izzi and Ohaukwu. *Anopheles* mosquitoes were collected monthly from human baited CDC light traps and pyrethrum spray collections and identified using morphological keys. Species specific polymerase chain reaction assays were conducted on all samples from the *An. gambiae* complex. The indoor resting density (IRD), human biting rate (HBR), entomological inoculation rate (EIR), and biting time of *Anopheles* mosquitoes pre- and post-distribution were compared using Chi square analysis. *An. gambiae* s.s., *An. coluzzii*, and *An. arabiensis* were the major vector species found. The number of *Anopheles* resting indoors/room/night reduced by 2.7-fold in Ezza North (9.78/3.60), 3.4-fold in Izzi (4.58/1.36), and 4.1-fold in Ohaukwu (5.46/1.32) post-intervention. Significant decreases in IRD were recorded post-intervention in all three LGAs ( $p \leq 0.03$ ). The average HBR (number of bites/person/night) was significantly reduced indoors ( $p \leq 0.05$ ) in Ezza North (14.28 vs 6.78), Izzi (8.22 vs 1.33) and Ohaukwu (11.10 vs 4.60). The baseline outdoor HBR did not differ significantly post-distribution in Ezza North (3.22 vs 1.10,  $p=0.48$ ), Izzi (2.04 vs 0.44,  $p=0.32$ ) and Ohaukwu (3.62 vs 1.34,  $p=0.21$ ). The proportion of mosquitoes (73% vs 72%) biting at peak indoor and outdoor times (10 p.m.-5 a.m.) was similar ( $p=0.93$ ). A significant reduction of mean EIRs (number of infective bites/person/year) was recorded indoors in Ezza North (29.50 to 0) and Ohaukwu (18.50 to 0). These results suggest that PBO ITNs improved protection for humans from mosquito bites and reduced malaria transmission.

<sup>1</sup>National Malaria Control Program - Ministry of Health and Population of Malawi, Lilongwe, Malawi, <sup>2</sup>U.S. President's Malaria Initiative, Lilongwe, Malawi, <sup>3</sup>Dure Technologies, Geneva, Switzerland, <sup>4</sup>Vestergaard, Lausanne, Switzerland, <sup>5</sup>U.S. President's Malaria Initiative, Washington, DC, United States, <sup>6</sup>FHI360, Durham, NC, United States, <sup>7</sup>Global Health Supply Chain Program - Procurement and Supply Management Malawi, Lilongwe, Malawi, <sup>8</sup>University of Pennsylvania, Philadelphia, PA, United States

Malawi reported over 5 million cases of malaria in 2019 and it remains the main cause of death for children under the age of 5. Successful malaria control efforts require: 1) timely and accurate data collection, analyses, and use; 2) optimization of proven interventions such as insecticide treated nets (ITN); 3) sufficient resources; and 4) community engagement. Mobile technology use in Malawi has increased to around 48 mobile phone subscriptions per 100 people in 2019. The Malawi SmartNet Initiative leverages 2/3/4G mobile technology to reach ITN users in real time. In March 2020, 300,000 ITN with a short code were distributed via antenatal clinics. The short code allowed recipients to complete a survey via their mobile phones. Questions included sociodemographic and geographic

indicators, net usage, presence of malaria-like illnesses, and location. Among the 300,000 recipients, as of March 2021, 54,682 voluntarily responded and of those 18,555 (34%) completed a Unstructured Supplementary Service Data (USSD) mobile phone survey; 14,947 of the 18,555 (80%) also provided the unique ITN code. Respondents answered 12 questions including basic demographics, number of household members, ITN possession and use, malaria-like illnesses and location. Dialling the short code was free and of respondents who completed the survey, the average response time of 2 min 25 seconds and 42% completed it during first call. Respondents were from each of the 28 districts and represented an estimated 273,410 household members (54,682 households) or 51% of the estimated households expected to be reached by the 300,000 ITNs. Limitations include potential lack of representativity of this sentinel sampling approach; biases include increased response from those who are literate and have mobile phones. Although generalizability of these data remains to be determined, through future surveys, this sentinel engagement with 21,434 individuals is one of the largest conducted in African malaria control and provides opportunities to both disseminate and collect information in real time.

### HOUSEHOLD OUTDOOR NIGHTTIME ACTIVITY AND SLEEPING BEHAVIOR AND POTENTIAL IMPLICATIONS FOR MALARIA VECTOR CONTROL IN THE NORTHERN BENIN, WEST AFRICA

**Martin C. Akogbeto<sup>1</sup>**, Ludovic N'tcha<sup>1</sup>, Germain G. Padonou<sup>1</sup>, Bruno Akinro<sup>1</sup>, Said Chitou<sup>1</sup>, Patrick Condo<sup>2</sup>, Michael Humes<sup>3</sup>

<sup>1</sup>Centre de Recherche Entomologique de Cotonou (CREC), Cotonou, Benin, <sup>2</sup>PMII/USAID, Cotonou, Benin, <sup>3</sup>PMII/USAID, Washington, WA, United States

Nighttime outdoor practices of household residents may limit the effectiveness of vector control interventions and sustain residual malaria transmission. To identify and characterize these practices, the location and nighttime activity of household members (HHMs) were observed in the departments of Alibori, Atacora, and Donga in northern Benin from 2018 to 2020. Monitoring of outdoor and nighttime resting and sleeping practices was done by direct overnight observation of the households. Three household visits were done per year, with one visit occurring during each rainy (wet period), dry (hot period), and harmattan season (cold period). A convenience sample of ninety-six households with at least 5-9 HHMs was enrolled each year in the study. One HHM was recruited as a household activity enumerator to monitor HHMs' nighttime activities and location every 30 minutes between 7 pm and 7 am for five nights per season per year. The activities monitored included resting or sleeping locations, ITN use, and other mosquito avoidance practices. More than 50% of the HHMs were resting or sleeping outdoors between 7 pm-10 pm throughout the study duration. During the hot and dry season, 80% of the HHMs were resting or sleeping outdoors. A high proportion of HHMs (44.4%) was observed staying all night outdoors. Most of them did not use mosquito nets or other mosquito avoidance paraphernalia such as mosquito coils, insecticide sprays, or repellents. Hot ambient temperature and limited lighting and space within the household were the main reasons given as to why HHMs rested or slept outdoors. Outdoor resting and sleeping are common behaviors for the majority of HHMs in northern Benin due to the heat during the dry season and limited lighting and space within their house; also, HHMs often forgo protecting themselves from mosquito bites, likely increasing the risk of HHMs receiving infectious bites. It may be necessary to enhance messaging on ITN use when resting or sleeping outdoors in Benin, specifically targeting the dry season. Also, hammock ITNs could be considered for use in Benin, or better outdoor tools, could be developed.

### CHARACTERIZING LATE NIGHT ANOPHELES MALARIA VECTORS IN NCHELANGE, ZAMBIA

Hannah L. Markle<sup>1</sup>, Mary E. Gebhardt<sup>1</sup>, David Mbewe<sup>2</sup>, Francis K. Mulenga<sup>2</sup>, James S. Lupiya<sup>2</sup>, Mbanga Muleba<sup>2</sup>, Mike Chaponda<sup>2</sup>, William J. Moss<sup>1</sup>, Jennifer C. Stevenson<sup>1</sup>, Douglas E. Norris<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Tropical Diseases Research Centre, Ndola, Zambia

With effective drugs and public health interventions in place, malaria remains a major burden in sub-Saharan Africa and is among the leading causes of hospitalization, morbidity, and mortality in this region. Vectored by mosquitoes of the *Anopheles* genus, the transmission dynamics of the *Plasmodium* parasite to humans are complex, and elements including time of day, season, location, and parasite infection rate within the mosquito must be considered. In the Nchelenge district of northern Zambia, *Anopheles funestus* is the predominate malaria vector, while species such as *An. gambiae* and other understudied vectors are present and contributing to transmission. Variable feeding behaviors exist between species, emphasizing the importance of understanding species-specific preferences to interrupt transmission via implementation of appropriate vector control interventions. To further discern these behaviors, mosquitoes foraging within twenty Nchelenge households were captured overnight during two weeks in August of 2019 utilizing CDC light traps placed in indoor sitting rooms of households between 4-10pm and from 10pm-6am. Overnight mosquitoes will be morphologically identified, species confirmation and bloodmeal source will be analyzed via PCR assays, and presence of parasite within mosquitoes will be determined by ELISAs specific for *P. falciparum*. It is expected that *An. funestus* make up a vast majority of captured mosquitoes and roughly 1-2% of these harbor *Plasmodium* sporozoites. Results from these analyses regarding species abundance, foraging patterns, host preference, and parasite infection rates will be compared with early evening collections and will translate to a better understanding of malaria transmission to humans. These results coupled with data from household surveys on human behavior including bed net usage and IRS status will assist in identification of risk factors for increased densities of anophelines, allowing for implementation of more species-specific vector control strategies, ultimately contributing to the continued effort to decrease the burden of malaria in Zambia.

### EFFICACY OF CDC LIGHT TRAP AND HUMAN DECOY TRAP (HDT) COMPARED TO HUMAN LANDING CATCH FOR ESTIMATING MALARIA VECTOR BITING RATES IN RURAL TANZANIA

Odufuwa<sup>3</sup>, Godfrey Ligema<sup>3</sup>, Hassan Ngonyani<sup>3</sup>, Isaya Matanila<sup>3</sup>, Noely Makungwa<sup>3</sup>, Jameel Zainul Bharmal<sup>4</sup>, Jason Moore<sup>3</sup>, David Kaftan<sup>5</sup>, Adam Saddler<sup>6</sup>, Amanda Ross<sup>1</sup>, Sarah Moore<sup>3</sup>, Manuel Hetzel<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>BC Centre for Excellence in HIV/AIDS, Vancouver, BC, Canada, <sup>3</sup>Ifakara Health Institute, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>Innovative Vector Control Consortium, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>Marquette University, Milwaukee, WI, United States, <sup>6</sup>Telethon Kids Institute, Perth, Australia

The human landing catch (HLC) is considered the best trap for biting mosquitoes, yet there are concerns about its safety for extensive use. We compared the numbers of mosquitoes caught by the CDC light trap, the human decoy trap (HDT) and HLC in Tanzania in 2017 and 2019. We collected the mosquitoes as part of an exercise to evaluate the impact of indoor residual spraying (IRS) products in a rural malaria-endemic setting. We conducted CDC light trap surveys indoors, the HDT outdoors and the HLC both indoors and outdoors. We used negative binomial mixed-effects models to compare nightly catches of the CDC light trap to the indoor HLC and of the HDT to the outdoor HLC. Overall, we trapped 14,606

*Anopheles arabiensis*, 66,807 *An. funestus* and 75,248 *Culex* spp adult female mosquitoes. We observed consistently higher numbers of *Culex* spp than *An. funestus* and higher numbers of *An. funestus* than *An. arabiensis* across all traps. Compared to indoor HLC, we found that the CDC light trap caught about half as many *An. arabiensis*, (RR = 0.42(0.31-0.58),  $p < 0.0001$ ), over two thirds of *An. funestus*, (RR = 0.64(0.50=0.83),  $p = 0.0008$ ), and an approximately equal number of *Culex* spp, (RR = 0.93(0.74-1.18),  $p = 0.57$ ). We found that HDT caught just about a tenth of both *An. arabiensis*, (RR = 0.07(0.01-0.31),  $p = 0.0006$ ) and *An. funestus*, (RR = 0.10(0.06-0.18),  $P < 0.0001$ ) and a third of *Culex* spp, (RR = 0.29(0.17-0.50),  $P < 0.0001$ ) caught by the reference trap. Differences between the CDC light trap and the indoor HLC did not appear to vary greatly depending on mosquito density. The CDC light trap may be used for regular indoor malaria vector monitoring as long as a correction factor is applied to match mosquito catches of the HLC gold standard trap. Due to low mosquito numbers caught by HDT in this study, we recommend further investigations with a more robust study design to reassess its efficacy and potential use as an alternative to outdoor HLC.

### KEY FINDINGS FROM DIGITIZING SUPERVISION OF CONTINUOUS DISTRIBUTION CHANNELS FOR INSECTICIDE TREATED NETS IN TANZANIA, 2019-2020

Kanuth Dimoso<sup>1</sup>, Peter Gitanya<sup>2</sup>, Mwinyi Khamis<sup>3</sup>, Charles Simba<sup>1</sup>, Mubita Lifwatila<sup>1</sup>, Naomi Serbantez<sup>4</sup>, Erik Reaves<sup>5</sup>, Jane Miller<sup>6</sup>, Luigi Nuñez<sup>6</sup>

<sup>1</sup>PMI VectorLink Tanzania, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>National Malaria Control Program, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Zanzibar Malaria Elimination Program, Zanzibar, United Republic of Tanzania, <sup>4</sup>USAID Tanzania, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania, <sup>6</sup>PMI VectorLink, Washington, DC, United States

Continuous distributions of insecticide treated nets (ITNs) through health facilities, schools, and communities have been shown to maintain high population access to ITNs and have the potential to replace mass campaigns in some settings. Supervision helps optimize these distribution channels by enabling supervisors and decision-makers to respond to identified gaps in logistics management (e.g. ITN storage), data management (e.g. accuracy of control cards against physical stock), and provider behavior (e.g. adherence to issuing ITNs to eligible clients). However, ensuring quality distribution of ITNs through these channels is limited by the lack of consistent supervision and timely access to supervision data. We implemented a digital tool of the supervision checklist and compared it to the customary paper-based system. In 2019, 4939 schools on the Mainland and 374 health facilities across the Mainland and Zanzibar received supervision visits using paper-based forms. Between January 2020 and March 2021, 2043 schools were visited (but only 89 were visited with digital forms) and all 990 visits to facilities used the digital tool. Access to supervision data for reporting and analysis improved from a minimum two week wait to real-time. Staff were not able to quantify past performance due to the vast number of paper reports. Among visits to facilities using the digital tool, 94% observed an ITN inventory control card (to measure stock levels) available, but card contents were correct in only 63% of visits. Approximately half of visits (56%) observed acceptable (5%) variance between card values and a physical stock count. In total, 85% of visits confirmed facilities had sufficient physical stock, but ITNs were stored appropriately in only 65% of visits. Qualitative results revealed many facilities lacked pallets. The digital tool highlighted nuances within continuous distribution of ITNs previously unquantified, enabled District Medical Officers to act more rapidly (e.g., to review unreported commodities), and provided data which can be further used to adapt training curricula to improve future ITN distributions.

### PYRETHROID-PIPERONYL BUTOXIDE (PBO) NETS REDUCE THE EFFICACY OF INDOOR RESIDUAL SPRAYING WITH PIRIMIPHOS-METHYL: AN EXPERIMENTAL HUT EVALUATION IN SOUTHERN BENIN

Thomas W. Syme<sup>1</sup>, Corine Ngufor<sup>1</sup>, Augustin Fongnikin<sup>2</sup>, Martial Gbegbo<sup>2</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>Centre de Recherche Entomologique de Cotonou, Cotonou, Benin

Most indoor residual spraying (IRS) campaigns are deployed against a background of high long-lasting insecticidal net (LLIN) coverage.

Pyrethroid-piperonyl butoxide (PBO) LLINs have recently been recommended for malaria control and are replacing pyrethroid LLINs in endemic communities. PBO acts by inhibiting enzymes responsible for pyrethroid resistance, namely cytochrome P450 monooxygenases (CYPs). Pirimiphos-methyl is also widely applied for IRS campaigns however; it is a pro-insecticide that requires activation by CYPs in order to exert full toxicity. The inhibitory action of pyrethroid-PBO LLINs against CYPs may, therefore, reduce the toxicity of pirimiphos-methyl IRS when these interventions are combined. We performed a series of experimental hut trials to evaluate the impact of combining different pyrethroid-PBO LLINs with pirimiphos-methyl IRS against a pyrethroid-resistant vector population in Benin. Comparison was made to either method alone and combinations based on pyrethroid LLINs as a positive control. WHO susceptibility bioassays were performed to determine the resistance profile of the vector population. WHO susceptibility bioassays revealed the vector population was highly resistant to pyrethroids but susceptible to organophosphates. PBO pre-exposure only partially restored pyrethroid susceptibility. Vector mortality in huts containing pirimiphos-methyl IRS and pyrethroid-only LLINs (81%) was similar to IRS alone (85%,  $p=0.129$ ). In contrast, mortality was significantly reduced with combinations of pirimiphos-methyl IRS and pyrethroid-PBO LLINs (55-59%) relative to IRS alone (77-78%,  $p<0.001$ ). This study provides evidence for reduced efficacy of pirimiphos-methyl IRS in the presence of pyrethroid-PBO LLINs. Control programmes may consider withholding pyrethroid-PBO LLIN distribution in areas scheduled for IRS with pirimiphos-methyl as a precaution.

### USING TRANSFER LEARNING COUPLED WITH DIMENSIONALITY REDUCTION TO IMPROVE GENERALISABILITY OF MACHINE LEARNING PREDICTIONS OF MOSQUITO AGES FROM MID INFRARED SPECTRA

Emmanuel P. Mwanga<sup>1</sup>, Joshua Mitton<sup>2</sup>, Doreen J. Siria<sup>1</sup>, Francesco Baldini<sup>2</sup>, Fredros O. Okumu<sup>1</sup>, Simon A. Babayan<sup>2</sup>

<sup>1</sup>Ifakara Health Institute, Dar es salaam, United Republic of Tanzania,

<sup>2</sup>University of Glasgow, Glasgow, United Kingdom

Accurate prediction of mosquito population age-structure helps to monitor the efficacy of interventions which target adult mosquitoes. Mid-infrared (MIR) spectroscopy provides biochemical signals of the mosquito cuticle that correlate with age, which can be used to train machine learning (ML) models for age prediction. We assessed whether dimensionality reduction and transfer learning (adding few observations of the target population into training data to improve model-performance) could improve generalisability of ML predictions for mosquito ages from MIR spectra. We used *Anopheles arabiensis* mosquitoes reared in two insectaries maintained at different rearing conditions. Heads and thoraces of day 1-17 mosquitoes were scanned using a MIR spectrometer to obtain high resolution MIR spectra. Mosquito ages were grouped into three classes (i.e. 1-5, 6-10, 11-17 day-olds). The dimensionality of the spectra data was reduced using either principal component analysis (PCA) or t-distributed stochastic neighbor embedding when training a deep learning (DL) and standard ML classifiers. Transfer learning was later used to improve generalisability of the models in predicting mosquito ages. We found that when dimensionality reduction by PCA was used, DL achieved an overall accuracy of 38% in generalizing prediction for

mosquito ages. On the other hand, when transfer learning (5% of the unseen data) and dimensionality reduction by PCA were both used, DL improved generalisability with an overall accuracy of 95% in predicting mosquito ages. Standard ML also achieved 94% accuracy in generalizing prediction of mosquito ages. Thus, dimensionality reduction itself does not improve generalisability of the models in predicting mosquito ages from another rearing condition. However, using both dimensionality reduction and transfer learning, generalisability of the deep learning in predicting mosquito ages improved, achieving >90% accuracy. Additionally, standard ML can reduce computational time and achieve high accuracy matching the DL performance, when dimensionality reduction and transfer learning are both used.

Medical University College, Moshi, United Republic of Tanzania

Insecticide resistance among mosquito species is now a pervasive phenomenon, which threatens to jeopardize global malaria control efforts. Novel vector control tools, including long-lasting insecticidal nets (LLINs) incorporating new active ingredients with different modes of action are urgently needed to delay the evolution and spread of resistance. During a four-arm cluster-randomised trial in Misungwi district, Tanzania, evaluating the effectiveness of (1) Royal Guard, a LLIN combining pyriproxyfen and alpha-cypermethrin; (2) Interceptor G2, a LLIN combining chlorfenapyr and alpha-cypermethrin; (3) Olyset Plus, a LLIN combining piperonyl butoxide (PBO) and the pyrethroid permethrin; compared to (4) Interceptor, a standard alpha-cypermethrin LLIN, we measured longitudinal trends in insecticide resistance among >27,000 wild mosquitoes collected over 24 months. Prior to LLIN distribution, pyrethroid resistance was high, with 30-min knock-down ranging from 43.7-59.4% for *Anopheles funestus* s.l. and *An. gambiae* s.l. following exposure to alpha-cypermethrin and mean 24-hr mortality of 38.3-56.5% in permethrin bioassays. Following LLIN distribution, we detected a significant increase in permethrin resistance intensity in *An. funestus* s.l. across all trial arms. Levels of alpha-cypermethrin resistance also increased but only in clusters which received Interceptor® or one type of LLIN under evaluation. PBO pre-exposure restored permethrin susceptibility among vector populations and high levels of chlorfenapyr susceptibility were also observed. We assessed oviposition inhibition to pyriproxyfen using dissection 3-days after exposure with variable results between trial years. *An. gambiae* s.s. populations were characterised by high frequencies of L1014FS-*kdr* (98%) and overexpression of *CYP6M2*, *CYP6P3*, *CYP6P4* and *CYP9K1*. Study findings highlight increasing pyrethroid resistance intensity in *An. funestus* s.l. associated with the deployment of next-generation LLINs, with additional work required to thoroughly understand the operational implications and potential mechanisms driving cross-resistance.

## ASSESSMENT OF THE DURABILITY OF LONG-LASTING INSECTICIDAL NETS FROM THE 2017 ITN MASS CAMPAIGN IN BENIN, WEST AFRICA

Idelphonse Bonaventure Ahogni<sup>1</sup>, Jean F. Dagnon<sup>2</sup>, Patrick Condo<sup>3</sup>, Germain G. Padonou<sup>1</sup>, Martin C. Akogbeto<sup>1</sup>

<sup>1</sup>Centre de Recherche Entomologique de Cotonou, Cotonou, Benin, <sup>2</sup>Malaria country engagement for the Western and Central African regions, Bill & Melinda Gates Foundation, Abuja, Nigeria, <sup>3</sup>US President's Malaria Initiative (PMI), US Agency of International Development (USAID), Cotonou, Benin

Long-lasting insecticidal nets (LLINs) are widely used for malaria prevention and control in Benin since 2007. Although LLINs have been used for nearly 15 years, there is limited information on LLIN durability in Benin. The survivorship, physical integrity, and bioefficacy of LLINs were assessed through longitudinal surveys conducted at 6, 12, 18, 24, 30, and 36 months following a July-October 2017 mass distribution campaign. Three brands of LLINs (DawaPlus<sup>®</sup>2.0, PermaNet<sup>®</sup>2.0, and Yorkool<sup>®</sup>) were distributed in 3 districts (Ketou, Dogbo, and Djougou). Five hundred LLINs per district (250 in rural areas and 250 in urban areas) were monitored for a total of 1500 LLINs. Bioefficacy tests were done on 50 LLINs per brand per site and assessed by WHO cone tests. After a 3-year follow-up period, only 16% (241/1500) of the original LLINs were found and assessed by the investigators in the sampled households. The associated net loss rate (84% overall) was similar across all three brands of LLINs ( $p=0.6868$ ). This high net loss rate was largely due to the displacement or replacement of LLINs. Out of the 241 LLINs found, 48% (95% CI: 32 – 64) of the LLINs had physical damage, of which 13% (95% CI: 9 – 18) were severely torn. The median pHI of LLINs (all brands) was 578 (IQR = 219 – 843) at 6 months versus 197 (IQR = 49 – 666) at 36 months. This poster further describes the proportion of bednets in “good condition” (pHI  $\leq$  64) as classified by the WHO, the loss rate, and the median survival. The bioefficacy of the three LLINs after 2 years was greater than 80% in mosquito mortality. Although our evaluation showed that all three brands of bednets were in a relatively good physical and chemical condition, the high loss rate observed may limit the overall efficacy of LLINs in preventing malaria. Strengthening behavioral change communication to encourage communities to retain, use, and maintain LLINs may improve and sustain their effectiveness.

<sup>1</sup>RTI International, Washington, DC, United States, <sup>2</sup>RTI International, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>National Malaria Control Programme, Dodoma, United Republic of Tanzania, <sup>4</sup>Zanzibar Malaria Elimination Programme, Ministry of Health, Zanzibar, United Republic of Tanzania, <sup>5</sup>US President's Malaria Initiative, United States Agency for International Development, Dar es Salaam, United Republic of Tanzania, <sup>6</sup>US President's Malaria Initiative, US Centers for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania

Indoor residual spraying (IRS) has been a key malaria intervention in Tanzania since 2006. This retrospective analysis aims to evaluate the impact of IRS on malaria incidence in Tanzania's high burden Lake Zone (district level) and Zanzibar (shehia [sub-district] level). Routine data from 2014 to 2020 were collected (District Health Information System 2 for mainland Tanzania and Malaria Case Notification system for Zanzibar) and separately analyzed. Districts and shehias were grouped into 'No IRS' and multiple years of IRS in the same locations ('1-2'; '3-4'; '>4' years). The

annual epidemiological trend was obtained by calculating the percentage difference between the incidence in the month pre-IRS (baseline month) and the incidence during the 9 months post-IRS (i.e., corresponding to the organophosphate insecticide's residual efficacy used for the corresponding IRS year). Spatial regression models, with random effect (to adjust for other factors), were developed to evaluate IRS's effect on incidence between and within years, and accounting for multiple IRS rounds. During the study period, 23 districts and 205 shehias received at least one round of IRS. For the entire period, model results showed a significant protective effect of IRS on malaria incidence in mainland Tanzania (-63.9%; 95% CI: -183.3%; 17.6%) and Zanzibar (-24.9%; 95% CI: -52.6%, -3.2%). However, on a yearly basis, the protective effect of IRS was temporally and spatially heterogeneous: in Mainland Tanzania, the highest number of sprayed districts where IRS showed a protective effect was in 2016 and 2017 (7/9, of which 4 were statistically significant); in Zanzibar, 19% of sprayed shehias in 2018 showed a significant protective effect versus 4% in 2019. In Zanzibar, incidence (OR 1.15; 95% CI: 1.10, 1.19) and cases in the prior year (OR 0.98; 95% CI: 0.96, 0.99) were positively and negatively associated with malaria incidence trends, respectively. Our analytical approach can be used to improve IRS monitoring as well as targeting, ensuring that the impact of IRS on malaria is maximized.

## 0321

### SITE-SPECIFIC INCIDENCE RATE OF DIFFERENT GENOMIC STRAINS OF ENTEROAGGREGATIVE ESCHERICHIA COLI & ASSOCIATION WITH ENTERIC INFLAMMATION & GROWTH IN CHILDREN OF A MULTICOUNTY BIRTH COHORT STUDY

Rina Das

International Centre for Diarrhoeal Disease Research, Bangladesh (icddr), Dhaka, Bangladesh

There is a lack of information that highlights the possible association between different potential virulence genes among the Enteroaggregative *Escherichia coli* (EAEC) and environmental enteric dysfunction (EED), and their eventual combined effects on nutritional status and growth among children. Infections by different genomic strains of EAEC were detected by the use of a customized multiplex quantitative polymerase chain reaction array system known as the TaqMan Array Card (TAC) from stool samples collected from a total of 1705 children enrolled in the MAL-ED birth cohort. We measured site-specific incidence rate by using Poisson regression models, identified the risk factors, and estimated the associations of different genomic strains of EAEC with the composite EED score and child growth at 24 months of age. Overall highest incidence rate (49.1%) was found among children having infection with the concomitant presence of *aaiC* and *aatA* gene, which was the greatest in Tanzania (65%). Less maternal education, lack of improved floor, and ownership of cattle in the household were found to be risk factors for EAEC infection by different genomic strains. In the multivariate models, after adjusting for age, sex, WAMI index (Wealth, Asset, Maternal education, Income), enrolment length-for-age z score, maternal BMI, number of children in the family, poultry/cattle in house, seasonality, serum zinc, and alpha-1-acid glycoprotein, co-pathogens, and site for the overall estimate; and different genomic strains of EAEC infections showed strong positive associations with different biomarkers of EED in generalized estimating equations and with poor linear growth at the age of 24 months. Different genomic strains of EAEC were associated with enteric inflammation and linear growth faltering among children. Our analyses may aid an epidemiologic investigation to propel a potential vaccine development aimed at reducing the burden of EAEC infections and resulting phenotypic aberrations in the form of combating EED and its consequent childhood malnutrition.

### COMPLICATED COURSE OF A PRIMARY KLEBSIELLA PNEUMONIAE LIVER ABSCESS REQUIRING EXPLORATORY LAPAROTOMY AND PARTIAL HEPATIC LOBECTOMY

Katherine E. Arn

Santa Barbara Cottage Health, Santa Barbara, CA, United States

*Klebsiella p.* is a well-known cause of community acquired pyogenic liver abscesses in Taiwan and East Asia. These abscesses can become invasive, and are even described as metastatic in some cases. Although previously uncommon in the US, there has been an increase in incidence of KLAS (Klebsiella Liver Abscess) in the past few decades. Case: 42 year old male with no known past medical history presented to the hospital for progressive abdominal pain, generalized weakness, and increased thirst. 3 weeks prior to presentation, he was seen at another facility for fever, chills, and body aches; he was prescribed amoxicillin with initial improvement of his symptoms. Later, his symptoms returned, along with the development of RUQ abdominal pain. He denied any significant past medical history, including any prior diagnosis of diabetes. He did not take any medications, denied any prior major illnesses, surgeries, or hospitalizations. He was born in the Philippines, but moved to the US in 1990. He had not travelled outside of the US since that time, and had not traveled outside of California in over 3 years. Vitals: temp 99.2, HR 112, RR 18, BP 121/71. Exam: RUQ tenderness and mild scleral icterus. labs: AST 213, ALT 136, Alk phos 459, t bili 3, WBC 11, crp 181, procal 7.8, glu 364, hba1c 11. Abdominal CT revealed an 11 cm liver abscess. A percutaneous drain was placed and he was started on IV abx. Cultures from the aspirate grew *Klebsiella p.* Initially he improved with IV abx and continued drainage, but worsened again on day 4 of the hospitalization with fever, chills, and worsening abdominal pain. Repeat CT showed improvement of the hepatic abscess, but interval development of perihepatic, perisplenic, and pelvic abscesses. General surgery was consulted. An exploratory laparotomy showed necrosis of hepatic lobes 6 & 7, gross inflammation of the gallbladder, paracolic gutter abscess involving the appendix, and multiple other abscesses in the peritoneal cavity. He underwent a partial hepatectomy, cholecystectomy, appendectomy, and drainage of multiple intraabdominal abscesses. He was treated with 4 weeks of abx therapy with resolution of his infection.

### IMMUNOGENICITY AND WANING OF IMMUNITY TO ORAL CHOLERA VACCINE (SHANCHOL™) IN ADULTS RESIDING IN LUKANGA SWAMPS OF ZAMBIA

Harriet Ng'ombe<sup>1</sup>, Caroline Cleopatra Chisenga<sup>1</sup>, Michelo Simuyandi<sup>1</sup>, John Mwaba<sup>1</sup>, Samuel Bosomprah<sup>1</sup>, Luiza M. Hatyoka<sup>1</sup>, Mutinta Muchimba<sup>1</sup>, Charlie C. Luchen<sup>1</sup>, Cynthia Mubanga<sup>1</sup>, Obvious N. Chilyabanyama<sup>1</sup>, Peter I. Alabi<sup>1</sup>, Geoffrey Kwenda<sup>2</sup>, Roma Chilengi<sup>1</sup>

<sup>1</sup>Centre for Infectious Disease Research in Zambia, Lusaka, Zambia,

<sup>2</sup>University of Zambia, Ridgeway campus, Lusaka, Zambia

In cholera endemic areas, the periodicity of cholera outbreaks remains unpredictable, making it difficult to organize preventive efforts. Lack of data on duration of protection conferred by oral cholera vaccines further makes it difficult to determine when to deploy preemptive vaccination. We report on the immunogenicity and waning of immunity to an oral cholera vaccine (Shanchol™) in Lukanga Swamps – a known hot spot in Zambia. We enrolled 223 participants aged 18-65 years from whom serum samples were collected at baseline prior to vaccination with dose 1 and at day 28 before administration of dose 2; then consecutively, at 6, 12, 24, 30, 36, and 48 months. We assessed vibriocidal antibody titres against *Vibrio cholerae* O1 Inaba and Ogawa serotypes. The vibriocidal antibody titres were log<sub>10</sub> transformed and expressed as geometric mean titres (GMTs) and vaccine seroconversion defined as four-fold increase in vibriocidal antibodies from baseline. From a baseline of 13.58, anti-Ogawa GMT increased to 21.95 after the first dose, but rapidly began to wane to 14.52, 13.13, and 12.78 at months 6, 12 and 24 respectively, and then

increased to 13.21, 18.67 and 23.65 at months 30, 36 and 48 respectively. A similar trend was observed for anti-Inaba GMT across the same time points. Overall, seroconversion against Inaba and Ogawa after 1st dose was 35/134 (26%) and 34/134 (25%) respectively, and these were statistically significant when stratified by baseline titre; Inaba (p=0.02), and Ogawa (p<0.0001). We found Shanchol™ to be immunogenic and that participants with high baseline titres were less likely to seroconvert. Vaccine response was highest soon after the first dose. The second dose did not seem to add any significant immunogenic value, suggesting that 1<sup>st</sup> dose deployment to a larger population may have protective value over second dose to a fewer population with the same vaccine stockpile. The observed rise in GMT's at months 36 and 48 suggests natural exposure, making this period a critical time for natural transmission. Therefore, we recommend re-vaccination at 36 months in high risk areas.

0324

### ASSESSMENT ON ENTEROPATHOGEN DIARRHEA-ASSOCIATED AMONG UNDER-FIVE CHILDREN IN BENGO ANGOLA

Elsa M. Fortes-Gabriel<sup>1</sup>, Maria F. Da Silva<sup>2</sup>, Jocelyne N. Vasconcelos<sup>2</sup>, Miguel Brito<sup>3</sup>

<sup>1</sup>Instituto Superior Tecnico Militar, Estado Maior General das Foras Armadas Angolanas, Luanda, Angola, <sup>2</sup>Centro de Investigato em Sade de Angola, Instituto Nacional de Investigatio em Sade, Bengo, Angola, <sup>3</sup>Escola Superior de Tecnologia da Sade de Lisboa, Instituto Politcnico de Lisboa, Lisboa, Portugal

Diarrhea is the most important event in children under five among the poorest people in Africa. Some studies in Angola show evidence of enterobacteria, viruses, and helminths in diarrhea diseases like *Giardia lamblia* strains. In Bengo province studies carried out between 2012-2013 before the introduction of *Rotavirus* vaccination, showed evidence of *Rotavirus* infection in acute gastroenteritis, and the most common G1-genotype (83.6%) was revealed. The Monitoring and the assessment of photogenic enterobacteria in Bengo, can provide data for outbreak prediction and forecast of several enteropathogens or emerging oldest agents in the same area. It allows epidemiologic studies which could be arising prophylactic measures and strength the decision make on health in remote locations in Bengo. This study aims to assess the most important pathogenic enterobacteria and *Rotavirus* among children aged 1-59 months in the main public Hospital of Bengo Province, in Angola, through fecal culture test, molecular approach, beside a questionnaire for the caregiver. Children were enrolled according to strict inclusion criteria. Fecal samples have been cultured in MacKonkey agar and XLD (18- 24h at 37°C) and tested (OD600nm) by Vitek2 Compact®. The rapid test (SD®) and PCR for *Rotavirus* detection performed. A preliminary result from n=112 samples analyzed, evidences infection by pathogenic *Echerichia coli* spp n=41 (36.6%), *Klebsiella* spp n=30 (26.78%), *Salmonella* spp n=3 (2.67%), and *Rotavirus* n=7 (6.48%). However, *Rotavirus* infection is common in children up to 3 years old and co-infection was observed n=6 (5.35%). Poverty in rural areas, low education, and the economic status of caregivers could be affecting the occurrence of diarrhea among children living in Bengo province.

*icddr, Dhaka, Bangladesh, <sup>3</sup>Research Department 2, Potsdam Institute for Climate Impact Research, Member of the Leibniz Association, Potsdam, Germany*

Key causes of undernutrition in children are insufficient intake of nutritious food as well as repeated infections and enteric dysfunction caused by poor sanitation and hygiene practices. We aimed to evaluate the impact of a combined home gardening, chicken rearing, nutrition education, and food hygiene intervention on diarrhea prevalence and markers of enteric dysfunction in young children in rural Bangladesh. We analyzed data on 614 children under 18 months of age participating in the Food and Agricultural Approaches to Reducing Malnutrition (FAARM) trial in Sylhet, Bangladesh. We analyzed diarrhea prevalence using 1-week recall and assessed fecal myeloperoxidase (MPO), neopterin (NEO), and alpha-1 antitrypsin (AAT) as biomarkers of enteric dysfunction and serum C-reactive protein (CRP) and alpha-1 acid glycoprotein (AGP) as biomarkers of systemic inflammation, measured by ELISA. We used multilevel regression to quantify the intervention's impact on diarrhea prevalence and enteric dysfunction biomarkers. Diarrhea prevalence was about 5% and did not differ between children from intervention and control arms. Biomarkers of enteric dysfunction were overall elevated, which was comparable to previous studies in similar settings and age groups. There was no difference in CRP, AGP, and AAT levels between arms. However, children from intervention households showed a 48% increase in MPO levels and a 25% increase in NEO levels compared to children from control households. Overall, we found high levels of biomarkers indicating widespread enteric dysfunction in children, while the prevalence of symptomatic diarrhea was rather low in both arms. Our data suggest that changes induced by the combined nutrition and food hygiene intervention were not sufficient to decrease intestinal dysfunction in young children in our study setting. We are currently investigating whether the increase seen in some biomarkers may be related to aspects of chicken rearing.

## 0326

### PROTECTION AFFORDED BY PREVIOUS VIBRIO CHOLERAE INFECTION AGAINST SUBSEQUENT DISEASE AND INFECTION: A REVIEW

**Tiffany Leung**, Laura Matrajt

*Fred Hutchinson Cancer Research Center, Seattle, WA, United States*

Cholera is an acute, diarrheal disease caused by *Vibrio cholerae* O1 or 139, with an estimated 2.8 million cases and 95,000 deaths worldwide annually. Knowledge of the duration of protection following infection with *V. cholerae* is critical as we seek to optimize intervention strategies in the prevention and control of cholera. However, current estimates of the duration of protection following natural infection span widely from a few months to ten years. We analyzed the estimated duration of immunity following cholera infection from available published studies. We searched Pubmed and Web of Science for studies of the long-term immunity following cholera infection. We identified 22 eligible studies and categorized them as either (i) an observational study; (ii) a challenge study in which participants were subsequently challenged after an initial challenge with *V. cholerae*; or (iii) a serological study in which potential immunological markers of long-term protection of cholera were measured and assessed. We found strong evidence of protection at three years after infection in observational and challenge studies. However, serological studies show that elevated humoral markers of potential correlates of protection returned to baseline within one year. We also found that a subclinical cholera infection may confer lower protection than a clinical one, as suggested by three studies that found that, albeit with small sample sizes, most participants with a subclinical infection from an initial challenge with cholera experienced symptoms when rechallenged with a homologous biotype. Given that as much as 75% of *V. cholerae* infections are asymptomatic, care must be taken to extrapolate the findings from symptomatic cholera infections to all cholera infections. This review underscores the need to elucidate potential differences in the protection provided by clinical and subclinical cholera infections. Further, more studies

are warranted to bridge the gap between the correlates of protection and cholera immunity. Understanding the duration of natural immunity to cholera can help guide control strategies and policy.

## 0327

### ASSOCIATIONS BETWEEN BACTERIAL ENTEROPATHOGENS AND SYSTEMIC INFLAMMATION, IRON STATUS, AND ANEMIA IN PRESCHOOL-AGE CHILDREN IN GHANA

**Nathalie J. Lambrecht**<sup>1</sup>, Dave Bridges<sup>1</sup>, Mark L. Wilson<sup>1</sup>, Bright Adu<sup>2</sup>, Joseph N. Eisenberg<sup>1</sup>, Gloria Folson<sup>2</sup>, Ana Baylin<sup>1</sup>, Andrew D. Jones<sup>1</sup>

*<sup>1</sup>University of Michigan, Ann Arbor, MI, United States, <sup>2</sup>Noguchi Memorial Institute for Medical Research, Legon, Ghana*

Poor water, sanitation, and hygiene (WASH) are associated with anemia in young children, yet linkages between bacterial enteropathogen infections and child anemia remain largely unexplored. Enteropathogens may cause anemia via reduced micronutrient absorption and inflammation-mediated functional iron deficiency. The aim of this cross-sectional study was to determine the burden of bacterial enteropathogen infections among children 6-59 months old in Greater Accra, Ghana, and examine associations between infections and systemic inflammation, iron status, and anemia. Blood samples from 262 children were analyzed for hemoglobin (Hb), serum ferritin (SF), serum transferrin receptor (sTfR), C-reactive protein (CRP), and  $\alpha$ -1-acid glycoprotein (AGP). Stool samples were analyzed for *Campylobacter jejuni/coli* (*C. jejuni/coli*), *Escherichia coli* (*E. coli*) pathotypes, *Shigella* spp., and *Salmonella* using quantitative polymerase chain reaction (qPCR). Logistic regression models, adjusting for child age and sex, were used to estimate associations between detection of each enteropathogen and elevated systemic inflammation (CRP > 5 mg/L or AGP > 1 g/L), iron deficiency (SF < 12  $\mu$ g/L or sTfR > 8.3 mg/L) and anemia (Hb < 11.0 g/dL). Forty-six percent of children had anemia though only 18% of children had iron-deficiency anemia. Enteropathogens were detected in 87% of children's stool, and infections were predominantly subclinical. *C. jejuni/coli* infection was significantly associated with elevated CRP [Odds Ratio (95% CI): 3.49 (1.45, 8.41)] and AGP concentrations [4.27 (1.85, 9.84)], but not with iron deficiency or anemia. Enteroinvasive *E. coli/ Shigella* infection was associated with higher odds of iron deficiency [SF: 2.55 (1.23, 5.29)] and anemia [2.34 (1.15, 4.76)], and with elevated CRP at higher relative detection of the *ipaH* gene [3.24 (1.18, 8.89)]. Subclinical enteropathogen infections, particularly involving enteroinvasive bacteria, appear to contribute to systemic inflammation and anemia in young children. These results suggest that improvements in WASH may help reduce the anemia burden among young Ghanaian children.

## 0328

### UNDERSTANDING THE INCIDENCE AND RISK FACTORS ASSOCIATED WITH TRAVELERS' DIARRHEA IN INTERNATIONAL TRAVELERS DEPARTING FROM UTAH, USA

**Valerie Fernandez**<sup>1</sup>, Sharia M. Ahmed<sup>1</sup>, Michael C. Graves<sup>1</sup>, Holly E. Shoemaker<sup>2</sup>, Holly Birich<sup>3</sup>, Nora Sooklaris<sup>4</sup>, Jakrapun Pupaibool<sup>1</sup>, L. Scott Benson<sup>5</sup>, Daniel Leung<sup>1</sup>

*<sup>1</sup>Division of Infectious Disease, University of Utah School of Medicine, Salt Lake City, UT, United States, <sup>2</sup>Division of Epidemiology, University of Utah School of Medicine, Salt Lake City, UT, United States, <sup>3</sup>Salt Lake County Health Department, Salt Lake City, UT, United States, <sup>4</sup>University of Utah Health, Salt Lake City, UT, United States, <sup>5</sup>Division of Public Health, University of Utah School of Medicine, Salt Lake City, UT, United States*

Despite current knowledge on the causes and prevention strategies for travelers' diarrhea (TD), TD continues to be one of the most common medical concerns experienced by international travelers in the US, with 10%-40% of travelers reporting TD over a two-week trip depending on the travel destination and other characteristics. However, studies involving US travelers are limited, and a nuanced understanding of the risks associated with specific travel behaviors is lacking. In this study, we aim to explore the frequency of TD among international travelers who

sought pre-travel counseling in Utah, and the risk factors associated with TD. In this cross-sectional study, we've collected and analyzed data from anonymous post-travel questionnaires submitted by international travelers seen at the University of Utah and Salt Lake County travel clinics. Questionnaires administered from October 2016 to March 2020 collected information on demographics and health-related behaviors during travel. To analyze the 22 potential risk factors, we fit bivariate logistic regression models adjusted for a priori selected confounders, and present the odds ratio (OR) and 95% confidence intervals (95% CI) of travelers' diarrhea. Out of 570 completed post-travel surveys, 477 (83.7%) answered the TD question, and 110 (23.1%) had TD. Risk factors associated with increased odds of travelers' diarrhea included travel to Southeast Asia (2.08; 1.34-3.23), visiting an urban destination (2.92; 1.32-6.98), taking medications/supplements to prevent TD (2.73; 1.78-4.22), and inadequate hand hygiene behaviors (2.84; 1.04-7.64). Travelers' diarrhea continues to be common in international travelers from the US. Our findings provide insight into traveler's behaviors, and shows the need for additional research into prevention strategies for travelers' diarrhea.

0329

### ETIOLOGY OF DIARRHEA AMONG PEOPLE LIVING WITH HUMAN IMMUNODEFICIENCY VIRUS AND HUMAN IMMUNODEFICIENCY VIRUS NEGATIVE PATIENTS IN IBADAN, NIGERIA

**Oyeni Stephen Bejide**<sup>1</sup>, Mariam A. Odebode<sup>1</sup>, Veronica Ogunleye<sup>2</sup>, Victoria Nwachukwu<sup>2</sup>, Olukemi Adekanmbi<sup>1</sup>, Babatunde O. Ogunbosi<sup>1</sup>, Kolawole O. Akande<sup>1</sup>, Temitope Illori<sup>1</sup>, Iruka N. Okeke<sup>1</sup>

<sup>1</sup>University of Ibadan, Ibadan, Nigeria, <sup>2</sup>University College Hospital, Ibadan, Nigeria

Diarrhea is common in sub-Saharan Africa and is one of the leading causes of infantile deaths globally. Few etiologic studies in West Africa focus on individuals who are not young children or travellers. This study profiles the etiologies of diarrhea among adults living with human immunodeficiency virus (HIV) and HIV-negative patients in Ibadan Nigeria. Following ethical approval, we examined 329 stool samples from 127 patients with diarrhea who are living with HIV and 202 HIV-negative patients with diarrhea for occult blood, parasites and bacterial enteropathogens. Parasites were sought using iodine and normal saline wet mount and modified acid fast methods. Stool samples were cultured on MacConkey, eosin methylene blue and xylose lysine deoxycholate agars after enrichment in selenite F broth for the isolation of pathogenic enterobacteriales. Diarrhoeagenic *Escherichia coli* pathotypes and *Salmonella* were confirmed by polymerase chain reaction. The results were analyzed using Chi square and Fischer's Exact tests. Seven parasites, *Ascaris lumbricoides*, *Trichuris trichiura*, *Strongyloides stercoralis*, *Entamoeba histolytica*, *Cryptosporidium parvum*, *Cyclospora cayetanensis* and *Isospora belli* were detected in the stool samples. Enteroaggregative *E. coli* (EAEC) was the most commonly detected bacterial pathotype, recovered from 103 (31.3%) of all the patients and *Salmonella spp.* were detected in 6 (1.8%) of stool specimens. *C. cayetanensis* ( $p = 0.0008$ ) and enterotoxigenic *E. coli* (ETEC) ( $p = 0.00005$ ) were recovered significantly more often in HIV-negative patients with diarrhea but HIV positive status was not associated with any of the other parasites or bacteria sought ( $p > 0.05$ ). Positive HIV status was strongly associated with detection of occult blood in patients' fecal samples ( $p = 0.000004$ ). We conclude that bacteria- and parasite-associated diarrhea is common in Ibadan, with a wide range of pathogens implicated. With the exception of ETEC and *C. cayetanensis*, enteropathogen local epidemiology is not dependent on HIV status. Our data support the need for routine use of laboratory diagnostics in patient care.

0330

### GUT MICROBIOME COMPOSITION PRIOR TO CAMPYLOBACTER GASTROENTERITIS AMONG NICARAGUAN INFANTS

**Claudia Mercedes Perez**<sup>1</sup>, Luis E. Zambrana<sup>2</sup>, Lester Gutiérrez<sup>1</sup>, Nadja A. Vielot<sup>3</sup>, Fredman González<sup>1</sup>, Christian Toval-Ruiz<sup>1</sup>, Patricia Blandón<sup>1</sup>, Roberto Herrera<sup>1</sup>, Filemón Bucardo<sup>1</sup>, Sylvia Becker-Dreps<sup>3</sup>, Samuel Vilchez<sup>1</sup>

<sup>1</sup>Department of Microbiology, National Autonomous University of Nicaragua, León, León, Nicaragua., <sup>2</sup>Department of Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>3</sup>Departments of Family Medicine and Epidemiology, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Campylobacter is increasingly recognized as a leading bacterial etiology of acute gastroenteritis (AGE) in young children in low- and middle-income countries. We have recently shown that *Campylobacter* species were detected in 22.4% (95% CI: 11.2-32.1) of AGE episodes in León, Nicaragua. Furthermore, experiencing a prior AGE episode of any cause conferred a threefold increase in the odds for *Campylobacter* AGE, which may modify the composition of the gut microbiome, altering susceptibility to *Campylobacter spp.* Thus, in the present study we assessed the gut microbiome composition among infants who went onto developing their first *Campylobacter* AGE episode as compared to those infants who did not. We conducted a pilot nested case-control analysis using a random subset of 20 *Campylobacter* gastroenteritis cases and their age-matched controls by comparing microbiome composition in the monthly routine stool specimen collected prior to the onset of AGE symptoms, and the corresponding routine stool specimen for the age-matched controls, from a population-based Nicaraguan birth cohort of 444 children. Characterization of gut microbiota was done by 16S rRNA amplicon sequencing and Quantitative Insights Into Microbial Ecology software. Relative abundance of bacterial taxa between cases and controls were compared using the Wilcoxon-Mann-Whitney test. We identified no significant differences in  $\alpha$ -diversity between cases and controls. However, there was a trend toward a higher relative abundance of *Lachnospiraceae* and *Veionellaceae*, in the control group when compared to cases, [should be explored in larger samples]. Contrary, in the group of cases, we found higher relative abundance of *Streptococcaceae* and *Enterobacteriaceae* as compared to the control group. Furthermore, independent of the *Campylobacter species*, we found decreased bacteria genus ( $\geq 0.5$ -fold differences), *Holdemanella*, *Lachnospiraceae UCG 004*, *Pseudocitrobacter* and *Eubacterium*, as compared to the control group. Additional research is needed to improve our understanding if prior AGE episode on gut microbiome might affect susceptibility to *Campylobacter* AGE.

0331

### MOST ANTIBIOTIC EXPOSURE TO ENTERIC PATHOGENS OCCURS DURING SUBCLINICAL INFECTIONS AMONG CHILDREN UNDER TWO YEARS OF AGE IN LOW-RESOURCE SETTINGS

**Stephanie A. Brennhof**<sup>1</sup>, Timothy L. McMurry<sup>1</sup>, James A. Platts-Mills<sup>1</sup>, Joseph A. Lewnard<sup>2</sup>, Elizabeth T. Rogawski McQuade<sup>1</sup>

<sup>1</sup>University of Virginia, Charlottesville, VA, United States, <sup>2</sup>University of California - Berkeley, Berkeley, CA, United States

Because subclinical enteric infections are common among children in low-resource settings, enteric pathogens may be frequently exposed to antibiotics even when they are not causing diarrhea that prompts treatment. We quantified antibiotic exposures to subclinical infections in the MAL-ED birth cohort study. We included 15697 antibiotic courses in 1715 children. We identified subclinical infections exposed to each antibiotic course as all pathogens detected in the most recent stool sample up to 30 days prior to starting the course of antibiotics. Antibiotic courses were attributed to specific pathogens if they occurred during a diarrhea episode in which the episode-specific attributable fraction for that pathogen from mixed-effects models associating pathogen quantity

with diarrhea was  $>0.5$ . We estimated the total incidence of antibiotic exposure to each subclinical pathogen and estimated the proportion of that exposure that was attributed to treatment of diarrhea caused by other pathogens. The incidence of antibiotic exposure for subclinical bacterial and parasitic infections was 366.5 and 198.1 antibiotic courses per 100 child years, respectively. *Shigella* and *Campylobacter*, for which antimicrobial resistance is of particular concern, were exposed to 45.5 and 147.2 antibiotic courses per 100 child years, respectively. Almost all antibiotic exposure for *Campylobacter* (98.7%), *Cryptosporidium* (95.7%), ETEC (95.4%), and tEPEC (99.2%), and majority for *Shigella* (75.6%), occurred when they were carried subclinically. Compared to other causes of diarrhea, treatment of *Shigella* and rotavirus were the largest contributors to antibiotic exposure. However, only 3.6% and 2.1% of antibiotic exposure for subclinical bacterial infections was due to *Shigella* and rotavirus, respectively. The vast majority of antibiotic exposure to enteric pathogens occurred during subclinical infections, and treatment of etiology-specific diarrhea was responsible for a minority of this exposure. Interventions preventing subclinical carriage in addition to diarrhea are important to reduce antibiotic selection pressure to these pathogens.

## 0332

### CLOSTRIDIODES DIFFICILE CARRIAGE IN THE FIRST TWO YEARS OF LIFE AMONG CHILDREN IN RESOURCE-LIMITED SETTINGS

**Stephanie A. Brennhofner**, Elizabeth T. Rogawski McQuade, Jie Liu, Richard L. Guerrant, James A. Platts-Mills, Cirla A. Warren  
*University of Virginia, Charlottesville, VA, United States*

*Clostridioides difficile* (*C. diff*) infection is an important cause of diarrhea associated with morbidity and mortality globally. In industrialized countries, colonization with *C. diff* is common among young children, but prevalence in low-resource settings is unknown. We included 34623 non-diarrheal monthly surveillance and 6731 diarrheal stools tested for *C. diff* toxin genes (*tcdA* and *tcdB*) from 1715 children in the 8-site MAL-ED cohort study. We estimated the prevalence, cumulative incidence, and seasonality of *C. diff* by site. Additionally, we investigated the associations of *C. diff* detection in the stool with risk factors of infection, markers of enteropathy, and growth. The prevalence of *C. diff* detection was lower in diarrheal stools (2.2%) compared to non-diarrheal stools (6.1%). *C. diff* detection was most prevalent in the second half of the first year of life and tapered off during the second year of life. Cumulative incidence of *C. diff* varied widely by site, ranging from 17% (Pakistan) to 76% (Peru) of children having at least one positive stool by 24 months of age. There were no seasonal differences in *C. diff* detection except in Bangladesh (peaked in rainy season,  $p=0.003$ ) and Pakistan (peaked in dry season,  $p=0.01$ ). After adjustment for site and age, female gender (RR:1.18, CI:1.02-1.35), cephalosporin use in the past 15 days (RR:1.73, CI:1.39-2.16), and treated water (RR:1.24, CI:1.02-1.50) were associated with *C. diff* positivity. Macrolide use in the past 15 days (RR:0.66, CI:0.51, 0.84) and diarrhea in the past 15 days (RR:0.71, CI:0.60, 0.83) were protective against *C. diff* detection. Across sites, *C. diff* carriage was significantly associated with elevated fecal myeloperoxidase, neopterin, and  $\alpha$ -1-antitrypsin, but there were no associations between *C. diff* and child weight or length attainment at 24 months of age. *C. diff* colonization among young children in low-resource settings was highly variable by site. Although not associated with diarrhea and growth shortfalls, detection of *C. diff* in stools was associated with significant elevation of intestinal inflammation markers suggesting subclinical impact of carriage.

### REAL-TIME SURVEILLANCE FOR PEDIATRIC ENTERIC PATHOGENS OF PUBLIC HEALTH CONCERN IN BELIZE

**Mary B. Fortini**<sup>1</sup>, Sarah M. Gunter<sup>1</sup>, Gerhaldine Morazan<sup>2</sup>, Adrianna Maliga<sup>1</sup>, Russell Manzanero<sup>2</sup>, Shannon E. Ronca<sup>1</sup>, Francis Morey<sup>2</sup>, Kristy O. Murray<sup>1</sup>

<sup>1</sup>Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Belize Ministry of Health and Wellness, Belmopan, Belize

Globally, gastrointestinal (GI) illness is the fourth leading cause of death in children under 5, particularly in low to middle income countries (LMIC). The aim of this study was to determine the prevalence and causes of enteric infections in children  $\leq 18$  years old presenting with two or more GI symptoms in Belize. We conducted a prospective study of children aged  $>60$  days to 18 years who presented with two or more GI symptoms to one of 11 participating healthcare facilities throughout all six Belize districts from January 16, 2020 to March 25, 2021. Stool specimens were tested for 22 pathogens using a film array panel. During this timeframe, 442 children were enrolled; 146 (33%) had two or more GI symptoms. Of 146 participants, 83 had stool specimens tested; 66 (79.5%) were positive for at least one pathogen, with 16 different pathogens identified. Positivity was higher among children  $\leq 5$  years (46/55; 83.6%) compared to those 6 to 18 years (20/28; 71.4%). The most common pathogens identified were enteropathogenic *E. coli* (EPEC;  $n=31$ ), followed by enteroinvasive *E. coli* (EIEC;  $n=21$ ), enteroaggregative *E. coli* (EAEC;  $n=21$ ), norovirus ( $n=13$ ), enterotoxigenic *E. coli* (ETEC;  $n=11$ ), *Campylobacter* ( $n=11$ ), *Giardia lamblia* ( $n=7$ ), *Salmonella* ( $n=5$ ), STEC ( $n=5$ ), adenovirus F40/41 ( $n=4$ ), sapovirus ( $n=3$ ), *Plesiomonas shigelloides* ( $n=2$ ), *E. Coli* 0157:H7 ( $n=2$ ), non-cholera *Vibrio* ( $n=2$ ), *Clostridium difficile* ( $n=2$ ), rotavirus ( $n=1$ ), and astrovirus ( $n=1$ ). Co-infections were common, with 143 positive results among the 66 positive panels (average of 2.2 pathogens/positive panel). In conclusion, more than 70% of children presenting with GI illness had a positive pathogen identified, with a higher percentage of positive results in those 5 years of age and younger. This pediatric population had a high rate of coinfections, with EPEC, EIEC, and EAEC most common. As EPEC and EAEC are frequently found in asymptomatic children, the significance of these pathogens in symptomatic children should be attributed more to the co-pathogen detected, with treatment focused on the other pathogen.

## 0334

### ESTIMATING THE ECONOMIC BURDEN OF TYPHOID IN CHILDREN AND ADULTS IN BLANTYRE, MALAWI: A COSTING COHORT STUDY

**Fumbani Loveness Limani**<sup>1</sup>, Christopher Smith<sup>1</sup>, James Meiring<sup>1</sup>, Richard Wachepa<sup>1</sup>, Frederic Debellat<sup>2</sup>, Clint Pacenka<sup>2</sup>, Melita Gordon<sup>1</sup>, Naor Bar-Zeev<sup>1</sup>

<sup>1</sup>Malawi Liverpool Wellcome Trust, Blantyre, Malawi, <sup>2</sup>PATH, Seattle, WA, United States

Typhoid fever continues to cause high morbidity and mortality in low and middle-income countries. WHO recommends using typhoid vaccine to control endemic disease in countries with high typhoid fever burden. Information on disease burden, cost of illness, delivery costs, and cost-effectiveness is relevant for policymakers' informed decision-making on national vaccine introduction. This study aimed to estimate the cost of typhoid fever illness among children and adults in Blantyre district, Malawi. A prospective facility-based cohort study was undertaken. The cost of illness was the sum of direct and indirect costs borne by typhoid patients and their families plus the direct cost of managing a confirmed case of typhoid fever at the three health facilities. One hundred and nine patients with confirmed typhoid fever were recruited. Forty-four (40%) participants were admitted overnight to the hospital, with a mean length of hospitalization of 8.4 (SD 6.7) days. Sixty-three of the one hundred and nine participants (58%) were less than 15 yrs old. The mean household and health facility cost, catastrophic cost and the total mean cost of

typhoid fever will be calculated. These results contribute to the further economic analysis of typhoid fever vaccination introduction in Malawi and other sub-Saharan African countries.

0335

### **NASOPHARYNGEAL COLONIZATION, ASSOCIATED FACTORS, AND ANTIMICROBIAL RESISTANCE OF STREPTOCOCCUS PNEUMONIAE AMONG CHILDREN UNDER FIVE YEARS OF AGE IN THE SOUTHWESTERN COLOMBIA**

**Juan Pablo Rojas**

*Club Noel Children's Clinic Foundation in Cali, Colombia, Cali, Colombia*

This work aims to evaluate the factors associated with *Streptococcus pneumoniae* nasopharyngeal colonization and antimicrobial susceptibility among pediatric outpatients in the southwestern-Colombia, 2019. A cross-sectional study was carried out using survey-based interviews and the collection of nasopharyngeal-swab specimens for microbiological characterization and antimicrobial susceptibility testing. Logistic regression analyses were performed for factors associated with nasopharyngeal carriage. A total of 452 children under-5 years of age were examined and 41.8% carried *S. pneumoniae*. Higher pneumococcal carriage frequencies were observed among participants <2-years and in individuals belonging to indigenous communities, which were lacking established PCV-10 immunization schemes. Additionally, children attending child-care institutions were also highly colonized by pneumococci. *S. pneumoniae* showed 57.7% non-susceptibility to benzylpenicillin (meningitiscut); 45.5% intermediate-sensitivity to benzylpenicillin (oralcut) and 21.7% to cefotaxime; and resistance to erythromycin (40.7%), tetracycline (36.0%), trimethoprim/sulfamethoxazole (24.9%), clindamycin (24.3%) and ceftriaxone (27.0%). The 41.8% of participants carrying *S. pneumoniae* show a scenario with the presence of multi-drug and extensively-drug resistant strains, which constitutes important reservoirs of bacterial transmission by children <5-years in Colombia, leading to an onset of pneumococcal diseases. Hence, there is an urgent need to expand conjugate pneumococcal immunization in the community and ensure compliance with established immunization schedules.

0336

### **POINT OF CARE ULTRASOUND IN MANAGEMENT OF LASSA FEVER AT IRRUA SPECIALIST TEACHING HOSPITAL, NIGERIA - A PILOT STUDY**

**Cyril Oshomah Eramah**

*Irrua Specialist Teaching Hospital, Irrua, Nigeria*

Point-of-care ultrasound (POCUS) is a standard of care in emergency medicine and has also proven to be useful in diagnostics and management of infectious diseases. In the management of patients with high-impact pathogens, where access to other medical imaging is limited, POCUS may be a useful tool in patient management. In this pilot-study we evaluated potential pathologies identifiable through POCUS in patients with Lassa fever. This observational study was conducted at the Irrua Specialist Teaching Hospital, Nigeria. We applied a modified eFAST protocol to identify typical pathologies of Lassa fever. Patients were evaluated using a DP50 machine (Mindray) with linear and curved array probes after admission to the isolation ward. Pathologies were recorded systematically and videos stored for assessment by an independent reviewer. The prevalence of specific pathologies was determined, and POCUS findings were correlated with laboratory parameters and clinical outcome. In total, 46 patients were evaluated using the modified POCUS assessment. Signs of serositis were found in 37 patients (80%) with pericardial effusion being the most common finding (67%), most of these were however minimal. Effusions at more than one site, reflecting the presence of polyserositis, were seen in eight patients (17%). Hyperechoic kidneys were observed in 5 patients (11%). All patients with hyperechoic kidneys had a creatinine >2g/dl and among all patients with a creatinine > 2g/dl only one individual did not show signs of renal pathology on POCUS examination. Of the five patients with renal pathology on POCUS two died (40%) compared to

12% of those without renal pathology. Pathological findings on POCUS examination were common in patients with Lassa fever evaluated in this pilot study. Assessment of specific pathologies such as hyperechoic kidneys by POCUS at admission may have an immediate impact on patient management. Further studies including larger sample sizes are needed to correlate findings with clinical parameters, clinical outcomes to better appreciate the value of POCUS for the clinical management of Lassa fever patients.

0337

### **ENTEROBACTERIACEAE PRODUCING EXTENDED-SPECTRUM B-LACTAMASES IN A SPECIALIZED CLINIC IN THE CITY OF MONTERÍA- CÓRDOBA-COLOMBIA**

**Linda M. Chams**, William Guerrero, Laura V. Machado, Carlos J. Castro

*Grupo de Investigaciones Microbiológicas y Biológicas de Córdoba (GIMBIC)-Universidad de Córdoba, Montería, Colombia*

Extended spectrum  $\beta$ -lactamases (ESBLs) are bacterial enzymes that are phenotypically characterized by conferring resistance to penicillins and cephalosporins, including those of the third and fourth generation. ESBLs-producing Enterobacteriaceae are of great clinical interest, due to the high probability of therapeutic failure they generate, increasing the periods of hospitalization of patients and the costs of treatment in health care institutions. The objective of this study was to determine the prevalence of ESBLs-producing enterobacteria in a specialized clinic in the city of Montería. A descriptive study was carried out, in which the results of the antibiograms carried out on the Enterobacteriaceae isolated from the patients admitted between the years 2017 and 2018 were analyzed. The variables included in the statistical analysis were: isolated microorganism, origin of the sample, service isolation and susceptibility profile. The data were analyzed using the statistical software SPSS Statistics version 2018. During the study period, a total of 1,292 isolates were recorded, from patients admitted to different services of the clinic, where the ICU was identified as the area with the highest frequency of bacterial isolation, 974 / 1,292 (75.3%) corresponded to species of the Enterobacteriaceae family, and of these 739/974 (75.8%) belonged to *Klebsiella* spp, *Escherichia coli* and *Proteus* spp. The ESBLs-producing Enterobacteriaceae isolates corresponded to 103/739 (13.9%) and non-producing to 636/739 (86.1%). In this study, no carbapenemase-producing strain was found, however, it is recommended to confirm it by molecular biology studies. The most frequently isolated resistant strains correspond to the species of *K. pneumoniae* and *E. coli*. The results obtained in this study are consistent with those recorded globally. The prevalence of ESBLs-producing Enterobacteriaceae is a growing problem that demands more studies that contribute to the optimization of empirical therapy and the continuous monitoring of this phenomenon.

### **PREVALENCE OF RESISTANT METICILIN STAPHYLOCOCCUS AUREUS (MRSA) PRESENT IN POLI-TRAUMA PATIENTS AT A SPECIALIZED CLINIC IN MONTERÍA- CÓRDOBA- COLOMBIA**

**Linda M. Chams**, William Guerrero, Jorge A. Ponce, Carlos J. Castro

*Grupo de Investigaciones Microbiológicas y Biológicas de Córdoba (GIMBIC)-Universidad de Córdoba, Montería, Colombia*

Methicillin-resistant *Staphylococcus aureus* (MRSA) is increasingly responsible for infections in hospitalized patients, affecting a large percentage of poly-trauma patients. A descriptive study of the type retrospective was carried out in a specialized clinic in the city of Montería during the years 2017, 2018 and 2019, where the databases of the area corresponding to Microbiology were analyzed, specifically the patients admitted positive for the isolation of *Staphylococcus aureus*. The determination of the susceptibility profile included the Oxacillin resistance test with the Kirby-Bauer methods (agar diffusion method) and Micro Scam with the Cefoxitin MIC incorporated. The study population

consisted of 1,674 polytraumatized patients admitted to the different medical services of this clinic between 2017 and 2019. Of the 16,541 patients admitted to the clinic in the study years, 10% (1,674) were polytraumatized patients of which 81.6% belonged to the male sex, possibly due to their type of occupation; The service with the highest number of hospitalized patients with multiple trauma was the ICU with a total of 680 patients, which represents 40.6% of the 1,674 hospitalized patients. During the study period 46/178 (25.8%) samples were reported as positive for MRSA. The sample where this bacterium was most frequently isolated was wound secretion with a total of 24/46 positive cultures, followed by bone sample with 9/46, bronchial secretion with 5/46 and blood culture 2/46. During the three years of the study, patients with infectious processes due to MRSA and whose anatomical location corresponded to skin, soft tissues and bone, were treated with antibiotic management guided by Antibiogram, most of them were treated with Trimethoprim Sulfa 160/800 each. 12 hours, taking into account that 98% of the isolated strains were sensitive to this antimicrobial. Patients with bacteremia were managed with Vancomycin at a dose of 1 gram every 12 hours, and in patients with pneumonic processes, Linezolid 600mg was given every 12 hours x 14 days.

### ANTIBIOTICS IN THE MANAGEMENT OF UNCOMPLICATED SEVERE ACUTE MALNUTRITION IN BURKINA FASO: A RANDOMIZED TRIAL COMPARING AZITHROMYCIN TO AMOXICILLIN

**Kieran S. O'Brien<sup>1</sup>**, Ali Sie<sup>2</sup>, Clarisse Dah<sup>3</sup>, Millogo Ouhore<sup>3</sup>, Moussa Ouedraogo<sup>3</sup>, Valentin Boudo<sup>3</sup>, Ahmed M. Arzika<sup>4</sup>, Elodie Lebas<sup>1</sup>, Fanice Nyatigo<sup>1</sup>, William W. Godwin<sup>1</sup>, J. D. Kelly<sup>1</sup>, Benjamin F. Arnold<sup>1</sup>, Catherine E. Oldenburg<sup>1</sup>

<sup>1</sup>University of California, San Francisco, San Francisco, CA, United States,

<sup>2</sup>Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso, <sup>3</sup>Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso, <sup>4</sup>Centre de Recherche et Interventions en Sante Publique, Niamey, Niger

Given the challenge of diagnosing infection in malnourished children, many national nutritional guidelines recommend provision of a broad-spectrum antibiotic like amoxicillin in the management of uncomplicated severe acute malnutrition (SAM). However, evidence on the role of amoxicillin for uncomplicated SAM is mixed. Azithromycin is a potential alternative to amoxicillin in the management of SAM as it can be administered as a single dose, has a long half-life, and has efficacy against pathogens responsible for common childhood infections. In this pilot randomized trial, we aimed to compare the efficacy of azithromycin to amoxicillin on weight gain in children with uncomplicated SAM in Burkina Faso. Between June and October 2020, 301 children were enrolled and randomized to receive a single dose of oral azithromycin or a 7-day course of oral amoxicillin (standard of care). Both groups received ready-to-use therapeutic food and the standard package of care for uncomplicated SAM in Burkina Faso. Children were followed weekly until nutritional recovery and again at 8 weeks for a final study visit. The primary outcome of weight gain velocity (g/kg/day) was compared by arm over the study period. Overall, 282 children (93.6%) completed the 8-week visit. Average weight gain velocity (g/kg/day) was 2.5 (SD 2.0) in the azithromycin group and 2.6 (SD 1.7) in the amoxicillin group (Mean Difference -0.1, 95% CI -0.5 to 0.3,  $P = 0.63$ ). Fewer adverse events were reported in the azithromycin group (Risk Ratio 0.50, 95% CI 0.31 to 0.82,  $P = 0.006$ ). With the ease of dosing and the potential for fewer adverse events, azithromycin may be a viable alternative to amoxicillin in the management of uncomplicated SAM.

0340

### DIFFERENCES IN THE EXTENT OF BREASTFEEDING BETWEEN HAITIAN CREOLE- AND SPANISH-SPEAKING HOUSEHOLDS IN THE DOMINICAN REPUBLIC

**Isabella Alatorre**, John D. McLennan

University of Calgary, Calgary, AB, Canada

Exclusive breastfeeding (EBF) rates in the Dominican Republic (DR) are lower than many other low- and middle-income countries and dropping. To further examine this problematic pattern, this study examined whether different groups in the DR have different breastfeeding rates. Specifically, it examined whether Haitian-Creole speaking households in the DR have a higher breastfeeding rate than Spanish speaking households. This is hypothesized based on Haitians in Haiti having much higher breastfeeding rates than the DR overall. However, as these two populations may vary on other potentially relevant factors for breastfeeding, this study considered potential confounders. Data from the 2014 DR Multiple Indicator Cluster Survey (MICS) was used for this study. MICS data contains key maternal and child health variables on a representative national sample. Subsamples of infants under six months of age at the time of the survey with complete data included 163 and 1487 Creole- and Spanish-speaking households, respectively. More Creole than Spanish speaking children were EBF, 11.0 vs. 4.1%. A greater percentage of Creole households were in the lowest wealth quintile and mothers in Creole-speaking households had lower education levels than the Spanish-speaking sample. In the final multivariate model, household language was no longer related to the extent of breastfeeding, but the wealth index was such that the group belonging to the poorest quintile retained a significant independent relationship with more breastfeeding. That living in Creole-speaking households was not independently related to breastfeeding may suggest a high degree of acculturation for this sample, which may be reflected in the relatively low rate of EBF compared to Haitians in Haiti. Future studies should examine variables such as duration of time of Haitian immigrants in the DR, in a larger sample size, to further examine possible acculturation mechanisms contributing to lower EBF in the DR.

0341

### DIFFERENCES IN EARLY INITIATION OF BREASTFEEDING BETWEEN CUBA AND THE DOMINICAN REPUBLIC

**Donovan Seidel**, John D. McLennan

University of Calgary, Calgary, AB, Canada

Early initiation of breastfeeding (EIBF) may decrease mortality and improve health of infants and young children. EIBF rates vary significantly between countries, however, contributors to these variations are poorly known. Examining and comparing practices in different countries, while considering potential confounding factors, may help identify contributors to EIBF differences. This study aimed to determine whether there are differences in EIBF rates between Cuba and the Dominican Republic (DR), and whether an association persists between country and EIBF rates when controlling for potential confounders. Cuba and the DR are both countries on Caribbean islands with similar populations but markedly different health care systems. The study used data from the Multiple Indicator Cluster Surveys from 2014 that collected data on nationally representative samples from both countries. For analysis, EIBF was defined as  $\leq 1$  hour post-delivery. A series of chi-square tests, Breslow-Day statistics, and logistic regression models were used for analysis. Cuba had a significantly higher rate of EIBF than the DR, 63.0% vs. 46.9%, respectively. The association between country and EIBF persisted even after controlling for cesarean section delivery (higher in the DR), place of residence, and maternal education (higher in Cuba). Although bivariate analysis identified that cesarean sections may have a less adverse impact on EIBF in Cuba compared to the DR, an interaction term examining this in the final multivariate model was not significant. Additional inquiry is required to understand what factors might explain higher EIBF rates in Cuba beyond those variables considered in this study. This may include examining health education and promotion of EIBF, determining the extent of support

for breastfeeding especially in the immediate postpartum period, and exploring maternal attitudes about breastfeeding in Cuba relative to other countries.

### FREQUENCY OF TYPHOID CARRIER IN PATIENTS UNDERGOING CHOLECYSTECTOMY FOR GALL BLADDER DISEASES USING REAL TIME PCR

**Sonia Qureshi**, Maria Fletcher, Tabish Chawla, Farah Naz Qamar  
*Aga Khan University Hospital, Karachi, Pakistan*

Annually millions of new typhoid cases are reported globally despite advancement in treatment and preventive measures. One of the major cause of typhoid endemicity is gallbladder carriage of typhoid etiological agent, *Salmonella enterica subsp. enterica, serovar Typhi (S. Typhi)* and *Salmonella Paratyphi (S. Paratyphi)*. This study is aimed to determine the frequency of typhoid carriers in patients who underwent cholecystectomy for gall bladder diseases. A cross-sectional study conducted at Aga Khan University Hospital and Jinnah Postgraduate Medical Center, Karachi from December 2018-February 2020. All individuals of age  $\geq 10$  years were included. Multiplex real time polymerase chain reaction (PCR) was performed on gall bladder specimens including gallstones, bile and gallbladder tissue and sera of same patients were screened against YncE IgG via ELISA. Out of 989 enrolled participants, 34 (3.4%) were carriers of either *S. Typhi* (2.3%) or *S. Paratyphi* (1.1%). It was found that most of the carriers harboring organism in their gallstones 24/34 (70.6%) while 20/34 (58.8%) in tissues and 11 (32.4%) in bile. ELISA was performed on sera of 34 PCR positive and 34 age and gender matched PCR negative samples (controls) to measure anti-*S. typhi Vi* IgG. Our results showed no association of Vi and YncE with PCR positive carriers. The mean age of participants was 40 ( $\pm 14.3$  SD) years. The reason of cholecystectomy in 949/989 (96%) of them was gallstones. Among typhoid carriers, majority 25/34(73.5%) of them were females. History of typhoid fever was not significantly associated with typhoid carrier. We found higher rates of salmonella carriage in gallstones compared to tissue and bile. To control the typhoid fever cases in the region, we should try to interrupt the transmission cycle by typhoid carriers by developing a cost effective, specific and non-invasive diagnostic tools to improve typhoid carrier identification.

### DEPRESSION AND QUALITY OF LIFE AMONGST FILARIAL LYMPHOEDEMA PATIENTS: DETERMINING DEMOGRAPHIC, SOCIO-ECONOMIC AND PHYSICAL RISK FACTORS, AND THE IMPACT OF ENHANCED SELF-CARE INTERVENTION

**Carrie Barrett**

*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Lymphatic filariasis (LF) is a major cause of disfiguring and disabling lymphoedema. This study aims to: i) determine the prevalence of and factors associated with depression and low quality of life (QOL) in lymphoedema patients; ii) understand if implementation of enhanced self-care (ESC) affects depression and QOL. A prospective cohort of ~150 patients in two regions of Malawi (North/South) was conducted over six months. Lymphoedema patients were surveyed before being trained in ESC (at baseline), involving hygiene, deep-breathing, massage and leg exercises. Follow-up surveys were at 3 and 6 months. Depression was assessed using Patient Health Questionnaire (PHQ-9) and QOL was assessed using an adapted LF Specific QOL Questionnaire (LFSQQ). Questionnaires used a normalized Likert scale scoring system. Beta regression was used to identify sociodemographic factors and lymphoedema severity associated with depression and QOL in individuals. Data were stratified by the three survey time periods. Baseline observations from 309 lymphoedema patients indicate that 23% (95%CI, 18%-28%) display mild/moderate depression (Likert score  $>5$ ). The LFSQQ identified 31% (95%CI, 26%-37%) of patients with a moderately/severely low QOL score (Likert score  $<70$ ). Factors significantly associated with higher

depression and lower QOL scores included patients requiring a caregiver ( $p<0.001$ ) and higher number of secondary bacterial infections (i.e. acute attacks) in last 6 months ( $p<0.001$ ). In addition, patients requiring family support ( $p=0.004$ ); higher number of sick days off work ( $p<0.001$ ) were also significantly associated with lower QOL scores. Preliminary PHQ-9 results from the North region indicate depression scores significantly reduced from baseline mean score of 2.5 to 0.7 in 3-month survey following ESC (t-test  $p<0.001$ ). Surveys are due to be completed in August 2021. Filarial lymphoedema is associated with a high prevalence of depression and lower QOL. ESC is a promising intervention in reducing disfigurement and disability caused by lymphoedema and may play a role reducing depression and improving quality of life for those affected.

0343

### DEPRESSION AND QUALITY OF LIFE AMONGST FILARIAL LYMPHOEDEMA PATIENTS: DETERMINING DEMOGRAPHIC, SOCIO-ECONOMIC AND PHYSICAL RISK FACTORS, AND THE IMPACT OF ENHANCED SELF-CARE INTERVENTION

**Carrie Barrett**

*Liverpool School of Tropical Medicine, Liverpool, United Kingdom*

Lymphatic filariasis (LF) is a major cause of disfiguring and disabling lymphoedema. ### TOWARDS THE DEVELOPMENT OF A CLINICAL MANAGEMENT DECISION TREE FOR DIAGNOSIS OF PATIENTS WITH ACUTE FEBRILE ILLNESS IN BANGLADESH: A PRELIMINARY ANALYSIS

**Angella Sandra Namwase<sup>1</sup>**, Pritimoy Das<sup>2</sup>, M Ziaur Rahman<sup>2</sup>, Mahmudur Rahman<sup>3</sup>, Cecilia Y. Kato<sup>1</sup>, Daniel W. Martin<sup>1</sup>, Mahabub UI Anwar<sup>1</sup>, Adam L. Cohen<sup>1</sup>

<sup>1</sup>Centers for Disease Control, Atlanta, GA, United States, <sup>2</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>3</sup>Independent Consultant, Dhaka, Bangladesh

Acute febrile illness (AFI) is a common reason for seeking medical care among patients in Bangladesh and may be caused by dengue, typhoid,

and other bacterial and viral diseases. Since AFI patients present with similar symptoms, clinicians may need additional guidance to identify the cause of AFI to guide care. The aim of this study was to develop a preliminary decision tree for common AFI etiologies that could inform the future development of decision trees for AFI patients. We conducted surveillance for patients presenting to government hospital outpatient care with AFI in Bangladesh between May 2019 and March 2020. Using a 5-fold cross-validated chi-squared automatic interaction detection (CHAID) algorithm, we developed a preliminary decision tree with data on symptoms and vital signs of AFI patients with common causes. These patients were identified using blood cultures, polymerase chain reaction assays, and rapid diagnostic tests. Co-infected patients and patients under 5 years were excluded. The most common etiologies identified among the 629 patients enrolled with AFI were dengue (24, 19.4%), *Escherichia coli* urinary tract infections (UTIs) (37, 29.8%), and typhoid (63, 50.8%). Among the 124 patients with one of these three etiologies, 65.3% (81) were male; 54.0% (67) were between 5 to 19 years and 12.1% (15) were above 35 years. The most common symptoms were headache (73.4%), lack of appetite (62.1%) and fatigue (54.8%). The CHAID algorithm used sore throat, elevated blood pressure, bone pain, and fatigue to distinguish dengue, *E. coli* UTI, and typhoid. Sore throat was the most significant factor in distinguishing dengue patients from *E. coli* UTI and typhoid patients. The CHAID model had an accuracy rate of 62.5% and a kappa statistic of 0.4. The sensitivity of the model was 64.7% for dengue patients, 11.5% for *E. coli* UTI patients, and 91.1% for typhoid patients. This analysis is limited by sample size and few prevalent etiologies. These results could guide future development of clinical management decision trees and should be validated on a larger dataset with additional clinical and demographic data.

#### IS EDUCATION ENOUGH? AN INTERVENTION TO IMPROVE SCREENING FOR CHAGAS DISEASE AT AN ACADEMIC SAFETY NET HOSPITAL IN THE US

**Alyse Wheelock<sup>1</sup>**, Sukhmeet Sandhu<sup>1</sup>, Catherine Bielick<sup>1</sup>, Katherine Reifler<sup>1</sup>, Maja Carrion<sup>2</sup>, Katherine Janiszewski<sup>3</sup>, David Hamer<sup>4</sup>, Natasha Hochberg<sup>5</sup>

<sup>1</sup>Boston Medical Center, Boston, MA, United States, <sup>2</sup>Boston University College of Health and Rehabilitation Sciences: Sargent College, Boston, MA, United States, <sup>3</sup>Boston University School of Public Health, Boston, MA, United States, <sup>4</sup>Boston University School of Public Health and School of Medicine, Boston, MA, United States, <sup>5</sup>Boston University School of Medicine and Boston University School of Public Health, Boston, MA, United States

Chagas disease, caused by the parasite *Trypanosoma cruzi*, causes significant morbidity and mortality related to late-stage cardiac and other sequelae. In the United States, Chagas disease remains vastly underdiagnosed though it is prevalent among individuals originating from continental Latin America. We aimed to increase knowledge of and testing for Chagas disease at a large academic safety-net hospital in Massachusetts. An interactive, one-hour educational program was developed and disseminated from April to July 2019 in five multi-disciplinary settings (departmental Grand Rounds, clinic conferences, etc.) that addressed the need for Chagas disease screening. We tracked the number of *T. cruzi* assays ordered from March 2016 – December 2019. A total of 299 tests were ordered overall, with transplant clinicians ordering the most (n = 71, 23.7%). In the five months pre-intervention, 86 tests were ordered (46 in transplant clinic and 40 in other settings including cardiology clinic and inpatient medicine services); among 45 patients with a recorded country of origin, 16 (35.6%) were from endemic regions. In the five months post-intervention, 53 tests were ordered (1 in transplant clinic and 52 in non-transplant settings); among 24 patients with a recorded country of origin, 16 (66.7%) were from endemic regions. Overall, Chagas disease screening in non-transplant settings increased slightly post-intervention; analyses are underway to see if this change was sustained. Testing of patients from non-endemic regions was common but decreased following the intervention. The high pre-intervention

rates amongst transplant clinicians might reflect the temporary hiring of a transplant ID physician (March-September 2019), suggesting that in-person reminders from a peer are effective in influencing medical practice. In summary, education is one component of a strategy to address Chagas disease but must be integrated with other interventions to realize substantive increases in screening and to ensure testing of individuals from endemic areas.

## 0346

#### AN UNUSUALLY LATE CLINICAL PRESENTATION

**Jordan Kit Mah**, Anthony Lieu, Emma Holmes, Steve Vaughan  
University of Calgary, Calgary, AB, Canada

A 71-year-old Chinese immigrant presented with 4-months of weight loss, anorexia, constipation and abdominal pain. He reported no travel in 5 years. His past medical history included biopsy proven IgG4 disease of the pancreas and kidneys and 3 episodes of gram-negative bacteremia in the last 4 years initially attributed to gallstone cholangitis and later suspected pancreatic cancer. He had received multiple courses of immunosuppression for recurrent flares of IgG4-disease including rituximab, MMF and repeat courses of high-dose steroids. This admission, the patient had *E. coli* bacteremia. CT imaging showed new extensive bilateral parenchymal lung abnormalities with dilated stomach and small bowel loops. IV ertapenem was administered, with clearance of bacteremia. 7 days later, he developed *E. faecium* bacteremia treated with IV vancomycin. *Strongyloides* hyperinfection syndrome (SHS) was considered but deemed less likely given prior history of steroid use. *Strongyloides* serology was negative and stool microscopy was not sent due to constipation. The patient died from overwhelming sepsis from suspected aspiration pneumonia. Autopsy revealed *Strongyloides* hyperinfection as the cause of death, with multiple round worms, 350-600x15µm, found in stomach and pancreatic tissue. Immunosuppression can trigger SHS, leading to life threatening consequences and mortality rates up to 85-100%. Our patient received various immunosuppressants for treatment of IgG4 disease over a 4-year period. It was unusual that SHS did not occur earlier and only resulted in death at the most recent hospitalization. We presumed this was a result of a remote infection given the lack of occupation risk and recent travel. SHS is described with corticosteroid usage irrespective of dose, route of administration, or duration, with cases reported as early as 6-17 days. There have been only two cases reported in kidney transplant patients presenting with delayed SHS 2-6 years after receiving immunosuppression. In rare cases, SHS can be delayed when using immunosuppression. This increases the risk of a delayed or unrecognized diagnosis leading to fatal consequences.

## 0347

#### ENVIRONMENTAL ENTERIC DYSFUNCTION: HISTOPATHOLOGICAL & IMMUNOHISTOCHEMICAL ANALYSIS OF DUODENAL BIOPSIES FROM PAKISTANI MALNOURISHED CHILDREN

**Zehra Jamil<sup>1</sup>**, Najeema Iqbal<sup>1</sup>, Kamran Sadiq<sup>1</sup>, Junaid Iqbal<sup>1</sup>, Sana Syed<sup>2</sup>, Zubair Ahmad<sup>1</sup>, Romana Idrees<sup>1</sup>, Kumail Ahmed<sup>1</sup>, Christopher A. Moskaluk<sup>2</sup>, Donna M. Denno<sup>3</sup>, Sean Moore<sup>2</sup>, Syed Asad Ali<sup>1</sup>

<sup>1</sup>Aga Khan University, Karachi, Pakistan, <sup>2</sup>University of Virginia, Charlottesville, VA, United States, <sup>3</sup>University of Washington, Seattle, WA, United States

Environmental Enteric dysfunction (EED) is a causative factor for malnutrition and further aggravates it. To gain insight in to its pathophysiology, this study examines expression of selected proteins and their association with duodenal histology. For histopathological workup, 63 biopsies from undernourished children refractory to nutritional intervention were processed for H & E staining. Slides were examined by pathologists using EED histology scoring system. For expression of protein markers, immunohistochemistry (IHC) was performed using tissue microarray. The core biopsies were arrayed on recipient paraffin block and

stained on robotic Ventana Discovery Ultra instrument with antibodies for epithelial cell subtyping, lymphocyte subtyping and to evaluate protein expression of various inflammatory markers. Paneth cell (PC) count on microscopy was positively associated with PC marker defensin alpha5 (DEFA5) [ $r=0.467$ ,  $p<0.001$ ] and brush border marker sucrase-isomaltase (SI) [ $r=0.336$ ,  $p=0.009$ ] on IHC. Similar trend was seen for aggregated histology scores with significant negative association with PC ( $r=-0.361$ ) and SI ( $r=-0.374$ ) while positive correlation with Reg1B expression ( $r=0.300$ ). Duodenal slides with histology confirmed *H. pylori* reported positive correlation with dual oxidase2 ( $r=0.355$ ,  $p=0.007$ ) and lipocalin ( $r=0.280$ ,  $p=0.035$ ) but not with Granzyme B ( $r=0.176$ ,  $p=0.186$ ). No association was seen between villous blunting and SI (brush border marker), goblet cell reduction and MUC2, intraepithelial lymphocytosis and CD45, CD3 or CD19. Based on histopathology scoring, protein expressions were compared between low ( $<6$ ) and high scorer ( $>6$ ). A heightened expression of Reg1B ( $p=0.034$ ) and CXCL10 ( $p=0.029$ ) was observed in cases with higher scores while PC marker ( $p=0.010$ ) and brush border marker ( $p=0.032$ ) were raised in lower scorers. Immunohistochemistry supports the findings of histopathology suggesting key role of Paneth cells in gut homeostasis. Overexpression of inflammatory markers in association with a decline in Paneth cell and brush border markers appear to be involved in pathophysiology of EED.

#### **AZITHROMYCIN FOR CHILD SURVIVAL IN NIGER: IMPLEMENTATION AND RESEARCH: AN ADAPTIVE CLUSTER-RANDOMIZED TRIAL TO DETERMINE THE OPTIMAL AGE GROUP FOR IMPLEMENTATION OF BIENNIAL ORAL AZITHROMYCIN DISTRIBUTION TO REDUCE CHILD MORTALITY IN NIGER**

**Emily Colby**<sup>1</sup>, Kieran S. O'Brien<sup>1</sup>, Ahmed M. Arzika<sup>2</sup>, Abdou Amza<sup>3</sup>, Ramatou Maliki<sup>2</sup>, Sani Ousmane<sup>4</sup>, Boubacar Kadri<sup>3</sup>, Beido Nassirou<sup>3</sup>, Alio Karamba Mankara<sup>4</sup>, Abdoul Naser Harouna<sup>4</sup>, Elodie Lebas<sup>1</sup>, Zijun Liu<sup>1</sup>, Victoria Le<sup>1</sup>, William Nguyen<sup>1</sup>, Catherine Oldenburg<sup>1</sup>, Travis C. Porco<sup>1</sup>, Thuy Doan<sup>1</sup>, Benjamin F. Arnold<sup>1</sup>, Thomas M. Lietman<sup>1</sup>

<sup>1</sup>University of California San Francisco F.I. Proctor Foundation, San Francisco, CA, United States, <sup>2</sup>Centre de recherche et interventions en santé publique, Niamey, Niger, <sup>3</sup>Programme national de santé oculaire, Niamey, Niger, <sup>4</sup>Centre de Recherche Médicale et Sanitaire, Niamey, Niger

In 2020, the World Health Organization (WHO) released conditional guidelines on azithromycin distribution to children aged 1–11 months in high mortality settings to promote child survival. However, distribution of this intervention to children aged 1–11 months alone remains untested. The MORDOR trial found a 14% reduction in mortality comparing communities in which children aged 1–59 months received biannual azithromycin distribution or placebo over 2 years in Malawi, Niger, and Tanzania. Although crude data from subgroup analyses showed a mortality reduction of approximately 23% in children aged 1–11 months, the trial was not powered to detect effect heterogeneity by age group and there may be indirect effects from older to younger children. AVENIR is a cluster-randomized trial designed to compare the effect of targeted azithromycin distribution to children aged 1–11 months vs children aged 1–59 months on mortality and antimicrobial resistance (AMR) in Niger. In the first stage of the study, 3,350 rural and peri-urban communities in Niger's Dosso and Tahoua regions will be enrolled. Dosso communities will be enrolled in the first year and randomized in a 1:1:1 fashion to one of three arms: azithromycin to 1–11-month-olds (placebo to 12–59-month-olds), azithromycin to 1–59-month-olds, or placebo to 1–59-month-olds. Tahoua communities will be enrolled in the second year, with the randomization allocation updated based on the probability of mortality in each arm. Response-adaptive allocation allows for a more ethical distribution, as communities will have a higher probability of receiving the intervention that reduces mortality the most. A biannual door-to-door census will occur over 2.5 years to enumerate the study population, administer treatment, and monitor mortality. AMR will be monitored in a random subset of 150

communities in Dosso at baseline and after 2 years of distributions. Census and treatment distribution began in November 2020, and the primary outcome analysis will occur in Fall 2023.

0349

#### **ACUTE FEBRILE ILLNESS IN EGYPT: ENHANCED SURVEILLANCE FOR ETIOLOGIES CAUSING THE SYNDROME**

**Rania Nada**<sup>1</sup>, Mahmoud El-Bendary<sup>2</sup>, Mustafa Neamatallah<sup>2</sup>, Ahmed El Shabrawi<sup>2</sup>, Adel Mansour<sup>1</sup>, Hanan El Mohammady<sup>1</sup>, Isabelle Nakhla<sup>1</sup>

<sup>1</sup>U.S. Naval Medical Research Unit No. 3, Cairo, Egypt, <sup>2</sup>Faculty of Medicine, Mansoura University, Mansoura, Egypt

Acute febrile illness (AFI) is a non-specific syndrome caused by many pathogens distributed differently according to the geographical area. This study aimed to describe the epidemiology and common etiologies of AFI cases presenting to Mansoura University Hospital, Nile Delta, Egypt. Blood samples were subjected to standard blood culture testing, as well as qPCR for the detection of *Salmonella spp.*, *Brucella spp.*, *Dengue virus*, *Chikungunya virus*, *West Nile virus*, *Plasmodium spp.*, *Rickettsia spp.*, *Leptospira spp.*, *Yellow Fever virus*, *S. pneumoniae*, *Coxiella burnetii* and *Rift Valley Fever virus*. From June 2019 to March 2021, 287 subjects were enrolled, and their data analyzed. Demographics showed that 49% were male and the median age of patients was 44 years. Median illness duration was 4 days. Other than fever, abdominal tenderness (21%) and sore throat (14%) were the most commonly associated signs and symptoms. Only a single pathogen was detected in 38 (13.2%) patients and two (0.7%) cases showed concomitant infections. *Rift valley virus*, *Salmonella*, *E. coli* and *S. aureus* were identified in 9 (3.1%), 7 (2.4%), 4 (1.4%) and 4 (1.4%) cases, respectively. This study reports the detection of *Leptospira spp* in Egypt using qPCR, in contrast to previous studies reporting *Leptospira* antibodies only. Antibiograms of *E. coli* showed that all isolates were resistant to 3<sup>rd</sup> and 4<sup>th</sup> generation cephalosporins and were Extended Spectrum Beta-Lactamase (ESBL) producers, but sensitive to gentamicin and fluoroquinolones. As well, 75% of *S. aureus* isolates were Methicillin-resistant *Staphylococcus aureus* (MRSA). In 2019 the detection rate of AFI pathogens showed a significant decrease that started in November compare to June to October 2019 and in 2020 there was a peak of pathogen detection rate in August. In conclusion, our data provided information regarding the epidemiology of AFI in Egypt, however, the testing panel will be broadened to minimize the percentage of the negative specimens.

#### **NON-INVASIVE DNA AMPLIFICATION AND SEX DETERMINATION OF CULTURED BRUGIA MALAYI LARVAE**

**Santiago Hernandez**, Canhui Liu, Hassan Hassan, Michelle Michalski, Thomas R. Unnasch

University of South Florida, Tampa, FL, United States

The Clustered Regularly Interspaced Short Palindromic Repeats (CRISPR) based technology is currently being used to develop a genetic toolkit and methods for the study of transcriptional and post-transcriptional regulation in all lifecycle stages and tissues of *Brugia malayi*. To genotype transgenic parasites, it is necessary to detect the genomic DNA of *B. malayi* in a non-invasive way. *B. malayi* third stage infective L3 were cultured with 1x10<sup>5</sup> Bovine Embryo Skeletal Muscle (BESM) cells/well and Minimal Essential Media (MEM) containing 20% fetal bovine serum (FBS). Following the collection of the molting media for day 8, DNA was extracted using the DNeasy® Blood & Tissue Kit and the Dynabeads™ M-280 Streptavidin method. A single distinct band of approximately 210-220 bp was obtained from molting media samples that contained one single L3 larvae using the toY-nest and shp2-nest nested primers. A single distinct band of approximately 420 bp was obtained from the same media samples using the rps12-nest nested primers. This study provides important tools to genotype and to optimize the sex ratio for the backcrossing of transgenic parasites.

### DIAGNOSTIC CHALLENGES IN THE LYMPHATIC FILARIASIS POST-ELIMINATION ERA IN SRI LANKA: A CASE OF CONJUNCTIVITIS CAUSED BY BRUGIA SP. FEMALE ADULT

Lalindi Nirmitha De Silva<sup>1</sup>, Sampath Ranaweera<sup>2</sup>, Lalitha Senarath<sup>3</sup>, Susiji Wickramasinghe<sup>4</sup>, Channa Yahathugoda<sup>1</sup>

<sup>1</sup>Department of Parasitology, Faculty of Medicine, University of Ruhuna, Galle, Sri Lanka, <sup>2</sup>Base Hospital Tangalle, Tangalle, Sri Lanka, <sup>3</sup>Teaching Hospital Karapitiya, Galle, Sri Lanka, <sup>4</sup>Department of Parasitology, Faculty of Medicine, University of Peradeniya, Peradeniya, Sri Lanka

Sri Lanka eliminated lymphatic filariasis in 2016 as a public health issue, yet sporadic cases of bancroftian and brugian filariasis (anthroponotic and zoonotic) are being reported. The majority of worms collected from eyes were *Dirofilaria repens* in Sri Lanka; however, rarely, *Brugia ceylonensis* and *Wuchereria bancrofti* were also reported. Therefore, a detailed discussion on a diagnosis of a rare case is presented here. A 35-year-old female patient with a history of allergies presented with irritation and redness of the right eye for two weeks. She was treated for allergic conjunctivitis for a week due to chemosis and conjunctival injection near the inferior limbus. However, symptoms remained, and a live subconjunctival worm with rapid wriggling movements was visualized in the follow-up visit after a week. The worm was near the lateral limbus with significant chemosis. Suspecting dirofilariasis, urgent extraction was performed via a conjunctival incision under topical anaesthesia. The worm was white, thread-like, 32 mm long and 95 µm wide. A distinct head bulb, two uterine tubes with unfertilized ova uniting to form a single vagina which looped just posterior to the vulva was noted. The vulva was 608 µm from the anterior end and was in relation to the posterior half of the oesophagus, which was 1026 µm long. Ovaries were placed 752 µm from the rounded posterior end. It was identified as a young but mature, unfertilized female filarial worm. Considering the epidemiology, dimensions of the worm and the position of the vulva in relation to the oesophagus, it is likely to be an adult *Brugia* sp. Differentiation of females of the genera *Wuchereria* and *Brugia* is difficult based on light microscopic morphology alone. Species confirmation is being done by PCR. No microfilaraemia was detected by night-thick-blood smear or membrane filtration. She was negative for the circulatory filarial antigen of *Wuchereria bancrofti* and eosinophilia. The diagnostic challenges will be discussed in detail once the molecular diagnosis is available.

### OPPORTUNISTIC MAPPING AND SURVEILLANCE FOR ONCHOCERCIASIS ELIMINATION PROGRAMS IN NIGERIA USING A MULTIPLEX BEAD ASSAY

Andrew Abbott<sup>1</sup>, Uwem F. Ekpo<sup>2</sup>, Michael A. Igbe<sup>3</sup>, David I. Olatunji<sup>4</sup>, Israel Nengi<sup>4</sup>, Ndodo Nnaemeka<sup>4</sup>, Chukwuma Anyaika<sup>3</sup>, Nyior A. Iveren<sup>3</sup>, Nse M. Akpan<sup>3</sup>, Joel Akilah<sup>3</sup>, Ryan E. Wiegand<sup>1</sup>, Nishanth Parameswaran<sup>1</sup>, Gretchen M. Cooley<sup>1</sup>, Stacie Greby<sup>5</sup>, Diana Martin<sup>1</sup>, Paul T. Cantey<sup>1</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Federal University of Agriculture, Abeokuta, Nigeria, <sup>3</sup>Federal Ministry of Health, Abuja, Nigeria, <sup>4</sup>Nigeria Centre for Disease Control, Abuja, Nigeria, <sup>5</sup>US Centers for Disease Control and Prevention, Abuja, Nigeria

Over the past 31 years, the Nigeria Federal Ministry of Health in collaboration with other governmental and non-governmental organizations, has reduced the prevalence of onchocerciasis through annual mass administration of medicines (MAM) with ivermectin. Despite great progress, much of the country remains under MAM and many states lack recent data on the status of transmission of onchocerciasis. Site specific surveillance can be used to determine prevalence but is expensive and labor intensive. Resources could be used more efficiently if multiple diseases could be evaluated simultaneously. In 2018, Nigeria conducted a cross-sectional, nationally-representative, household-based survey to assess the distribution of HIV in the country. Along with survey data, blood samples, Global Positioning System (GPS) information, and

consent for future analysis for other diseases of public health importance were collected. A multiplex bead assay (MBA) was used to measure IgG to multiple pathogens in stored blood samples. Antibody reactivity to OV-16 was used as a marker of onchocerciasis exposure in 31,459 children aged 0-14 years. The prevalence of OV-16 seropositivity was highest in Kogi State at 7.7% (95% confidence interval (CI) 4.6% - 11.8%), followed by Ondo at 6.6% (95% CI 3.8% - 10.8%), Ebonyi at 5.9% (95% CI 3.2% - 10.0%), and Cross River at 5.3% (95% CI 3.4% - 8.0%). Prevalence was lower in the 5 states where MAM had been stopped (0.9-2.8%). Clusters of seropositivity were identified at the sub-local government area level using GPS coordinates. MBA testing of existing samples allowed the Nigeria onchocerciasis control program to gather critical data on onchocerciasis transmission across the nation, including in areas where no recent surveillance had occurred. Linking these data to breeding sites may allow for identification of potential hotspots of transmission in both treated and untreated areas. The addition of geospatial analyses enhanced data interpretation in a program-relevant way. Opportunistic use of blood samples collected for other purposes may be an efficient way to gather critical surveillance data for NTD programs.

### POST-TREATMENT SURVEILLANCE FOR LYMPHATIC FILARIASIS IN HAITI: RESULTS FROM TRANSMISSION ASSESSMENT SURVEY IN SAUT D'EAU AND LA TORTUE

Luccène Désir<sup>1</sup>, Madsen Beau De Rochars<sup>2</sup>, Brianna Poovey<sup>1</sup>, Marc-Aurèle Telfort<sup>3</sup>, Gregory S. Noland<sup>1</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>University of Florida, Gainesville, FL, United States, <sup>3</sup>Ministère de la Santé Publique et de la Population, Port-au-Prince, Haiti

Haiti is one of four countries in the Americas endemic for lymphatic filariasis (LF), a chronic neglected tropical disease commonly known as elephantiasis and transmitted by mosquitoes. In 1997, the World Health Organization (WHO), called for elimination of LF as public health problem. Since 2000, Haiti implemented annual mass drug administration (MDA) with albendazole and diethylcarbamazine in all 140 districts (*communes*) of the country. Currently, 122 (87%) communes do not require MDA, including two communes, Saut d'Eau (Centre Department) and La Tortue (Nord-Ouest Department), which stopped MDA in 2014 and 2004, respectively. After stopping MDA, WHO recommends a minimum of four years of post-treatment surveillance, including repeated transmission assessment surveys (TAS) at two- to three-year intervals to determine if LF parasite prevalence remains significantly beneath putative transmission thresholds (<2% antigen prevalence in areas with *Culex quinquefasciatus* the primary vector). From August 22 to September 8, 2020, children 6-7 years old were tested for circulating filarial antigen (CFA) by filariasis test strip (Abbott) in community-based TAS-3, with each commune considered an evaluation unit (EU). In each EU, the target sample size was 911 and the critical cut-off was 11, which corresponds to the 2% antigen threshold. In Saut d'Eau, 5 (0.54%) of 928 children tested in 62 localities were CFA-positive. In La Tortue, 3 (0.33%) of 914 children in 55 localities were CFA-positive. Results demonstrate that each commune 'passed' TAS-3, as the number of CFA-positive children in each EU was less than the critical cut-off. However, the presence of antigen positive children indicates that LF transmission may not be fully interrupted. Follow-up surveys are needed to assess the risk of on-going transmission in these areas and determine the need for targeted interventions to achieve elimination.

0354

### COVERAGE AND IMPACT OF A SINGLE DOSE OF IVERMECTIN, DEC AND ALBENDAZOLE FOR LYMPHATIC FILARIASIS: RESULTS FROM A COMMUNITY STUDY

Krishnamoorthy Kaliannagounder<sup>1</sup>, Subramanian Swaminathan<sup>1</sup>, Srividya Adinarayanan<sup>1</sup>, Vijesh Sreedhar Kuttia<sup>1</sup>, Weil J. Gary<sup>2</sup>, Jambulingam Purushothaman<sup>1</sup>

<sup>1</sup>Vector Control Research Centre (ICMR), Pondicherry, India, <sup>2</sup>Washington University, St. Louis, MO, United States

A community study was performed in several villages in Yadgir district India (endemic for bancroftian filariasis) to assess the impact of mass drug administration (MDA) with a triple drug treatment (ivermectin, DEC, & albendazole, IDA). Household enumeration and community sensitization were carried out prior to MDA in the selected villages. Consenting residents aged > 5 years, not pregnant and not seriously ill were targeted for treatment. Participants were screened for microfilaraemia (Mf) at baseline (60 µl night blood smears). Baseline Mf prevalence was higher in males (8.0%) vs. females (5.9%) and in adults (≥20 years, 9.2%) vs. children (<20 years, 3.6%). Directly observed treatment with IDA was provided to 4758 persons with overall population adherence of 70.5% out of eligible population. Adherence was approximately 20% lower in adult males than in females. A second cross-sectional survey was performed one year after MDA. The ratio of males to females who participated in the second survey was 0.84. Since males have higher Mf prevalence than females, underrepresentation of adult males in assessment surveys may lead to overestimation of the impact of MDA. Mf prevalence (6.9 to 3.6%, 47% reduction) and geometric mean Mf density per 60µl blood (0.19 to 0.09, 52.6% reduction) were significantly reduced after MDA, but CFA prevalence (26.3%) was not reduced. Percent reductions in community Mf prevalence were greater in females (52.5%) than in males (42.5%). A separate efficacy study in the area had shown that a single dose of IDA cleared Mf in 84% of persons with Mf at baseline. Reductions in community Mf prevalence were consistent with this efficacy estimate and the MDA adherence data. These results show that high adherence will be required for the superior impact of MDA with IDA to be fully realized in India. Special effort and community specific strategies will be needed to increase adherence in adult males.

0355

### MONITORING THE IMPACT OF TWO ANNUAL ROUNDS OF MASS DRUG ADMINISTRATION USING A 3-DRUG REGIMEN ON LYMPHATIC FILARIASIS IN AMERICAN SAMOA

Tara A. Brant<sup>1</sup>, Aifili Tufa<sup>2</sup>, Fara Utu<sup>2</sup>, Noelle Tavale<sup>2</sup>, Lynette Suaiono-Scanlan<sup>3</sup>, Ula Pele<sup>3</sup>, June Vaifanua-Leo<sup>2</sup>, Benjamin Sili<sup>2</sup>, Keri Robinson<sup>1</sup>, Emily A. Dodd<sup>1</sup>, Ryan E. Wiegand<sup>1</sup>, Janet Camacho<sup>4</sup>, Emi Chutaro<sup>4</sup>, Kimberly Y. Won<sup>1</sup>, Motusa Tuileama Nua<sup>2</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States,

<sup>2</sup>American Samoa Department of Health, Pago Pago, American Samoa,

<sup>3</sup>Pacific Island Health Officers' Association, Pago Pago, American Samoa,

<sup>4</sup>Pacific Island Health Officers' Association, Honolulu, HI, United States

In 2018, the American Samoa Department of Health (DOH) began mass drug administration (MDA) for lymphatic filariasis with a 3-drug regimen of ivermectin, diethylcarbamazine and albendazole (IDA). After round one, surveyed drug coverage was high (76.7%), but circulating filarial antigen (CFA) prevalence was 2.7%, above the 1% MDA stopping threshold. DOH completed round two of IDA MDA in November 2019 and conducted a targeted impact survey after round two. In Sep-Oct 2020, DOH surveyed 831 people (≥5 years) in 8 villages with high prevalence (defined as having ≥3 CFA or ≥1 microfilariae (Mf) positive people in 2019). People were asked about participation in both MDAs. We used fingerstick blood samples to assess CFA, and tested CFA positive participants for Mf. All CFA and Mf positive people were offered treatment with IDA. Those positive for Mf were examined 7 days after treatment for Mf clearance. CFA prevalence in the 8 villages declined from 4.3% (95% confidence

interval [CI] 2.8-6.4) in 2019 to 2.0% (95% CI 1.2-3.0) in 2020, but Mf prevalence was similar (2019: 1.2% (95% CI 0.6-2.7); 2020: 1.1% (95% CI 0.5-2.1). Drug coverage increased from 78.3% (95% CI 74.7-81.6) to 90.0% (95% CI 87.5-92.2). Of those surveyed, 9.0% (95% CI 6.8-12.0) did not take the medicines either year. Of 47 CFA positive participants, 46 were examined for Mf; 9 were positive. Six (66.7%) Mf positive participants took the medicines both years; 3 took them only once. Of the 9 Mf positive people, 6 were available for follow up after treatment in 2020; Mf had cleared in all. CFA prevalence was higher in males (3.2%) than females (0.8%, p<0.01) and those ≥10 years (2.9%) compared to children 5-9 years (0.8%, p=0.84). Similarly, Mf prevalence was higher in males (1.0%, p<0.001) and those ≥10 years (1.0%, p<0.05); no children 5-9 years were positive. Despite high coverage and low systematic noncompliance, CFA >1% in these villages indicates the need for continued MDA and suggests that targeted treatment might be required to meet stopping thresholds. Significantly higher active infection among older people, particularly men, suggests this may be an appropriate group to monitor in American Samoa.

### PROGRESS TOWARD ELIMINATION OF LYMPHATIC FILARIASIS IN CAMEROON FOLLOWING SUCCESSFUL TAS2 IN 41 HEALTH DISTRICTS OF THE EAST, FAR-NORTH, LITTORAL, SOUTH AND WEST REGIONS

Biholong Benjamin<sup>1</sup>, Ebene Clarisse<sup>1</sup>, Georges NKO'Ayissi<sup>2</sup>, Julie Akame<sup>3</sup>, Patrick Mbia<sup>3</sup>, Carine Fokam<sup>3</sup>, Ismael Teta<sup>3</sup>, Michel Hendji Yoya<sup>3</sup>, Benoit Demebele<sup>4</sup>, Patricia Houck<sup>5</sup>, Jennifer Magalong<sup>6</sup>, Ernest Mensah<sup>6</sup>, Yaobi Zhang<sup>5</sup>, Steven D. Reid<sup>5</sup>, Angela Weaver<sup>5</sup>

<sup>1</sup>Ministry of Public Health, PNLO, Yaounde, Cameroon, <sup>2</sup>Ministry of Public Health, NTD Coordination Unit, Yaounde, Cameroon, <sup>3</sup>Helen Keller International, Yaounde, Cameroon, <sup>4</sup>Helen Keller International, Regional Office for Africa, Dakar, Senegal, <sup>5</sup>Helen Keller International, New York, NY, United States, <sup>6</sup>Family Health International 360, Washington, DC, DC, United States

Cameroon is endemic for lymphatic filariasis (LF) in 137 of 189 health districts (HDs). The country aims to eliminate LF as a public health problem by 2025 by conducting annual mass drug administration (MDA), among other activities, as per World Health Organization recommendations. By 2018, all endemic HDs had received at least five effective rounds of MDA (≥65% epidemiological coverage) and passed a pre-transmission assessment survey (pre-TAS). From 2014 to 2018, 136 of 137 HDs met the criteria to stop MDA by passing TAS1, and one HD has not yet been assessed due to insecurity. Between 2018 and 2020, 41 out of 136 HDs successfully completed TAS2 in the East, Far-North, Littoral, South and West regions. These HDs were grouped into 14 evaluation units (EUs) according to their epidemiological profile, geographic location and population size. The Survey Sample Builder was used to calculate sample sizes and select clusters. The sampled population consisted of children aged 6-7 years. The survey was conducted in communities in all regions (schools were closed in some regions due to the COVID-19 pandemic). The Filariasis Test Strip (FTS) was used to detect *Wuchereria bancrofti* infection. Data were captured on smartphones and processed using electronic data collection system with control measures. Field teams performed day-time calibrated blood smears in *Loa Loa* co-endemic areas. Children testing positive were all confirmed by a second FTS test. All field activities were completed using appropriate COVID-19 prevention measures. Overall, 21,512 children in 498 clusters were tested and only three children were confirmed positive. All 14 EUs passed the TAS2. Children testing positive received a single dose of Mectizan® and albendazole and their parents were sensitized on the necessity of treating LF. In summary, these 41 HDs have completed TAS2 and successfully sustained interruption of LF transmission. This is a significant progress towards the elimination of LF in Cameroon.

### REPEAT PRE-TRANSMISSION ASSESSMENT SURVEY FOR LYMPHATIC FILARIASIS IN HOTSPOT DISTRICTS IN SIERRA LEONE

Ibrahim Kargbo-Labour<sup>1</sup>, Mohamed S. Bah<sup>2</sup>, Victoria Turay<sup>2</sup>, Habib I. Kamara<sup>2</sup>, Abdulai Conteh<sup>1</sup>, Gandi Kallon<sup>2</sup>, Alhassan Konneh<sup>2</sup>, Abdulai Koroma<sup>2</sup>, Unidiatu Kabia<sup>2</sup>, Beah J. Lebby<sup>2</sup>, Patricia Houck<sup>3</sup>, Benoit Dembele<sup>4</sup>, **Mustapha Sonnie**<sup>2</sup>, Mary H. Hodges<sup>2</sup>, Ernest Mensah<sup>5</sup>, Achille Kabore<sup>5</sup>, Yaobi Zhang<sup>4</sup>, Angela Weaver<sup>3</sup>

<sup>1</sup>Neglected Tropical Disease Program, Ministry of Health and Sanitation, Freetown, Sierra Leone, <sup>2</sup>Helen Keller International, Freetown, Sierra Leone, <sup>3</sup>Helen Keller International, New York, NY, United States, <sup>4</sup>Helen Keller International, Regional Office for Africa, Dakar, Senegal, <sup>5</sup>Family Health International 360, Washington, DC, United States

All 16 districts in Sierra Leone were endemic for lymphatic filariasis (LF). Annual mass drug administration (MDA) with ivermectin and albendazole to interrupt LF transmission reached national geographic coverage in 2009. To date, nine districts have stopped MDA and transitioned to surveillance. Six districts failed pre-transmission assessment survey (pre-TAS) in 2013 and 2017 and Western Area Rural (WAR) failed the pre-TAS in 2017. The national program implemented enhanced strategies to improve MDA quality: sub-district-level reporting; updated census data for drug allocation; supportive supervision and mop-ups; community drug distributor (CDD) stipends; and adapting social mobilization materials for hard-to-reach communities. In 2020, repeat pre-TAS was conducted in all 7 districts using convenience sampling at sentinel sites selected from the baseline survey and spot check sites selected based on local knowledge of LF cases, hard-to-reach, likelihood of low MDA coverage and/or vector efficacy. Blood samples from 310 people aged five years and above were tested per site using the Filariasis Test Strip (FTS). Enhanced pre-survey community engagement with stakeholders was conducted to reduce participation hesitancy due to COVID-19 and risk mitigation measures were implemented during field activities. All FTS positive results were confirmed by a second FTS test and remote confirmation by a supervisor. The site antigenemia prevalence was 4.1%, 2.6%, 5.8% and 7.7% in Bombali and Karene, 1.3%, 4.8% and 0.6% in Koinadugu and Falaba, 0.7%, 1.0%, and 1.6% in Kailahun, 0.0% and 0.6% in Kenema, and 0.0% and 0.6% in WAR. Three districts successfully passed pre-TAS and will move on to conduct TAS1 in 2021. Four districts failed to meet the criteria for conducting TAS1 (>2% in one or more sites) for the third time and will conduct two more rounds of MDA. Compared with the results in 2017 (prevalence ranging from 7.5% to 25.9%), there was a significant drop in LF antigenemia prevalence suggesting that the revised strategies were effective and with continued programmatic progress, Sierra Leone is on course to achieve LF elimination.

### ASSESSING ACCEPTABILITY OF MASS DRUG ADMINISTRATION FOR LYMPHATIC FILARIASIS AS PART OF ROUTINE MONITORING AND EVALUATION: FEASIBILITY AND OPERATIONAL IMPLICATIONS

**Charles Thickstun**<sup>1</sup>, Krufinta Bun<sup>2</sup>, Moses Laman<sup>3</sup>, Benedict Mode<sup>4</sup>, Makoto Sekihara<sup>5</sup>, Daniel Dillio<sup>6</sup>, Afzaa Rajabali<sup>6</sup>, William Pomat<sup>3</sup>, Christopher L. King<sup>2</sup>

<sup>1</sup>University of Ottawa, Ottawa, ON, Canada, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>3</sup>Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, <sup>4</sup>Division of Health, East New Britain Provincial Administration, Kokopo, Papua New Guinea, <sup>5</sup>Japan International Cooperation Agency, Port Moresby, Papua New Guinea, <sup>6</sup>Bruyere Research Institute, Ottawa, ON, Canada

Population level acceptability of mass drug administration (MDA) for lymphatic filariasis will improve efforts to eliminate LF as a public health problem. A recently validated metric of acceptability demonstrated a more nuanced understanding of community participation than MDA coverage survey. Here we embedded an acceptability metric within a monitoring

and evaluation survey in four districts of East New Britain Province, Papua New Guinea to assess acceptability on a larger scale than previously conducted. The acceptability survey included nine questions forming the composite acceptability score using a common 4-point Likert scale (range 9-36; threshold of acceptability > 22.5). To understand factors related to acceptability we used population-averaged linear regression to assess key demographic and operational variables, controlling for clustering at the village level from 3,350 persons aged 18 or older. We found acceptability scores were high (mean = 31.71 ± 4.29) which corresponded to overall MDA coverage of 81.1% in the province. Regression modeling found respondents living in two districts (Gazelle and Rabaul districts) had higher acceptability scores (2.16; p = 0.0283 and 3.69; p < .0001 respectively) than those living in Pomio or Kokopo. Higher acceptability scores were also associated with higher levels of education (Completed Middle School: 0.54; p = 0.0308, Completed Higher Education: 0.88; p = 0.0142 compared with those with no schooling), and MDA coverage (2.76; p < .0001). Sex, age, socioeconomic variables, and use of vector control measures were not associated with acceptability. Acceptability is influenced by regional differences and significant associations between MDA coverage reinforce the validity of the acceptability metric. Acceptability may provide further detail for targeting the MDA approach to account for regional and sub-population differences. Enumerators were not burdened by inclusion of the acceptability questions. Continued assessment of acceptability over consecutive M&E surveys would allow for trends to be assessed over time, further enriching the operational value of the metric.

### PROGRESS IN NATIONWIDE MAPPING OF ONCHOCERCIASIS ENDEMICITY IN ETHIOPIA USING SEROLOGICAL AND ENTOMOLOGICAL INDICATORS OF TRANSMISSION

**Emily Griswold**<sup>1</sup>, Yewondwossen Bitew<sup>2</sup>, Aderajew Mohammed<sup>2</sup>, Fikre Seife<sup>3</sup>, Firdaweke Bekele<sup>2</sup>, Rory Post<sup>4</sup>, Tom Unnasch<sup>5</sup>, Moses Katarbarwa<sup>1</sup>, Frank Richards<sup>1</sup>, Gregory Noland<sup>1</sup>, Zerihun Tadesse<sup>2</sup>

<sup>1</sup>The Carter Center, Atlanta, GA, United States, <sup>2</sup>The Carter Center, Addis Ababa, Ethiopia, <sup>3</sup>Federal Ministry of Health, Addis Ababa, Ethiopia, <sup>4</sup>Liverpool John Moores University, Liverpool, United Kingdom, <sup>5</sup>University of South Florida, Tampa, FL, United States

Onchocerciasis in Ethiopia was mapped by the African Programme for Onchocerciasis Control using nodule rates, indicating ivermectin mass drug administration (MDA) in portions of western Ethiopia. After declaring a goal of eliminating transmission in 2015, Ethiopia embarked on (re) mapping the untreated parts of the country using a combination of entomological and serological studies. Guided by recommendations from the Ethiopia Onchocerciasis Elimination Advisory Committee (EOEEAC), the Federal Ministry of Health began by excluding districts ecologically unsuitable for transmission, namely those without streams or rivers, whether seasonal or otherwise, that would support vector *Simulium* flies. This was done using a variety of maps and satellite imagery. Next, entomologists used the Rapid Epidemiological Mapping of Onchocerciasis approach to identify a minimum of three "first line" or high-risk villages for sampling. Consenting residents gave a dried blood spot (DBS) for laboratory testing using Ov16 ELISA at the Ethiopia Public Health Institute. The age group of interest shifted from children under 10 to adults 20 and older over the course of the initiative, based on EOEEAC's consideration of new guidance from the WHO Onchocerciasis Technical Subcommittee. The current threshold triggering MDA is an aggregate ≥2% positive adults from a minimum sample of ≥300 adults from ≥3 villages in a district. The mapping effort focused on 650 districts of unknown endemicity, starting with those adjacent to districts under treatment. Investigators found 158 to be ecologically unsuitable for transmission. DBS have been collected from 492; to date, 141,905 DBS have been collected and 134,705 have been analyzed. Fifty-two of districts have met transmission thresholds and MDA has begun for 5.5 million people across the country, and another 2.5 million await initiation of treatment. Entomological inspections of rivers and streams at more than 3000 sites demonstrate broad yet varied

presence of vector flies across the country, with mixed relationships to level of parasite exposure observed in humans. Only 17 districts remain to be mapped in Ethiopia.

0360

### EPSTEIN BARR VIRUS CENTRAL NERVOUS SYSTEM INFECTION IN PATIENTS PRESENTING WITH SUSPECTED MENINGITIS IN BOTSWANA

Jayne Ellis<sup>1</sup>, Margaret Mokomane<sup>2</sup>, Madisa Mine<sup>3</sup>, Charles Muthoga<sup>4</sup>, Kwana Lechiile<sup>4</sup>, Chris Williams<sup>4</sup>, Tshepo Leeme<sup>5</sup>, Mark Tenforde<sup>4</sup>, Richard Hayes<sup>1</sup>, Joseph Jarvis<sup>1</sup>

<sup>1</sup>London School Hygiene and Tropical Medicine, London, United Kingdom, <sup>2</sup>University of Botswana, Gaborone, Botswana, <sup>3</sup>Princess Marina Hospital, Gaborone, Botswana, <sup>4</sup>Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana, <sup>5</sup>Monash University, Melbourne, Australia

Epstein-Barr virus (EBV) central nervous system (CNS) infection in immunocompromised hosts and amongst meningitis cohorts is well recognised. The clinical significance of EBV CNS infection however is poorly understood. We determined the prevalence of EBV CNS co-infection amongst a cohort of patients with meningitis and explored associations between EBV co-infection and in-hospital mortality. Data were collected as part of the Botswana Nationwide Meningitis Surveillance study. EBV CNS infection (CSF BioFire FilmArray multiplex positive) prevalence was described and associations between baseline covariates and EBV CNS infection reported. Logistic regression modelling was conducted to investigate the association between EBV infection and in-hospital mortality. 601 participants with suspected meningitis were recruited: 54% male, median age 29 (IQR 1-42), 50.1% HIV positive. Cryptococcal meningitis was the most common infectious meningitis (11%, 66/601), 7.5% (45/601) had either probable/possible tuberculous meningitis. EBV CNS infection was common (25%); co-infection (16%) exceeded EBV mono-infection (9%). Amongst participants with EBV CNS infection there was evidence that a higher CNS EBV viral load was associated with greater CSF inflammation ( $p = 0.001$ ). There was no association overall between EBV CNS infection and mortality aOR 1.27 (95% CI 0.76-2.12,  $p = 0.36$ ), however there was weak evidence ( $p = 0.099$ ) that the association between EBV co-infection and mortality varied according to meningitis diagnostic group. Amongst participants with cryptococcal meningitis, EBV co-infection was associated with reduced odds of mortality aOR 0.15 (95% CI 0.02-0.93,  $p = 0.03$ ). Conversely, amongst patients with tuberculous meningitis, EBV co-infection was associated with increased mortality (aOR 4.91, 0.85 – 28.5,  $p = 0.04$ ). Overall EBV CNS infection was not associated with in-hospital mortality amongst this heterogeneous cohort. Larger longitudinal studies are required to understand the association between EBV, CSF inflammation and outcome, and to investigate how mechanistic pathways may differ across meningitis sub-groups.

### EPSTEIN-BARR VIRUS AND CYTOMEGALOVIRUS CENTRAL NERVOUS SYSTEM CO-INFECTIONS AND MORTALITY RISK IN PATIENTS WITH HIV-ASSOCIATED CRYPTOCOCCAL MENINGITIS

Jayne Ellis<sup>1</sup>, Margaret Mokomane<sup>2</sup>, Madisa Mine<sup>3</sup>, Charles Muthoga<sup>4</sup>, Kwana Lechiile<sup>4</sup>, James Hepburn<sup>1</sup>, Chris Williams<sup>4</sup>, Tom Harrison<sup>5</sup>, Tshepo Leeme<sup>6</sup>, Mark Tenforde<sup>4</sup>, Richard Hayes<sup>1</sup>, Joseph Jarvis<sup>1</sup>

<sup>1</sup>London School Hygiene and Tropical Medicine, London, United Kingdom, <sup>2</sup>University of Botswana, Botswana, Botswana, <sup>3</sup>Princess Marina Hospital, Gaborone, Botswana, <sup>4</sup>Botswana-Harvard AIDS Institute Partnership, Gaborone, Botswana, <sup>5</sup>University of Exeter, Exeter, United Kingdom, <sup>6</sup>Monash University, Melbourne, Australia

Cryptococcal meningitis case fatality in sub-Saharan Africa remains devastatingly high at 24-45%. Recent data suggest that co-prevalent opportunistic infections may contribute to poor patient outcomes. No

studies to date have investigated whether Epstein-Barr virus (EBV) and/or cytomegalovirus (CMV) central nervous system (CNS) co-infection is associated with mortality amongst adults with HIV-associated cryptococcal meningitis. We analysed CSF samples - including molecular EBV and CMV testing - and clinical data collected prospectively from adults with confirmed HIV-associated cryptococcal meningitis, recruited into one of two meningitis studies in Botswana and Tanzania. We compared 10-week survival rates among those with and without evidence of EBV and/or CMV CNS co-infection using multivariate Cox models. Of 140 participants, 60% (84/140) were male, median age 38 years, median CD4 count 37 cells/ $\mu$ L. EBV CNS co-infection was detected in 58.6% (82/140), CMV CNS co-infection in 3.6% (5/140). EBV CNS co-infection was associated with increasing age ( $p = 0.01$ ), and CSF pleocytosis ( $p = 0.004$ ). On multivariate analyses, EBV co-infection was associated with lower cumulative 10-week mortality (26.9% versus 44.3%, aHR 0.43, 95% CI 0.23 – 0.78). Conversely participants with CMV co-infection had higher cumulative 10-week mortality (80.0% versus 32.3%, aHR 4.59, 95% CI 1.56 – 13.49). EBV and/or CMV CNS co-infection is common amongst adults with HIV-associated cryptococcal meningitis. EBV CNS co-infection - which was strongly associated with CSF pleocytosis and improved survival - is a probable "by-stander" infection, and of doubtful clinical significance. Conversely, CMV co-infection was associated with a 4-fold increased risk of death; anti-CMV therapy warrants further investigation as a potential intervention to reduce mortality in HIV-associated cryptococcal meningitis.

### LIBERIA ADHERENCE AND LOSS-TO-FOLLOW-UP IN HIV/AIDS STUDY: A RETROSPECTIVE COHORT OF ADOLESCENTS AND ADULTS

Keith L. Gray<sup>1</sup>, Jethro S. Zawolo<sup>2</sup>, Murphy V. Kiazolu<sup>1</sup>, Janjay M. Jones<sup>1</sup>, Anna Konstantinova<sup>3</sup>, Wahdae-mai Harmon-Gray<sup>1</sup>

<sup>1</sup>Ministry of Health, Monrovia, Liberia, <sup>2</sup>STAIPIJhpiego, Monrovia, Liberia, <sup>3</sup>Evidence Action, Washington, DC, United States

To describe the progression of newly enrolled patients along the care cascade and quantify factors associated with LTFU, retention, and treatment adherence, we conducted a retrospective cohort study using facility-level patient records. We collected patients' care and treatment records from 28 urban and rural facilities from the 5 subregions of Liberia. HIV+ patients 15 years and older, enrolled between January 2016 – December 2017, were selected and followed for 2 years. Patients were stratified into 2 cohorts based on the year of enrollment. We illustrated the operational outcomes of the care cascade and used separate univariable and multivariable logistic regression models to explore factors associated with LTFU and retention. 4185 patient records were assessed, 1905 and 2280 for 2016 and 2017, respectively. In 2016, 845 patients were LTFU as well as 906 in 2017. The probability of poor adherence for 2016 and 2017 cohorts were 0.102 (SD 0.176) and 0.072 (SD 0.148), respectively. Multivariable analysis showed that being pregnant during the last visit (OR 1.66,  $p = 0.02$ , 95%CI: 1.08 – 3.72), drug side effects (OR 2.00,  $p = 0.02$ , 95%CI: 1.08 – 3.72), and WHO stage 3 (OR 2.62,  $p < 0.01$ , 95%CI: 1.42 – 4.80) were associated with increased risk of LTFU among patients in 2016. In 2017, drug side effects (OR 1.54,  $p < 0.01$ , 95%CI: 1.11 – 2.14) combined with WHO stage 2 (OR 2.65,  $p < 0.01$ , 95%CI: 2.16 – 3.65) and stage 3 (OR 2.81,  $p < 0.01$ , 95%CI: 2.16 – 3.65) were predictors of LTFU. In 2016, age 25 – 34 years (OR 1.35,  $p = 0.01$ , 95%CI: 1.05 – 1.73), 35 – 44 years (OR 1.74,  $p < 0.01$ , 95%CI: 1.32 – 2.29) and 45 years and older (OR 2.10,  $p < 0.01$ , 95%CI: 1.59 – 2.75) in a rural facility (OR 1.50,  $p < 0.01$ , 95%CI: .990 – 2.29) were associated with retention. In 2017, patients aged 25 – 34 years (OR 1.54,  $p = 0.034$ , 95%CI: 1.03 – 2.32) and 35 – 45 years (OR 1.92,  $p < 0.01$ , 95%CI: 1.27 – 2.90) and 45 years and older (OR 2.52,  $p < 0.01$ , 95%CI: 2.07 – 3.05) were likely to remain in care. LTFU and treatment adherence is still a major challenge and newer strategies are needed to improve patient tracking. Retention is higher in older patients, whereas stronger engagements and dedicated services are needed for youths.

## PREGNANT WOMEN KNOWLEDGE ABOUT THE INTERVENTIONS RECEIVED AT THE ANTENATAL CLINIC IN RURAL AFRICA

Tacilita H. Nhampossa

*Centro de Investigatio em Sade da Manhia and Instituto Nacional de Sade, Maputo, Mozambique*

Current prevention and treatment guidelines for HIV in Mozambique require that pregnant women living with HIV (PWLHIV) self-administer five tablets on average from different medications daily. However, HIV-related maternal and neonatal mortality is still high, suggesting that compliance with the medication might be low. To optimize this compliance, we explored pregnant women's knowledge about common diseases in pregnancy, their prevention and the indication of prescribed medications given at the antenatal care (ANC) to HIV-infected pregnant women in Manhiça District, Mozambique. This qualitative study collected data through semi-structured exit and in-depth interviews with pregnant women attending the ANC clinic during December-2019 to October-2020. The ability to distinguish the different tablets was assessed by presenting them without any identification to the pregnant women. Forty PWLHIV were enrolled. We found a high level of knowledge on the most common diseases in pregnancy and their preventive measures. HIV, malaria, sexually transmitted diseases and tuberculosis were all considered serious infectious in pregnancy. Interviewed women used the container, format, color, size and stamping to identify the tablets. The stamping of a figure at the antiretroviral tablet was the recognition marker. Cotrimoxazole was frequently confused with paracetamol and isoniazid. Few women recognized mebendazole. Knowledge about the indication of the drugs prescribed was limited, and it was specially referred to antiretroviral drugs and ferrous sulfate. Participants tend to several indications to each drug. Interestingly, it was generally perceived that all the drugs prescribed could serve to treat malaria infection. African pregnant women attending the ANC in a rural area showed a high level of knowledge of the most common diseases in pregnancy and their prevention. Their poor recognition of the drugs prescribed, and their indication may cause medications errors and affect compliance. Strategies are needed to increase the information provided to pregnant women at ANC clinics considering the high number of medications prescribed.

## PREVALENCE OF CERVICAL DYSPLASIA BY VISUAL INSPECTION ACETIC ACID (VIA) IS INCREASED IN WOMEN WITH FEMALE GENITAL SCHISTOSOMIASIS; A CROSS-SECTIONAL STUDY IN ZAMBIA

Hannah Rafferty<sup>1</sup>, Amy Sturt<sup>1</sup>, Comfort Rutty Phiri<sup>2</sup>, Emily Webb<sup>1</sup>, Maina Mudenda<sup>3</sup>, Joyce Mapani<sup>3</sup>, Namakau Chola<sup>2</sup>, Paul Corstjens<sup>4</sup>, Govert Van Damm<sup>5</sup>, Lisette Van Lieshout<sup>5</sup>, Richard Hayes<sup>1</sup>, Helen Ayles<sup>1</sup>, Hansingo Isaiah<sup>3</sup>, Amaya L. Bustinduy<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>Zambart, Lusaka, Zambia, <sup>3</sup>Livingstone Central Hospital, Livingstone, Zambia, <sup>4</sup>Leiden Medical Center, London, Netherlands, <sup>5</sup>Leiden Medical Center, Leiden, Netherlands

Female genital schistosomiasis (FGS) is a disabling gynaecological disease caused by the waterborne parasite *Schistosoma haematobium*. Evidence on the relationship between FGS and cervical cancer is limited. Visual inspection with acetic acid (VIA) is widely used in Sub-Saharan Africa to screen for cervical dysplasia. We aimed to assess the association between FGS and cervical dysplasia by VIA positivity. Women were recruited from Livingstone, Zambia as part of a home-based FGS diagnostic study nested within the HIV prevention trial HPTN 071 (PopART). Procedures included polymerase chain reaction (PCR) to detect parasite DNA from genital samples, urine CAA and microscopy, demographic and reproductive health questionnaires, and available HIV serostatus. All women were offered VIA to test for cervical dysplasia. VIA, and FGS association were explored through multivariable analysis. In 237 women, positive FGS-PCR and

VIA positivity were strongly correlated (OR: 6.08, 95% CI: 1.58-23.37,  $p=0.016$ ). FGS diagnosed by imaging, urine CAA or microscopy were not associated with VIA positivity (OR: 0.58, 95% CI: 0.20-1.69,  $p=0.303$ , OR 2.21, 95% CI 0.83-5.89,  $p=0.129$  respectively). This is the first study to find an association between genital FGS-PCR and cervical dysplasia, diagnosed by VIA. More studies are urgently needed to further investigate the role of FGS in cervical cancer to define better diagnostic and treatment algorithms across Sub-Saharan Africa.

## THE COST-EFFECTIVENESS OF A FAMILY-BASED ECONOMIC EMPOWERMENT INTERVENTION (SUUBI+ADHERENCE) IN IMPROVING ADHERENCE TO ANTIRETROVIRAL TREATMENT AND OUTCOMES IN ADOLESCENTS LIVING WITH HIV IN SOUTHERN UGANDA

Sooyoung Kim<sup>1</sup>, Ariadna Capasso<sup>1</sup>, Sicong Sun<sup>2</sup>, Torsten B. Neilands<sup>3</sup>, Christopher Damulira<sup>4</sup>, Flavia Namuwonge<sup>4</sup>, Gertrude Nakigozi<sup>5</sup>, Ozge Sensoy Bahar<sup>2</sup>, Proscovia Nabunya<sup>2</sup>, Claude A. Mellins<sup>6</sup>, Mary M. McKay<sup>2</sup>, Fred M. Ssewamala<sup>2</sup>, Yesim Tozan<sup>1</sup>

<sup>1</sup>New York University School of Global Public Health, New York, NY, United States, <sup>2</sup>Brown School, Washington University in Saint Louis, Saint Louis, WA, United States, <sup>3</sup>Center for AIDS Prevention Studies, School of Medicine, University of California, San Francisco, CA, United States, <sup>4</sup>International Center for Child Health and Development, Washington University in St. Louis, Uganda Field Office, Masaka, Uganda, <sup>5</sup>Rakai Health Sciences Program, Kalisizo, Uganda, <sup>6</sup>HIV Center for Clinical and Behavioral Studies, Department of Psychiatry, New York State Psychiatric Institute and Columbia University, New York, NY, United States

A randomized controlled trial conducted in southern Uganda over 24 months demonstrated the efficacy of a family-based economic empowerment (FEE) intervention, Suubi+Adherence, in improving adherence to antiretroviral therapy (ART) among adolescents living with HIV (ALHIV). To aid policy makers to consider the integration of FEE as part of routine HIV care in Uganda, this study assessed the longer-term costs and health outcomes of the Suubi+Adherence intervention using decision analytical modelling. A Markov model was developed to compare the costs and health benefits of the FEE intervention to the bolstered standard of care (BSOC) in a hypothetical cohort of 1,000 ALHIVs in Uganda (median age 12) from a health care provider's perspective. The model included 3 mutually exclusive health states: undetectable viral load (<40 copies/ml), detectable viral load ( $\geq 40$  copies/ml,  $\leq 1000$  copies/ml), and virological failure ( $> 1000$  copies/ml) and was run for 8 years, until ALHIVs reached the age of 20 and were no longer eligible for the intervention. We used cost, probability, and intervention efficacy data from the Suubi+Adherence trial and the published literature. All costs were adjusted to 2020 US dollars, and a 3% discount rate was used for costs and health effects. Uncertainty was assessed using deterministic and probabilistic sensitivity analyses. The incremental cost-effectiveness ratio (ICER) was \$3,440 per disability-adjusted life year (DALY) averted (95% credible interval = -\$19,710 to \$34,540). Our results showed that the Suubi+Adherence intervention was cost-effective with a 51% probability against a cost-effectiveness benchmark of 3 times Uganda's gross domestic product per capita based on WHO guidelines. ICERs were most sensitive to the baseline transition probability from undetectable to detectable viral load under ART, intervention efficacy, and per-child intervention cost. The results suggest the feasibility of integrating FEE-based interventions into routine HIV care as a long-term cost-effective solution to improve treatment adherence outcomes and overall health of ALHIVs in resource-poor settings.

0366

### HIGH MORTALITY IN ADULT PATIENTS WITH HIV ADMITTED WITH FEVER TO HOSPITALS IN MALAWI, MOZAMBIQUE, AND ZIMBABWE - RESULTS FROM THE FIEBRE STUDY

Ioana D Oлару<sup>1</sup>, Marta Valente<sup>2</sup>, Sara Ajanovic<sup>2</sup>, Justina M Bramugy<sup>3</sup>, Sham Lal<sup>1</sup>, Mabvuto Chimanya<sup>4</sup>, Edward W Green<sup>5</sup>, Nicholas A Feasey<sup>5</sup>, David Mabey<sup>1</sup>, Quique Bassat<sup>6</sup>, Katharina Kranzer<sup>1</sup>, Heidi Hopkins<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, <sup>3</sup>Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique, <sup>4</sup>Malawi-Liverpool-Wellcome Trust Clinical Research Programme, Blantyre, Malawi, <sup>5</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>6</sup>ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, Madrid, Spain

Despite important advances in HIV diagnosis and roll-out of antiretroviral therapy (ART) in sub-Saharan Africa, HIV-associated conditions continue to be a major cause of hospitalisation and death. The aim of this study was to compare mortality and causes of death among HIV-infected and uninfected adults hospitalised with febrile illnesses in Malawi, Mozambique, and Zimbabwe. This is a preliminary analysis including patients aged  $\geq 15$  years who were admitted to seven hospitals in Malawi, Mozambique and Zimbabwe and enrolled into the FIEBRE (Febrile Illness Evaluation in Broad Range of Endemicities) study evaluating infectious causes of fever. Participants provided detailed clinical information and samples were collected for laboratory diagnosis of infections. A follow-up visit was conducted at 28 days to assess patient outcome. Causes of death were assessed by combining information from hospital records, family reports, and the FIEBRE study data. Among 940 adult patients admitted to hospital, the median age was 35 years (IQR 26-49) and 498 (53.0%) were female. HIV status was determined in 926 (98.5%); 383 (41.4%) were HIV-infected. Outcome information was available for 889 patients and of those 122 (13.7%) died. Mortality at 28 days was 22.4% and 7.1% ( $p < 0.001$ ) in patients with and without HIV, with 69.8% of the deaths occurring among patients with HIV. The most common causes of death among HIV-infected individuals in whom a cause of death was available ( $n=73$ ) were tuberculosis in 29 (39.7%) and other conditions associated with advanced HIV infection in 37 (50.7%). In patients without HIV infection, 16 (51.6%) and 15 (48.4%) of deaths were attributed to infectious and non-infectious causes, respectively. Mortality among adult patients with HIV was three times higher than in HIV uninfected patients. Tuberculosis and other preventable and treatable conditions associated with advanced HIV represented major causes of death in our population. This highlights the need for improved HIV diagnosis, monitoring, therapy and retention in care to decrease HIV-associated mortality. Comprehensive data from all sites will be presented in November.

0367

### CHANGES IN THYROID STATUS OF PEOPLE LIVING WITH HIV AFTER HAART ATTENDING ANTI-RETRO VIRAL THERAPY CENTER OF A TERTIARY CARE HOSPITAL OF BANGLADESH

Shrebash Paul, Fazle Rabbi Chowdhury, Md. Rafiqul Alam  
Bangabandhu Sheikh Mujib Medical University, Dhaka, Bangladesh

The aim of this prospective observational study was to study the changes in thyroid function amongst people living with HIV (PLHIV) attending anti-retroviral therapy (ART) center of Bangabandhu Sheikh Mujib Medical University (BSMMU), Bangladesh. We enrolled 61 HIV patients before starting treatment. Baseline investigations along with thyroid function tests were done including TSH, FT<sub>3</sub>, FT<sub>4</sub>, Anti-thyroglobulin antibody and Anti-thyroid peroxidase antibody. Patients were in follow up for six months and again investigated for the above mentioned thyroid investigations. Due to COVID-19 pandemic situations we could not complete follow up of all 61 patients. Until now we have completed follow-up of 40 patients and amongst them, four patients expired. Majority patients were male, hailing from Dhaka division. Unprotected promiscuous sexual activity and

use of commercial saloon was the commonest source of transmission. Unexplained weight loss (79%) was the commonest mode of presentation and majority presented with stage 2 or stage 3 of disease severity. Syphilis and tuberculosis was the commonest co-infection. We found that 14% of patients had thyroid dysfunction before starting HAART, and 20% patients develop thyroid dysfunction 6 months after treatment with HAART, this change was not statistically significant ( $p=0.7531$ ). This study also revealed that 6% of patient had positive auto antibody before starting HAART and it reached to 25% six months post treatment. This increment was statistically significant ( $p=0.0457$ ) and indicates an underlying IRIS. We also found that both of these changes were common amongst patients presented with advanced disease (WHO clinical stage 4). Total four patients died during the whole study period and three of them were due to severe COVID. In conclusion, thyroid dysfunctions particularly development of auto antibody are common amongst PLHIV. However large scale robust follow up is mandatory to draw any final conclusion.

0368

### ACCEPTABILITY AND PENETRATION OF A SUPERVISED AND PEER-LED HIV SELF-TESTING INTERVENTION AMONG UNIVERSITY STUDENTS IN EASTERN ZIMBABWE

Fadzai Naomi Mutseyekwa, Paddington Tinashé Mundagowa, Mandla Tirivavi, Tsitsi Murapa, Elizabeth Marian Chadambuka, Samantha Tozivepi, Waraidzo Mukuwapasi, Mazvita Machinga  
Africa University, Mutare, Zimbabwe

Given the low HIV testing rates among young people, inventive interventions are needed to reach them with HIV services. Despite the elevated risk of HIV acquisition among youths, a 2015 Zimbabwean survey revealed that young people were less likely to go for HIV testing mainly due to facility-based and provider-initiated testing-related barriers like stigma and lack of privacy. This study aimed to assess the penetration and acceptability of a supervised, peer-led oral HIV self-testing (HIVST) intervention among young adults at a university in Zimbabwe. A formative assessment was conducted by utilizing administrative data reviews; a baseline survey, three community dialogue sessions with the students; and recruitment of peer counselors. The implementation phase (August 2018 to February 2019) involved three brainstorming sessions by a team of multi-disciplinary experts of researchers, health workers, government agents, and student board representatives at Africa University. Peer counselors and university clinic health workers were trained on HIVST and the distribution process. Peer counselors disbursed the HIVST kits under the supervision of the nurses. The HIVST information leaflets were printed in English, French, and Portuguese to accommodate the enrolled students from 29 African countries. An end-line survey and in-depth interviews were conducted post-implementation. Intervention penetration was measured using administrative data to measure the kit uptake while acceptability was assessed by self-reported use of the HIVST kit. All the 744 HIVST kits were collected within the six months of the intervention. The initiative managed to increase the HTS uptake rate from 6.3% during the 12 months of 2017 to 49.6% during the six months of the intervention. Overall, the acceptability of HIVST was high with the use of trained peer counselors, multi-lingual pre-packaged leaflets, college seniority, and previous HIV test/s being associated with willingness to test. However, post-test services were poorly utilized. The study findings support the acceptability of scaling up HIV testing services among university students in Zimbabwe.

### INNATE-LIKE T CELL RESPONSES IN HIV EXPOSED UNINFECTED MALAWIAN INFANTS

David Thomas Rach<sup>1</sup>, Hao-Ting Hsu<sup>2</sup>, Ngina Nampota<sup>3</sup>, Godfrey Mvula<sup>3</sup>, Franklin R. Toapanta<sup>4</sup>, Marcelo B. Sztein<sup>4</sup>, Miriam Laufer<sup>4</sup>, Kirsten E. Lyke<sup>4</sup>, Cristiana Cairo<sup>2</sup>

<sup>1</sup>Molecular Microbiology and Immunology Graduate Program, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>2</sup>Institute

for Human Virology, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Blantyre Malaria Project, University of Malawi College of Medicine, Blantyre, Malawi, <sup>4</sup>Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States

Each year, an estimated 1.5 million HIV+ women give birth. Increased access to antiretroviral therapy (ART) ensures most infants born to HIV+ women do not contract the infection vertically, and thus remain HIV exposed but uninfected (HEU). During their first year of life, HEU infants exhibit increased rates of lower respiratory tract infections and diarrheal diseases, compared to HIV unexposed (HU) infants. It is hypothesized that exposure to HIV (and ART) before birth perturbs the developing fetal immune system by increasing inflammation at the fetal-maternal interface and induces long term effects that contribute to the increased infectious morbidity in HEU infants. The specific immunologic mechanisms behind this clinical outcome remain unclear. Among the subsets that may be perturbed by increased inflammation, innate-like T cells ( $\gamma\delta$ , MAIT, NKT cells) may play an important role against pathogens in early life. We hypothesize that prenatal HIV exposure results in early life activation of innate-like T cell subsets. Utilizing a well-characterized cohort of Malawian infants, we compare three groups of infants born to women with: 1) HIV infection but undetectable viremia through pregnancy (HEU-lo); 2) HIV infection diagnosed at mid-gestation or later, with high viral loads (HEU-hi); 3) no HIV infection (HU). A preliminary analysis of cord blood V $\delta$  T cells suggests that production of Th1 cytokines in response to polyclonal stimulation is increased in HEU neonates. The frequency of TNF $\alpha$ + V $\delta$  T cells is highest in HEU-hi neonates, while the frequency of polyfunctional (IFN $\gamma$ +TNF $\alpha$ +) V $\delta$  cells is highest in HEU-lo neonates. These findings, if confirmed, would suggest that exposure to replicating maternal HIV results in more robust TNF $\alpha$  production, while prolonged exposure to ART in HEU-lo neonates may contribute to the observed differences in V $\delta$  cells polyfunctionality. This study provides an opportunity to assess immune perturbation of innate-like subsets in HEU infants, contributing to our understanding of immune responses and mechanisms of increased infectious morbidity in this vulnerable population.

## 0370

### PREVALENCE, INCIDENCE AND PREDICTORS OF CHRONIC KIDNEY DISEASE IN PERSONS WITH HUMAN IMMUNODEFICIENCY VIRUS RECEIVING PROTEASE-INHIBITORS IN RURAL TANZANIA

**Herry Mapesi**<sup>1</sup>, James Okuma<sup>2</sup>, Fabian Franzeck<sup>3</sup>, Herieth Ismael Wilson<sup>1</sup>, Elizabeth Senkoro<sup>1</sup>, Theonestina Byakuzana<sup>1</sup>, Robert Ndege<sup>1</sup>, Fiona Vanobberghen<sup>2</sup>, Tracy Renée Glass<sup>2</sup>, Manuel Battegay<sup>3</sup>, Maja Weisser<sup>3</sup>, Daniel Henry Paris<sup>2</sup>

<sup>1</sup>Ifakara Health Institute, Morogoro, United Republic of Tanzania, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>3</sup>Division of Infectious Diseases and Hospital Epidemiology, University Hospital Basel, Basel, Switzerland

Ritonavir-boosted protease inhibitors (bPI) in people living with HIV (PLWH) have been associated with chronic kidney disease (CKD). Limited data are available from rural sub-Saharan Africa where people are at increased risk for CKD. Using data from the Kilombero and Ulanga Antiretroviral Cohort Study (KIULARCO) in rural Tanzania from 2005-01/2020, we assessed i) the prevalence of CKD (estimated glomerular filtration rate <60 mL/min/1.73m<sup>2</sup>) at the time of switch from first-line ART to bPI-regimen and ii) the incidence of CKD while being on bPI-regimens. We used logistic and Cox regression models to assess the relationship between clinical and demographic characteristics and CKD prevalence at the time of switch to bPI and subsequent incidence. CKD was present in 52/687 PLWH (7.6%) at the switch to bPI. Among 556 participants with normal kidney function at switch 41 (7.4%) developed CKD after a median time of 3.5 (IQR 1.6-5.1) years (incidence 22/1,000 person-years (95%CI 16.1-29.8)). Factors associated with CKD at switch were older age (adjusted odds ratio (aOR) 1.55 per 10 years; 95%CI 1.15-2.11), body mass index (BMI) <18.5 kg/m<sup>2</sup> (aOR 2.80 versus  $\geq$ 18kg/m<sup>2</sup>; 95%CI 1.28-6.14) and arterial hypertension

(aOR 2.33; 95%CI 1.03-5.28). The risk of CKD was lower with increased duration of ART use (aOR 0.78 per one-year increase; 95%CI 0.67-0.91). The CKD incidence under bPI was associated with older age (adjusted hazard ratio 2.01 per 10 years; 95%CI 1.46-2.78). This study shows a high prevalence of CKD at the time of switch from first-line ART to bPI and a high incidence of CKD after switch to bPI-regimens. Strong associations between CKD and older age, BMI, arterial hypertension and time on ART before the switch were seen. Given the need for lifelong ART, these data support the implementation of universal routine monitoring of renal function and improved pharmacovigilance monitoring.

## 0371

### A SYSTEMATIC REVIEW OF THE EPIDEMIOLOGY AND CLINICAL FEATURES OF HIV AND TRYPANOSOMA CRUZI (CHAGAS DISEASE) CO-INFECTION

**Natalie Elkheir**<sup>1</sup>, Jessica Carter<sup>2</sup>, Catherine Dominic<sup>3</sup>, Pat Lok<sup>4</sup>, Temitope Fisayo<sup>5</sup>, Melina Michelen<sup>6</sup>, Jaimie Wilson-Goldsmith<sup>7</sup>, Michael Butler<sup>8</sup>, Anushka Mehotra<sup>9</sup>, Barbara de Barros<sup>1</sup>, Amy Price<sup>10</sup>, Nadia Ahmed<sup>11</sup>, Peter Chiodini<sup>12</sup>, David Moore<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>St George's University, London, United Kingdom, <sup>3</sup>Barts and the London School of Medicine, London, United Kingdom, <sup>4</sup>Anglia Ruskin Medical School, Cambridge, United Kingdom, <sup>5</sup>King's College London, London, United Kingdom, <sup>6</sup>International Severe Acute Respiratory and Emerging Infection Consortium, Oxford, United Kingdom, <sup>7</sup>Guy's and St Thomas' NHS Trust, London, United Kingdom, <sup>8</sup>Imperial College Healthcare NHS Trust, London, United Kingdom, <sup>9</sup>One Health Lewisham (GP Federation), London, United Kingdom, <sup>10</sup>London North West University Healthcare NHS Trust, London, United Kingdom, <sup>11</sup>Central and North West London NHS Foundation Trust, London, United Kingdom, <sup>12</sup>Hospital for Tropical Diseases, London, United Kingdom

Chagas disease (caused by *Trypanosoma cruzi*) can behave as an opportunistic infection in patients with HIV, leading to reactivation, with atypical manifestations such as multiple space-occupying lesions and necrohaemorrhagic meningoencephalitis. There are significant differences in the way co-infection is screened for and managed in different countries and there has been little advance in our understanding of its epidemiology and clinical features. We present the results of our systematic review on the epidemiology and clinical features of HIV and *Trypanosoma cruzi* co-infection. Medline, Embase, Global Health, Global Index Medicus, Web of Science and Scopus databases were searched, with no language or date limits, giving a total of 3628 records. Following abstract and full-text screening, 151 articles were included for data extraction. Study details, population demographics, medical history, clinical presentations, investigations, management, and outcomes were extracted for over 700 patients with co-infection. In the majority of patients, HIV status was already known, and they were acutely unwell at presentation. Mean age at presentation was 37 years and 64% were male. Common presentations included fever, headache, weight loss, seizures, syncope, neck stiffness and focal neurological signs. Toxoplasmosis was the most common opportunistic infection also present. The most common neuroimaging finding was a single lesion; in around half these were ring-enhancing. Approximately half the patients with co-infection died, and in those who survived, the most common disability was hemiparesis. As the most conclusive and only up-to-date systematic review on HIV and Chagas disease co-infection, our findings will inform clinical and public health management, screening policy, healthcare service planning and identify future research priorities.

0372

## EPIDEMIOLOGY OF TB/HIV CO-INFECTION IN THE GAMBIA, MARCH 2019 - FEBRUARY 2020

Madiba Jabbi

Farafenni General Hospital, Banjul, Gambia

Tuberculosis (TB) still remains a major public health problem causing ill-health among millions of people around the world. HIV co-infection, together with drug-resistant TB and other co-morbidities are the growing problems that are fueling the epidemics of TB. HIV/AIDS is the leading risk factor for the reactivation of latent tuberculosis. TB on the other hand is also regarded as the most common opportunistic infection and the leading cause of death among people infected with HIV. The two diseases (TB and HIV) have a synergistic interaction; each promotes the progression of the other. Tuberculosis in The Gambia mainly affects people in the productive age group (15 - 59 years), with males being the majority of the patients. The aim of this study is to determine the prevalence of HIV co-infected TB patients in The Gambia. A retrospective study was carried out from March 2019 to February 2020. The inclusion criterion was all smear positive TB patients within the stated time span. Data was extracted from the National Leprosy and Tuberculosis Program and was reviewed, analyzed and presented into proportion and rates using excel, out of which a total of 2359 smear positive tuberculosis patients were screened for HIV. Out of which the majority were males. Less than quarter of the sample tested seropositive for HIV. However, more than half of the HIV positive cases were females. Moreover, the regional distribution shows that West Coast-2 has the highest number cases and Lower River Region registered the lowest. In conclusion, the prevalence of HIV co-infection among TB patients still remains a burden in the Gambia especially among female and in the West Coast Regions. This emphasizes the need to strengthen the routine surveillance in the two regions to ensure timely detection and management of cases. The use of Isoniazid preventive therapy among HIV seropositive patients without TB infection is also needed. This will help to minimize the risk of reactivation of latent TB thereby reducing the prevalence TB/HIV co-infection. Further studies should be done to investigate the factors responsible for high burden of TB/HIV co-infection among females.

0373

## CO-INFECTION OF DISSEMINATED HISTOPLASMOSIS AND MYCOBACTERIUM TUBERCULOSIS IN A PATIENT WITH AIDS: A CASE REPORT

Stefania Carmona<sup>1</sup>, Rigoberto Samaniego<sup>2</sup>, German Henostroza<sup>1</sup>

<sup>1</sup>University of Alabama at Birmingham Medical Center, Birmingham, AL, United States, <sup>2</sup>Hospital Santo Tomas, Panama City, Panama

It is estimated that the prevalence of histoplasmosis and Mycobacterium tuberculosis (MTB) are equivalent, in Latin America. In a Colombian case series, up to 70% of patients with disseminated histoplasmosis (DM) were co-infected with MTB. This case examines the diagnostic barriers encountered in Latin American countries and management of co-infections. We present a case of a Panamanian 35-year-old male who presented to the emergency room with a 48-hour history of fatigue, confusion, somnolence, and fever. He had recently been diagnosed with HIV (CD4 count 4). Based on his imaging (CT chest with a diffuse miliary pattern), his labs (pancytopenia), and profound immunosuppression the empiric diagnosis of DH was made. Yeast compatible with histoplasmosis was confirmed in a peripheral smear. He was started on amphotericin deoxycholate with mild improvement. Due to his persistent encephalopathy, fevers, and generalized weakness MTB became a concern. He was started on rifampin, isoniazid, pyrazinamide, and ethambutol. His clinical status began to improve and his mental status returned to baseline. His sputum AFB and CSF MTB PCR have been negative, leaving the MTB an empiric diagnosis. The patient continued on amphotericin deoxycholate past the 2-week transition point due to the scarcity and high prices of itraconazole. At the time of this patient's care, the histoplasma reagent was not available, which leads to a delay

in diagnosis unless it can be identified in culture or tissue biopsy. DH is treated with amphotericin for the first 2 weeks then itraconazole for 12 months. In mild to moderate cases, histoplasmosis is treated with itraconazole. The scarcity and price of itraconazole is a barrier for outpatient treatment in some countries. Hospital Santo Tomas has developed an ambulatory amphotericin deoxycholate infusion clinic for weekly infusions to continue treatment. This case has a third layer of complexity due to co-infection of DH and MTB. Currently, there are no guidelines for treatment of co-infections and the medication interactions require frequent monitoring as rifampin can decrease itraconazole serum levels.

0374

## RECONSTITUTION OF CATALYTIC ACTIVITIES OF TWO ESSENTIAL LEISHMANIAL CYTOCHROME P450 ENZYMES REVEALS NOVEL AND DISTINCT BIOCHEMICAL ROLES IN THE ERGOSTEROL BIOSYNTHESIS

Yiru Jin, Mei Feng, Lijun Liu, Michael Z. Wang

University of Kansas, Lawrence, KS, United States

CYP51 and CYP5122A1 are two cytochrome P450 (CYP) enzymes essential for the survival of *Leishmania donovani*, a major causative agent of human visceral leishmaniasis. Leishmanial CYP51 acts as a sterol C14 $\alpha$ -demethylase during ergosterol biosynthesis, and it has been considered as an attractive target for developing new antileishmanial drugs. CYP5122A1 is also involved in the leishmanial ergosterol biosynthesis pathway. However, its exact biological role remains unknown. We have proposed that CYP5122A1 act as a sterol C4-demethylase. To determine its exact biochemical function, it is important to reconstitute its catalytic activity with endogenous substrates and redox partner. In this study, recombinant *L. donovani* CYP51 and CYP5122A1 and *Trypanosoma brucei* NADPH-CYP reductase (*TbCPR*) were expressed and purified from *Escherichia coli*. Purified CYP51 and CYP5122A1 exhibited characteristic UV-Vis spectrophotometric properties of CYP enzymes and were reduced by *TbCPR* in the presence of NADPH. Using lanosterol as the substrate, CYP51 and CYP5122A1 were reconstituted *in vitro* with *TbCPR* and NADPH. Their catalytic activities showed a pH-dependence, with maximum activities at pH 6.2. LC-MS/MS-based sterol analysis confirmed that leishmanial CYP51 catalyzes lanosterol C14 $\alpha$ -demethylation to form FF-MAS. However, CYP5122A1 catalyzes hydroxylation of lanosterol at a position different from the methyl group at the C14 position, yielding a mixture of alcohol, aldehyde, and acid metabolites. Furthermore, when probed with several intermediate sterols (4,14-dimethylzymosterol, FF-MAS and T-MAS) in the ergosterol biosynthesis pathway, CYP51 and CYP5122A1 showed selectivity to 14-methylated and 4-methylated sterols, respectively. These results support that CYP5122A1 plays a different biochemical role than CYP51 during ergosterol biosynthesis. In conclusion, this study improved our understanding of the biological roles of CYP51 and CYP5122A1 in *Leishmania* parasites and provided new insights to target ergosterol biosynthesis for developing novel therapeutics against leishmaniasis.

0375

## ANALYSIS OF RELEASED PEPTIDASES AND THEIR ROLE IN THE TRANSMISSION BIOLOGY OF AFRICAN TRYPANOSOMES

Mabel Deladem Tetley, Federico Rojas, Keith R. Matthews

School of Biological Sciences, Ashworth Laboratories, The University of Edinburgh, Edinburgh, United Kingdom

Molecules released by African trypanosomes have an identified role in parasite virulence and quorum-sensing and may also be important at various stages of the parasite life cycle. Some of these secreted proteins include peptidases, with functions in creating the density-sensing signal in the bloodstream and potentially interacting with the mammalian immune system or during infectivity of the tsetse fly. Here, we analysed proteins released/secreted by parasites in the bloodstream and early during differentiation to the tsetse midgut procyclic form. Using detailed mass spectrometric analysis of the *T. brucei* secretome,

we have identified twelve peptidases released by the parasites during these developmental stages. Each was then validated for their release from parasites using individually epitope-tagged lines. Systematic ectopic overexpression and gene knockout using CRISPR/Cas9 of each peptidase gene was then used to identify that two peptidases (oligopeptidase B and metalloprotease 1) significantly contribute to the generation of the trypanosome's quorum-sensing signal. Knockout of each peptidase gene reduced development of bloodstream parasites to stumpy forms, whereas add back experiments restored normal stumpy formation for oligopeptidase B, with metalloprotease 1 add back experiments in progress. Furthermore, combined knockout of both peptidases demonstrated their additive contribution to the generation of the quorum-sensing signal. This systematic analysis of parasite released molecules identifies that two major peptidase activities released by the parasite dominate the generation of the quorum-sensing signal. Their further analysis will identify their oligopeptide products, pinpointing the specificity that drives the parasite's developmental response in preparation for transmission.

0376

### HOMOLOGIES IDENTIFIED BETWEEN TRYPANOSOMA CRUZI ANTIGEN 36 AND THE TRIM FAMILY OF PROTEIN GENES

Martin A. Winkler<sup>1</sup>, Alfred A. Pan<sup>2</sup>

<sup>1</sup>Biotech Advisor, LAWRENCE, KS, United States, <sup>2</sup>TNTC, Inc., Pleasant Hill, CA, United States

We have previously reported on a partial homology between the gene for *Trypanosoma cruzi* Clone 36 repetitive antigen ("Antigen 36"), and human TRIM21, which codes for the ubiquitin dependent ligase that regulates Interferon transcription production factors or degradation in innate immunity. TRIM21 is a member of the TRIM family of vertebrate proteins that has a tripartite domain structure, where the three domains are RING, B box, and coiled-coil structures. We compared the Antigen 36 gene, GenBank M21331, with 47 mammalian TRIM genes using the Needleman-Wunsch algorithm for genes alignment at <https://usegalaxy.org>. TRIM40 showed 10% partial gene homology; TRIM73 and TRIM74 showed 6% homology; TRIM6, TRIM7, TRIM10, TRIM43, TRIM61, TRIM64 showed 5% homology; TRIM15, TRIM17, TRIM21, TRIM31, TRIM47, TRIM48, TRIM50, TRIM60, and TRIM75, showed 4% partial homology; and TRIM11, TRIM27, TRIM34, TRIM49, TRIM52, and TRIM65, showed 3% homology. Twenty-three other TRIM genes showed homology ranging from 0-2.3%. The variation in gene size, from TRIM40 having only 777 nucleotides, to TRIM28 with 13,247 nucleotides, may account for differences in the percent homology observed. The Antigen 36 gene has two stretches of bases that are duplicated, and these may facilitate its partial homology to multi-domain genes such as the TRIM genes. The Antigen 36 gene is duplicated at least three times in *T. cruzi*. Its mRNAs, exported to the host cell cytoplasm in exosomes, for example, may recognize host TRIMs' mRNAs, possibly silencing these genes. This could impact the host innate immune response to the parasite, or the host's cellular growth.

0377

### ENZYMATIC AND MOLECULAR CHARACTERIZATION OF ANTI-LEISHMANIA MOLECULES THAT TARGET THE LEISHMANIA EUKARYOTIC TRANSLATION INITIATION FACTOR 4A, LEIF

Yosser Zina Abdelkrim<sup>1</sup>, Imen Bassoumi<sup>1</sup>, Emna Harigua-Souiai<sup>1</sup>, Josette Banroques<sup>2</sup>, Khadija Essafi-Benkhadir<sup>1</sup>, Mourad Barhoumi<sup>1</sup>, N. Kyle Tanner<sup>2</sup>, Ikram Guizani<sup>1</sup>

<sup>1</sup>Institut Pasteur de Tunis, Tunis, Tunisia, <sup>2</sup>Institut de Biologie Physico-Chimique, Paris, France

The two structural analogues 7-aminocholesterol and 6-aminocholestanol, and the rocaglamide, were previously described as anti-*Leishmania* molecules, but no experimental data were provided for their mode of action. However, we demonstrated that 6-aminocholestanol was an inhibitor of the *Leishmania* eIF4A-like protein, LeIF. In this study, we

investigated the mode of action of these molecules on the enzymatic activity of LeIF. We compared their biochemical effects and molecular interactions on the RNA-dependent ATPase activity of LeIF and its mouse ortholog eIF4A<sub>Mus</sub>. Michaelis-Menten kinetics of the ATPase activity of LeIF and eIF4A<sub>Mus</sub> were conducted using increasing concentrations of ATP and saturating whole yeast RNA. Kinetic measurements of the inhibition of the ATPase activity were also done using increasing concentrations of the compounds. Moreover, their anti-leishmanial activity was confirmed in *L. infantum* promastigotes. The Michaelis-Menten ATPase parameters in the absence of compounds measured a  $K_m$  of 151  $\mu$ M for eIF4A<sub>Mus</sub>, which showed a similar binding affinity to what we previously measured with LeIF (150  $\mu$ M). However, the  $k_{cat}$  of eIF4A<sub>Mus</sub> was 0.65  $\text{min}^{-1}$ , which was 3.7-fold lower than our previously measured value for LeIF (2.4  $\text{min}^{-1}$ ). The kinetic analyses showed that 7-aminocholesterol inhibited LeIF with a higher affinity ( $K_i = 8.594 \mu\text{M}$ ) than for eIF4A<sub>Mus</sub> ( $K_i = 30.14 \mu\text{M}$ ). We previously found that in the presence of 6-aminocholestanol, the  $K_i$  values were similar for LeIF and eIF4A<sub>Mus</sub> (19.5  $\mu$ M and 13.5  $\mu$ M, respectively). Cholesterol, a negative control, showed no effect on LeIF nor on eIF4A<sub>Mus</sub> ATPase activity. In contrast, rocaglamide increased the ATPase activities of both proteins to different extent (6.2-fold for eIF4A<sub>Mus</sub> vs 0.64-fold for LeIF). All tested compounds affected the promastigote viability. We are currently using docking simulations and model analyses to investigate the molecular interactions and mechanisms underlying the observed results. In conclusion, the tested compounds affected LeIF and eIF4A<sub>Mus</sub> differently. The inhibitory effects probably involve different binding pockets on the two proteins.

0378

### DEEP SEQUENCING OF THE MINI-EXON GENE IMPROVES GENOTYPING OF MULTICLONAL TRYPANOSOMA CRUZI INFECTIONS ASSOCIATED WITH CONGENITAL CHAGAS DISEASE

Julie Thompson<sup>1</sup>, Carine Truyens<sup>2</sup>, Eric Dumonteil<sup>1</sup>, Claudia Herrera<sup>1</sup>

<sup>1</sup>Tulane University School of Public Health & Tropical Medicine, New Orleans, LA, United States, <sup>2</sup>Université Libre de Bruxelles, Brussels, Belgium

It is estimated over 1.1 million women of childbearing age in Latin America are infected with *Trypanosoma cruzi*, and there are approximately 8668 new cases of congenital Chagas disease (CD) each year. Lacking treatment, approximately 30% of infected infants will develop potentially fatal forms of chronic disease later in life and girls can chronically harbor the parasite and transmit it to their own children during their reproductive years. Genetic variability of the parasite, which has been divided into 7 discrete typing units (DTUs) named TcI-TcVI and TcBat, has been suspected to impact vertical transmission, but data from our group suggests parasite haplotypes are more closely associated with congenital transmission rather than specific DTUs. Common methods for genotyping *T. cruzi*, including PCR and Sanger sequencing, are only capable of identifying a single dominant haplotype or strain and are insufficient for detecting multiclonal infections, thus limiting our ability to understand how sequence diversity impacts congenital transmission. This study aimed to fully characterize the *T. cruzi* profile among women and newborns through next-generation sequencing of the mini-exon gene among 90 clinical samples (57 maternal blood, 33 umbilical cord blood) originating from Argentina (n=32), Honduras (n=31), and Mexico (n=27). Multiple mini-exon haplotypes were identified across all samples and ranged in frequency from a single sequence to 19 haplotypes per sample. Infections with multiple DTUs were observed in the majority of cases, and phylogenetic analyses showed a predominance of infections with TcII-V-VI DTUs, as well as parasites from the TcI DTU. In addition, the diversity of dominant haplotypes (>1%) from each DTU varied depending on the country of origin. These data provide a more thorough understanding of the makeup of *T. cruzi* strains associated with congenital transmission and validates our sequencing methodology for parasite genotyping and detecting multiclonal infections among congenital CD cases.

0379

### DEVELOPMENT OF QUANTITATIVE RAPID ISOTHERMAL AMPLIFICATION ASSAY FOR ABSOLUTE QUANTIFICATION OF LEISHMANIA DONOVANI

**Md Anik Ashfaq Khan<sup>1</sup>**, Khaledul Faisal<sup>1</sup>, Rajashree Chowdhury<sup>1</sup>, Prakash Ghosh<sup>1</sup>, Manfred Weidmann<sup>2</sup>, Ahmed Abd El Wahed<sup>3</sup>, Dinesh Mondal<sup>1</sup>

<sup>1</sup>International Center for Diarrheal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Brandenburg Medical School Fontane, Senftenberg, Germany, <sup>3</sup>University of Leipzig, Leipzig, Germany

Quantification of pathogen load is of paramount importance for accurate diagnosis and clinical management of a range of infectious diseases. In a point-of-care testing (POCT) scenario such as in resource-limited settings, this is highly challenging with regards to availability, establishment, and operation of real-time quantitative PCR (qPCR) based applications. We devised a method to examine the absolute quantification ability of fluorophore-based isothermal recombinase polymerase amplification (RPA) assay. As for test of principle, two 10-fold dilution series of *Leishmania donovani* (LD) genomic DNA extracted from culture broth (CB) and culture-spiked peripheral blood (PB) were prepared, and a modified 15-minute assay protocol was performed in replicates. The quantification algorithm minimized the sample-to-sample variation in noise and defined the exponential amplification phase. The threshold times (Tt) in seconds thus obtained were plotted against the initial load of parasite genomes. The best-fitted regression models were found linear with mean  $r^2$ /RMSE values of residual points estimated as 0.996/8.063 and 0.992/7.46 for replicated series of CB and PB, respectively. In both series, the lower limit of detection reached less than 1 parasite equivalent genomic DNA. Inter-assay mean coefficients of variation were found to be 1.19% (95% CI: 0.07-2.32%) and 1.84% (95% CI: 0.46-3.21%) for CB and PB series, respectively. The method was blindly evaluated against qPCR in DNA samples that were extracted from visceral and post Kala-azar dermal leishmaniasis case specimens and stratified into high, moderate, and low Ct values. Absolute agreement between the two methods was found for test positivity, and strong positive correlations were observed between the Tt and Ct values ( $r = 0.89$ ;  $p < 0.0001$ ) as well as between the absolute parasite loads ( $r = 0.87$ ;  $p < 0.0001$ ) quantified by respective assays. The findings in this very first quantitative isothermal assay for leishmaniasis are suggestive of its potential in monitoring of LD load upon need (e.g. test of cure) and for the development of quantitative RPA assay for other infectious diseases.

0380

### MILTEFOSINE FAILURE AND SPONTANEOUS RESOLUTION OF CUTANEOUS LEISHMANIASIS BRAZILIENSIS

**Sheridan M. Joseph<sup>1</sup>**, Timothy J. Whitman<sup>2</sup>, Frederick Buckner<sup>3</sup>, Anna L. Cogen<sup>4</sup>

<sup>1</sup>University of Washington School of Medicine, Seattle, WA, United States, <sup>2</sup>University of Vermont Larner College of Medicine, Burlington, VT, United States, <sup>3</sup>Division of Infectious Diseases, Department of Medicine, University of Washington, Seattle, WA, United States, <sup>4</sup>Division of Dermatology, Department of Medicine, University of Washington, Seattle, WA, United States

Cutaneous leishmaniasis (CL) is the most common manifestation of leishmaniasis, and in South America is most often caused by *Leishmania braziliensis* (*L. braziliensis*), but treatment failures do occur. Here, we present a case of miltefosine failure in a patient with CL followed by spontaneous resolution. A 19-year-old previously healthy female traveled to Peru. One month after she returned, she developed a single lesion on her ankle. Clinical examination revealed a 1.5 cm erythematous plaque with central ulceration. A skin biopsy was sent to the CDC, which was positive for *L. braziliensis* on RT-PCR. The patient completed a 28-day course of miltefosine, however the lesion never fully healed, and a second proximal plaque developed 1.5 months later. An additional biopsy was performed of the initial plaque which was positive for *L. braziliensis* by culture. After consideration of other treatment options, the patient

decided to wait and both lesions spontaneously resolved over 9 months. Despite this, the risk for mucosal spread remains. For treatment to be considered curative, the lesion should decrease in size by more than 50%, begin reepithelializing, and new lesions should not develop by 4-6 weeks after completion. If not fully epithelialized after 3 months, treatment failure should be considered. The effectiveness of miltefosine against *L. braziliensis* CL in clinical trials ranges from 33-75% depending on the country. Cutaneous lesions do have a propensity to spontaneously heal, and it can take 6-15 months for *L. braziliensis* specifically. In 2-10% of untreated cases of New World CL, mucosal involvement occurs. It causes lesions that can be disfiguring and life-threatening, so systemic treatment is recommended for all cases of New World CL. The risk of mucosal spread is highest within 2 years, but can take decades to develop, so specific questioning about the development of new mucosal symptoms should be assessed at all subsequent visits. This case highlights the challenges associated with treatment of *L. braziliensis* infection and need for greater understanding of factors leading to treatment failure and/or self-resolution.

0381

### EVALUATION OF CHAGAS DISEASE TESTING AND MANAGEMENT PRACTICES IN A TEXAS SAFETY-NET HEALTHCARE SYSTEM

**Jose I. Echeverri Alegre<sup>1</sup>**, Jesica Hayon<sup>2</sup>, Roumen Iordanov<sup>2</sup>, Caryn Bern<sup>3</sup>, Jeffrey D. Whitman<sup>4</sup>, Eva Clark<sup>2</sup>

<sup>1</sup>Department of Medicine, Baylor College of Medicine, Houston, TX, United States, <sup>2</sup>Department of Medicine, Section of Infectious Diseases, Baylor College of Medicine, Houston, TX, United States, <sup>3</sup>Department of Epidemiology and Biostatistics, University of California, San Francisco, San Francisco, CA, United States, <sup>4</sup>Department of Laboratory Medicine, University of California, San Francisco, San Francisco, CA, United States

Chagas disease, a chronic infection caused by the protozoan parasite *Trypanosoma cruzi*, is a neglected tropical disease of the Americas; 6-7 million people are estimated to be infected globally, including 300,000 in the US. 20-30% of infected people develop cardiac or gastrointestinal sequela. US medical provider knowledge of *T. cruzi* screening and diagnosis is key to decreasing morbidity. Implementation of screening protocols is important in regions with large populations of people with Chagas disease risk factors, such as Texas. The objective of this project is to evaluate Chagas disease screening and management practices among medical providers in a county healthcare system with a large at-risk population. The Harris Health System is a safety-net system that cares for >1 million patients annually; 58% identify as Hispanic. Using the SlicerDicer tool of Harris Health's Epic electronic health record, we retrospectively identified patients  $\geq 18$  years old evaluated between 2010-2020 who had (1) undergone *T. cruzi* testing (identified via lab test codes) or (2) received a Chagas disease diagnosis (identified via ICD-9/10 codes). This resulted in 463 patient records, including 75 (16.2%) with a Chagas disease diagnosis. A systematic chart review is underway. In a preliminary analysis of 205 patient records, the average age was 47.5 years (SD=14.50); regions of birth include Central America (n=99, 48.3%), North America (n=91; Mexico = 30.7%, US = 13.7%), and South America (n=8, 4.0%). 25 (12.2%) had positive results by initial single *T. cruzi* IgG test. Only 9 underwent appropriate confirmatory testing. Of these, 9 (3.9%) were confirmed positive, and 7 received treatment (with benznidazole). Medical provider specialties ordering initial *T. cruzi* testing included Internal Medicine (n=91, 44.4%), Infectious Diseases (n=37, 18.0%), Cardiology (n=30, 14.6%), and other (n=47, 23.0%); no tests were ordered by Obstetrics. Once data analysis is complete, we will develop recommendations for potential interventions to improve Chagas disease screening and management practices and identify targets for patient and provider education and research.

### UTILITY OF SKIN BIOPSIES IN DIAGNOSIS AND PROGNOSIS OF CUTANEOUS LEISHMANIASIS

Hasna Riyal<sup>1</sup>, Nilakshi Samaranyake<sup>1</sup>, Priyani Amarathunga<sup>2</sup>, Deepani Munidasa<sup>3</sup>, Nadira Karunaweera<sup>1</sup>

<sup>1</sup>Department of Parasitology, Faculty of Medicine, University of Colombo, Colombo 08, Sri Lanka, <sup>2</sup>Department of Pathology, Faculty of Medicine, University of Colombo, Colombo 08, Sri Lanka, <sup>3</sup>Teaching Hospital, Anuradhapura, Sri Lanka

The recurrence rate & the number of patients with partially healed cutaneous leishmaniasis (CL) lesions in Sri Lanka is just the tip of an iceberg. The major challenge in curing a cutaneous leishmaniasis patient completely in a Sri Lankan hospital setting is ensuring adherence to the weekly treatment sessions. This study evaluated the findings from skin biopsies obtained from patients with CL in relation to diagnosis & as a prognostic marker. 116 CL suspected patients were recruited to the study & 3mm punch skin biopsies were obtained from the edge of their lesions. Fresh biopsies were gently rolled over the microscopic slides to create impression smears. Histological examinations were made using the FFPE tissue blocks. Patients were followed up until the end of treatment & the number of sodium stibogluconate (SSG) doses required for complete healing was recorded. Biopsy impression smears had a positivity rate of 86.2% indicating 100 positive patients while standard slit skin smears (SSS) had a positivity rate of 88.8% reporting 103 patients. The number of SSG doses required for complete healing ranged from 7 to 21 doses with a mean of 12.2±0.622 doses (nearly 4 months). Patients with heavy parasite loads required more than 13 treatment doses for complete cure ( $p=0.001$ ). Intensity of the inflammation ( $p=0.008$ ), number of macrophages ( $p=0.001$ ) & epidermal atrophy ( $p=0.033$ ) were associated with the parasite load. Granuloma formation & epidermal acanthosis were features of low parasite loads. Higher parasite loads and epidermal acanthosis were more frequent in delayed responders. Detection rates of impression smears were similar to slit skin smears suggesting impression smears to be a reliable diagnostic tool in settings where technicians lack expertise in obtaining SSS. Histology findings may be used to predict delayed responders to treatment which can thus be applied to monitor patients more closely to assess the need for alternative treatment.

### INCREASED LEVELS OF CHEMOKINES AND CYTOKINES MEDIATORS OF EOSINOPHIL AND T CELL RECRUITMENT IN SUBJECTS WITH CHRONIC CHAGAS DISEASE WITH HYPERSENSITIVITY REACTIONS TO BENZNIDAZOLE

Mara Ailen Natale<sup>1</sup>, Melisa Daiana Castro Eiro<sup>1</sup>, Dabora Seigelfischer<sup>2</sup>, Mara Belen Caputo<sup>1</sup>, Marisa Fernandez<sup>1</sup>, Mara Josefina Elias<sup>1</sup>, Rodolfo Viotti<sup>2</sup>, Bruno Lococo<sup>2</sup>, Mara Cecilia Albareda<sup>1</sup>, Eduardo Gaddi<sup>3</sup>, Jeanette Balbarski<sup>3</sup>, Gonzalo Cesar<sup>1</sup>, Marra Gabriela Ilvarez<sup>2</sup>, Susana Adriana Laucella<sup>1</sup>

<sup>1</sup>Instituto Nacional de Parasitología Dr. Mario Fatala Chaben, Buenos Aires, Argentina, <sup>2</sup>Hospital Interzonal General de Agudos Eva Peron, San Martin, Argentina, <sup>3</sup>Hospital General de Niños Pedro de Elizalde, Buenos Aires, Argentina

Chagas disease is caused by the intracellular parasite *Trypanosoma cruzi* and it is the main cause of infectious myocardopathy in the world. Benznidazole and nifurtimox are the two drugs approved for the treatment of Chagas disease. A suspension rate of approximately 17-30 percent primarily due to the appearance of severe dermatitis is observed during treatment with benznidazole in chronic Chagas disease. In this study, 49 adult subjects with diagnosis of *T. cruzi* infection were recruited prescribed for etiological treatment. The treatment consisted of benznidazole administered at 5 mg/kg body weight per day for 30 days. All subjects with severe dermatitis discontinued benznidazole therapy. Through cytometric bead assays and ELISA capture techniques, we measured the levels of pro-inflammatory cytokines, pro-apoptotic molecules and mediators of activation, differentiation and migration of eosinophils and

T cells in sera of *T. cruzi*-infected subjects treated with benznidazole who exhibited skin adverse events (n=23) and compared with those without adverse events (n=26). The amounts of IL-5, soluble FAS-L, IP-10 and MIG significantly increased at 7-30 days post-treatment and decreased thereafter, in subjects with dermatitis but not in subjects without dermatitis, compared with uninfected subjects. Additionally, granzyme B levels increased in a proportion of the treated subjects who had skin adverse events. In contrast, normal levels of eotaxin were observed in treated subjects with or without dermatitis. The levels of different hematologic parameters, cholesterol and IgE were not found to be predictors of adverse drug reaction. These results support a delayed type hypersensitivity reaction to drugs, with eosinophils and T cell recruitment and release of cytotoxic molecules.

### PROFILE OF COVID-19 POSITIVE PATIENTS ADMITTED FROM MARCH TO JUNE 2020 AT THE SINO-CONGOLESE FRIENDSHIP HOSPITAL IN N'DJILI FROM KINSHASA, DEMOCRATIC REPUBLIC OF THE CONGO

Mwana-Yile Hassan<sup>1</sup>, Giscard Kampanga<sup>1</sup>, Henriquet Mathe<sup>1</sup>, Erick Kamangu<sup>2</sup>, Kahunu Mesia<sup>3</sup>, Hippolyte Situakibanza<sup>4</sup>

<sup>1</sup>Sino-Congolese Friendship Hospital of N'djili, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>Molecular Biology Department, Department of Basic Science, Faculty of Medicine, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Department of Pharmacology and Therapeutics, Unit of Clinical Pharmacology and Pharmacovigilance, Faculties of Medicine and Pharmaceutical Sciences, University of Kinshasa, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Infectious and Parasitic Diseases, Departments of Internal Medicine and Tropical Medicine, Faculty of Medicine, Kinshasa, Democratic Republic of the Congo

The recent emergence of COVID-19 worldwide, including in the Democratic Republic of Congo has led to a better understanding of the mode of transmission, severity, clinical features, and risk factors of the infection. This study was undertaken to determine the epidemiological, clinical, paraclinical and therapeutic profile of COVID-19 positive patients followed at the Sino-Congolese Friendship Hospital. A descriptive study carried out on a group of 83 COVID-19 positive patients from March 10 to June 30, 2020. The mean age was 46 years of which 63% are under 50. Sixty-two patients (75%) were not severe cases, and twenty-one patients (25%) were severe cases. Male gender was predominant (63%) and the sex ratio (M/F) was 1.68%. Thirty percent of the patients had comorbidities of which high blood pressure was predominant (20.5%). Symptoms were dominated by the tetrad "fever-respiratory distress signs-headache-cough" of which fever was predominant (39.8%). The radiographic sign was basal interstitial lung disease (2.4%) and the CT sign was ground glass (1.2%). The case fatality rate was 12.3%. Fifty patients (60%) were treated with (Chloroquine + azithromycin + vitamin C + zinc) and twenty-three patients (27%) treated with (amoxicillin-clavulanic acid + azithromycin) were cured. This study, carried out in the context of the pandemic, showed that age over 50 years appears to be strongly associated with the development of acute respiratory disease.

### IN VITRO ACTIVITY OF MYCOBACTERIOPHAGES AGAINST MYCOBACTERIUM TUBERCULOSIS BIOFILMS

Deus Kanya, Willy Ssengooba, Beatrice Achan, Jesca L. Nakavuma

Makerere University, Kampala, Uganda

Tolerance of *Mycobacterium tuberculosis* to antibiotics has been associated with its tendency to grow in cell aggregates also known as biofilms. These biofilms are thought to favour the persistence of *M. tuberculosis* in the body of their hosts by physically shielding the infectious bacilli from antibiotics and the host immune defences; providing a platform for quorum sensing, as well as harbouring mycolic acids, an important

carbon source in the 'persister state'. This highlights the need for targeting biofilms when treating persistent tuberculosis. This study evaluated the activity of mycobacteriophages (viruses of mycobacterium) against biofilms of *M. tuberculosis*. Mycobacteriophages (phages) were isolated from soil and sewage collected along the Nakivubo sewage channel in Kampala, Uganda. The phages were characterized based on their plaque morphologies, adsorption time, latent period and burst size. The spot test was used to determine the mycobacteriophage host range against 60 clinical isolates of *M. tuberculosis*, obtained from both the pulmonary and extra-pulmonary compartments. Phage-susceptible *M. tuberculosis* isolates were cultured on MBEC® plates for one and two weeks in order to establish active and mature biofilms respectively. These biofilms were infected with a cocktail of three broad-host-range phages at multiplicities of infection (MOI) 100, 10, 1, 0.1 and 0.01. Phage anti-biofilm activity was expressed as a percentage reduction in biofilm formation in the no phage treated biofilms. Mycobacteriophages reduced biofilm formation up to 40% in active biofilms and up to 30% in mature biofilms. Anti-biofilm activity of the mycobacteriophages was directly proportional to the MOI used. Although pulmonary *M. tuberculosis* isolates were more susceptible to phage infection compared to the extra-pulmonary, there was no significant difference in anti-biofilm activity against pulmonary and extra-pulmonary isolates. This study has demonstrated the potential of mycobacteriophages as anti-biofilm agents. However, the underlying mechanisms for the anti-biofilm activity reported here are yet to be understood.

#### EPIDEMIOLOGICAL ANALYSIS OF TUBERCULOSIS IN ADULTS IN OTTAWA, CANADA FROM 2009-2018

Scott G. Pharand, Shirley Sarfo-Mensah, Phoebe A. Ampaw, Anne E. McCarthy

Ottawa Hospital Research Institute, Ottawa, ON, Canada

All adult cases of tuberculosis (TB) in Ottawa are referred to the Regional Tuberculosis Clinic at The Ottawa Hospital (TOH) for treatment and management. Prior to this study, there was no comprehensive database of local TB data at TOH. This study reported informative data to improve the quality of care for TB patients. A retrospective chart review of TB cases at TOH from 2009-2018 was completed to report on demographics, TB risk factors, clinical history, diagnostics, antimicrobial resistance (AMR), treatment, and clinical outcomes. A total of 399 cases (77.4% foreign-born; 8.5% Indigenous) were seen at TOH. The average annual incidence was 40 cases (4.2/100,000). HIV co-infection was present in 4.3%. Diabetes was present in 12.5%. Pulmonary-involved TB comprised 55.1% of cases. AMR was identified in 9.3%. Directly observed therapy (DOT) was implemented in 86.2%. TB rates in Ottawa are slightly lower than the national average. Foreign-born patients comprised a majority of TB cases. Out of Canadian-born cases, Indigenous peoples were disproportionately affected by TB. Cases with diabetes and HIV had increased mortality and morbidity. Antimicrobial stewardship and DOT remained essential.

0387

#### COMPLETE GENOME SEQUENCE OF BORDETELLA PERTUSSIS STRAINS IN THE AMHARA REGIONAL STATE, ETHIOPIA

Solomon Taye

University of Gondar, Gondar, Ethiopia

Pertussis, or whooping cough is an acute respiratory tract disease caused by *Bordetella pertussis*. In 2014, globally, there were an estimated 24.1 million pertussis cases and 160,700 deaths from pertussis in children younger than 5 years. Due to vaccine pressure there have been genotype changes in the circulating *B. pertussis* strains. The aim of this study was to determine distribution of *B. pertussis* strains in the Amhara Regional State, Ethiopia. Methods: Cross-sectional study design was employed on clinically suspected pertussis patients. Sixteen DNA samples these positive for IS481 (Ct<28 cycles) were sequenced using next generation illumina whole genome sequencing. The sequenced data was analyzed using software's

and sequenced data was compared with reference strains using BLAST and phylogenetic tree. The ptxP1, fim4 and prn1 alleles were found in 11/15 (73%) of sequenced samples. The remaining four samples (27%) carried the ptxP3, fim2 and prn2 alleles. None of the samples carrying the ptxP1 allele was found to carry the fim2 or prn2 allele and none of the samples carrying the ptxP3 allele was found to carry the fim4 or prn1 allele. The ptxP1 allele carrying *B. pertussis* was the commonest strains circulating in the Amhara Regional State, Ethiopia. The increased number of ptxP3 strains in Ethiopia indicates that the shift from ptxP1 to ptxP3 strains. This ptxP allele shift needs further investigation whether it is associated with the type of vaccine used or not.

#### SETTING UP A TUBERCULOSIS RESEARCH DATABASE IN ZIMBABWE THROUGH THE NATIONAL TUBERCULOSIS PROGRAM

Nokuthula Samantha Tozivepi<sup>1</sup>, Collins Timire<sup>2</sup>, Wietske Mushonga<sup>3</sup>, Charles Sandy<sup>2</sup>, Kudakwashe Collin Takarinda<sup>2</sup>, Elton Mugomeri<sup>3</sup>, Fadzai Naomi Mukora-Mutseyekwa<sup>1</sup>

<sup>1</sup>Africa University Clinical Research Centre, Mutare, Zimbabwe, <sup>2</sup>Ministry of Health and Child Care, National AIDS & TB Program, Harare, Zimbabwe, <sup>3</sup>Africa University Department of Health Sciences, Mutare, Zimbabwe

Zimbabwe is a high-burden country for Tuberculosis (TB), Multi-drug resistant tuberculosis (MDR-TB) as well as Tuberculosis/ Human Immunodeficiency Virus (TB/HIV) co-infection. The Government of Zimbabwe is committed to ending TB by 2030. By 2025, the National Tuberculosis Program (NTP) aims to reduce TB incidence and mortality by 80%. To achieve this goal, a Tuberculosis Research Technical Working Group (TBR TWG) was created to support the NTP through working in consultation with various stakeholders to scale-up evidence-based programmes through operational in-country research. The TBR TWG facilitated stakeholder meetings to establish an inventory of current TB research to identify gaps, avoid duplication of research and allow smooth coordination on mapping the way forward. This process involved creating a TBR database which the country never had before. The TBR database was created through a literature extraction which was done to capture published work. Other methods which will be employed to feed into the TBR database include conducting an online survey and seeking for researches done through the Medical Research Council of Zimbabwe (MRCZ) to capture program work in operational research which has not published. A literature extraction was conducted by searching two major databases PubMed and Google Scholar, to identify articles pertinent to Tuberculosis in Zimbabwe from 2010 to date. Over 90 publications were found and computed into the TBR database. The database includes various information such as authors, titles, thematic areas, study setting, year research was done, year of publication, funding and publication link. We went on to develop the online survey using google forms. A stakeholder mapping exercise will be done first, to send the survey via email and the social media WhatsApp platform. Information obtained from both the survey and MRCZ will be consolidated and merged into the TBR database. We will eventually create an online repository, by hosting the TBR database on a server under the Ministry of Health and Child Care of Zimbabwe. The online repository will be accessible to everyone interested in TB research in Zimbabwe.

0389

#### EFFECT OF INDOOR AIR QUALITY ON NEONATAL DEATH DUE TO PNEUMONIA: FINDINGS FROM BANGLADESH DEMOGRAPHIC AND HEALTH SURVEY DATA

Jaynal Abedin<sup>1</sup>, Tania Jahir<sup>2</sup>

<sup>1</sup>Centre for Data Research and Analytics, Dhaka, Bangladesh, <sup>2</sup>icddr, Dhaka, Bangladesh

Improving child survival in low and middle-income countries faces a major difficulty due to death of newborn child within first 28 days of their birth. In Bangladesh neonatal mortality rate higher than global, 41 vs 31 per

1000 live births. Pneumonia is an inflammatory condition of the lungs caused by infection, which could be triggered by higher exposure to the particulate matter (PM<sub>2.5</sub>) and is the third leading cause of neonatal death in Bangladesh. Among the top 10 countries with the highest level of Ambient PM<sub>2.5</sub>, produced by all types of combustion common in urban and rural places, Bangladesh is in the ninth position. Household cooking fuel is one of the prime sources of PM<sub>2.5</sub> in indoor settings. We explored association between neonatal death in pneumonia and mothers' and neonates' exposure to PM<sub>2.5</sub> in indoor settings. Exposure to PM<sub>2.5</sub> is measured by the type of cooking fuel used in the household. An indoor cooking with unimproved biomass fuel is defined as high exposure to PM<sub>2.5</sub>. We designed an unmatched case-control study from Bangladesh Demographic and Health Survey 2017-18. Deaths due to pneumonia were extracted from verbal autopsy module and then, randomly selected controls from the same geographic area where death occurred. We fitted a logistic regression model to estimate the association between neonatal death and exposure to PM<sub>2.5</sub>. Findings shows that, among the neonates, who died due to pneumonia is 1.2 (95% CI 0.6-2.7) times more likely to have higher exposure to PM<sub>2.5</sub> while adjusting by potential covariates. The major portion of the confidence interval is above one which indicates a higher risk, though the association is statistically not significant due to smaller sample size. The results suggests that neonatal death due to pneumonia could be explain by higher exposure to PM<sub>2.5</sub> in indoor settings. A larger longitudinal study to quantify level of PM<sub>2.5</sub> exposure during pregnancy and after birth in the household setting could reveal more insights about the association. The result presented here will serve as an important basis for such future research.

0390

#### FACTORS ASSOCIATED WITH COMMUNITY ACQUIRED SEVERE PNEUMONIA AMONG UNDER FIVE CHILDREN IN DHAKA, BANGLADESH: A CASE CONTROL STUDY

**Sabiha Nasrin**<sup>1</sup>, Marufa Sultana<sup>2</sup>, Md. Tariqujjaman<sup>1</sup>, Mohammad J. Chisti<sup>1</sup>, Abu S. Faruque<sup>1</sup>, Tahmeed Ahmed<sup>1</sup>, George J. Fuchs<sup>3</sup>, Niklaus Gyr<sup>4</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Deakin University, Australia, Australia, <sup>3</sup>University of Kentucky, Lexington, KY, United States, <sup>4</sup>University of Basel, Basel, Switzerland

Pneumonia is the leading cause of death in children globally with the majority of these deaths observed in resource-limited settings. The annual incidence of clinical pneumonia in children under 5 years of age is approximately 152 million each year worldwide, mostly in the low- & middle-income countries. Of these, 8.7% progressed to severe pneumonia requiring hospitalization. However, data to predict children at greatest risk to develop severe pneumonia from pneumonia are limited. Secondary data analysis was performed after extracting relevant data from a prospective cluster randomized controlled clinical trial; children of either gender, aged two months to five years with pneumonia or severe pneumonia acquired in the community were enrolled over a period of three years in 16 clusters in urban Dhaka city. The analysis comprised of 2,597 children aged 2-59 months. Of these, 904 & 1693 were categorized as pneumonia (controls) and severe pneumonia (cases), respectively based on WHO criteria. The median age was 9.2 months (range, 5.1-17.1) and 1,576 (60%) were male. After adjustment for covariates, children with temperature  $\geq 38$  °C, duration of illness  $\geq 3$  days, presence of crepitation, male gender, and severe stunting showed a significantly increased likelihood of developing severe pneumonia compared to those with pneumonia. Severe pneumonia in children occurred more often in older children who presented commonly from wealthy quintile families, and who often sought care from private facilities in urban settings. Male gender, longer duration of illness, fever, crepitation, and severe stunting were significantly associated with development of WHO-defined severe childhood pneumonia in our population. The results of this study may help to develop intervention targets to reduce morbidity and mortality. 1

0391

#### WHICH IS BETTER TREATMENT OPTION IN SEVERE PNEUMONIA: INTRAVENOUS AMPICILLIN OR AMOXICILLIN? AN OPEN-LABEL, RANDOMIZED, CONTROLLED TRIAL IN BANGLADESH

**Lubaba Shahrin**

International Centre for Diarrheal Disease Research Bangladesh, Dhaka, Bangladesh

To treat severe pneumonia, intravenous ampicillin needs to be administered at a six-hourly interval, which requires frequent nursing intervention and bed occupancy for 5-7 days, limiting its utility in resource-poor settings. We compared the efficacy of a potential alternative drug, intravenous amoxicillin, which requires 12 hourly administration and less frequent nursing intervention and can be switched to oral form after clinical improvement. We conducted an unblinded, randomized, controlled, non-inferiority trial in the Dhaka Hospital of icddr. Children from 2-59 months of age presenting with WHO-defined severe pneumonia with respiratory danger signs were randomly assigned 1:1 to either 50 mg/kg ampicillin or 40 mg/kg amoxicillin per day 7.5mg/kg gentamicin. The primary outcome was treatment failure as per the standard definition of persistent danger sign(s) of severe pneumonia beyond 48 hours or deterioration within 24 hours of therapy initiation. We undertook an intention-to-treat analysis to compare treatment failure. The trial is registered in Clinicaltrials.gov (NCT03369093) and received institutional ethical approval. We enrolled 308 participants, 154 in each arm, between 1st January 2018 to 31st October 2019. Baseline characteristics were similar among the two groups. Sixty-two (20%) children ended up with treatment failure, 21 (14%) in amoxicillin, and 41 (27%) in ampicillin arm. A significantly lower proportion of children in the amoxicillin arm experienced treatment failure than the ampicillin arm (relative risk [RR] 0.22, 95% CI 0.23-0.81;  $p=0.004$ ). We reported 14 deaths for serious adverse events, 4 (3%) and 10 (6%) among amoxicillin and ampicillin arm, respectively, which was not statistically significant. Intravenous amoxicillin plus gentamicin combination is not non-inferior to intravenous ampicillin plus gentamicin in treating severe pneumonia in under-five children in Bangladesh. Considering the less frequent dosing and more compliance, parenteral amoxicillin is a better choice for treating children with severe pneumonia in resource-limited settings.

0392

#### ASPIRATION PNEUMONIA REVIEW: CASE REPORTS FROM KENYA CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE NETWORK (CHAMPS) PROGRAM

**Victor Akelo**<sup>1</sup>, Dianna M. Blau<sup>2</sup>, Joyce Were<sup>3</sup>, Aggrey Igunza<sup>3</sup>, Dickson Gethi<sup>3</sup>, Cynthia G. Whitney<sup>4</sup>, Janet Agaya<sup>3</sup>, Richard Omoro<sup>3</sup>, Magdalene Kuria<sup>5</sup>, Emily Rogena<sup>6</sup>, Beth A. Tippet Barr<sup>1</sup>, Dickens Onyango<sup>5</sup>

<sup>1</sup>U.S. Centers for Disease Control and Prevention-Kenya, Kisumu and Nairobi, Kenya, <sup>2</sup>U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Kenya Medical Research Institute (KEMRI), Kisumu, Kenya, <sup>4</sup>Emory Global Health Institute, Emory University, Atlanta, GA, United States, <sup>5</sup>Kisumu County Health Department, Kisumu, Kenya, <sup>6</sup>Jomo Kenyatta University of Agriculture and Technology, Nairobi, Kenya

Aspiration pneumonia (AP), thought to be related to swallowing difficulties, is common in children with neurological or complex medical conditions. Children with AP have longer hospitalizations, higher intensive care unit admission and readmission rates compared to children with non-aspiration pneumonia, but data characterizing AP deaths in Africa are lacking. We describe AP among child deaths enrolled in the Kenya Child Health and Mortality Prevention Surveillance (CHAMPS) Network. CHAMPS is a multi-country surveillance program that systematically identifies causes of under-five mortality from defined catchment areas. Between May 2017 and December 2020, causes of death (COD) were determined by a panel of experts for 325 deceased children 0-59 months in Kenya using data from post-mortem minimally invasive tissue specimen

testing, clinical records, and verbal autopsy. Twenty-five (7.7%) had AP in the causal chain (15 as immediate COD and 10 as underlying COD). Four (16%) AP cases were in neonates, 13 (52%) in infants, and, 8 (32%) in children (12-60 months). Ten (40%) cases died in the community while 15 in the hospital. Fifteen of 19 (79%) children with AP as immediate COD had a condition that likely increased aspiration risk or poor outcome from pneumonia, including: gastroenteritis (3), malnutrition (2), chronic malaria (2), down syndrome (1), cleft palate and lip (1), cerebral palsy (1) and convulsive disorder (1). Of the 24 cases with lung tissue findings, the most common included interstitial inflammation (21/24, 88%), increased alveolar macrophages (18/24, 75%), hyaline membranes (5), alveolar neutrophilic infiltrate (4) and intra-alveolar hemorrhage (3). Four cases had super-imposed pneumonia with bacterial (2) and viral (2) etiologies. Only eight (50%) children had a diagnosis of AP ante-mortem. CHAMPS revealed AP—associated pediatric deaths that would have otherwise been unreported. Given medical complexity of managing children with AP, a high index of clinical suspicion and routine clinical audits of child deaths should be encouraged to identify and manage aspiration pneumonia cases.

0393

### GENOMIC SURVEILLANCE OF SARS-COV-2 IN A PACIFIC MILITARY POPULATION

**Rachael L. Downham**, Timothy Horseman, Zakariae Bram, Lindsey O'Neal, Catherine Uyehara, Viseth Ngauy, Alexander Kayatani, Jonathan D'Ambrozio

*Tripler Army Medical Center, Honolulu, HI, United States*

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) emerged as a novel respiratory virus in December 2019. It is important to characterize variant strains to assess the mutagenesis and evolution of the virus circulating in geographical locations where our service members are stationed. Routine clinical diagnostics are unable to differentiate variant SARS-CoV-2 strains; therefore, whole genome characterization is critical for surveillance. In this study we characterized positive nasopharyngeal specimens submitted to Tripler Army Medical Center (TAMC) on Oahu, Hawaii. Genomes were analyzed using the Illumina Next-Generation Sequencing (NGS) on the MiSeq platform to align sequence reads to the SARS-CoV-2 reference, NCBI RefSeq NC\_045512, and construct consensus sequences from the mapped reads. Initial analyses were conducted with Geneious Prime v2021.1. Clade assignments were performed using Nextclade, and lineages established using Pangolin. Thus far, 74 full SARS-CoV-2 genomes of samples collected from March 2020 to April 2021 have been sequenced. Clades 20A, 20B, 20C, 20G, and 19B were represented, with nonsynonymous mutations relative to the reference. The G614D amino acid (AA) and P681H AA mutations were the dominant nonsynonymous changes in the spike protein, found in almost all genomes sequenced. Identified variants of concern include B.1.1.7 and B.1.429. Multiple B.1.526.2 variants were also present. Of note, a potential novel unassigned lineage containing the critical N501Y substitution in the spike protein, along with a large ORF8 deletion, was also observed. These data demonstrate that NGS is an important tool to investigate the role of viral adaptation in the transmissibility and pathogenicity of SARS-CoV-2. Increased genetic surveillance capabilities in unique geographical locations like TAMC will significantly shorten the turn-around-time for rapidly informing the public health community of any concerning genetic changes.

0394

### COMPARATIVE DIAGNOSTIC POTENTIAL OF SCHISTOSOMA MANSONI-DERIVED ANTIGENS FOR CHRONIC INTESTINAL SCHISTOSOMIASIS IN LOW ENDEMIC AREAS

**Oyetunde T. Oyeyemi**<sup>1</sup>, Camila Corsini<sup>2</sup>, Rafaella F.Q. Grenfell<sup>2</sup>

<sup>1</sup>*University of Medical Sciences, Ondo, Nigeria*, <sup>2</sup>*Rene Rachou Institute, Oswaldo Cruz Foundation (Fiocruz), Belo Horizonte, Brazil*

The study aimed to determine the schistosomiasis diagnostic potential of crude antigens prepared from different stages in *Schistosoma mansoni* life cycle. *S. mansoni* egg antigen (SEA), *S. mansoni* worm antigen (SWA) and schistosomula crude antigen (SCA) were prepared from the eggs, adult worms and schistosomula stages respectively. The diagnostic potentials of SEA, SWA and SCA were evaluated using ELISA test. Either Kato-Katz or saline gradient method or both were employed as the diagnostic reference. The areas under the ROC curve were 0.90 (CI 0.82 - 0.98,  $p < 0.0001$ ), 0.96 (CI 0.90-1.00,  $p < 0.001$ ), and 0.95 (CI 0.88-1.01,  $p < 0.0001$ ) for SEA, SWA and SCA respectively. The sensitivity of SWA and SEA was similar (90%) but was lower than that of SCA (96.7%). The human IgG-specific responses against the *S. mansoni*-derived antigens were significantly higher in *S. mansoni* infected individuals compared to the non-infected population ( $p < 0.0001$ ). Our study showed that SEA, SWA, and SCA are reliable diagnostic tools for chronic schistosomiasis.

### NEW AVENUES FOR THE VISUAL DIAGNOSIS OF FEMALE GENITAL SCHISTOSOMIASIS

**Solrun Soefteland**<sup>1</sup>, Motshedisi H. Sebitloane<sup>2</sup>, Myra Taylor<sup>3</sup>, Borghild B. Roald<sup>4</sup>, Sigve Holmen<sup>1</sup>, Hashini N. Galappaththi-Arachchige<sup>1</sup>, Svein G. Gundersen<sup>5</sup>, Eyrun F. Kjetland<sup>3</sup>

<sup>1</sup>*Norwegian Center for Imported and Tropical Diseases, Department of Infectious Diseases Ullevaal, Oslo University Hospital, Oslo, Norway*, <sup>2</sup>*Discipline of Obstetrics and Gynecology, Nelson R Mandela School of Medicine, College of Health Sciences, University of KwaZulu-Natal, Durban, South Africa*, <sup>3</sup>*Discipline of Public Health Medicine, Nelson R Mandela School of Medicine, College of Health Sciences, University of KwaZulu-Natal, Durban, South Africa*, <sup>4</sup>*Center for Pediatric and Pregnancy Related Pathology, Department of Pathology, Oslo University Hospital, Oslo, Norway*, <sup>5</sup>*Institute for Global Development and Planning, University of Agder, Kristiansand, Norway*

*Schistosoma haematobium* infection may lead to Female Genital Schistosomiasis (FGS) in women and girls. FGS is associated with abnormal vaginal discharge, ectopic pregnancies, and HIV. Due to the range of symptoms, FGS is a differential diagnosis for many gynecological conditions. In rural health care settings, where syndromic diagnosis is performed, FGS is consistently misdiagnosed and treated as cancer or sexually transmitted infections. The reference standard for diagnosis of FGS is a thorough inspection for lesions on the cervix, fornices, and the vaginal walls with a stationary colposcope. However, the colposcope is not practical in resource-limited settings as it is expensive, requires extensive training, and electricity. Our aim was to systematically review handheld equipment which could potentially be used for point-of-care diagnosis of FGS, and to assess the quality of the evidence. We searched Medline and Embase 2015–2020 for handheld devices used in cervical cancer screening and FGS diagnosis. We excluded studies that did not compare the device to standard-of-care colposcopes or histopathology. We found 11 studies that fit the criteria, where four handheld colposcopes, two smartphones, and one compact digital camera could be evaluated. Some requirements for FGS diagnosis were unaddressed by the studies, such as vaginal wall inspection and adequate lighting for FGS lesions. No device provided automatic lesion recognition. However, the Gynocular and Mobile ODT seemed best suited. For patients from schistosomiasis endemic areas, we suggest that handheld devices could be used in FGS diagnosis. Cervical cancer screening should be done simultaneously. Studies are needed to

determine which of the two devices is most adequate for FGS diagnosis. Further studies are needed to explore computer-assisted diagnosis for FGS, and effective management of FGS.

### THE PRAZIQUANTEL IN PRESCHOOLERS TRIAL: STUDY PROTOCOL FOR A PHASE II PK/PD DRIVEN RANDOMISED CONTROLLED TRIAL OF PRAZIQUANTEL IN CHILDREN UNDER FOUR YEARS OF AGE

Emily Webb<sup>1</sup>, Andrew Edielu<sup>1</sup>, Wu Hannah<sup>2</sup>, Narcis Kabatereine<sup>3</sup>, Tukahebwa Edridah<sup>3</sup>, Alfred Mubangizi<sup>3</sup>, Moses Adriko<sup>3</sup>, Alison Elliott<sup>1</sup>, William Hope<sup>4</sup>, Patrice Mawa<sup>5</sup>, Jennifer Friedman<sup>2</sup>, Amaya L. Bustinduy<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>2</sup>Center for International Health Research, Lifespan Hospital, Providence, RI, United States, <sup>3</sup>Vector Control Division, Ministry of Health, Kampala, Uganda, <sup>4</sup>University of Liverpool, Liverpool, United Kingdom, <sup>5</sup>MRC unit, London, United Kingdom

Over 200 million individuals worldwide are infected with *Schistosoma* species, with over half of infections occurring in children. Despite most children experiencing first infections early in life impacting their growth and development, praziquantel (PZQ) the only available drug for the treatment of schistosomiasis only has regulatory approval among adults and children over the age of four, but frequently used "off label" in endemic settings. Furthermore, pharmacokinetic/pharmacodynamics (PK/PD) evidence suggests the standard PZQ dose of 40 mg/kg is insufficient in preschool aged children (PSAC). Our goal is to understand the best approaches to optimising treatment of PSAC with intestinal schistosomiasis. We are conducting a randomised, controlled Phase II trial in a *Schistosoma mansoni* endemic region of Uganda and a *Schistosoma japonicum* endemic region of the Philippines (the praziquantel in pre-schoolers (PIP) trial; NCT03640377). Six hundred children, 300 in each setting, aged 12-47 months with *Schistosoma* infection are being randomised in a 1:1:1:1 ratio to receive either (1) 40 mg/kg PZQ at baseline and placebo at six months, (2) 40 mg/kg PZQ at baseline and 40 mg/kg PZQ at six months, (3) 80 mg/kg PZQ at baseline and placebo at six months, or (4) 80 mg/kg PZQ at baseline and 80 mg/kg PZQ at six months. Following baseline treatment, children will be followed up three times over a period of 12 months. The primary outcome is drug efficacy assessed by cure rate and egg reduction rate at four weeks. Secondary outcomes include drug efficacy assessed by novel antigenic endpoints at four weeks, actively collected adverse events and toxicity for 24 hours post-treatment, morbidity and nutritional outcomes at 6 and 12 months, biomarkers of inflammation and environmental enteropathy and PZQ PK/PD parameters. Recruitment has started in Uganda in April of 2021. In conclusion, the PIP trial will provide valuable information on the safety and efficacy of the 80 mg/kg PZQ dose in PSAC, and on the impact of six-monthly versus annual treatment, in this vulnerable age group.

### MULTIPLE ANTIGEN BLOT ASSAY AS AN ANTIBODY SCREENING TECHNIQUE FOR SCHISTOSOMIASIS MANSONI IN RESOURCE-LIMITED SETTINGS

Jorge Cardenas<sup>1</sup>, Sandra Losada<sup>2</sup>, Maria Elisa Campos<sup>3</sup>, Gabriel Motoa<sup>1</sup>, Cecilia Colmenares<sup>2</sup>, Belkisyolé Alarcón de Noya<sup>2</sup>, Oscar Noya<sup>2</sup>

<sup>1</sup>University of Miami Miller School of Medicine, Miami, FL, United States,

<sup>2</sup>Institute of Tropical Medicine, Caracas, Bolivarian Republic of Venezuela,

<sup>3</sup>Luis Razetti School of Medicine, Caracas, Bolivarian Republic of Venezuela

Schistosomiasis is a leading cause of morbidity in Sub-Saharan Africa and South America, with about 207 million estimated cases per year. Like other helminthiasis, human exposure is related to occupations usually performed by low-to-middle income populations. Therefore, rapid and inexpensive testing for schistosomiasis in limited-resource settings is paramount. Multiple Antigen Blot Assay (MABA) is a simple, reproducible,

and inexpensive technique that can detect IgG against up to 26 antigens simultaneously, including *Schistosoma mansoni* and can be used for screening in asymptomatic individuals. 122 African medical students who arrived in Venezuela for an educational exchange program were tested for serum IgG against 3 antigens of *Schistosoma mansoni* (adult worm soluble antigen, soluble egg antigen and the synthetic peptide IMT180/1086 from Sm31 cathepsin B protein). Briefly, the antigens were loaded onto a nitrocellulose membrane and were exposed to serum from the subjects. After washing, the membranes were incubated with secondary antibodies and detected using chemiluminescence. Reactivity against any of the three antigens was considered as a positive result. All individuals were screened using both SMP-ELISA and MABA, and positive cases were confirmed with Circumoval Precipitin Test (COPT) (gold standard). 78 individuals were seropositive by SMP-ELISA and 12 were positive by MABA. All individuals that had positive serology by MABA were also SMP-ELISA-positive. Using COPT as the confirmatory test for active infection, 6 patients were confirmed to carry *Schistosoma mansoni*. MABA appears to be an inexpensive and reliable method for screening of schistosomiasis in resource-limited settings, even more so than SMP-ELISA. Discordance between SMP-ELISA and MABA results needs further research, but the latter appears to be more specific based on our results. The simultaneous evaluation of multiple antigens (synthetic peptides, crude antigens and purified or recombinant proteins) in MABA makes it more appealing for massive screening purposes, which is needed to adequately manage a disease with such severe implications.

### DEVELOPMENT OF A REAL-TIME PCR ASSAY FOR DETECTION OF SCHISTOSOMA JAPONICUM IN HUMAN STOOL

Sara Halili, Jessica R. Grant, Nils Pilotte, Steven A. Williams  
Smith College, Northampton, MA, United States

Schistosomiasis is a debilitating Neglected Tropical Disease estimated to infect at least 230 million people worldwide. Thus, its elimination requires sensitive diagnostic tools to accurately determine prevalence of infection in endemic areas. *Schistosoma japonicum*, the most virulent of the schistosomiasis-causing parasites, has historically been detected using the Kato-Katz technique, a method shown to radically underestimate levels of infection. However, the ever-improving capabilities of next-generation sequencing and bioinformatic analysis tools have enabled the development of sensitive molecular diagnostic assays with nucleic acid targets. Utilizing Tandem Repeat Analyzer (TAREAN) and RepeatExplorer2, we performed a cluster-based analysis of the *S. japonicum* genome to identify a tandemly arranged genomic repeat which was selected as the target for a real-time PCR diagnostic assay. Upon optimization, this species-specific assay consisting of a primer/probe set can reliably detect as little as 200 ag of *S. japonicum* genomic DNA and as little as 1 egg per gram of human stool. While additional validation studies using field samples are required, this extremely sensitive diagnostic assay should facilitate the accurate detection of *S. japonicum*, particularly in regions with low levels of endemicity, appropriately aiding disease control and elimination efforts.

### STUDIES RELATED TO FIBROSIN, A CYTOKINE

Sadhana Prakash, Sadhana Prakash

Massachusetts Institute of Technology, Cambridge, MA, United States

We have identified a novel heparin binding cytokine. Fibrosin. It was originally identified from activated T cells from granulomas of mice infected with *S. mansoni*. It affects hepatic fibrosis in infected mice and other pathologies. Binding studies using biotinylated fibrosin identifies bound ligands with a molecular mass of 25 to 40 kD. These could be receptor ligands and may have therapeutic applications in fibrosis and other autoimmune disease. We are also interested in developing biomarker related studies.

0400

### THERAPEUTIC ACTIVITY OF A SALMONELLA-VECTORED SCHISTOSOMA MANSONI VACCINE IN A MOUSE MODEL OF CHRONIC INFECTION

Adam S. Hassan, Dilhan J. Perera, Brian J. Ward, Momar Ndao  
Research Institute of the McGill University Health Centre, Montreal, QC, Canada

Schistosomiasis is an important fresh-water-borne parasitic disease caused by trematode worms of the genus *Schistosoma*. With >250 million people infected worldwide and approximately 800 million people at risk, the World Health Organization considers schistosomiasis to be the most important human helminth infection. Several prophylactic non-living vaccines are in pre-clinical and clinical development, but only one has been assessed for therapeutic effect in an animal model with modest results. Live attenuated *Salmonella* have multiple potential advantages as vaccine vectors. We have engineered an attenuated *Salmonella enterica* Typhimurium strain (YS1646) to produce a vaccine that targets the parasite digestive enzyme Cathepsin B (CatB). A multi-modality immunization schedule was used in chronically infected mice that included three oral (PO) doses of this CatB-bearing YS1646 strain on days one, three, and five as well as an intramuscular (IM) dose of recombinant CatB on day one. Parasite burden (worm count, intestinal and liver egg numbers) were 46.5 – 50.3% lower than in control animals 1 month post-vaccination and relative reductions further increased to 63.9 – 73.3% at 2 months. Serum anti-CatB IgG increased significantly after vaccination with the development of a more balanced  $T_H1/T_H2$  pattern of response (ie: a shift in the IgG1:IgG2c ratio). Compared to control animals, a broad and robust CatB-specific cytokine/chemokine response was seen in splenocytes isolated 1-month post-vaccination. A vaccine that has both prophylactic and therapeutic activity would be ideal for use in conjunction with mass treatment campaigns with praziquantel in schistosome-endemic countries.

### MORPHOLOGICAL AND GENOMIC CHARACTERIZATION OF PARAGONIMUS FROM CAMEROON INDICATE A DISTINCT CLADE OF LUNG FLUKES

Lucia S. Di Maggio<sup>1</sup>, Young-Jun Choi<sup>1</sup>, Iya Sasse Ruth Nyaba<sup>2</sup>, John Martin<sup>1</sup>, Kerstin Fischer<sup>1</sup>, Samuel Wanji<sup>2</sup>, Makedonka Mitreva<sup>1</sup>, Peter U. Fischer<sup>1</sup>

<sup>1</sup>Washington University in Saint Louis, Saint Louis, MO, United States, <sup>2</sup>University of Buea, Buea, Cameroon

*Paragonimus* lung flukes are important food-borne trematodes that cause serious diseases. More than 30 *Paragonimus* species have been described from Asia, Africa and the Americas, and about one third of them is confirmed to infect humans with an estimated 21 million infections. *Paragonimus* species are widely distributed in wildlife in Africa, but only *P. uterobilateralis* and *P. africanus* have been documented to infect humans and only a 445 bp DNA sequence of *P. africanus* is available in GenBank. In order to improve diagnostics, to better understand the epidemiology of paragonimiasis and to develop new intervention strategies, detailed phylogenetic and phylogeographic information is crucial. Therefore, we isolated metacercariae from freshwater crabs collected in areas endemic for human paragonimiasis in the South West Province of Cameroon, infected rats and recovered adult flukes. Detailed morphological examination of several specimens showed that the flukes are most similar to *P. africanus* with characteristic antler-shaped testis and medium size eggs measuring 102 X 66 µm. Genomic DNA was extracted from 4 specimens and sequenced using Oxford Nanopore and Illumina technology. A mitochondrial genome of 16.6 Kb assembled as a single scaffold contained 12 protein and 24 tRNA coding sequences as well as 3.2 Kb non-coding repetitive DNA comprised of two distinct repeat units. The 934 Mb nuclear genome had a BUSCO score completeness of 84.5%. Based on the ITS2 sequence our specimens were most similar to *P. africanus*, the only African *Paragonimus* species in the database. Comparison of the mitochondrial genomes and selected nuclear

sequences of several *Paragonimus* species revealed that our *P. africanus* is more similar to *P. kellicotti* from North America than to *P. westermani* and other Asian species. This study fills a molecular phylogenetic gap in *Paragonimus* species from Africa, links this information with a detailed morphological description, and informs the ongoing comparative genomic analysis with an improved taxonomic sampling to better understand the global diversity of this important pathogen.

### SCHISTOSOMA MANSONI - NO LOWER GENITAL TRACT LESIONS{ A STUDY IN CONSECUTIVE CASES WITHOUT S. HAEMATOBIIUM

Huldah Sang<sup>1</sup>, Pauline N. Mwinzi<sup>1</sup>, Maurice R. Odieri<sup>1</sup>, Isaac Onkanga<sup>1</sup>, Fredrick Rawago<sup>1</sup>, Pavitra Pillay<sup>2</sup>, Eyrun F. Kjetland<sup>3</sup>

<sup>1</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>2</sup>Durban University of Technology, Durban, South Africa, <sup>3</sup>University of KwaZulu-Natal, Durban, South Africa

Female genital schistosomiasis (FGS) constitutes four different lesions known to be caused by *Schistosoma haematobium* ova deposited in the genital tract. Both *Schistosoma haematobium* and *S. mansoni* have been found to be associated with HIV infection. The mechanism for HIV transmission has been thought to be through FGS lesions, such as the sandy patches, rubbery papules and friable blood vessels. *Schistosoma mansoni* ova have been found in the genital tract, however, it is not known if *S. mansoni* also causes the typical FGS lesions. The study was conducted in eight villages along the shores of Lake Victoria, Western Kenya. Stool and urine samples collected from women of reproductive age on three consecutive days were analysed for *S. mansoni* and *S. haematobium*. Willing participants, aged 18 - 50 years, *S. mansoni* positive and *S. haematobium* negative, were invited to answer a questionnaire (demographics, symptoms), undergo a gynaecological examination by an FGS expert and cytology specimen collection. Gynaecologic investigations were conducted in 147 *S. mansoni*-positive women who had a mean infection intensity of 253.3 epg (95% CI: 194.8-311.9 epg). Nearly 90% of them used Lake Victoria as their main water source. None were found to have grainy sandy patches or rubbery papules, 49/147 (33.3%) had abnormal blood vessels, homogenous yellow patches were found in 12/147 (8.2%). Women with homogenous yellow patches were significantly older (47 years) than the rest (34 years,  $p = 0.001$ ). No association was found between intensity of *S. mansoni* infection and homogenous yellow patches ( $p = 0.70$ ) or abnormal blood vessels ( $p = 0.14$ ). *S. mansoni* infection intensity was not associated with genital discomfort, genital itch, post-coital bleeding, bloody or malodorous vaginal discharge. We did not find grainy sandy patches in any women. The homogenous yellow patches could potentially have been a result of an old *S. haematobium* infection. *S. mansoni* infection was not associated with lower genital tract lesions or symptoms typical of FGS.

### HEPATIC FIBROSIS BIOMARKING BY PLASMA CYTOKINE PROFILING DURING HUMAN SCHISTOSOMIASIS

Donald Severin Kamdem<sup>1</sup>, Erve Martial Kuemkon<sup>2</sup>, Francis Konhawa<sup>2</sup>, Leonel Meyo Kamguia<sup>3</sup>, Gladys K. Tchanana<sup>2</sup>, Frungwa Nche<sup>4</sup>, Alim Oumarou<sup>4</sup>, Rene Ghislain Essomba<sup>2</sup>, Frank Brombacher<sup>5</sup>, Justin Komgouep Nono<sup>3</sup>

<sup>1</sup>University of Utah, Salt Lake City, UT, United States, <sup>2</sup>School of Health Sciences, Catholic University of Central Africa, Yaoundé, Cameroon, <sup>3</sup>Laboratory of Immunobiology of Helminth Infection, Ministry of Scientific Research and Innovation, Yaoundé, Cameroon, <sup>4</sup>Ministry of Public Health, Yaoundé, Cameroon, <sup>5</sup>International Centre for Genetic engineering and Biotechnology, University of Cape Town, Cape Town, South Africa

Human and preclinical studies have now convincingly showed that hepatic fibrosis occurs and progresses dissimilarly in Schistosomiasis diseased-individuals with same egg burden, with similar biosocial determinants and subjected to similar environmental conditions. This suggests that parasite-

independent and currently poorly defined host intrinsic factors might play a defining role in the regulation of liver fibrosis. A screening of the literature allow us to report in a review article a library of host regulators of hepatic fibrosis during Human Schistosomiasis. Among those factors, cytokines were the most represented. We then hypothesized that cytokines could play a crucial role in driving hepatic fibrosis (HF) upon infection and could be used as biomarkers to diagnose hepatic fibrosis in Schistosomiasis endemic areas. A cross sectional study was performed in five villages in a previously identified endemic area for *Schistosoma mansoni* (*Sm*) in the Centre region of Cameroon. In total 1,002 participants, all schoolchildren were screened for *Sm* eggs by Kato Katz and for HF in 642 consenting participants using ultrasound. We then clustered our participants in four groups based on their infectious and HF status: i) non infected for *Sm* eggs without HF (controls); ii) non infected for *Sm* eggs with HF; iii) infected for *Sm* eggs without HF; iv) infected for *Sm* eggs with HF. Subsequently, blood samples were collected from 350 compliant participants, screened for other liver affecting diseases prevalent in the study area prior to Luminex analysis. Subsequent to Luminex screening, we identified four cytokines that plasma levels associate with HF and correlated with the severity of fibrosis. Correlation and PLSDA analyses further confirmed the potential of those cytokines as good biomarkers for the diagnostic of hepatic fibrosis. Receiver Operating Characteristic analysis, showed sensitivities above 80.0% for each biomarker and up to 95% when biomarkers were combined in a same model. These results imply that the identified cytokines could be used as a tool for the rapid diagnostic of HF in Schistosomiasis endemic areas.

0404

#### IDENTIFICATION OF NOVEL MODULATORS OF A SCHISTOSOME TRANSIENT RECEPTOR POTENTIAL ION CHANNEL ACTIVATED BY PRAZIQUANTEL

Evgeny G. Chulkov, Jonathan S. Marchant

Medical College of Wisconsin, Milwaukee, WI, United States

Given the worldwide burden of neglected tropical diseases, there is need to develop new anthelmintic agents to strengthen the pipeline of drugs to combat these burdensome infections. Many diseases caused by parasitic flatworms are treated using praziquantel (PZQ), a drug employed for decades as the key clinical agent to treat schistosomiasis. PZQ activates a flatworm transient receptor potential (TRP) channel within the melastatin family (TRPM<sub>PZQ</sub>) to mediate sustained Ca<sup>2+</sup> influx and worm paralysis. As a druggable target present in many parasitic flatworms, TRPM<sub>PZQ</sub> is a promising target for a target-based screening campaigns with the goal of discovering novel regulators of this channel complex. Here, we have optimized methods to miniaturize a Ca<sup>2+</sup>-based reporter assay for *Schistosoma mansoni* TRPM<sub>PZQ</sub> (*Sm*.TRPM<sub>PZQ</sub>) activity enabling a high throughput screening (HTS) approach. A pilot screen of ~16,000 compounds yielded a novel activator of *Sm*.TRPM<sub>PZQ</sub>, and numerous potential blockers. The new activator of *Sm*.TRPM<sub>PZQ</sub> represented a distinct chemotype to PZQ, and is a known chemical entity previously identified via phenotypic screening. The fact that a compound prioritized via phenotypic screening is revealed to act, like PZQ, as an *Sm*.TRPM<sub>PZQ</sub> agonist underscores the validity of TRPM<sub>PZQ</sub> as a druggable target engaged by antischistosomal compounds.

0405

#### CHARACTERIZING SPATIAL AND TEMPORAL CHANGES OF MALARIA TRANSMISSION FROM PREGNANT WOMEN AT ANTENATAL CARE VISITS

Arnau Pujol<sup>1</sup>, Garia Matambisso<sup>2</sup>, Sania Maculuvé<sup>2</sup>, Pau Cistera, Henriques Mbeve<sup>2</sup>, Judice Miguel<sup>2</sup>, Boaventura Cuna<sup>2</sup>, Cardoso Melembe<sup>2</sup>, Nelo Ndimande<sup>2</sup>, Llorene Quinta, Eusebio Macete<sup>2</sup>, Alfredo Mayor<sup>1</sup>, Beatriz Galatas<sup>1</sup>, Humberto Munguambe<sup>2</sup>, Helena Marta-Soler<sup>1</sup>, Julia Montana<sup>1</sup>, Lidia Nhamussua<sup>2</sup>, Wilson Simone<sup>2</sup>, Francisco Sante<sup>2</sup>, Caterina Guinovart<sup>1</sup>, Pedro Aide<sup>2</sup>

<sup>1</sup>ISGlobal, Barcelona Institute for Global Health, Barcelona, Spain, <sup>2</sup>Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique

Estimating malaria trends directly from passive detection of clinical malaria cases at health facilities remains difficult due to challenges associated with availability of access to care and the estimation of denominator population. Estimates of burden from nationally-representative household surveys are expensive, so that these surveys are typically carried out every 2-3 years and lack power to estimate prevalence and to detect trends when transmission declines to low levels. We present a study comparing the spatial and temporal changes of transmission estimated from pregnant women at first antenatal care visit with those estimated from clinical cases and cross-sectional surveys. The study was conducted in southern Mozambique, comparing data from pregnant women (9,000 samples), cross-sectional surveys (18,000 samples) and from clinical cases between November 2016 and October 2019. Multigravid women had higher *P. falciparum* positivity rates (estimated by qPCR) than primigravid women in high transmission settings, but the difference between both populations decreased for lower transmission levels. Data from pregnant women allowed to detect temporal changes of transmission that are consistent with estimates from clinical cases and at the same time characterise the spatial patterns of transmission identified from cross-sectional surveys. We have calculated the Pearson correlation coefficients (PCC) between the parasite positivity rate estimations from pregnant women and from the cross-sectional surveys. The high values of PCC suggest that malaria transmission patterns in pregnant women represent those from the general population. In high transmission levels, primigravid women show better consistency with children 2-10 years old, but all pregnant women give good consistency with children for low transmission levels, giving more precise measurements and finer time granularity of the estimations than those from cross-sectional surveys.

0406

#### SCHOOL-AGED CHILDREN ARE THE MOST IMPORTANT CONTRIBUTORS TO THE HUMAN INFECTIOUS RESERVOIR FOR MALARIA IN AREAS OF HIGH AND LOW PLASMODIUM FALCIPARUM TRANSMISSION INTENSITY IN UGANDA

Melissa D. Conrad<sup>1</sup>, Alex Musiime<sup>2</sup>, John Rek<sup>2</sup>, Chiara Andolina<sup>3</sup>, Joseph Okoth<sup>2</sup>, Ismael Onyige<sup>2</sup>, Daniel Ayo<sup>2</sup>, Joaniter I. Nankabirwa<sup>2</sup>, Emmanuel Arinaitwe<sup>2</sup>, Moses R. Kamya<sup>2</sup>, Grant Dorsey<sup>1</sup>, Chris Drakeley<sup>4</sup>, Teun Bousema<sup>3</sup>, Sarah Staedke<sup>4</sup>

<sup>1</sup>UCSF, San Francisco, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>Radboud University, Nijmegen, Netherlands, <sup>4</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

To determine how transmission intensity influences the infectious reservoir, we quantified parasite carriage and contribution to transmission to mosquitoes longitudinally in two settings of markedly different malaria transmission intensity in Uganda. Cohorts of Ugandan children and adults were recruited from an area under highly effective malaria control in Nagongera, Tororo district (n=531) and from an area of intense malaria transmission spanning the border between Tororo and Busia districts (border area; n=636). Cohorts were followed by continuous passive surveillance and routine assessments every 28 days for 2 years (Nagongera) or 6 months (border area). *Plasmodium falciparum* total parasites and gametocytes will be quantified using molecular techniques; membrane

feeding assays were performed to assess infectivity to mosquitoes. We found that clinical malaria incidence was 0.04 episodes/per person per year (PPY) in Nagongera and 1.3 episodes/PPY in the border area. Parasite carriage at densities above 100 parasites/ $\mu$ L, a level previously associated with transmission potential, was observed in 1.2% of samples in Nagongera and 14.2% in the border area. When mosquitoes fed on blood from these parasite carriers, 1.2% (446/37,404; Nagongera) and 1.8% (215/11,831; border area) of mosquitoes became infected. When feeding on blood from clinical malaria cases, 0.3% (4/1,586; Nagongera) and 1.3% (58/4,499; border area) of mosquitoes became infected. Considering both transmissibility of infections and their relative frequency, school-aged children (5-15 years) comprised 58.7% of the human infectious reservoir in Nagongera and 74.1% in the border area. Adults were considerably less important for the infectious reservoir (15.6% and 0%, respectively in preliminary analyses). Despite marked differences in transmission intensity and clinical malaria incidence, children were responsible for most mosquito infection events in both settings. This suggests that interventions targeting infections in children, including older school-aged children, will have a pronounced effect on community-wide malaria transmission.

0407

### SPATIAL AND TEMPORAL CLUSTERING OF MALARIA INCIDENCE AMONG CHILDREN AGED 5 TO 14 YEARS IN KOULIKORO, MALI

**Mahamoudou Touré<sup>1</sup>**, Mathias Dolo<sup>1</sup>, Abdoul Zamilou<sup>1</sup>, Fousseyni Doucouré<sup>1</sup>, Fousseyni Kané<sup>1</sup>, Drissa Konaté<sup>1</sup>, Ayouba Diarra<sup>1</sup>, Hamady Coulibaly<sup>1</sup>, Sophie Sarrassat<sup>2</sup>, Immo Kleinschmidt<sup>2</sup>, Jeffrey G. Shaffer<sup>3</sup>, Seydou O. Doumbia<sup>1</sup>

<sup>1</sup>University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Tulane University, New Orleans, LA, United States

Despite the significant decrease in malaria incidence reported worldwide during the last decade, malaria remains a serious public health problem, particularly in Sub-Saharan African countries, where it is a leading cause of morbidity and mortality. Identifying spatial and temporal variation of malaria hot spots over one transmission season and associated risk can provide evidence-based guidance for efficient implementation of control strategies. This study aims to detect clustering of *Plasmodium (P.) falciparum* malaria cases from the start to the end of malaria transmission in two health districts of Koulikoro: Kati and Kangaba. As part of a cluster-randomized trial, malaria infection incidence was assessed in 20 communities (N=1,100 children aged 5 to 14 years) from July to December 2020. Patient visits were performed every four weeks, and all children with fever or history of fever were tested using rapid diagnostics. Clusters of high and low risk for malaria incidence were analyzed and quantified using the Kulldorff scanning method. Temporal clustering analysis was based on the incidence of malaria infection per person per week in relation with climatic variables (cumulative rainfall, relative humidity, and minimum and maximum temperature). Malaria hot spots showed significant spatial and temporal variation during the malaria transmission season. The risk of malaria infection within clusters varied from August to November, with the highest risk occurring in September and November (RR=5.7 and RR=5.4, respectively). Risk analyses revealed a positive correlation between the number of malaria cases and relative humidity (P<0.001) and a negative correlation between the number of malaria cases and maximal temperature (P<0.001). Testing for spatial and temporal variation of clustering using incidence data is a valuable tool for assisting researchers in understanding the variability of malaria distribution within and between local communities and guiding targeted control interventions.

0408

### MALARIA IMPORTATION INTO AN EPIDEMIC-PRONE SETTING IN ARID NORTHWEST KENYA

**Christine F. Markwalter<sup>1</sup>**, Diana Menya<sup>2</sup>, Amy Wesolowski<sup>3</sup>, Joseph Kipkoech<sup>4</sup>, Elizabeth Freedman<sup>1</sup>, Kelsey M. Sumner<sup>5</sup>, Lucy Abel<sup>6</sup>, George Ambani<sup>4</sup>, Hannah R. Meredith<sup>1</sup>, Adrew Obala<sup>4</sup>, Wendy P. O'Meara<sup>1</sup>, Steve M. Taylor<sup>1</sup>

<sup>1</sup>Duke University, Durham, NC, United States, <sup>2</sup>Moi University School of Public Health, Eldoret, Kenya, <sup>3</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>4</sup>Moi University, Eldoret, Kenya, <sup>5</sup>University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>6</sup>Moi Teaching and Referral Hospital, Eldoret, Kenya

Parasite importation can undermine malaria elimination efforts in low-transmission settings. The arid Turkana region in Northwest Kenya has traditionally been unsuitable for sustained transmission, but increased development, land-use changes, and travel to the region are enhancing the ability to permit transmission. In this study, we investigated *Plasmodium falciparum* importation events and their impact on local transmission, and we hypothesized that importation of malaria genotypes was driving local transmission in the region. To do this, we collected parasites in two groups, using active case detection in passengers on the few weekly bus trips and plane flights into the region (n = 1891) and using re-active case detection following RDT-positive infection at 6 clinics in index patients (n = 1891) in their household members in and around Lodwar (n = 3314). All participants provided detailed travel histories. We genotyped all parasites using PCR amplification and amplicon deep sequencing of polymorphic *P. falciparum* targets *pfscsp* and *pfama1*, for which we inferred haplotypes using established methods. Despite some individuals traveling from areas of high malaria transmission, the prevalence of *P. falciparum* was much lower among bus and plane passengers (6.72% [95% CI: 5.65% - 7.96%]) compared to local household members (30.7% [29.2% - 32.3%]) as measured by PCR. Overall, we observed 72 *pfscsp* haplotypes and 88 *pfama1* haplotypes. The mean (standard deviation) multiplicity of infection based on *pfscsp* in bus and plane passengers was 3.3 (2.9), significantly higher than that of individuals residing in Turkana (1.8 (1.5)), with similar patterns observed for *pfama1*. A small number of facility cases and household members also reported travel in the month prior to sample collection (157/5205). Using computational modeling methods and parasite genotype data, we detected *P. falciparum* importation events due to travel and estimated their contributions to local transmission. These analyses can inform the design and management of interventions to mitigate parasite importation and control local malaria transmission.

### IMPACT OF FOURTEEN-DAY PRIMAQUINE RADICAL CURE ON PLASMODIUM VIVAX RELAPSE RATES AMONG PUBLIC SECTOR PATIENTS IN CAMBODIA: AN INTERRUPTED TIME SERIES ANALYSIS

**Lek Dysoley<sup>1</sup>**, Jillian Dunning<sup>2</sup>, Yucheng Tsai<sup>3</sup>, Evelyn Wong<sup>4</sup>, Michelle Pah<sup>3</sup>, Julia Dunn<sup>5</sup>, Siv Sovannaroeth<sup>1</sup>, Huy Rekol<sup>1</sup>

<sup>1</sup>National Center for Parasitology Entomology and Malaria Control, Phnom Penh, Cambodia, <sup>2</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>3</sup>Clinton Health Access Initiative, Phnom Penh, Cambodia, <sup>4</sup>Clinton Health Access Initiative, Yangon, Myanmar, <sup>5</sup>Clinton Health Access Initiative, Vientiane, Lao People's Democratic Republic

Cambodia has accomplished an 86% decline in malaria cases from 2010 to 2020 and aims to eliminate all malaria by 2025. However, a significant proportion of remaining infections are due to *Plasmodium vivax* (90% of total cases in 2020), historically treated using the ACT first-line treatment which does not cure the liver stage of parasite development, risking relapse. In November 2019, Cambodia introduced 14-day primaquine for treatment of *P. vivax* infections (known as radical cure) in G6PD-normal males across four provinces to fully treat *P. vivax* and prevent relapse. An interrupted time series analysis was conducted to estimate the impact of radical cure implementation on relapse cases compared to a control

group of five provinces with similar *P. vivax* incidence. Patient records were compiled from January 2018 to December 2020 to match key patient identifying fields (name, sex, age and village of residence) by calculating a Jaro-Winkler similarity score. If a matched patient had received a prior diagnosis within one to nine months, they were considered a relapse case. Matches with a difference of 30 days or fewer were excluded to account for potential treatment failure. Of a total 31,175 *P. vivax* patient records with complete identifying field information, 13,047 (41.8%) met the criteria for relapse cases. Post-intervention, the trend in relapse cases decreased by 15.8 ( $p < 0.001$ ) cases per month in the intervention group relative to the control group. In the fourteenth month following rollout the average monthly relapse cases in radical cure provinces were 286 fewer than would have been expected if radical cure had not been implemented, representing a 90% reduction in relapse cases. The proportion of observed relapse rates decreased from 59.2% pre-intervention to 53.3% post-intervention in radical cure provinces; however, this may underestimate the effect of radical cure and with a 9-month relapse period it should take additional time to see the impact reflected in observed data. As Cambodia scales up radical cure to all provinces in 2021, radical cure treatment may serve as a catalyst for progress towards national elimination of *P. vivax* infections.

McCaffery<sup>1</sup>, Eric Rogier<sup>1</sup>, Douglas Nace<sup>1</sup>, Samaly Souza Svigel<sup>1</sup>, Camelia Herman<sup>1</sup>, Ashenafi Assefa<sup>2</sup>, Jimee Hwang<sup>1</sup>, Simon Kariuki<sup>3</sup>, Aaron Samuels<sup>1</sup>, Arsene Ratsimbaoa<sup>4</sup>, Milijaona Randrianarivelosia<sup>5</sup>, Aline Uwimana<sup>6</sup>, Papy Mandoko Nkoli<sup>7</sup>, Gauthier Mesia Kahunu<sup>8</sup>, Venkatachalam Udhayakumar<sup>1</sup>, Eric S. Halsey<sup>1</sup>

<sup>1</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Ethiopia Public Health Institute, Addis Ababa, Ethiopia, <sup>3</sup>Kenya Medical Research Institute, Nairobi, Kenya, <sup>4</sup>Madagascar National Malaria Control Program, Antananarivo, Madagascar, <sup>5</sup>Institut Pasteur de Madagascar, Antananarivo, Madagascar, <sup>6</sup>Malaria and Other Parasitic Division, Institute of HIV/AIDS, Disease Prevention & Control, Rwanda Biomedical Center, Kigali, Rwanda, <sup>7</sup>National Institute of Biomedical Research, Kinshasa, Democratic Republic of the Congo, <sup>8</sup>Department of Pharmacology & Therapeutics, Kinshasa, Democratic Republic of the Congo

Histidine-rich protein 2 (HRP2) and HRP3 proteins are highly expressed throughout blood stage *Plasmodium falciparum* infection, with diagnostic antibodies binding to repeat epitopes on each. Thus, HRP2-based rapid diagnostic tests (RDTs) are widely used throughout sub-Saharan Africa (SSA) to diagnose *P. falciparum* malaria. However, multiple SSA countries have reported *pfhrp2* and *pfhrp3* (*pfhrp2/3*) gene deletions, which threaten the validity of HRP2-based RDTs. To evaluate the presence of *pfhrp2/3* deletions, we used 1109 dried blood spot (DBS) samples from Democratic Republic of Congo (DRC), 147 from Ethiopia, 332 from Kenya, 620 from Madagascar, and 218 from Rwanda collected as part of routine therapeutic efficacy studies (TES) conducted between 2016-2018 from individuals presenting to health facilities with microscopically confirmed, uncomplicated *P. falciparum* mono-infection. Using multiplex antigen detection, DBS samples from day of enrollment were screened for low HRP2 expression compared to pan-LDH and pan-aldolase antigens; *Pfhrp2/3* genotyping was carried out based on antigen profile. No deletions were found in Kenya. *Pfhrp2* single deletions were identified in DRC, Ethiopia, and Madagascar in 0.3%, 2.0%, and 0.6% of screened samples, respectively. No *pfhrp2* deletions were found in Rwanda. *Pfhrp3* single deletions were found in 0.3%, 2.7%, 0.2%, and 0.5% of screened samples from DRC, Ethiopia, Madagascar, and Rwanda, respectively. Dual *pfhrp2* and *pfhrp3* deletions were observed only in Ethiopia (2.0% of samples). Although our study was not designed or powered for precise

prevalence estimates, we found low levels of *pfhrp2/3* deletions (<5%) in the samples from each of the TES study sites in four SSA countries. In Pawe, Ethiopia, we detected deletions in 3.4% of samples, which suggests that close monitoring of *pfhrp2/3* deletions in this region is needed. TESs are routinely conducted throughout SSA and provide a set of samples from children with microscopically confirmed infection. Testing samples from TESs for *pfhrp2/3* deletions may be a useful screening approach.

#### PLASMODIUM FALCIPARUM MALARIA SURVEILLANCE IN GUYANA USING WHOLE-GENOME AND MICROHAPLOTYPE ANALYSIS

Philipp Schwabl<sup>1</sup>, Angela Early<sup>2</sup>, Emily LaVerriere<sup>1</sup>, Pablo Martinez de Salazar<sup>1</sup>, Manuela Carrasquilla<sup>1</sup>, Ruchit Panchal<sup>2</sup>, Tim Straub<sup>2</sup>, Meg Shieh<sup>1</sup>, Zack Johnson<sup>1</sup>, Aimee Taylor<sup>1</sup>, Margaret Laws<sup>1</sup>, Bronwyn MacInnis<sup>2</sup>, Lise Musset<sup>3</sup>, Jean Alexandre<sup>4</sup>, Helen Imhoff<sup>5</sup>, Horace Cox<sup>5</sup>, Caroline Buckee<sup>1</sup>, Daniel Neafsey<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States, <sup>2</sup>Broad Institute of MIT and Harvard, Cambridge, MA, United States, <sup>3</sup>Institut Pasteur de la Guyane, Cayenne, French Guiana, <sup>4</sup>Pan American Health Organization, Georgetown, Guyana, <sup>5</sup>Ministry of Health Guyana, Georgetown, Guyana

Malaria control in South America is challenged by a resurgence of cases within Venezuela and cross-border spillover via migrant workers and refugees. Molecular surveillance is especially urgent in neighboring Guyana, where gold mining activities are proliferating through remote malaria-endemic regions and, alarmingly, *de novo* emergence of artemisinin resistance-associated kelch13 mutation (C580Y) has been detected in a clonal subpopulation of *Plasmodium falciparum* parasites. The present study applies a new multiplexed amplicon sequencing protocol (128 *Plasmodium falciparum* microhaplotypes simultaneously amplified in a single PCR reaction) for rapid molecular surveillance in this context. We apply the new tool to monitor the persistence and possible expansion of C580Y-carrying parasites in >1000 *P. falciparum*-infected blood samples collected from individuals in Guyana in 2020-21. We intersect the amplicon sequencing results with whole-genome sequencing (WGS) data from 2016-17 (>800 samples) and find that different clonal clusters predominate between the two time points, suggesting stochastic boom-bust dynamics that can skew haplotype estimates inferred from cross-sectional sampling. The spatiotemporal dynamics we describe also inform maps of drug resistance marker distribution and malaria source-sink dynamics among mining and non-mining communities. Additionally, we make various comparisons of microhaplotype vs. WGS-based epidemiological inference, assessing how well geographic attribution correlates with travel history metadata and how pairwise relatedness and complexity of infection (COI) estimates differ between the two data types. By joining amplicon sequencing and WGS data from over 1800 *P. falciparum* samples collected in Guyana over a period of five years (periodically representing ca. 5-10% of cases nationwide), we have created the most comprehensive genomic epidemiological profile of any parasite population in the Americas, leading to insights about factors that may contribute to the *de novo* emergence and potential disappearance of drug resistance mutations in the region.

<sup>1</sup>Eck Institute for Global Health, Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Disease Intervention and Prevention Program, Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>3</sup>Center for Global Infectious Disease Research, Seattle Children's Research Institute, Seattle, WA, United States, <sup>4</sup>Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Mahidol University, Mae Sot, Thailand, <sup>5</sup>Host Pathogen Interactions Program, Texas Biomedical Research Institute, San Antonio, TX, United States

In addition to the large effect of *pfcr*t on *Plasmodium falciparum* chloroquine resistance, additional transporters, such as *pfmdr*1, have been shown to influence the level of resistance in some genetic backgrounds. These resistance-modulating mutations may share some physiological overlaps with *pfcr*t natural function and thus could impact the fitness cost of mutant *pfcr*t. We generate experimental genetic crosses using human liver-chimeric mice (FRG huHep/huRBC mouse) and measure phenotypes of the resulting recombinant progeny to determine the interactions of specific loci. Using a cross between the lab-line NF54 (chloroquine-sensitive, CQS) and a recent Southeast Asian isolate NHP4026 (chloroquine-resistant, CQR), we first took a bulk segregant approach with chloroquine drug pressure followed by sequencing of the bulk population. As expected, we observed a strong selection signal at a locus on chromosome 7 that encompasses *pfcr*t as well as a second locus on chromosome 6. Subsequently, we isolated clones from this selected population and chose 16 recombinant progeny with different combinations of parental alleles at the chromosome 6 and 7 loci to investigate their fitness effects. All-on-all pairwise competitive growth assays between these 16 progeny and both parents revealed an unambiguous fitness relationship from 153 competitive growth outcomes. Notably, the CQR parent, NHP4026 ranks as more fit than NF54 (CQS), demonstrating that the inheritance of CQR *pfcr*t alone does not ensure an unfit competitor. Four progeny ranked higher in fitness than NHP4026, one of which was CQR. Therefore, the allele combination that contributes to NHP4026 being both CQR and a good competitor is inherited in some of the CQR progeny. In this analyzed set of progeny, the chromosome 6 x 7 interaction did not account for the range of observed competitive outcomes. Additional experiments show that the relationship between individual growth rates and competitive outcomes was non-linear, indicating that growth rates do not by themselves predict *in vitro* competitive outcomes. Together these data indicate multiple genes interact to generate fit CQR parasites.

### ILLUMINATING THE BLACK BOX OF PLASMODIUM FALCIPARUM LIVER STAGE GENE EXPRESSION

**Gigliola Zanghi**<sup>1</sup>, Hardik Patel<sup>1</sup>, Nelly Camargo<sup>1</sup>, Ian H. Cheeseman<sup>2</sup>, Ashley M. Vaughan<sup>1</sup>, Stefan H. Kappe<sup>1</sup>

<sup>1</sup>Seattle Children's, Seattle, WA, United States, <sup>2</sup>Texas Biomedical Research Institute, San Antonio, TX, United States

The liver stages (LS) of *Plasmodium falciparum* (*Pf*) remain poorly characterized, limiting our knowledge to develop new effective intervention strategies. The study of the asymptomatic LS remains difficult however due to the parasites tropism for primary human hepatocytes and low infection rates. The use of a liver-humanized mouse model (FRGHuHep) for *Pf* LS infection has ameliorated some of

these limitations. We have generated a *Pf* NF54 line that constitutively expresses green fluorescent protein (GFP) under the circumsporozoite protein promoter, which confers strong fluorescence to sporozoites and LS. Infection of FRGHuHep mice with this parasite enabled the isolation of LS-infected hepatocytes at different timepoints of development using cell sorting. We conducted extensive RNA-seq analysis of isolated LS, spanning development from early LS trophozoite/early schizont to late LS schizont stage. The data revealed that the LS parasite increases gene expression over time consistent with its developmental stage and biomass expansion. We identified unique LS-expressed transcripts, LS-specific processes associated with the different maturation stages such as cell cycle, metabolism and host-parasite interaction pathways. Furthermore, we found subsets of AP2 transcription factors expressed throughout LS development. Interestingly, we also observed extensive expression of variant multigene families including *var* gene transcripts. In order to establish LS translation efficiency, we analyzed how the introns retained in mature mRNAs regulate parasite liver stage gene expression. Our results provide the first comprehensive gene expression profile of *Pf* LS isolated during *in vivo* intrahepatocytic development. This will inform biological studies and the search for new interventions points that can prevent infection.

### LONG READ SINGLE CELL RNA SEQUENCING OF PLASMODIUM VIVAX REVEALS DIVERSITY IN TRANSCRIPT ISOFORMS

**Brittany Hazzard**<sup>1</sup>, Juliana Sa<sup>2</sup>, Sean Connelly<sup>2</sup>, Angela Ellis<sup>2</sup>, Tomas Wellemers<sup>2</sup>, David Serre<sup>1</sup>

<sup>1</sup>University of Maryland Baltimore, Baltimore, MD, United States, <sup>2</sup>NIH, Bethesda, MD, United States

Single cell RNA sequencing (scRNA-seq) is becoming a valuable tool for investigating malaria infections as it allows differentiating the developmental stages of the parasites present in the same blood stage infection. This technique is particularly valuable for the study of *Plasmodium vivax* for which there is no long-term *in vitro* culture system and little sequestration *in vivo*. We have previously used 10X scRNA-seq to characterize the gene expression profiles of individual *P. vivax* blood stage parasites using a non-human primate model. However, the sequence information from the 10X assay derive almost exclusively from a small portion of the 3' end of each mRNA molecule, which 1) is sometimes difficult to associate to a specific gene given the incomplete annotation of *P. vivax* untranslated regions (UTRs) and 2) does not provide any information of the actual isoform expressed. Here, we combine standard 10X scRNA-seq library preparation with long-read PacBio sequencing to characterize full-length transcripts expressed in 2,787 individual *P. vivax* blood stage parasites. Using more than three million high-quality reads, we identified 8,553 different protein-coding mRNAs, transcribed from 7,159 unique genes. Of those, 2,423 shared less than 30% amino acid identity with any annotated *P. vivax* coding sequences and represent potential new genes. Additionally, our data revealed many alternative transcription start sites, previously unidentified gene isoforms, and numerous antisense transcripts. Interestingly, some of these transcripts/isoforms appear to be expressed in a stage-specific manner. Overall, these data provide a detailed description of the variations in isoform expression throughout the *P. vivax* intraerythrocytic life cycle.

### DRIVERS OF DIVERSIFICATION OF THE MULTICOPY VAR GENE FAMILY IN PLASMODIUM FALCIPARUM

**Xu Zhang**, Akshay Vishwanatha, Manish Goyal, Annie Leung, Yi Jing Liu, Ron Dzikowski, Kirk Deitsch, Laura Kirkman  
Weill Cornell Medicine, New York, NY, United States

*Plasmodium* parasites that infect humans have evolved an extremely high degree of antigenic diversity, thereby giving them the ability to maintain lengthy, chronic infections and to avoid generating an immune

response that provides protection against subsequent infections. For *P. falciparum*, the most virulent of the human malaria parasites, this diversity is exemplified by the *var* gene family that encodes the major surface antigen displayed on infected red blood cells. The parasite's ability to continuously generate sequence diversity within their genomes is key to parasite persistence in the human host. We have previously identified recombination events between subtelomeric *var* genes, notably a cascade of recombination that led to the generation of novel chimeric *var* genes in disparate subtelomeric regions. We showed that small regions of sequence identity between *var* genes served as sites for homologous recombination and the generation of free DNA end fragments that were then used for subsequent HR events and the generation of two additional chimeric *var* genes. We proposed that this recombination cascade relies on HR machinery and assessed *var* gene recombination in a parasite line where Rad51 was deleted. These parasite lines have normal growth under standard *in vitro* conditions but are sensitive to the genotoxic stress of irradiation. They have both a growth delay and persistent signs of DNA damage that lasts longer than in wildtype parasites. We have also found that these parasites are unable to repair directed DNA double strand breaks when a template is given for repair, consistent with a lack of HR. We have also generated parasite lines that are knock outs of the specialized error prone polymerases, Rev3 and Rev1. These parasite lines also display normal growth in standard *in vitro* conditions and display sensitivity to irradiation, specifically at the ring stage. HR to housekeeping genes remained intact. However, for all three parasite lines we could not induce a recombination cascade between subtelomeric *var* genes. We propose that the parasite has evolved specialized mechanisms to handle DNA damage and diversify multicopy gene families.

0416

#### THE ROLE OF PFCORONIN IN THE REGULATION OF ACTIN DYNAMICS REQUIRED FOR CYTOSKELETON-LINKED CELLULAR PROCESSES IN PLASMODIUM FALCIPARUM

Imran Ullah<sup>1</sup>, Sara H. Shin<sup>1</sup>, Aabha I. Sharma<sup>1</sup>, Selina Bopp<sup>1</sup>, Sarah K. Volkman<sup>1</sup>, Daniel L. Hartl<sup>2</sup>, Dyann F. Wirth<sup>1</sup>

The frontline artemisinin (ART) drug class has been critical to malaria control. However, treatment failures of ART and artemisinin combination therapy (ACTs) in some parts of the world threaten their efficacy. ART treatment failures in Southeast Asia have been attributed to mutations in *Plasmodium falciparum* (*Pf*) *kelch13* locus. Recently, *Pfkelch13* mutations evolved independently in South America, raising concern about the expansion of ART resistance to Africa. Thus, mitigating the spread of ART resistance to Africa, where malaria is most prevalent, remains a critical global public health priority. Previously, we sought insights into potential ART resistance in African parasites by performing *in vitro* evolution to generate ART resistance in Senegalese isolates. We found the actin-bundling protein, *Pfcoronin*, to be a major driver of ART resistance *in vitro*, as measured by the ring-stage survival assay (RSA). Given the possible role of actin in endocytosis, a pathway recently found to be disrupted in *Pfkelch13*-mediated ART resistance, we explored resistance synergy between *Pfcoronin* and *Pfkelch13* mutations by generating single and double mutants in the Senegalese genetic background and measuring ART susceptibility using RSA. We found a similar RSA phenotype in *Pfcoronin/Pfkelch13* double mutants as in *Pfkelch13* single mutants: *Pfcoronin*-mediated resistance is masked by that of *Pfkelch13*. To functionally probe *Pfcoronin*, we used CRISPR-Cas9 to generate parasites expressing HA-tagged *Pfcoronin*. In pulldown experiments, we identified several interacting proteins, including *Pf*actin-1 and actin-2, tubulin alpha and beta chains, and myosin-A. These findings suggest that *Pfcoronin* may regulate actin dynamics and cytoskeleton-linked cellular processes. Further studies are underway to elucidate how *Pfcoronin* mutations may confer ART resistance by modifying cytoskeletal dynamics.

<sup>1</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Kisumu, Kenya, <sup>2</sup>Kwame Nkrumah University of Science & Technology/Agogo Presbyterian Hospital, Agogo, Asante Akyem, Ghana, <sup>3</sup>Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya, <sup>4</sup>GSK, Wavre, Belgium, <sup>5</sup>PATH, Seattle, WA, United States, <sup>6</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Center for Global Health, Centers for Disease Control and Prevention, Atlanta, GA, United States

A phase 3 trial showed that RTS,S/AS01<sub>E</sub> has moderate vaccine efficacy (VE) against malaria in African children when administered according to a 0, 1, 2-month (M) primary schedule (M012) with a 4<sup>th</sup> dose given at M20. Subsequent controlled human malaria infection studies in malaria-naïve adults demonstrated improved VE of RTS,S/AS01<sub>E</sub> with a delayed 3<sup>rd</sup> and/or 4<sup>th</sup> fractional (Fx) dose. We present initial results, including the primary objective, of an ongoing phase 2b open label randomized, controlled trial (NCT03276962) evaluating the efficacy of RTS,S/AS01<sub>E</sub> Fx dose regimens under conditions of natural exposure. A total of 1500 Kenyan and Ghanaian children aged 5-17M were randomized (1:1:1:1) to receive RTS,S/AS01<sub>E</sub> (4 regimens) or a rabies control vaccine (M012). Children in the RTS,S/AS01<sub>E</sub> groups received 2 full doses at M0 and M1 and either full doses at M2 and M20 (R012-20) or at M2 and M14 (R012-14), Fx doses (1/5 of full dose) at M2 and M14 (Fx012-14) or at M7 and M20 (Fx017-20). The primary objective was to demonstrate superiority of the Fx012-14 regimen vs the full 3 dose regimen (R012-14+R012-20) against first episode of clinical malaria over 12M post dose 3. Safety and reactogenicity were also evaluated. All vaccine regimens were well tolerated with no safety signals observed. Each regimen showed statistically significant VE against first episode of clinical malaria 12M post dose 3 compared to the control group; VE ranged from 35% (Fx012-14; 95% confidence interval [CI]: 13, 51), to 47% (R012-14+R012-20; 95%CI: 31, 59), and 54% (Fx017-20; 95%CI: 38, 66). Neither Fx dose regimen showed superior VE vs the full dose regimen up to data lock (M20). We did not demonstrate superior VE of Fx012-14 vs R012-14+R012-20 over 12M post dose 3 (incremental VE: -21%, 95%CI: -57, 7). The trial is ongoing and annual Fx or full dose boosters are given to the children per allocated vaccination group. Continued follow-up until study end (M50) may provide further insight on possible flexibility of the 4 dose regimen currently recommended by WHO and the potential of alternative regimens for public health benefit.

0418

### THE R21/MATRIX-M™ MALARIA VACCINE CANDIDATE: A PHASE III TRIAL

Ewer<sup>1</sup>, Halidou Tinto<sup>2</sup>, Adrian V. Hill<sup>1</sup>

<sup>1</sup>Jenner Institute, University of Oxford, Oxford, United Kingdom, <sup>2</sup>Unite de Recherche Clinique de Nanoro, Institut de Recherche en Sciences de la Sante, Nanoro, Burkina Faso, <sup>3</sup>Department of Primary Care, University of Oxford, Oxford, United Kingdom, <sup>4</sup>KEMRI-Wellcome Trust Institute, Kilifi, Kenya, <sup>5</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>6</sup>Institut des Sciences et Techniques (INSTech), Bobo-Dioulasso, Burkina Faso, <sup>7</sup>Malaria Research & Training Center, Department of Epidemiology of Parasitic Diseases, Faculty of Medicine, Pharmacy and Dentistry, University of Sciences Techniques and Technologies of Bamako, Bamako, Mali, <sup>8</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>9</sup>Novavax, Gaithersburg, MD, United States, <sup>10</sup>Novavax AB, Uppsala, Sweden, <sup>11</sup>Serum Institute of India Private Ltd, Pune, India

The last year has seen some significant progress in malaria vaccine development. R21/Matrix-M (R21/MM), a circumsporozoite protein-based vaccine, initially showed high-level efficacy in phase I/IIa controlled human malaria infection (CHMI) trials in malaria-naïve adults in the UK. Following this, a phase 1b age de-escalation trial in Kilifi, Kenya, showed good safety and potent immunogenicity in 91 adults, children and infants. A phase IIb field-efficacy study in 450 infants, aged 5-17-months, in Nanoro, Burkina Faso was initiated in 2019, administering three monthly doses prior to the malaria season. 77% efficacy was observed over 12 months of follow-up. This appears to be the first time any vaccine has reached the WHO-specified efficacy goal of ≥75% in the target population of African children. Follow-up for a second year, after a booster dose at 12 months, is ongoing and efficacy results will be updated, together with a design to assess the value of a further booster dose at 24 months. In this phase IIb trial, R21/MM had a favourable safety profile and high NANP specific IgG levels were observed, which correlated with vaccine efficacy. These antibodies were re-stored to peak levels following one booster dose at 12 months. This year, a phase III double-blind, randomised controlled trial has been initiated across five African sites in Kenya, Tanzania, Mali and Burkina Faso, with differing seasonal and perennial transmission patterns and differing malaria burdens, in a broader age-range of children. 4800 participants, aged 5-36 months, are receiving 3 vaccine doses 4 weeks apart and a booster dose one year later. The primary objectives are efficacy at 12 and 24 months following three vaccine doses and a booster at 12 months, with safety outcomes measured throughout the trial. We will report on progress of this Phase III trial of R21/MM along with updated findings from other parts of the overall R21/MM clinical development programme.

0419

### CHARACTERIZATION OF MALARIA PFCSP MRNA-LNP INDUCED INHIBITORY ANTIBODIES

Justin Taylor<sup>1</sup>, Xiaoyan Zou<sup>2</sup>, Katherine Mallory<sup>1</sup>, Ishita Waghela<sup>1</sup>, Cosette Schneider<sup>1</sup>, Sheetij Dutta<sup>1</sup>, Norbert Pardi<sup>3</sup>, Paulo J. Lin<sup>4</sup>, Ying Tam<sup>4</sup>, Drew Weissman<sup>3</sup>, Evelina Angov<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>3</sup>University of Pennsylvania, Philadelphia, PA, United States, <sup>4</sup>Acutitas Therapeutics, Vancouver, BC, Canada

Human malaria affects the vast majority of the world's population with the *Plasmodium falciparum* species causing the highest rates of morbidity

and mortality. Recent approval and demonstration of efficacy of mRNA vaccines has led to increased excitement surrounding mRNA as a platform for infectious disease vaccines in humans. The immunodominant coat protein of the invasive malaria parasite stage, circumsporozoite protein (PfCSP), was selected to assess the immunogenic and protective potential of an mRNA malaria vaccine with an array of dosing factors such as formulation, dose, interval, and number of immunizations. PfCSP mRNA-LNP achieved sterile protection against infection in mice utilizing two PfCSP transgenic parasite strains to varying degrees depending on the PfCSP mRNA-LNP (TriLink/unmodified versus UPenn/nucleoside-modified). Notably, serum antibodies tested for their ability to inhibit sporozoites in the *in vitro* inhibition of liver stage development assay (ILSDA) revealed significant reductions in liver stage burden, comparable to an established reference PfCSP repeat-specific monoclonal antibody (NSF1). We will report on the relationship of PfCSP mRNA-LNP-induced *in vivo* protective responses in mice, the antibody inhibition observed in the ILSDA with antibody specificities to well-documented regional, junctional, and repeat-specific PfCSP epitopes. These findings may have major implications for the suitability of mRNA-LNPs for use as vaccines in malaria.

### EVALUATION OF PLASMODIUM VIVAX ANTIGENS AS VACCINE CANDIDATE TO PLASMODIUM SPP.

Luna Barroco de Lacerda, Camila Barbosa, Cristopher Gomes, Guilherme Maia, Ricardo Gazzinelli, Caroline Furtado Junqueira Oswaldo Cruz Foundation Fiocruz-minas, Belo Horizonte, Brazil

The bottleneck of the malaria vaccine is the challenge to find multi-stage antigens conserved in different *Plasmodium spp.* Most malaria vaccines focus on antibody induction to the pre-erythrocytic stage, even though the sterile vaccine protection induced by attenuated sporozoites is directly related to cytotoxic T cells (CTLs). Our group lately demonstrated that *P. vivax* (Pv)-infected reticulocytes can activate CTLs, in an antigen-dependent manner, describing a protective mechanism against blood-stage parasites. In unpublished data, we perform the immunopeptidomics analysis aiming to identify HLA-I-associated peptides of Pv-infected reticulocytes. It was assessed that 60% of the eluted peptides are derived from 'housekeeping' proteins, which are conserved in *Plasmodium* cross-stage and cross-species. Afterward, we selected 50 peptides and their source proteins to be studied, for the first time, as a potential malaria vaccine candidate. *P. yoelii* (Py) infection is an excellent experimental model for investigating malaria immune response. First, we tested the 50 peptides in an anti-IFN $\gamma$  ELISPOT assay with Py-infected mice splenocytes. Then, we produce three recombinant proteins (L30, S25, and H2A) in the *E. coli* expression system for immunization protocols. Mice were immunized three times with each protein associated with Alum + CpG as an immunological adjuvant. Twenty-one days after the last boost, mice were challenged with 10<sup>6</sup> PyX17NL-infected red blood cells, and the parasitemia was monitored for 30 days. We identify 23 of the 50 Pv peptides were immunogenic in the acute infection. Moreover, 12 remain in the convalescent phase, suggesting an immunological memory. Regarding the immunization assessment, we identify that 2 of 3 tested proteins can induce antigen-specific IgG Total, IgG1, and IgG2c levels, additionally, to decrease up to 50-80% the parasitemia compared to the control group. Therefore, we newly identify Pv antigens that can induce a protective response to Py infection, indicating cross-species protection and a potential vaccine candidate.

### EFFICACY OF PFS230D1-EPA-AS01 VACCINE, A TRANSMISSION BLOCKING VACCINE AGAINST PLASMODIUM FALCIPARUM, ASSESSED WITH A DIRECT SKIN FEEDING USING ANOPHELES GAMBIA (COLUZZI) IN CHILDREN 9-18 YEARS OLD IN MALI

**Issaka Sagara**<sup>1</sup>, Sara A. Healy<sup>2</sup>, Abdoulaye Katile<sup>1</sup>, Bourama Kamate<sup>1</sup>, Jennifer Kwan<sup>2</sup>, Bayaya Haidara<sup>1</sup>, Mamady Kone<sup>1</sup>, Jon Fintzi<sup>2</sup>, Bruce Swihart<sup>2</sup>, Amatique Zeguime<sup>1</sup>, Sidiki Perou<sup>1</sup>, M'Bouye Doucoure<sup>1</sup>, Alemush Imeru<sup>2</sup>, Kelly Rausch<sup>2</sup>, David L. Narum<sup>2</sup>, Puthuppampall Scaria<sup>2</sup>, Nicholas MacDonald<sup>2</sup>, Daming Zhu<sup>2</sup>, Daman Sylla<sup>1</sup>, Amagana Dolo<sup>1</sup>, Mahamadou S. <sup>1</sup>Mali, Bamako-Mali, Mali, <sup>2</sup>National Institute of Allergy and Infectious Diseases, Bethesda, MD, United States

Transmission blocking vaccines (TBV) prevent mosquito infections and community spread of malaria parasites but require durable functional antibody responses and need to be safe to administer at the population level for elimination efforts. A phase 2 double-blind, 1-1 randomized, family compound, comparator-controlled trial in Mali is underway to assess safety, tolerability, vaccine activity and vaccine efficacy of Pfs230D1-EPA-AS01 versus comparator administered on a 0, 1, 2, 14 month schedule, at a community level. Family compounds were aggregated by proximity and mosquito habitat into Vaccine Units (VU) that were randomized as a whole for receipt of vaccinations by all eligible subjects 5 years or older; children 1-4 years of age received AL treatment (but not vaccine), prior to their VU receipt of third and fourth vaccine doses, and then were followed for parasitemia endpoints. The trial began Apr 2019 with an age de-escalation pilot phase and proceeded to the main phase with third dose completed in Aug-Nov 2019 the first year; fourth dose was given in Aug 2020 the second year. In prior studies at this site, 9-18-year old children transmitted parasites most frequently to mosquitoes, and for this trial participated in mosquito direct skin feeding (DSF) assays as the primary endpoint of vaccine activity (reduction in the rate of positive DSF assays). DSF was performed every 2 weeks post third vaccination for a total of 8 DSFs and a total of 10 DSFs for the booster fourth dose. A total of 380 and 311 subjects respectively during the first and second year underwent at least one DSF procedure. No AEs was recorded as related to the 5946 DSF performed during the study. Using the rate of positive DSF assay in vaccines as compared to the control group, in the 1<sup>st</sup> year, the vaccine efficacy (VE) was 71.9% and 75% in the 2<sup>nd</sup> year with overall VE of 73.6% (p<0.001) over the 2-year trial. Parasite speciation of infected DSF samples is ongoing to confirm Pf-specific VE. These results justify further development of Pfs230D1-EPA-AS01 as a malaria vaccine candidate alone or in combination with pre-erythrocytic vaccines.

### PFS230D1-EPA-AS01 VACCINE IMMUNIZATION IN WOMEN OF CHILDBEARING POTENTIAL AND IMPACT ON MALARIA DURING SUBSEQUENT PREGNANCIES: A TWO-YEAR STUDY

**Sara A. Healy**<sup>1</sup>, Halimatou Diawara<sup>2</sup>, Djibrilla Issiaka<sup>2</sup>, Aye Diallo Sousa<sup>1</sup>, Seydou Traore<sup>2</sup>, Ibrahim Soumbounou<sup>2</sup>, Mahamadou Samassekou<sup>2</sup>, Oumar Dicko<sup>2</sup>, Oumar Attaher<sup>2</sup>, Almahamadou Mahamar<sup>2</sup>, Amagana Dolo<sup>2</sup>, Balla Diarra<sup>2</sup>, Amatique Zeguime<sup>2</sup>, Souleymane Traore<sup>2</sup>, L.W. Kim Lee Sim<sup>3</sup>, Peter Billingsley<sup>3</sup>, Irfan Zaidi<sup>1</sup>, Robert Morrison<sup>1</sup>, Blair Wylie<sup>4</sup>, Michal Fried<sup>1</sup>, Zonghui Hu<sup>5</sup>, Thomas L. Richie<sup>3</sup>, Alassane Dicko<sup>2</sup>, Patrick E. Duffy<sup>1</sup>

<sup>1</sup>NIH/NIAD/ILMIV, Bethesda, MD, United States, <sup>2</sup>Malaria Research & Training Center, Faculty of Medicine, Pharmacy and Dentistry, University of Bamako, Bamako, Mali, <sup>3</sup>Sanaria, Inc, Rockville, MD, United States, <sup>4</sup>Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, United States, <sup>5</sup>NIH/NIAD/IRB, Bethesda, MD, United States

Pregnant women are highly susceptible to *Plasmodium falciparum* (Pf) malaria, leading to substantial maternal, perinatal, and infant mortality.

Sanaria® PfSPZ Vaccine, composed of Pf sporozoites (SPZ), is an advanced malaria vaccine candidate being developed for use in pregnant women based on a highly favorable safety profile and proven vaccine efficacy (VE) over at least a 6-month period. This randomized, double blind, normal saline (NS) placebo-controlled study assessed the safety and VE of two dosage regimens, 9x10<sup>5</sup> and 1.8x10<sup>6</sup> PfSPZ of PfSPZ Vaccine administered on days 1, 8 and 29 in Malian women of childbearing potential who reported a plan to become pregnant in the next 1-2 years but were willing to undergo pregnancy prevention during vaccinations and for 1 month post vaccination. 300 women were randomized 100/arm to receive 9 x10<sup>5</sup> or 1.8x10<sup>6</sup> PfSPZ or placebo before peak of the 2019 malaria transmission season. All received artemether-lumefantrine 2 weeks prior to 1<sup>st</sup> and 3<sup>rd</sup> vaccination to clear any existing parasitemia. The women were immunized July-August 2019 and followed for malaria endpoints over the course of two years (peripheral Pf; clinical malaria; placental malaria) including during pregnancy. Post-vaccination, 163 women had 180 pregnancies: 60 pregnancies in 56 women receiving 9 x10<sup>5</sup> PfSPZ, 69 in 60 women receiving 1.8x10<sup>6</sup> PfSPZ and 51 in 47 women receiving NS. The first pregnancy was identified September 2019; first pregnancies were detected at a similar pace in the two vaccine arms (median: 213 days post vaccination) but with a delay in the placebo arm (median 264 days). Peripheral Pf occurred at least once during pregnancy in 19/60 (31.7%) women in the 9x10<sup>5</sup> PfSPZ arm, 22/69 (31.9%) in the 1.8x10<sup>6</sup> PfSPZ arm, and 25/51 (49%) in the placebo arm; 5 placental malaria episodes have occurred (9x10<sup>5</sup> PfSPZ: 2; 1.8x10<sup>6</sup> PfSPZ: 1; NS: 2). Further analysis, including time to first peripheral Pf, Pf frequency, and severity of malaria episodes during pregnancy will be presented, taking into account prior parasitemias, antibody and T-cell responses, seasonal variation, and IPTp dosing.

### GLYCOLIPID-ADJUVANTED RADIATION-ATTENUATED SPOOROZOITES IMPROVES THE EFFICACY OF A HETEROLOGOUS PRIME-AND-TRAP MALARIA VACCINE

Malaria is caused by *Plasmodium* parasites and is responsible for an estimated 250 million infections every year. Many leading candidate malaria vaccines target the sporozoite and liver stages to block the subsequent blood stage, clinical disease, and transmission. For liver stage vaccines, inducing liver-resident memory CD8+ T (Trm) cells appears to be critical for protection in mice. Liver Trm cells are induced by a 'Prime-and-Trap' vaccine that combines sporozoite antigen DNA priming with a single intravenous (IV) dose of liver-homing radiation-attenuated sporozoites (RAS) to direct and "trap" activated and expanding T cells in the liver. Although Prime-and-Trap confers durable protection in a rodent malaria model, the requirement for high doses of IV administered RAS is a potential impediment for translation to larger animal models or humans. Here, we investigated methods to improve the translational potential of Prime-and-Trap by reducing the RAS dose, eliminating the IV administration requirement, and adding a co-administered glycolipid adjuvant, 7DW8-5. In *P. yoelii* circumsporozoite protein-encoded DNA primed mice, 7DW8-5 potentiated the efficacy of otherwise sub-therapeutic doses of RAS such that Prime-and-7DW8-5-adjuvanted Trap protected mice against challenge. Additionally, we showed that intradermally-administered RAS and 7DW8-5 improved protection against challenge. These findings in mice demonstrate that Prime-and-Trap is a versatile malaria vaccine that can induce protective liver stage immunity using a single RAS dose and warrants further translation to human studies.

The 10<sup>th</sup> Ebola virus disease (EVD) outbreak in the Democratic Republic of the Congo (DRC) lasted from 1 August 2018 to 26 July 2020 and, in DRC, was the longest, the most geographically widespread, and the largest EVD outbreak with 2,287 deaths and 1,171 survivors. Challenges in controlling this outbreak included security threats, widespread community mistrust in the response activities, low acceptance of systematic safe and dignified burials (SDBs), and long turnaround times of required RT-qPCR results to bereaved families prior to burials. To quickly return laboratory test results to families and improve community engagement and acceptance of SDBs, we trained local healthcare workers to screen cadavers' oral fluids for Ebola infections in Beni Health zone using the OraQuick® Ebola rapid diagnostic test (RDT) (OraSure Technologies, Inc., Bethlehem, PA, USA). Bodies were returned to families for traditional burial within 30-60 minutes when RDT were non-reactive. Molecular confirmation was done by RT-qPCR. Data were collected with tablets outfitted with Kobo-based data collection that operated online. The study was approved by the DRC Ministry of Health. An RDT Consortium and a Technical Working Group coordinated the RDT implementation activities. RDT testing was conducted on 443 cadavers from health facilities (77%) or the community (23%) between 1 August - 31 October 2020 by 19 local teams, each composed of a laboratorian or nurse, a hygienist, a community engagement specialist, and a supervisor. In total, 425 (96%) samples had non-reactive RDTs, 11 (2%) were invalid and 7 (2%) were reactive. Molecular confirmation yielded only 2% false positives and zero false negatives. With a 100% negative predictive value, the post-mortem OraQuick® Ebola RDT effectively complemented outbreak response efforts during the

10<sup>th</sup> EVD outbreak in DRC. Our study shows that in-depth training of the local workforce equipped with innovative Ebola RDT data collection tools adapted to low resource environment could contribute to the detection of EVD related deaths, enables quick public health actions, reduces the risk of community transmission and saves lives.

## TYPHINET: AN ONLINE DASHBOARD FOR GENOMIC SURVEILLANCE OF SALMONELLA TYPHI

**Zoe Anne Dyson**<sup>1</sup>, Louise Cerdeira<sup>2</sup>, Marie Chattaway<sup>3</sup>, François-Xavier Weil<sup>4</sup>, Deborah Williamson<sup>5</sup>, Silvia Argimón<sup>6</sup>, David Aanensen<sup>7</sup>, Stephen Baker<sup>8</sup>, Kathryn Holt<sup>1</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>3</sup>Public Health England, London, United Kingdom, <sup>4</sup>Institut Pasteur, Paris, France, <sup>5</sup>The University of Melbourne, Melbourne, Australia, <sup>6</sup>Centre for Genomic Pathogen Surveillance, Hinxton, United Kingdom, <sup>7</sup>University of Oxford, Oxford, United Kingdom, <sup>8</sup>University of Cambridge, Cambridge, United Kingdom

Typhoid fever is a faeco-orally transmitted systemic infection caused by the bacterium *Salmonella Typhi* (*S. Typhi*). Each year >10 million cases occur worldwide of which >100,000 are associated with mortalities making it a public health threat in many low- to middle-income countries with limited hygiene and sanitation infrastructure. Whole genome sequencing (WGS) and core-genome phylogenetics have become the standard for typhoid molecular epidemiology in both research and public health settings, providing insights into population structure, transmission dynamics, antimicrobial resistance (AMR) emergence and dissemination, as well as outbreak investigation and monitoring of implemented intervention strategies. Despite the relatively widespread adoption of WGS these data are not united and summarised in a single surveillance platform for maximum public health benefit. Here we present TyphiNET; an automated online surveillance dashboard (available at: <http://typhi.net>) developed as a MERN (MongoDB, Express, React, Node.js) stack JavaScript application. TyphiNET imports public data from Typhi Pathogenwatch (available at: <https://pathogen.watch/>) producing interactive visual summaries of public health utility including global and country level overviews of population structure and AMR over time. TyphiNET successfully captures previously reported changes in the *S. Typhi* population structure including the emergence of extensively drug-resistant (XDR) typhoid in Pakistan, the emergence of mutations associated with azithromycin resistance in South Asia, and replacement of antimicrobial sensitive genotypes in Malawi following the introduction of multidrug-resistant (MDR) H58 genotypes. Data and visualisations can be filtered to report data from different sampling frames, time spans and geographic locations, and can be downloaded for use in presentations and reports. Subsequently, TyphiNET provides an up-to-date overview of the global *S. Typhi* population structure to better capture the emergence and spread of AMR variants, changes in population structure, and impacts of intervention strategies worldwide.

Humans exhibit remarkable inter-individual and inter-population immune response variability upon microbial challenges. Cytokines play a vital role in regulating inflammation and immune responses, but dysregulation of cytokine responses has been implicated in different disease states. Host genetic factors were previously shown to have a strong impact on cytokine response variability mainly based on European-based studies, but it is not known whether these findings are transferable to non-European individuals. We examined both cytokine and genome-wide SNPs data of approximately 300 and 500 healthy adults of East-African ancestry from Tanzania and Western European ancestry respectively. We performed cytokine quantitative trait loci (cQTLs) mapping and functional enrichment analyses to identify genetic regulators cytokine responses in both populations. In the Tanzanians, cQTLs mapping identified 80 independent suggestive and one genome-wide significant locus (**TBC1D22A**) at chromosome 22; SNP rs12169244 was associated with IL-1 $\beta$  release after *Salmonella enteritidis* stimulation. Remarkably, the identified cQTLs varied significantly when compared to the European cohort, with a very limited percentage of overlap (1.6% to 1.9%). We further observed ancestry-specific pathways regulating induced-cytokine responses, with significant enrichment of the interferon pathway specifically in the Tanzanian cohort. Furthermore, contrary to the European cohort, genetic variants in the *TLR10-TLR1-TLR6* locus showed no effect on cytokine response. Our data reveals both ancestry-specific effects of genetic variants and pathways on cytokine response heterogeneity, hence arguing for the importance of initiatives to include diverse populations into genomics research.

0427

#### **THE ROLE OF MULTIDIMENSIONAL POVERTY IN ANTIBIOTIC MISUSE IN EAST AFRICA: A MIXED-METHODS STUDY**

**Dominique L. Green<sup>1</sup>**, Sarah Huque<sup>1</sup>, Mary Abed Al Ahad<sup>1</sup>, Mike Kesby<sup>1</sup>, Stephen E. Mshana<sup>2</sup>, Benon B. Asiimwe<sup>3</sup>, John Kiiru<sup>4</sup>, Stella Neema<sup>3</sup>, Joseph R. Mwanga<sup>2</sup>, Annette Aduda<sup>4</sup>, Wilber Sabiiti<sup>1</sup>, Derek J. Sloan<sup>1</sup>, Katherine Keenan<sup>1</sup>, Matthew T. Holden<sup>1</sup>

<sup>1</sup>University of St Andrews, St Andrews, United Kingdom, <sup>2</sup>Catholic University of Health and Allied Sciences, Mwanza, United Republic of Tanzania, <sup>3</sup>Makerere University, Kampala, Uganda, <sup>4</sup>Centre for Microbiology Research, Kenya Medical Research Institute, Nairobi, Kenya

Antimicrobial resistance (AMR) is a 'wicked' problem that poses a particularly stark threat in low- and middle-income countries (LMICs), where antibiotics are widely available without prescriptions. Poverty has been suggested as an important upstream driver of both AMR and inappropriate antibiotic (AB) use. However, we know little about how population-level poverty inequalities relate to AB use. This mixed-methods study investigated the role of poverty in patient-reported AB use in East Africa. The Holistic Approach to Unravelling Antimicrobial Resistance (HATUA) consortium collected data (2018-20) from 6,559 patients presenting with urinary tract infection (UTI) symptoms at public clinics in Tanzania, Kenya, and Uganda. Applying hierarchical regression models, we investigated the association between multidimensional poverty (measured using the Global Multidimensional Poverty Index, capturing acute deprivation in education, living standards, and health simultaneously) and self-reported patterns of AB use. While general AB use was not socio-economically patterned, AB misuse- self-medicating with antibiotics, skipping a dose, and not completing the course- was statistically more common among the better off. These patterns were consistent across contexts, with the exception that in Tanzania, self-medication was equally common across the poverty gradient. In-depth qualitative interviews with a subset of patients (n=90) suggested that these findings are driven by the perceived inconvenience of the healthcare system, ease of access to antibiotics, and inconsistent knowledge about best practices. In Uganda and Kenya, symptoms stigma contributed to skipping doses while at work or in public. Notwithstanding potential reporting differences, the propensity to misuse ABs increases as level of deprivation decreases.

Contrary to previous research in which poverty-driven behaviour has been shown to fuel inappropriate use due to inadequate access to and lack of money for effective ABs, these key findings have implications for future trends in AB use and AMR within LMICs and the development of policies to tackle the issue.

0428

#### **COMPLEX TREATMENT-SEEKING FOR SYMPTOMS OF URINARY TRACT INFECTION IN EAST AFRICA AND LINKS TO ANTIBIOTIC MISUSE: A MIXED-METHODS STUDY**

**Mary Abed Al Ahad<sup>1</sup>**, Sarah Huque<sup>1</sup>, Dominique L. Green<sup>1</sup>, Mike Kesby<sup>1</sup>, Stephen E. Mshana<sup>2</sup>, Benon B. Asiimwe<sup>3</sup>, John Kiiru<sup>4</sup>, Stella Neema<sup>3</sup>, Joseph R. Mwanga<sup>2</sup>, Annette Aduda<sup>4</sup>, Wilber Sabiiti<sup>1</sup>, Derek J. Sloan<sup>1</sup>, Katherine Keenan<sup>1</sup>, Matthew T. Holden<sup>1</sup>

<sup>1</sup>University of St Andrews, St Andrews, United Kingdom, <sup>2</sup>Catholic University of Health and Allied Sciences, Mwanza, United Republic of Tanzania, <sup>3</sup>Makerere University, Kampala, Uganda, <sup>4</sup>Centre for Microbiology Research, Kenya Medical Research Institute, Nairobi, Kenya

Past research has shown that patients with urinary tract infections (UTIs) in low and middle-income countries (LMICs) struggle to access appropriate care, exacerbating the risk of antibiotic misuse and leading to antimicrobial resistance (AMR). This mixed-methods study aims to investigate the socioeconomic and attitudinal factors of patient treatment-seeking pathways (self-treatment, antibiotic use, pathway complexity) for UTI-like symptoms in three East African countries. The Holistic Approach to Unravelling Antimicrobial Resistance consortium collected quantitative data on patient pathways from 5,945 patients with UTI-like symptoms at public clinics in Tanzania (n=2,788), Uganda (n=1,701) and Kenya (n=1,456) [2018-20]. Multilevel logistic regression was used to assess the factors associated with having complex multi-step pathways, first choice of treatment/provider, and antibiotic use before coming to clinic. Qualitative patient interviews were collected from a subset (n=103) and analysed using thematic content analysis. Results showed that 55% of patients tried something else before coming to clinic: 29% had 1 step, 16% 2 steps, and 10% 3+ steps. Among those who tried something else, 74% went to other clinics, 26% self-treated with either drugs or home remedies/herbs, 40% took antibiotics suitable for UTI, and 9% used unsuitable antibiotics. Tanzanian and Ugandan patients were more likely to have complex pathways than those in Kenya. Long waiting times at clinics, not having close access to health centres, and being able to afford drugs made self-treatment more probable. Men, those who previously attended other clinics, and those who felt symptoms stigma were more likely to take antibiotics. Wealthier patients were more likely to have complex pathways and take unsuitable antibiotics. Our findings challenge common presumptions around drivers of AMR in East Africa. Our mixed methods approach was essential in demonstrating the complexity of structural factors which contribute to patient behaviours and identifying under-explored themes for further analysis, including stigma and healthcare structure/accessibility.

0429

#### **ENHANCED PARTICIPATION OF ROHINGYA REFUGEES INCREASES IMMUNIZATION COVERAGE IN A CAMP-BASED POPULATION IN COX'S BAZAAR, BANGLADESH**

**Anam Ali<sup>1</sup>**, Rumana Akter<sup>2</sup>, Mohammad Ariful Islam<sup>2</sup>, Arifuzzaman<sup>→2</sup>, Nyo Yamonn<sup>3</sup>, Tom Traill<sup>3</sup>, Adam Richards<sup>4</sup>

<sup>1</sup>Community Partners International, Cox's Bazar, Bangladesh, <sup>2</sup>Green Hill / Community Partners International, Cox's Bazar, Bangladesh, <sup>3</sup>Community Partners International, Yangon, Myanmar, <sup>4</sup>George Washington University Schol of Public Health, Washington, DC, United States

During the SARS-CoV2 pandemic routine vaccination coverage fell below 20% among Rohingya refugees in Bangladesh, creating conditions conducive to outbreaks of vaccine-preventable illness. We evaluated a pilot program implemented by and for refugees whose objective was to increase vaccinations among pregnant women and children under

age three living in two camps. Rohingya community immunization volunteers (CIVs) conducted baseline and midline census surveys and ongoing household surveillance and identified 2,877 individuals due for one or more immunizations, including 353 newly enlisted beneficiaries not previously recorded in official registries. After CIVs visited the household of each target beneficiary to explain the vaccination process half (49%) of beneficiaries were vaccinated. CIVs returned within 72 hours to visit beneficiaries who missed their initial appointments (51%) and accompanied them to vaccination sites. After excluding beneficiaries who moved outside the study area or died (2%), over 99% of eligible beneficiaries were successfully vaccinated. The CIV pilot achieved vaccination coverage that exceeded respective coverage rates estimated in this population prior to and during the pandemic, and in similar camp populations adjacent to the pilot area. Qualitative interviews with refugees and vaccination stakeholders suggested keys to success included the ability of CIVs to earn the trust of both community members and government vaccination staff, and to accompany beneficiaries as they navigated long distances, vaccine shortages and other perceived barriers to immunization. Our findings align with other evidence of community health worker effectiveness and suggest Rohingya refugees themselves can collect and manage timely information on household composition and conduct targeted outreach to dramatically increase vaccination coverage during the acute-on-chronic crisis of the SARS-CoV2. Policies that limit refugee participation in the delivery of health and other services deserve critical scrutiny for their possible adverse impacts on coverage and outcomes.

### IMPACT OF THE INTRODUCTION OF PCV7OR 13 ON ANTIMICROBIAL RESISTANCE IN INVASIVE PNEUMOCOCCAL DISEASE IN WESTERN REGION OF THE GAMBIA

Ebrima M. Jammeh

*Bundung Maternal and Child Health Hospital, Banjul, Gambia*

We describe antimicrobial resistance in invasive pneumococcal disease due to all serotype and non-vaccine type(NVT) pre and post pneumococcal conjugate vaccine(PCV) implementation in The Gambia in all age groups. We identified, serotyped and performed antimicrobial susceptibility testing using disc diffusion methods on pneumococcal isolates obtained from invasive samples collected from standardize population-based pneumococcal disease surveillance in the Bundung maternal and Child health demographic system. The study commenced May 2010. PCV7 was introduced in August 2011 and PCV13 in September in 2012. Antibiotic susceptibility was interpreted using clinical laboratory standard institute guidelines. 390 pneumococcal isolates were screened against five antimicrobial agents. There was a moderate decline in antibiotic resistance in all age groups in invasive pneumococcal disease during vaccine implementation. In the 2-23-month age group, annual counts of oxacillin, chloramphenicol, and tetracycline resistant case fell from 10-15 in 2010 and 2011 to 6-7 in 2014 and 2015. In the 24-59-month age group, there was a large fall in tetracycline resistant cases. In those under 5 years, oxacillin, chloramphenicol and tetracycline fell to zero case in 2013 and 2014. Resistance fell primarily due to reduction in vaccine serotypes 1, 5, 14 and 23F. The proportion of resistant cases increase over time, particularly in the 2-23-month age group with tetracycline resistance mainly in serotypes 10A, 12F, 11B,7C and 25A and tetracycline resistance in serotype in 12F in 2016. Isolates were generally sensitive to erythromycin but in 95-98% were resistant to clotrimazole throughout the study. Although there is an overall reduction in cases of antimicrobial resistant. We hypothesis that increased transmission of NVT after the introduction of PCV and exposure to antimicrobials agents. Ongoing surveillance is important to determine future trends in resistance as it has both clinical and public health importance in PCV era.

### FRONTLINE HEALTH WORKER AND COMMUNITY HEALTH VOLUNTEER EXPERIENCES WITH DELIVERY OF MASS DRUG ADMINISTRATION USING TRIPLE DRUG THERAPY FOR LYMPHATIC FILARIASIS IN PAPUA NEW GUINEA: A MIXED METHOD STUDY

Alison Krentel<sup>1</sup>, Krufinta Bun<sup>2</sup>, Daniel Dillio<sup>3</sup>, Afzaa Rajabali<sup>3</sup>, Moses Laman<sup>4</sup>, Benedict Mode<sup>5</sup>, Makoto Sekihara<sup>6</sup>, Charles Thickstun<sup>1</sup>, William Pomat<sup>4</sup>, Christopher L. King<sup>2</sup>

<sup>1</sup>University of Ottawa, Ottawa, ON, Canada, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>3</sup>Bruyere Research Institute, Ottawa, ON, Canada, <sup>4</sup>Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, <sup>5</sup>Division of Health, East New Britain Provincial Administration, Kokopo, Papua New Guinea, <sup>6</sup>Japan International Cooperation Agency, Port Moresby, Papua New Guinea

A three-drug regimen of ivermectin, diethylcarbamazine citrate and albendazole (IDA) for lymphatic filariasis has been found to be more effective for achieving sustained clearance of microfilariae than the standard two-drug regimen. This exploratory study, undertaken across four treatment-naïve implementation units of East New Britain Province (ENBP), Papua New Guinea, aimed to understand the performance, motivation, and resilience of frontline health workers (FLHW) and community health volunteers (CHV) responsible for distributing the IDA treatment regimen for the first time. Our mixed methods study included a FLHW/CHV survey, a focus group discussion (FGD), and in-depth interviews (IDIs). FLHW (n=41) and CHV (n=33) involved with the mass drug administration were purposefully selected and surveyed. The behavioural and outcome aspects of FLHW/CHV performance were measured using a 20-item Likert scale. Items on the scale assessed task and contextual performance across four domains (adherence to protocol/achievement of goals, interpersonal skills, self-efficacy/behaviour in response to challenges, and teamwork). Motivation was explored using a micronarrative survey. Resilience was measured using the Connor-Davidson Resilience Scale 25. Qualitative data were collected from one FGD and three IDIs. When surveyed, 51.4% of FLHW/CHV said they "always" delivered the medicine to the households they planned to reach each day, with 33.8% saying they "never" did. Only 45.9% felt they could "always" contact a program supervisor for help if they encountered problems or didn't know what to do. Survey data also showed that 78.4% said they "always" watched people swallow the medicines. Mean resilience scores were reported out of a total score of 100, for FLHW 67.39 (± 20.20) and CHV 73.02 (± 19.33). A short time frame for distribution, transportation issues, drug shortages, and lack of drinking water were some of the challenges mentioned in the FGD and IDIs. These results validate the high treatment coverage rate across ENBP and provide the health department information for future implementation of the new regimen in Papua New Guinea.

### POST-TREATMENT SURVEILLANCE FOR ONCHOCERCIASIS IN PLATEAU AND NASARAWA, NIGERIA: EVIDENCE FOR ELIMINATION OF TRANSMISSION

Abel Eigege<sup>1</sup>, Barminas Kahansim<sup>1</sup>, Kenrick Nwodu<sup>1</sup>, Yohana Sambo<sup>1</sup>, John Umaru<sup>1</sup>, Bulus Mancha<sup>1</sup>, Solomon Adelamo<sup>1</sup>, Jonathan Kadimbo<sup>2</sup>, Jacob Danboyi<sup>3</sup>, Hayward Mafuyai<sup>4</sup>, Nse Akpan<sup>5</sup>, Joel Akilah<sup>5</sup>, Michael Igbe<sup>5</sup>, Lindsay Rakers<sup>5</sup>, Emily Griswold<sup>6</sup>, Thomas R. Unnasch<sup>7</sup>, Bertram E. Nwoke<sup>8</sup>, Emmanuel S. Miri<sup>1</sup>, Gregory S. Noland<sup>6</sup>, Frank O. Richards<sup>6</sup>

<sup>1</sup>The Carter Center, Nigeria, Jos, Plateau State, Nigeria, <sup>2</sup>Plateau State Ministry of Health, Jos, Nigeria, <sup>3</sup>Nasarawa State Ministry of Health, Lafia, Nigeria, <sup>4</sup>University of Jos, Jos, Nigeria, <sup>5</sup>Federal Ministry of Health, Abuja, Nigeria, <sup>6</sup>The Carter Center, Atlanta, GA, United States, <sup>7</sup>University of South Florida, Tampa, FL, United States, <sup>8</sup>Imo State University, Owerri, Nigeria

Nigeria has 480 onchocerciasis-endemic districts or local government areas (LGAs), of which 12 (2.5%) are in Plateau and Nasarawa States. In 2017

these two states were the first in the country to interrupt transmission and stop mass drug administration (MDA) for onchocerciasis after 8 – 26 years of MDA with ivermectin in the 12 hyper-/meso-endemic LGAs and ivermectin-albendazole treatment for LF in 18 other LGAs non-endemic or hypo-endemic for onchocerciasis. A three-year post-treatment surveillance (PTS) entomological evaluation, required to declare transmission elimination, was completed in 2019-2020 transmission season per WHO and National Onchocerciasis Elimination Committee (NOEC) guidelines. Entomology collections for *Simulium damnosum* s.l. blackflies were carried out from mid-June through October 2019 and 2020 in 42 sites (21 sites per state) in formerly hyper-/meso-endemic areas. Collections were from known high risk LGAs as well as hypo-endemic LGAs bordering with other endemic Nigerian states. Blackflies were tested for the presence of L3 infective-stage *Onchocerca volvulus* by O-150 polymerase chain reaction. In Nasarawa State, results from 93 pools comprised of 7925 flies found 0 positive pools (0%, 95% confidence interval [CI] 0% - 0.024%). In Plateau State, 89 pools comprised of 7368 flies resulted in 0 positive (0%, 95% CI 0% - 0.026%). These results meet the 2016 WHO entomological criteria for elimination of transmission infectivity threshold of less than 0.05% (<1/2000). Other PTS activities included tracking and treating immigrants and internally displaced persons (IDPs), and health educating the communities. A total of 21,994 immigrants and IDPs were tracked and treated with ivermectin in the border villages as well as those in identified camps. Health education messages were disseminated through radio jingles, posters and face-to-face contact by community-directed drug distributors. Pending approval of the NOEC, these results indicate Plateau and Nasarawa states could be the first to eliminate onchocerciasis transmission in Nigeria.

## 0433

#### ONCHOCERCIASIS ELIMINATION STATUS IN FIVE CARTER CENTER-SUPPORTED STATES IN SOUTHERN NIGERIA: MEASURING PROGRESS TOWARDS ONCHOCERCIASIS ELIMINATION IN NIGERIA

**Emmanuel Emukah**<sup>1</sup>, Abel Eigege<sup>1</sup>, Cephas Ityonzughul<sup>1</sup>, Adamu Sallau<sup>1</sup>, Lindsay Rakers<sup>2</sup>, Barminas Kahansim<sup>1</sup>, Andrew Obasi<sup>1</sup>, Chidi Njoku<sup>1</sup>, Bertram E. Nwoke<sup>3</sup>, Emmanuel S. Miri<sup>1</sup>, Emily Griswold<sup>2</sup>, Chukwuma Anyaika<sup>4</sup>, Michael Igbe<sup>4</sup>, Gregory S. Noland<sup>2</sup>, Frank O. Richards<sup>2</sup>

<sup>1</sup>The Carter Center, Nigeria, Jos, Plateau State, Nigeria, <sup>2</sup>The Carter Center, Atlanta, GA, United States, <sup>3</sup>Imo State University, Owerri, Nigeria, <sup>4</sup>Federal Ministry of Health, Abuja, Nigeria

In 2013, Nigeria adopted a goal of onchocerciasis transmission elimination and formed the National Onchocerciasis Elimination Committee (NOEC). Between June 2019 and October 2020, we conducted cross-sectional epidemiological sero-surveys in five states (Abia, Anambra, Delta, Enugu, and Imo) to collect dried blood spots (DBS) from children aged 5 – 9 years for OV16 ELISA analysis; positive children were tested by O-150 PCR for *Onchocerca volvulus* microfilariae in skin snips. DBS were collected from 167 high-risk villages (within 5km of known breeding sites) pre-selected by the NOEC. In Delta, 2/3,380 children were OV16 positive (0.06%, upper 95% CI [UCL] 0.14%); skin snip samples from the two positive children were PCR negative. In Imo, 1/3,197 was OV16 positive (0.03%, UCL 0.09%). In Abia, 1/3,174 was OV16 positive (0.03% UCL 0.09%), skin snips were not obtained. In Enugu, 2/3,180 were OV16 positive (0.10%, UCL 0.15%); skin snips were negative. Finally, in Anambra, 3/3,167 children were OV16 positive (0.10%, UCL 0.20%); skin samples were available for two of the three positives, and PCR was positive for one of these. The WHO threshold for transmission interruption is UCL <0.1%, but guidelines permit OV16 positive/PCR negative children to be excluding from the calculations if less than 10 children are positive. In all but Anambra State recalculation of the UCL using skin snip PCR results showed <0.1% threshold was reached. An entomological study of 6,591 vector heads of *Simulium damnosum* s.l. carried out in Delta state from May – November 2020 showed all pools to be O-150 PCR negative (0%, UCL 0.58). The WHO threshold is <1/2000. We believe Delta State has met the WHO criteria for 'transmission interrupted' classification, and

that MDA could be stopped here in 2021. Abia, Imo and Enugu should proceed to entomology studies for a potential stop MDA decision for 2022. Anambra should wait for the outcome of the last skin PCR. These recommendations are pending decision by the NOEC May 2021 meeting. If the Delta recommendation is accepted, it will be the first state in southern Nigeria to stop onchocerciasis MDA.

## 0434

#### THE IMPACT OF MASS DRUG ADMINISTRATION WITH A TRIPLE DRUG REGIMEN (IVERMECTIN, DIETHYLCARBAMAZINE AND ALBENDAZOLE) ON LYMPHATIC FILARIASIS IN PAPUA NEW GUINEA AND IMPLICATIONS FOR POST-MDA SURVEILLANCE

**Krufinta Bun**<sup>1</sup>, Moses Laman<sup>2</sup>, Melinda Susapu<sup>3</sup>, Makoto Sekihara<sup>4</sup>, Emanuele Giorgi<sup>5</sup>, Peter J. Diggle<sup>5</sup>, Michael Payne<sup>1</sup>, Daniel Tisch<sup>1</sup>, Catherine Bjerum<sup>1</sup>, Benedict Mode<sup>6</sup>, Leanne Robinson<sup>7</sup>, Gary Weil<sup>8</sup>, Christopher L. King<sup>1</sup>

<sup>1</sup>Case Western Reserve University, Cleveland, OH, United States, <sup>2</sup>Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, <sup>3</sup>Papua New Guinea Department of Health, Port Moresby, Papua New Guinea, <sup>4</sup>Japan International Cooperation Agency, Tokyo, Japan, <sup>5</sup>Lancaster University, Lancaster, United Kingdom, <sup>6</sup>East New Britain Provincial Health Department, Kokopo, Papua New Guinea, <sup>7</sup>Burnet Institute, Melbourne, Australia, <sup>8</sup>Washington University, St Louis, MO, United States

The impact of mass drug administration (MDA) with triple drug therapy (ivermectin, diethylcarbamazine and albendazole) on lymphatic filariasis (LF) in treatment naïve areas has been little studied. WHO recommends two rounds of MDA with IDA in treatment naïve areas, or areas that have failed repeated rounds of two drug therapy outside of sub-Saharan Africa. Endpoints for stopping MDA in implementation units following IDA remain to be defined, but Mf surveillance may be better than surveys for circulating filarial antigen (CFA) which declines slowly after IDA and may take years to decline below <2%. We studied the impact of MDA on LF in the East New Britain Province (ENBP) of Papua New Guinea with a population of ~375,000 residents without previous MDA for LF. Prior to MDA, we surveyed 49 clusters or villages (30 randomly selected and 19 purposely selected) of ~100 persons each (n=50 ages 6-9 years; n=50 >10 years). We found 24 of 49 clusters had >2% CFA and 14 >1% Mf with overall Mf prevalence of 2.2% (95% CI: 1.8, 3.2, range 0-18%). We also observed little LF infection in children. In November 2019, MDA was performed for the entire province with 82% epidemiological coverage. We used geostatistical modelling of baseline data to select 46 clusters for monitoring and evaluation following MDA. The model prioritized 23 of the 24 hot spot clusters identified at baseline and identified an additional 23 clusters likely to have high endemicity for post-MDA surveillance. Because of the low baseline LF prevalence in children, post-MDA surveys focused on adults (~100 per village). One-year post-MDA, only 2 of 23 previously surveyed hotspots had Mf >1%, and none of the other 23 clusters had Mf >1%. The overall Mf prevalence post-MDA was 0.26% (95% CI: 0.2, 0.5, range 0-3.9%). These results show that a single round of MDA with IDA can result in a dramatic decrease in Mf prevalence to a level that may not sustain transmission apart from a few hotspots. Geospatial modeling may also be useful for focusing post-MDA surveys to high-risk areas. Surveys of adults for persistence of Mf in high-risk areas is likely to be superior to CFA surveys in children for endpoint surveillance in PNG.

0435

### THE IMPACT OF ANNUAL VS SEMI-ANNUAL MASS DRUG ADMINISTRATION WITH ALBENDAZOLE AND IVERMECTIN ON HELMINTH INFECTIONS IN HARPER DISTRICT, LIBERIA

**Obiora A. Eneanya**<sup>1</sup>, Lincoln Gankpala<sup>2</sup>, Charles W. Goss<sup>1</sup>, Gary J. Weil<sup>1</sup>, Fatorma K. Bolay<sup>2</sup>, Peter U. Fischer<sup>1</sup>

<sup>1</sup>Washington University School of Medicine, St. Louis, MO, United States, <sup>2</sup>National Public Health Institute of Liberia, Charlesville, Liberia

The World Health Organization recommends annual mass drug administration (MDA) with ivermectin plus albendazole (IA) to eliminate lymphatic filariasis (LF) in most endemic countries in Africa. In this study, we compared the impact of three rounds of annual MDA with five rounds of semi-annual MDA with IA on LF and on soil-transmitted helminth (STH) infections in separate treatment areas within Harper District, Liberia. LF infections were detected by tests for circulating filarial antigenemia (CFA); persons with CFA were screened for *Wuchereria bancrofti* microfilaremia (Mf) by microscopic examination of 60 µl night blood thick smears. STH infections were detected with duplicate Kato-Katz smears. Microfilariae of *Onchocerca volvulus* were detected by examination of skin snips. The primary outcomes for the study were % reductions in infection prevalence from baseline to month 36 (12 mo after the last treatment). *W. bancrofti* CFA and Mf prevalences decreased by 78.2% (from 19.7% to 4.3%) and by 100% (from 8.6% to 0%), respectively after annual MDA; reductions in CFA and Mf after semi-annual MDA were 55% (from 37.8% to 16.8%) and 94.4% (17.9% to 1%) respectively. Reductions in hookworm and *Trichuris* prevalences and intensities were slightly greater in the annual treatment area. *Ascaris* prevalences were relatively unchanged in both areas, although infection intensities decreased. Interestingly, a follow-up survey found that reductions in LF and STH infection parameters at 36 mo were sustained or improved further at 72 mo, i.e. 3 yrs after the Liberian Ministry of Health (MOH) assumed responsibility for annual MDA in the district. These results show that annual and semi-annual MDA were equally effective for reducing LF and STH infection parameters over a three-year period and that these improvements were sustained for an additional three years by routine annual MDA provided by the Liberian MOH.

0436

### RAPID SOCIAL SCIENCE ASSESSMENT IN LYMPHATIC FILARIASIS HOTSPOTS IN SIERRA LEONE

Luisa Enria<sup>1</sup>, Angus F. Tengbeh<sup>2</sup>, Ekundayo Karim<sup>3</sup>, James King<sup>3</sup>, Umu H. Jalloh<sup>4</sup>, Gandhi Kallon<sup>4</sup>, Alhassan Konneh<sup>2</sup>, Victoria Turay<sup>4</sup>, Habib I. Kamara<sup>4</sup>, **Mustapha Sonnie**<sup>4</sup>, Mary H. Hodges<sup>4</sup>, Patricia Houck<sup>5</sup>, Benoit Dembele<sup>6</sup>, Kisito Ogooussan<sup>7</sup>, Yaobi Zhang<sup>6</sup>, Steven D. Reid<sup>5</sup>, Angela Weaver<sup>5</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Queen Margaret University, Edinburgh, United Kingdom, <sup>3</sup>Neglected Tropical Disease Program, Ministry of Health and Sanitation, Freetown, Sierra Leone, <sup>4</sup>Helen Keller International, Freetown, Sierra Leone, <sup>5</sup>Helen Keller International, New York, NY, United States, <sup>6</sup>Helen Keller International, Regional Office for Africa, Dakar, Senegal, <sup>7</sup>Family Health International 360, Washington DC, MD, United States

Four districts in Sierra Leone failed lymphatic filariasis pre-transmission assessment survey (pre-TAS) twice despite effective reported treatment coverage. High baseline prevalence, migratory movements across West Africa, non-biomedical beliefs on disease causation and MDA hesitancy may have contributed to the failure in these hotspots. A deeper analysis of social factors including COVID-19 that may lead to MDA hesitancy was conducted to develop adaptive community engagement strategies. A rapid qualitative assessment tool was used for participatory observations, power mapping and rumor tracking. Trained teams visited nine high-risk communities planned for repeat pre-TAS. They conducted nine in-depth interviews and 18 focus group discussions (males vs females, young vs old). Data were transcribed, analyzed and coded using framework and thematic analysis. Traditional and political leaders were seen to be powerful but not necessarily trusted homogeneously across communities

and demographic groups. Religious leaders were the most trusted. Young men highlighted “Ataya” base while females identified mother’s group as sources of information. Discussions around preference of traditional healers for LF showed more layers into it and highlighted the importance of including them in mainstream approaches. Trust in health workers and NTD programming was influenced by non-NTD interactions and rumors of adverse events in earlier MDAs. Trust in community drug distributors/health workers was driven by sharing same local languages. COVID-19 affected trust levels, and participants reported lower attendance at health facilities. Knowledge of NTDs/MDA was high but coexisted with different explanations and channels of health seeking behavior. Social mobilization approaches should shift from a focus on health education to a more comprehensive engagement to address drivers of community mistrust of health system and seeing rumors as a window into more deeply rooted mistrust in health systems. Creating content targeting specific social groups in multiple dialects will help reduce MDA-hesitancy.

0437

### POST-TREATMENT SURVEILLANCE FOR LYMPHATIC FILARIASIS IN THE DOMINICAN REPUBLIC

**Manuel Gonzales**<sup>1</sup>, Luccene Desir<sup>2</sup>, Gregory S. Noland<sup>2</sup>

<sup>1</sup>Centro de Control de Enfermedades Tropicales, Ministerio de Salud Publica, Santo Domingo, Dominican Republic, <sup>2</sup>The Carter Center, Atlanta, GA, United States

The Dominican Republic is one of four countries in the Americas endemic for lymphatic filariasis (LF). Also known as elephantiasis, LF is caused by repeated infection with the parasite *Wuchereria bancrofti* and transmitted by *Culex quinquefasciatus* mosquitoes. Transmission in the Dominican Republic was limited to 19 districts clustered into three geographic foci. Following three to five rounds of annual mass drug administration (MDA) with albendazole and diethylcarbamazine, MDA stopped in the three foci after 2006 (La Ciénaga), 2007 (Southwest), and 2017 (East), respectively. The La Ciénaga and Southwest foci have completed multiple post-treatment surveillance (PTS) surveys, including successfully passing a third transmission assessment survey (TAS-3) in 2018, while the East passed TAS-1 the same year. The purpose of the current surveys was to conduct TAS-2 in the East and continued PTS in the other foci. The surveys followed the TAS protocol of testing children 6–7 years old for the presence of circulating filarial antigen (CFA) by filariasis test strip (FTS) in community-based surveys, with each focus considered a single evaluation unit. Additionally, one other individual age 15 years or older from the same household as child participants was randomly selected for FTS testing. In La Ciénaga, none (0%) of 478 children and 478 adults tested were CFA-positive in a census survey of the foci in March 2021. In the Southwest, none (0%) of 1574 children and 1591 adults tested in 56 clusters were CFA-positive in October 2020. In the East, sampling is ongoing, but none (0%) of 228 children and 223 adults tested in 36 clusters to date were positive. Household surveys also contributed information for estimating LF morbidity. A total of 41 individuals with lymphedema were identified across the three foci. These results indicate that LF transmission has been eliminated in the formerly endemic areas of the Dominican Republic and indicate the need to provide morbidity management and disability prevention services to LF patients.

0438

### MALARIA DOES NOT RESPECT NATIONAL BORDERS: TACKLING MALARIA ON THE BRAZIL-GUYANA-VENEZUELA BORDERS, THE BIGGEST CHALLENGE IN THE AMERICAS REGION

**Horace Cox**<sup>1</sup>, Erika Wetzler<sup>2</sup>, Paola Marchesini<sup>3</sup>, Sara Canavati<sup>2</sup>, Jorge Moreno<sup>4</sup>, Maria Villegas<sup>5</sup>, Leopoldo Villegas<sup>6</sup>

<sup>1</sup>Vector Control Service (VCS), Ministry of Health Guyana, Georgetown, Guyana, <sup>2</sup>World Vision, Washington DC, DC, United States, <sup>3</sup>Ministry of Health, Brasilia, Brazil, <sup>4</sup>Centro de Investigacion de Campo Francesco

Vitanza, Tumeremo, Bolivar, Bolivarian Republic of Venezuela, <sup>5</sup>Global Development One, Silver Spring, MD, United States, <sup>6</sup>ASOCIS, Tumeremo, Bolivar, Bolivarian Republic of Venezuela

Globally, human population movement across international borders presents one of the major challenges for malaria elimination. The Brazil-Guyana-Venezuelan (BRA-GUY-VEN) border area harbors the highest concentration of malaria cases in the Americas region. Unofficial mining activities and the VEN political and economic crisis have contributed to increased population movement. This study aims to assess malariometric trends and explore risk factors for *P. falciparum* (Pf) versus *Plasmodium vivax* (Pv) in those border areas between 2016 and 2020, using data on reported malaria cases (local and imported) from government/non-government organizations. During the study period, there were 645,096 malaria cases reported (BRA=27,852; GUY=42,118; VEN=575,126) along border areas. Most infections were due to Pv (75%), followed by Pf (21%), and mixed infections/others (4%). A malaria resurgence in the VEN border area peaked in 2018 (from 119,984 in 2016 to 160,367 cases in 2018). This increase in cases was also seen in BRA (from 2,027 in 2016 to 6,734 in 2018) and GUY (from 8,487 in 2016 to 11,016 in 2018). The Brazilian state of Roraima was the largest receiver of imported cases (15,089 cases in 2016-2020, 81.8% of these from Venezuela). Overall, during the study period reported malaria cases in border areas decreased 65% in VEN, in contrast to increases of 354% and 57% in BRA and GUY, respectively. The key affected populations were miners, followed by indigenous groups, and males over 15 years old. The design of future policies and interventions should use approaches that most effectively target these high-risk groups. There is a pressing need for coordination and multicountry strategic investments. Recommendations for resilient strategic planning for malaria elimination in border areas will be also presented.

0439

#### **BURDEN OF MALARIA IN PREGNANCY AMONG ADOLESCENT GIRLS FROM FIVE SUB-SAHARAN AFRICAN COUNTRIES: A META-ANALYSIS OF INDIVIDUAL-PARTICIPANT DATA**

Malaria is among the most important causes of death in adolescent girls (10-19 years) globally. However, information on the actual burden of the infection in this population is limited. The objective of this study was to estimate the prevalence of malaria in pregnancy among adolescent girls compared to that of adult women from five sub-Saharan African countries. An individual participant-level meta-analysis was conducted including data from 5804 pregnant women (1069 HIV-infected and 4735 HIV-uninfected) participating in two malaria prevention clinical trials in Benin, Gabon, Kenya, Mozambique, and Tanzania. Clinical episodes during pregnancy, peripheral parasitaemia at delivery and placental malaria were the main study outcomes. A two-stage meta-analysis approach was followed by pooling single multivariable regression results into standard DerSimonian-

Laird random-effects models. Adolescent girls were more likely than adult women to present clinical malaria episodes during gestation (IRR 1.94, 95%CI 1.21;3.09, p-value<0.01), parasitaemia at delivery (OR 2.53, 95% CI 1.77;3.61, p-value<0.0001), and placental infection (OR 2.42, 95%CI 1.75;3.35, p-value<0.0001). Differences in malaria burden indicators between adolescent and adult women were not modified by HIV status. Subgroup analysis by gravidity showed similar associations between adolescence and study outcomes both for primigravid and multigravid women. The burden of malaria in pregnancy was higher in adolescent girls compared to adult women, making them a highly susceptible population regarding this infection. Provision of malaria control strategies should prioritise adolescent girls in malaria endemic settings.

0440

#### **IMPACT OF PROACTIVE COMMUNITY CASE MANAGEMENT ON COMMUNITY MALARIA PREVALENCE IN BANKASS, MALI**

Julie Thwing<sup>1</sup>, Saibou Doumbia<sup>2</sup>, Mahamadou Sylla<sup>2</sup>, Idrissa Kamara<sup>2</sup>, Mahamadou Sogoba<sup>2</sup>, Caroline Whidden<sup>2</sup>, Emily Treleaven<sup>3</sup>, Ari Johnson<sup>2</sup>, Kassoum Kayentao<sup>2</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>MUSO, Bamako, Mali, <sup>3</sup>Institute for Social Research, University of Michigan, Ann Arbor, MI, United States

Despite ongoing efforts to improve access to malaria diagnosis and treatment at health facility and community levels, the proportion of children with fever who receive a diagnostic test and appropriate treatment remains low. The proactive community case management (ProCCM) model deploys community health workers (CHWs) to conduct proactive case finding, via door-to-door home visits for at least two hours daily, six days a week, with the goal of visiting each household at least twice monthly. For residents of all ages with febrile illness, CHWs perform rapid diagnostic tests (RDT) and offer antimalarial treatment for those with positive tests. Previous studies suggest that this strategy may decrease malaria burden. From 2017-2020, a three-year cluster randomized controlled trial (137 clusters) of ProCCM was conducted in rural Mali. All clusters had a CHW who received training, supervision, and supply chain support; only the proactive visit component was unique to the intervention arm. The endline household survey measured all-cause mortality, care seeking behavior, and case management, as well as RDTs for participants of all ages. Of 4,636 children < 5 years, 15.9% (95%CI 14.8-17.1) reported having a fever in the last two weeks, 68.3% (95% CI 64.4-72.1) sought care, and 48.0% (43.7-52.2) received care from a CHW. Of those who sought care, 70.3% (95% CI 65.5-75.0) received a diagnostic test. In total, 14,402 randomly selected participants consented to receive an RDT at endline across both arms. Overall, 31.0% had a positive RDT (95% CI 29.0-33.1); 25.7% (95% CI 22.9-28.4) among children < 5 years, 50.9% (95% CI 48.2-53.6) among children 5-14 years, 19.3% (95% CI 17.4-21.1) among non-pregnant adults >15 years, and 16.8% (95% CI 14.9-18.7) among pregnant women. The study will be unblinded in June 2021; results will be presented by arm to determine whether three years of ProCCM improved all-cause mortality and malaria prevalence by RDT compared to the traditional model of passive community case management. These results will inform malaria policy makers as to the impact of ProCCM on malaria prevalence.

#### **INCREASING COVERAGE OF COMMUNITY CASE MANAGEMENT OF MALARIA IS ASSOCIATED WITH REDUCTION IN SEVERE MALARIA AND MALARIA INPATIENT DEATHS IN ZAMBIA**

Ruth A. Ashton<sup>1</sup>, Busiku Hamainza<sup>2</sup>, Steven Bwalya<sup>2</sup>, Christopher Lungu<sup>3</sup>, Marie-Reine I. Rutagwera<sup>3</sup>, Travis Porter<sup>1</sup>, Michael Hainsworth<sup>4</sup>, Sarah M. Burnett<sup>4</sup>, Hannah Slater<sup>5</sup>, Thomas P. Eisele<sup>1</sup>, John M. Miller<sup>3</sup>

<sup>1</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>2</sup>National Malaria Elimination Centre, Zambia Ministry of

Health, Lusaka, Zambia, <sup>3</sup>PATH MACEPA, Lusaka, Zambia, <sup>4</sup>PATH MACEPA, Washington, DC, United States, <sup>5</sup>PATH MACEPA, Seattle, WA, United States

Community case management of malaria (CCM) has been intensively expanded across Zambia since 2013, with the goal that all Zambians can access quality basic health services within 5km or one hour travel of their home by 2021. However, data describing CCM impact in routine implementation settings are limited. This retrospective and observational study evaluates the impact of CCM expansion on inpatient malaria cases and deaths from 2015-2020 in 7 of Zambia's 10 provinces. We hypothesize that increasing the number of malaria providers per population (through CCM expansion) reduces delays in treatment seeking, consequently reducing the proportion of individuals progressing from uncomplicated to severe malaria or malaria-related death. We used a dose-response approach to explore associations between malaria service provider density and inpatient malaria cases and deaths by district and month. All data describing exposure, outcome, and covariates (vector control, rainfall) were extracted from existing routine and programmatic sources. Negative binomial mixed-effect models were generated using continuous and categorised exposure (providers per 1000) for outcomes of inpatient confirmed malaria cases and inpatient malaria deaths among all-ages and among under-fives (U5s). Data from 83 districts over 65 months were compiled, encompassing 310,855 inpatient malaria cases and 7158 malaria deaths. After controlling for vector control access and rainfall, final models found an increase of 1 provider per 1000 population was associated with a 20% reduction in malaria admissions in U5s (incidence rate ratio 0.80,  $p < 0.001$ ) and 17% reduction in malaria admissions among all ages (IRR 0.83,  $p < 0.001$ ). Similar effect sizes were observed for malaria inpatient deaths (IRR 0.79  $p = 0.005$  for U5s, IRR 0.80  $p = 0.001$  for all-ages). Models using a categorised exposure variable consistently found a significant reduction in malaria admissions and deaths only when malaria service provider density reached saturation: a least one provider per 750 people. These findings highlight the gains that can be achieved from expanding CCM in high transmission settings.

#### **GEOGRAPHICAL ACCESS TO HEALTH FACILITIES AND SEVERE MALARIA AMONG MALARIA POSITIVE CHILDREN IN RURAL AREAS: ANALYSIS OF HOUSEHOLD SURVEYS FROM 18 COUNTRIES IN SUB-SAHARAN AFRICA**

**Cameron Taylor**<sup>1</sup>, Joanna Lowell<sup>2</sup>, Livia Montana<sup>1</sup>, Jean de Dieu Bizimana<sup>2</sup>, Yazoume Ye<sup>3</sup>

<sup>1</sup>The DHS Program-ICF, Rockville, MD, United States, <sup>2</sup>The DHS Program-Vysnova Partners, Landover, MD, United States, <sup>3</sup>PMI Measure Malaria-ICF, Rockville, MD, United States

Access to a health facility is a key determinant of health seeking behavior in malaria endemic countries, particularly in rural settings. In this analysis, we examined the association between severe malaria and a rural household's geographical access (defined as walking time) to formal health facilities. We hypothesized that children from households located far from health facilities are more likely to have severe malaria symptoms compared to those from households close to health facilities, because of a delay in treatment seeking. This analysis used data from 25 Demographic and Health Surveys (DHS) and Malaria Indicator Surveys (MIS) across 18 countries in sub-Saharan Africa collected between 2015 and 2019. Severe malaria was defined as children age 6-59 months with positive rapid diagnostic test for *Pfalciparum* malaria and at least one guardian-reported symptom of severe malaria, including loss of consciousness, rapid breathing, seizures, or severe anemia. The analysis includes a weighted descriptive pooled statistic and a multilevel mixed-effects logistic regression model adjusting for gender, age, wealth quintile, mother's education, and malaria endemicity. Children were excluded from the analysis if they recently sought care from a formal health facility or took ACTs in the past two weeks. Among malaria positive rural children who have not sought care or took an ACT in the past two weeks, 2.8% (95% CI 2.4-3.2) had at least one severe malaria symptom. Severe malaria was significantly

associated with the child's age and the walking time to health care facility. Children who reside over an hour walking distance away from a health facility were 1.4 times more likely to have severe malaria as compared to children who reside less than 1 hour walking distance from a health facility ( $p < 0.05$ ). This analysis highlights distance to health facilities is a strong predictor of severe malaria. Improving access to prompt treatment could potentially minimize the progression from uncomplicated to severe malaria.

#### **RECTAL ARTESUNATE ADMINISTRATION IS ASSOCIATED WITH LOWER REFERRAL COMPLETION OF CHILDREN WITH SUSPECTED SEVERE MALARIA IN NIGERIA AND THE DEMOCRATIC REPUBLIC OF THE CONGO**

**Nina Brunner**<sup>1</sup>, Giulia Delvento<sup>1</sup>, Tristan Lee<sup>1</sup>, Phyllis Awor<sup>2</sup>, Prosciova Athieno<sup>2</sup>, Joseph Kimera<sup>2</sup>, Antoinette Tshetu<sup>3</sup>, Jean Okitawutshu<sup>3</sup>, Jean-Claude Kalenga<sup>3</sup>, Elizabeth Omoluabi<sup>4</sup>, Kazeem Ayodeji<sup>4</sup>, Charles Okon<sup>4</sup>, Ocheche Yusuf<sup>4</sup>, Mughi Adamu<sup>4</sup>, Theodoor Visser<sup>5</sup>, Harriet Napier<sup>5</sup>, Valentina Buj<sup>6</sup>, Mark Lambiris<sup>1</sup>, Aita Signorelli<sup>1</sup>, Christian Burri<sup>1</sup>, Christian Lengeler<sup>1</sup>, Manuel Hetzel<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Makerere University School of Public Health, Kampala, Uganda, <sup>3</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>4</sup>Akena Associates, Abuja, Nigeria, <sup>5</sup>Clinton Health Access Initiative, Boston, MA, United States, <sup>6</sup>UNICEF, New York, NY, United States

Rectal artesunate is a potentially life-saving pre-referral treatment for children with suspected severe malaria. However, the rapid improvement of a child's condition after the administration of rectal artesunate may result in children not being taken to a potentially distant referral facility where appropriate treatment for severe malaria is available. Within the framework of the Community Access to Rectal Artesunate for Malaria (CARAMAL) project, we enrolled 3,964 children with suspected severe malaria attending a community health worker and 2,202 children attending a primary health facility in Nigeria, Uganda and the Democratic Republic of the Congo (DRC) between June 2018 and July 2020. Data collection started 10 months before and ended 15 months after the roll-out of rectal artesunate. All children were followed up 28 days after enrollment and their treatment seeking history was recorded. Referral completion was 68% in DRC, 49% in Nigeria, and 58% in Uganda. In country-specific multivariable logistic regression models, rectal artesunate administration was significantly associated with lower referral completion in DRC (adjusted odds ratio [aOR] = 0.46, 95% CI 0.35-0.59) and among children attending primary health facilities in Nigeria (aOR = 0.16, 95% CI 0.06-0.46). In Uganda, referral completion decreased after the roll-out of rectal artesunate (aOR = 0.74, 95% CI 0.64-0.86) but there was no direct association between rectal artesunate administration and referral completion after the roll-out. In the three countries, referral completion was higher among children presenting at primary health facilities compared to children presenting to community health workers. The roll-out of rectal artesunate seems to have an impact on referral rates and hence should be complemented by measures to ensure referral completion. Children who do not complete referral after rectal artesunate administration may be less likely to receive appropriate severe malaria treatment, with potentially negative consequences for their health outcome.

An estimated 409,000 deaths occurred due to severe malaria in 2019, with the WHO African Region disproportionately accounting for approximately 95% of global malaria deaths. Quantifying the burden of severe malaria and identifying which areas are affected most has important implications for resource allocation. Here, we quantify the relationship between age and the probability of severe malaria cases presenting with specific phenotypes using a large dataset from hospital admissions across different geographical locations, using a Bayesian framework. Further, we apply this relationship and an existing and extensively validated model of malaria transmission to quantify the number of severe malaria cases with a specific phenotype, as well as the number of deaths expected for all upper-level administrative divisions in countries of Sub-Saharan Africa. Severe malarial anaemia (SMA) was more common in infants and younger children whereas presentation with cerebral malaria (CM) increased in older children. In areas with lower transmission intensity, the distribution of severe malaria is skewed towards older ages and consequently, a larger proportion of severe cases presenting with CM. In children under 5, we estimate an incidence of 15.9 (events per 1000 persons per year) for severe malaria (SMA=8.5, CM=2.0, RDS=4.3, hyperlactatemia=6.0, other=3.0). Preliminary findings suggest that the estimated proportion of malaria deaths in under-fives that had SMA, CM, respiratory distress syndrome, and hyperlactatemia was 0.46, 0.39, 0.57, 0.62, respectively, with a large number of deaths characterised by the presence of multiple phenotypes. Further work aims to identify whether there is an interaction in the effects on mortality between different phenotypes or whether case fatality rates of individual phenotypes are independent. Understanding spatial variations in the burden of severe malaria and its phenotypes is important in informing distribution of community case management programmes in areas with higher burden or interventions targeting specific phenotypes (e.g. allocation of post-discharge prophylaxis interventions for SMA).

### EARLY TRANSCRIPTIONAL PROFILES INDUCED BY LMCEN-/- PARASITES IN EX VIVO INFECTION OF HUMAN MACROPHAGES

Sreenivas Gannavaram<sup>1</sup>, Charles Thomas<sup>1</sup>, Sydney Fenstermaker<sup>1</sup>, Abhay Satoskar<sup>2</sup>, Hira L. Nakhasi<sup>1</sup>

<sup>1</sup>US FDA, Silver Spring, MD, United States, <sup>2</sup>Ohio State University, Columbus, OH, United States

Live attenuated *Leishmania* parasites are being tested as potential vaccines against the blood borne parasitic pathogen *Leishmania*. We have developed centrin deleted live attenuated *Leishmania major* parasites using CRISP-Cas9 (LmCen<sup>-/-</sup>) as potential vaccine. Preclinical studies showed excellent safety and protective efficacy against wild type *Leishmania major* induced cutaneous infection following immunization with LmCen<sup>-/-</sup> parasites. To identify immune correlates of protection induced by infection with LmCen<sup>-/-</sup> parasites for advancing to clinical studies we performed ex-vivo infection of human macrophages obtained from blood donors (n=10) with wild type (LmWT) and attenuated (LmCen<sup>-/-</sup>) parasites. RNA sequencing followed by bioinformatic analysis were performed. Results revealed that distinct transcription profiles were induced in human macrophages infected with LmCen<sup>-/-</sup> parasites compared to uninfected controls or LmWT infections. Ingenuity pathway analysis revealed distinct networks of transcripts induced in LmCen<sup>-/-</sup> infection compared to LmWT infection. Notably, STAT5B mediated pro-inflammatory cytokines, INSIG1 mediated cholesterol biosynthesis, and TLR-9/CCR-7 mediated programming of M1 phenotype were all observed uniquely in LmCen<sup>-/-</sup> infection compared to LmWT infection. In contrast, pathogenicity associated IL-10 response was mainly observed in LmWT infection, consistent with previous studies. Our studies revealed novel immune correlates of protection in LmCen<sup>-/-</sup> infections of macrophages from non-endemic population and help validate the immunogenicity characteristics obtained from the pre-clinical studies in rodent models. These results would enable evaluation of the efficacy of LmCen<sup>-/-</sup> parasites as vaccine candidates by advancing our understanding of the immune mechanisms of protection induced by live attenuated LmCen<sup>-/-</sup> parasitic vaccines.

### INFLAMMATORY MONOCYTES HAVE A PROMINENT ROLE IN LEISHMANIA DONOVANI DISSEMINATION AFTER SKIN INFECTION IN MALNOURISHED MICE

Ashanti Concepcion Uscanga-Palomeque, E. Yaneth Osorio, Grace E. Patterson, Sara M. Dann, Bruno L. Travi, Peter C. Melby  
University of Texas Medical Branch, Galveston, TX, United States

Malnutrition plays an important role in dissemination of the visceralizing *Leishmania*. Our previous results showed that inflammatory monocytes (Imo) from malnourished MN mice have increased CCR7 expression, intrinsic migratory capacity, and trafficking from skin to spleen. For that reason, we hypothesized that Imo mediate *Leishmania donovani* dissemination in MN mice from skin to visceral organs. We used CCR7-specific siRNAi to knock-down CCR7 in monocytes isolated from bone marrow. A non-targeting siRNA was used as control. Transfer of CCR7-deficient monocytes into MN reduced parasite visceralization to the spleen compared to control monocytes ( $p=0.0015$ ). *Ex vivo* migration assay showed spleen soluble factors from MN mice induced greater monocyte migration compared with WN mice ( $p<0.001$ ). The migration was blocked by antibody neutralization of CCL19 and CCL21 (CCR7 ligands) and by inhibition of prostaglandin E<sub>2</sub> (PGE<sub>2</sub>) synthase inhibitor, which also reduced PGE<sub>2</sub> production and CCR7 expression. These results were corroborated using CCR7-KO mice where skin-derived infected Imo were decreased in spleen and draining lymph node (dLN) ( $p=0.01$ ). Since Imo egress from bone marrow is CCR2-dependent, we investigated *L. donovani* dissemination in CCR2-KO mice. CCR2 positive Imo were absent in the knockout mice, however, Imo CCR2 negative Ly6C<sup>hi/int</sup> were present in spleen. The proportion of monocytes and infected monocytes was decreased in the spleen and dLN of CCR2-KO mice. Finally, we use

an inducible Cre-diphtheria toxin transgenic system (CSFR1-DTR mice) to deplete Imo using diphtheria toxin (DT). Imo were effectively depleted from peripheral blood in CSFR1-DTR mice after DT treatment, reducing parasite dissemination to the dLN and liver, but not spleen. Cell population analysis in spleen showed that the DT did not deplete all monocytic populations. These results indicate that Imo have an important role in *L. donovani* dissemination, but other cell populations, such as neutrophils, may also contribute.

### IDENTIFICATION OF KLRC1+ Vδ2+ γδ T CELLS AS A CORRELATE OF PROTECTION IN PFSPZ VACCINATION USING A NOVEL PLATFORM FOR THE TRANSCRIPTOMICS META-ANALYSIS

Irfan Zaidi<sup>1</sup>, Robert L. Morrison<sup>1</sup>, Sara A. Healy<sup>1</sup>, Judith Epstein<sup>1</sup>, Mahamadou S. Sissoko<sup>2</sup>, Solomon Conteh<sup>1</sup>, B. Kim Lee Sim<sup>3</sup>, Thomas L. Richie<sup>4</sup>, Stephen L. Hoffman<sup>4</sup>, Patrick E. Duffy<sup>1</sup>

<sup>1</sup>National Institutes of Health, Bethesda, MD, United States, <sup>2</sup>Malaria Research and Training Center, Mali-NIAID ICER, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, <sup>3</sup>Protein Potential LLC, Rockville, MD, United States, <sup>4</sup>Sanaria Inc., Rockville, MD, United States

Sanaria PfSPZ@ Vaccine has demonstrated significant efficacy against *Plasmodium falciparum* (Pf) infections in both malaria naïve and exposed populations, where expansion of the Vδ2<sup>+</sup> γδ T cells have been associated with acquisition of sterile immunity. Similarly, in preclinical models, sterile immunity requires γδ T cells during the vaccination period, but these cells are not required as effectors during sporozoite infections. We performed RNA sequencing of peripheral blood samples on 56 subjects from three independent PfSPZ vaccine trials (two Mali, one US) and applied novel tools to report gene expression level and impute immune system differences at the cellular level. Specifically, we gathered 174 published RNAseq datasets spanning 28 sorted human immune cell subsets, including innate, B, and T cell subpopulations and differentiation status. A 28-way differential expression analysis identified associations of each gene to its cell type of highest differential expression, and created canonical cell type transcriptomes. Deconvolution was used to mathematically describe each PfSPZ participant sample as a blend of all 28 cell types, allowing quantification of changing cell type proportions directly from RNAseq data. KLRC1 was the most differentially expressed gene (along with Vδ2 γδ T cells markers such as TRDV2, TRGV9) between protected and unprotected vaccinees across all three trials. Cell subtypes Vδ2<sup>+</sup> and Vδ2<sup>-</sup> γδ T cells as well as NK cells, which have overlapping transcriptomes, associated with protection. Using ex vivo flow cytometry, we show that a subset of the Vδ2 γδ T cells express high levels of KLRC1 and are expanded in protected vaccinees after PfSPZ vaccinations. In a murine model of whole organism vaccination, we show that KLRC1 is highly expressed on the Vδ6.3 γδ T cell subset in the liver, and sterile immunity is diminished when these cells are depleted prior to vaccinations. In summary, we report a novel and robust approach for the analysis of transcriptomics data that identified KLRC1 as a key molecule during PfSPZ vaccinations and further validates the requirement of Vδ2 γδ T cells expansion in inducing sterile immunity.

France, <sup>6</sup>University of Leiden, Leiden, Netherlands, <sup>7</sup>Radboud University Medical Center, Nijmegen, Netherlands, <sup>8</sup>University of Abomey-Calavi, Cotonou, Benin

IgG specific for members of the *Plasmodium falciparum* erythrocyte membrane protein 1 (PfEMP1) family, which mediates receptor- and tissue-specific sequestration of infected erythrocytes (IEs), is a central component of naturally acquired malaria immunity. PfEMP1-specific IgG is thought to protect via inhibition of IE sequestration, and through IgG-Fc Receptor (FcγR)-mediated phagocytosis and killing of antibody-opsonized IEs. The affinity of afucosylated IgG to FcγRIIIa is elevated up to 40-fold compared to fucosylated IgG, resulting in enhanced antibody-dependent cellular cytotoxicity. Most IgG in plasma is fully fucosylated, but afucosylated IgG is elicited in response to enveloped viruses and to paternal alloantigens during pregnancy. Here we show for the first time ever that naturally acquired PfEMP1-specific IgG is likewise markedly afucosylated in a stable and exposure-dependent manner. In contrast, immunization with a soluble subunit vaccine based on VAR2CSA-type PfEMP1 resulted in fully fucosylated specific IgG. Finally, we demonstrate that afucosylation markedly impacts the ability of PfEMP1-specific IgG to induce NK-cell antibody-dependent cellular cytotoxicity (ADCC), as fucosylated IgG is unable to induce this response. These results have profound implications for understanding natural and vaccine-induced antibody-mediated protective immunity to malaria, and identifies a completely new aspect of antibody-mediated immunity to this disease.

#### **MATERNAL SCHISTOSOMIASIS REDUCES HUMORAL IMMUNITY OF OFFSPRING VIA DYSFUNCTIONAL B CELL PROGENITOR MATURATION AND RECEPTOR EDITING**

**Lisa C. Gibbs**, Juan Marcos Oviedo, Keke Fairfax

University of Utah, Salt Lake City, UT, United States

Maternal helminth infections are a global public health concern that correlates with altered infant immune responses to childhood immunizations and infection. A mechanistic understanding of how maternal infection and inflammation alters the immune responses of offspring is lacking but is critical to decrease childhood morbidity and to understand the consequences of specific long-lived immunity defects. Using our model of maternal *Schistosoma mansoni* infection, we have shown that murine pups born to mothers chronically infected with *Schistosoma mansoni* have reduced responses to vaccinations, similar to what has been reported in humans. Additionally, these pups have reduced humoral immunity cell frequencies in the draining lymph node following Tetanus/Diphtheria immunization. To determine the origin of this humoral immunity defect, we began investigating the plasticity and functionality of progenitors of lymphoid cells critical for a protective humoral response. We found an increase in the common lymphoid progenitors (CLPs) in the bone marrow of pups from Schistosome-infected mothers. Additionally, there is an increase in B cell skewing in pups from infected mothers, but a decrease in transitional B cells and mature B cells in the periphery. When immunized with a Tetanus/Diphtheria vaccination, there is a significant reduction in expansion of these progenitors in comparison to controls from uninfected mothers coupled with a decrease in bone marrow B cells after positive selection, suggesting a more exclusive selection process or differential selective pressure than in pups from uninfected mothers that is confirmed by single-cell RNAseq. We hypothesize that altered transcriptional regulation at the progenitor level caused by maternal Schistosomiasis is the mechanistic root of long-lived defects in humoral immunity to foreign antigens.

0450

#### **ESTIMATING TIMELINES TO ELIMINATION OF TRANSMISSION FOR SLEEPING SICKNESS AND MEASUREMENT OF THIS GOAL IN THE PRESENCE OF POSSIBLE CRYPTIC HUMAN AND ANIMAL RESERVOIRS**

**Maryam Aliee**<sup>1</sup>, Ron E. Crump<sup>1</sup>, Ching-I Huang<sup>1</sup>, Simon E. Spencer<sup>1</sup>, Chansy Shampa<sup>2</sup>, Matt J. Keeling<sup>1</sup>, Erick Mwamba Miaka<sup>2</sup>, Kat S. Rock<sup>1</sup>

<sup>1</sup>*Zeeman Institute: SBIDER, Warwick University, Coventry, United Kingdom,*

<sup>2</sup>*Programme National de Lutte contre la Trypanosomiase Humaine Africaine, Kinshasa, Democratic Republic of the Congo*

Sleeping sickness (*gambiense* human African trypanosomiasis, gHAT) is a vector-borne disease and one of the neglected tropical diseases. The World Health Organization has targeted gHAT for global elimination of transmission (EOT) by 2030. Despite this ambitious target, there are still unknowns surrounding the transmission cycle and natural history of disease in humans, which have the potential to impact the path to EOT and measurement of this goal. Firstly, there is evidence of asymptomatic infection of gHAT - with potential to self-cure or to harbour skin-only infection - and secondly there is also evidence of gHAT infection in animals and a debate around the possibility of animals maintaining transmission and the resultant impact on the goal. In this work, we compare predictions from two extensions of a baseline model to explore the potential role of asymptomatic human infection and animal reservoirs on achieving the elimination goals. We calibrated each model independently using the available historical human incidence data (from the WHO HAT Atlas) in different health zones in DRC and investigated how gHAT transmission changes in the two modified frameworks compared to the baseline model. This study provides a careful estimate of the impact of asymptomatic infections and animal reservoirs on reaching EOT and how this would alter monitoring of progress towards or achievement of EOT using routine surveillance data from active and passive screening. Our results suggest minor influences of animal transmission and asymptomatic infection on overall gHAT dynamics in many regions when models are fitted to the available data; in these regions the successful reduction in case burden to date could not have been achieved with large contributions from these infection reservoirs. However, neither animal reservoirs nor asymptomatic skin-only human cases contribute directly to the incidence data and so even low-level infection in these groups could impact how we should interpret case reporting data and our estimates of the likelihood that a health zone has already met EOT.

0451

#### **COST EFFECTIVENESS OF A COMMUNITY-BASED STRATEGY FOR THE DIAGNOSIS AND FOLLOW-UP OF TREATMENT IN PATIENTS WITH CUTANEOUS LEISHMANIASIS IN COLOMBIA**

**David E. Rebellen-Sanchez**<sup>1</sup>, Cesar Augusto Guevara-Cuellar<sup>2</sup>, Elizabeth Parody-Ra<sup>3</sup>, Jimena Jojoa<sup>4</sup>, Ruth Mabel Castillo<sup>4</sup>, Maria del Mar Castro<sup>4</sup>, Nancy G. Saravia<sup>4</sup>, Alexandra Cossio<sup>4</sup>

<sup>1</sup>*Centro Internacional de Entrenamiento e Investigaciones Medicas, Cali, Colombia,* <sup>2</sup>*Universidad Icesi, Cali, Colombia,* <sup>3</sup>*Universidad Icesi, Facultad de Ciencias Naturales, Centro de Estudios en Proteccion Social y Economia de la Salud (PROESA), Cali, Colombia,* <sup>4</sup>*Centro Internacional de Entrenamiento e Investigaciones Medicas, Universidad Icesi, Cali, Colombia*

Cutaneous leishmaniasis is a global public health problem. Over 40,000 cases per year occur in the Americas and Colombia has the second highest incidence. Most cases (82%) occur in rural areas and affect people living in poverty. Access to diagnosis and treatment is a challenge due to geographic, economic and armed conflict barriers. First line medication (intramuscular meglumine antimony for 20-28 days) is highly toxic; approximately 50% of patients lack access to treatment, and effectiveness of treatment is largely undocumented. We developed a community-based strategy to facilitate access to diagnosis, treatment and follow-up. We conducted a prospective cohort study between 2016 and 2019 in the Colombian Pacific coast to evaluate the cost-effectiveness of

this community-based strategy compared to the standard of care, from the patient, healthcare and societal perspectives. For diagnosis, a novel molecular test using filter paper samples taken by community leaders in rural areas and processed in a primary health facility was adapted, and Directly Observed Treatment using oral miltefosine, supervised by community leaders, was implemented. In the diagnostic phase 118 patients were enrolled. From the society and healthcare perspectives, microscopy of direct smear of lesions was less costly and more effective than the new molecular test, with an incremental cost-effectiveness ratio of \$ -7.46 dollars [mean US dollar 2017-2018 (1 USD = 2,956.43 Colombian pesos)] per patient correctly diagnosed. In the treatment phase (n=70), the costs of the intervention with miltefosine were lower than antimonials (\$3.99 ± \$1.12 vs \$87.99 ± \$8.13) from patients' perspective. Implementation of the new treatment strategy has a societal cost of \$4,071.24 / Quality Adjusted Life Years. Using the gross domestic product of Colombia as a reference, the new treatment intervention was cost-effective. Our study shows that a community based Directly Observed Treatment follow-up strategy is cost-effective and has potential to overcome the treatment access barriers for patients with leishmaniasis from isolated rural areas.

### MATHEMATICAL MODELLING OF SLEEPING SICKNESS IN NORTHERN UGANDA

**Ron E. Crump**<sup>1</sup>, Ching-I Huang<sup>1</sup>, Marina Antillon<sup>2</sup>, Paul R. Bessell<sup>3</sup>, Richard Selby<sup>4</sup>, Albert Mugenyi<sup>5</sup>, Paul E. Brown<sup>1</sup>, Andrew Hope<sup>4</sup>, Michelle Stanton<sup>4</sup>, Joshua Longbottom<sup>4</sup>, Simon E. Spencer<sup>1</sup>, Joseph Ndung'u<sup>6</sup>, Steve J. Torr<sup>4</sup>, Charles Wamboga<sup>5</sup>, Kat S. Rock<sup>1</sup>

<sup>1</sup>The University of Warwick, Coventry, United Kingdom, <sup>2</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>3</sup>Epi Interventions Ltd, Edinburgh, United Kingdom, <sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>5</sup>National sleeping sickness control programme, Kampala, Uganda, <sup>6</sup>Foundation for Innovative New Diagnostics, Geneva, Switzerland

Sleeping sickness (*gambiense* human African trypanosomiasis, gHAT) is a vector-borne disease targeted by the World Health Organisation for elimination of transmission (EOT) in humans by 2030. Uganda's gHAT cases have been reported in seven districts in the north of the country during the last two decades. Through a combination of medical interventions and, since 2011, vector control, the case burden has now been reduced to very low numbers. Between 2018 and 2020 only four Ugandan cases were reported across the districts as well as two additional reports of isolated importations from South Sudan diagnosed in Uganda. The goal of this study is to ascertain whether the current interventions are sufficient to maintain the gains and ensure permanent interruption of transmission while considering the resource implications. In this study we utilise a mathematical transmission model to assess the infection dynamics and case reporting in each district between 2000-2020 using data from the WHO HAT Atlas and the Ugandan National Programme. The model factors in improvements to passive screening, the introduction of vector control and variable active screening coverage over time. The fits suggest that local EOT has already been met in all districts, and that subsequent case reporting in the Ugandan population is likely to arise only from people infected several years ago, even if active screening and vector control are stopped. We expect there to be no indigenous case reporting beyond the next few years. These results support a plan to scale back vector control deployment, however this should be done with careful monitoring in place, especially with the potential of imported cases from South Sudan and the DRC to cause resurgence.

### ENVIRONMENTAL AND CLIMATIC DETERMINANTS OF LEISHMANIASIS RISK IN SRI LANKA: HISTORICAL VERSUS CONTEMPORARY CLIMATIC FACTORS AND LOCALIZED SEASONALITY

**Guofa Zhou**<sup>1</sup>, Nadira D. Karunaweera<sup>2</sup>

<sup>1</sup>University of California at Irvine, Irvine, CA, United States, <sup>2</sup>University of Colombo, Colombo, Sri Lanka

Leishmaniasis is a neglected tropical vector-borne infectious disease that poses an increasing public health threat in Sri Lanka. Disease assessment will help to identify high-risk areas to aid targeted intervention planning. We collected division-level leishmaniasis incidence data 2015-2019, historical average climatic data 1970-2000 and contemporary climatic and environmental data 2014-2019, and Sri Lanka-specific geoclimatic zones, climatic seasons, population and landscape data. We built three models using a gradient boosting machine (GBM) with multinomial logistic regression (MLR) analysis to examine the importance of historical versus contemporary climatic/environmental factors in predicting the high, moderate and low risks of leishmaniasis in Sri Lanka. Based on the observed clinical incidence, about half of the divisions could be classified as low risk and about a quarter of divisions with high risk. GBM-MLR results indicated that contemporary precipitation seasonality (relative influence RI = 1), log-transformed population density (RI = 0.90) and 2014-2018 average October-November minimum temperature (RI = 0.62) were the top three risk factors. Higher variation in 2014-2018 precipitation and lower population density were associated with higher leishmaniasis risk. Fourteen of the contemporary climatic/bioclimatic/climatic-season variables were among the top 20 risk factors. Land use land cover, geoclimatic zones, and vegetation indices were not among the top 20 risk factors. Model-predicted areas with high probability of low risk were along the coast, except in the south, and in the southwest of the country. Model predictions identified two high-risk areas, the north central and south coast, with high probability (>0.8). All models showed high uncertainty in predicting moderate-risk divisions and low uncertainty in predicting high- and low-risk divisions. Contemporary localized climatic/bioclimatic/climatic-season data were more powerful than historical data for predicting leishmaniasis transmission risks in Sri Lanka. Targeted interventions should focus on the high-risk areas.

### DEEP LEARNING APPROACHES FOR CUTANEOUS LEISHMANIASIS DIAGNOSIS BASED ON SKIN LESION IMAGES

**Emna Harigua-Souiai**<sup>1</sup>, Mohamed Ould Maouloud<sup>2</sup>, Ines Tej Abdeljaoued<sup>3</sup>, Maaoui Hariga<sup>4</sup>, Mourad Mokni<sup>5</sup>, Ikram Guizani<sup>2</sup>

<sup>1</sup>Artificial Intelligence for Health Development (AI4HD); Laboratory of Molecular Epidemiology and Experimental Pathology – LR16IPT04, Institut Pasteur de Tunis, Université de Tunis El Manar, Tunis, Tunisia, <sup>2</sup>Laboratory of Molecular Epidemiology and Experimental Pathology – LR16IPT04, Institut Pasteur de Tunis, Université de Tunis El Manar, Tunis, Tunisia, <sup>3</sup>Laboratory of Bioinformatics, Mathematics and Statistics – LR16IPT09, Institut Pasteur de Tunis, Université de Tunis El Manar, Tunis, Tunisia, <sup>4</sup>Artificial Intelligence for Health Development (AI4HD), immeuble Tamayouz B1.1, Centre Urbain Nord, Tunis, Tunisia, <sup>5</sup>Department of Dermatology – LR18SP01, Hopital La Rabta, Tunis, Tunisia

Cutaneous Leishmaniasis (CL) are a major public health issue worldwide. Although not lethal, these neglected diseases inflict major social impediment and morbidity. They affect the quality of life and self-esteem through life-lasting stigma, which leads to social isolation of the patients. Early diagnosis efficiently enhances patient management and treatment outcomes, thus mitigating the disfiguring aspects of CL. In this context, digital tools using artificial intelligence can be applied during the screening and decision-making steps, as they may easily be deployed in remote, peripheral and low-resources settings. We herein present a skin lesion processing system based on deep learning architectures,

able to recognize CL based on a simple photograph of a skin lesion. We gathered 636 images of CL lesions, collected from various sources including the Atlas of Leishmaniasis in the Americas. Besides, we used the ISIC dataset containing 25331 images of 8 types of skin cancer. The workflow is articulated in three components: Region Of Interest (ROI) detection, segmentation and classification. The first step is mandatory in preprocessing CL images as they present noise, different levels of contrast and are not lesion-focused. We trained YOLOv3 to detect lesions using 600 ISIC images and tested its performances on 150 images. A mean Average Precision mAP=89% was obtained. We then applied it to extract the lesions as ROI from the CL dataset and cropped lesions were subject to data augmentation. Second, we used the ISIC segmentation set to train the U-Net algorithm. This consists in making the algorithm able to differentiate normal skin from a lesion. With 95% accuracy, U-Net was used to segment the CL dataset prior to classification. Finally, we trained 4 architectures (VGG-16, ResNet50, InceptionV3 and NasNetLarge) on the ISIC (cancer) and the CL datasets. VGG-16 performed as the best classifier with 96% of accuracy. In next steps, we will evaluate the VGG-16 performances in classifying multiple skin conditions presenting a differential diagnosis with CL. This tool will be then deployed as a mobile application and validated in clinical settings.

### ONE-YEAR EFFICACY OF BENZNIDAZOLE OR NIFURTIMOX AMONG ASYMPTOMATIC TRYPANOSOMA CRUZI SEROPOSITIVE IN COLOMBIA: A PLACEBO-CONTROLLED RANDOMIZED TRIAL

Juan C. Villar<sup>1</sup>, Eliana Váquiro-Herrera<sup>2</sup>, Skarlet M. Vásquez<sup>3</sup>, Víctor M. Herrera<sup>3</sup>, Mario J. Olivera<sup>4</sup>, Juan D. Ramirez<sup>5</sup>, Adelina R. Riarte<sup>6</sup>

<sup>1</sup>Universidad Autónoma de Bucaramanga and Fundación Cardioinfantil - Instituto de Cardiología, Bogotá, Colombia, <sup>2</sup>Fundación Cardioinfantil - Instituto de Cardiología, Bogotá, Colombia, <sup>3</sup>Universidad Autónoma de Bucaramanga, Bucaramanga, Colombia, <sup>4</sup>Instituto Nacional de Salud, Bogotá, Colombia, <sup>5</sup>Universidad del Rosario, Bogotá, Colombia, <sup>6</sup>Instituto Nacional de Parasitología "Mario Fatala Chabén", Buenos Aires, Argentina

Despite apparent geographical variations in their effects, Benznidazole (BZN), and Nifurtimox (NFX, with less supporting data) are widely recommended treatments for *Trypanosoma cruzi* infection. Whether NFX is an effective trypanocidal therapy, and equivalent to BNZ, among Colombian patients, remains uncertain. We conducted a randomized trial (CHICAMOCHA 3, NCT02369978), allocating *T. cruzi*-seropositive (TCS+) adults with no apparent clinical disease to a 120-day blinded treatment BID with BZN, NFX or matching placebo (2:2:1 ratio). Active medication arms included a) 60-day conventional-dose (60CD) regimens with either BZN 300mg/day or NFX 480mg/day, (ratio 1:1), followed or preceded by a 60-day treatment with placebo in a randomly allocated sequence, or b) 120-day half-dose (120HD) regimens with either BZN 150mg/day or NFX 240mg/day (ratio 1:1). The primary outcome was the (intention-to-treat) proportion of participants with a positive PCR 12 months after randomization, after up to 3 tests (repeated if negative in the months 13 or 14). Out of 358 eligible individuals completing a 10-day run-in phase with placebo, 307 participants were randomized (mean age 50.6, SD 8.1 years, 42.7% females, 60% with normal EKG). Eighteen of 246 participants receiving active agents (7.3%, 4.0% on CD vs. 10.7% on HD,  $p=0.042$ ) abandoned their treatment, as opposed to 3/61 on placebo. After the first run of PCR ( $n=288$ , 93.8%, 2-5 lost for analysis in each group), 45/59 (76.3%) placebo-treated participants tested positive. This compares with 84/116 (72.4%) for NFX-treated,  $p=0.584$  (40/58 [69%] and 44/58 [75.9%] in the 60CD and 120HD groups), and 74/113 (65.5%),  $p=0.146$  for BZN-treated (38/57 [66.7%] and 36/56 [64.3%] for 60CD and 120HD groups). We found no evidence that treatment regime impacted on the effect of the agents used ( $p$  value for interaction=0.100). In conclusion, neither a treatment with NFX, nor BZN significantly reduced the parasitic load in this sample of Colombian TCS+ individuals. Using 120HD vs. 60CD regimens did not change efficacy, but implied lower adherence. Testing new agents for this population is warranted.

0456

### IN HOUSE ENZYME LINKED IMMUNOSORBENT ASSAY (ELISA) AS A SENSITIVE DIAGNOSTIC TOOL OF CUTANEOUS LEISHMANIASIS CAUSED BY LEISHMANIA DONOVANI

H.S.B. Piyasiri<sup>1</sup>, T.N. Samaranyake<sup>1</sup>, N.H. Silva<sup>1</sup>, N. Manamperi<sup>2</sup>, N.D. Karunaweera<sup>1</sup>

<sup>1</sup>Department of Parasitology, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka, <sup>2</sup>Department of Parasitology, Faculty of Medicine, University of Kelaniya, Kelaniya, Sri Lanka

Leishmaniasis includes several clinical forms. Serological tests with high sensitivity and specificity are currently available diagnosis of visceral leishmaniasis. While routine diagnosis of cutaneous leishmaniasis (CL) is by microscopy an antibody response to CL has been reported in several recent studies. The objective of this study was to evaluate the detection of anti-leishmanial IgG antibodies as a diagnostic tool in a setting endemic for CL caused by *Leishmania donovani*. Study was carried out with sera collected from patients (50 untreated patients and 140 patients under treatment) and 280 healthy controls from endemic areas as part of an epidemiological survey. All patients had cutaneous lesions positive for *Leishmania* parasites by microscopy and or culture. Clinical features of the patients were recorded using a standardized questionnaire. Sera from patients, endemic healthy controls and 14 healthy controls from non-endemic areas were tested by an in-house indirect enzyme linked immunosorbent assay (ELISA) established using crude antigens of *L. donovani*. Receiver operating characteristics curve (ROC) was used to determine the cut-off. Cut-off was 0.147 at 98.0% test sensitivity and 91.4 % test specificity. The mean absorbance level of anti-leishmanial antibodies was significantly higher ( $p = 0.000$ ) in untreated patients ( $0.392 \pm 0.152$ , Range: 0.112 - 0.928) in comparison to patients under treatment ( $0.210 \pm 0.154$ , range: 0.030 - 0.882), endemic healthy controls ( $0.091 \pm 0.046$ , range: 0.012 - 0.290) and non-endemic healthy controls ( $0.071 \pm 0.019$ , range: 0.040 - 0.104). Positive ELISA results were observed in 96/140 (68.6%) patients under treatment, 49/50 (98.0%) of untreated CL patients and 22/280 (7.85 %) of endemic healthy controls and were found to be seropositive for anti-leishmanial IgG antibodies whereas the non-endemic healthy controls were 100% seronegative. The present study demonstrates that the developed indirect ELISA can reliably diagnose a person with active disease in an endemic setting.

Acetyl-CoA is an essential metabolite at key junctions of cellular and metabolic processes including gene regulation through protein acetylation. One route to producing this cofactor in the human malaria pathogen, *Plasmodium falciparum*, is via direct synthesis from acetate catalyzed by the parasite's acetyl-CoA synthetase, *PfAcAS* (PF3D7\_0627800). To study *PfAcAS*, we used CRISPR-Cas9 to introduce a C-terminal epitope tag and a TetR-DOZI- RNA aptamer module to conditionally regulate *PfAcAS* expression levels. We determined that *PfAcAS* is essential for parasite growth, and its knockdown results in multiple defects across the intra-erythrocytic developmental cycle including: stalling of development at

trophozoite stage; compromised daughter cell segmentation; and failure to egress from the host red blood cell. *PfAcAS* predominantly localizes to the nucleus, but redistributes to nuclear-associated punctate structures in late stages, suggesting a potential role in acetylation of nuclear proteins such as histones involved in gene regulation. Indeed, functional studies demonstrated inhibition of histone acetylation in *PfAcAS* knockdown but not in wild-type parasites. Amongst other systems-level approaches, we are using developmental stage-dependent transcriptomic analyses to determine whether *PfAcAS* knockdown impacts global gene expression. Interestingly, evolution of resistance and whole-genome sequencing identified several compounds as potential inhibitors of *PfAcAS*. A phenotypic screening platform, based on our conditional gene regulation technology, provided further verification of these compounds as specific *PfAcAS* inhibitors. Altogether, these findings demonstrate that *PfAcAS* is critical for proper blood stage parasite development and constitutes a promising antimalarial target.

0458

### GETTING IN SHAPE: A NEW PROTEIN COMPLEX REQUIRED FOR MALARIA BLOOD-STAGE PARASITE FORMATION

**James Blauwkamp**, Sabrina Absalon

*Indiana University School of Medicine, Indianapolis, IN, United States*

The human malaria parasite *Plasmodium falciparum* is a major cause of death around the world, and resistance to current treatments is a threat to malaria control. Clinical symptoms of malaria are caused by the parasite replication inside of host red blood cells and exploring the mechanisms of this replication can identify novel therapeutic targets. The inner membrane complex (IMC) is a membranous organelle that coordinates that shape of parasites and invasion into host cells. Despite our knowledge of IMC function and composition, we do not know the molecular mechanisms that underly IMC biogenesis. Here we describe a novel *Plasmodium* specific protein that is required for IMC biogenesis, which we have named PfAnchor. We utilized a CRISPR/Cas9-based system to endogenously tag PfAnchor and introduce the Tet-repressor knockdown system. Using immunofluorescence assays, we localized PfAnchor near the IMC during blood stage replication. PfAnchor deficient parasites halted IMC biogenesis at early stages of formation, leading to parasite death. Co-immunoprecipitation experiments showed PfAnchor interacting with a GTPase-containing protein named Dynammin-like protein 2 (PfDyn2). We also generated parasites with tagged PfDyn2 under the control of the Tet-repressor knockdown system. Like PfAnchor, PfDyn2 localized near the growing IMC, and IMC biogenesis halted in PfDyn2-deficient parasites leading to parasite death. All together, we have identified two novel *Plasmodium* specific proteins that are required for IMC formation and parasite blood stage replication. Currently, we are investigating potential PfAnchor interacting proteins using proximal labeling combined with co-immunoprecipitation to gain an understanding of the mechanism of the PfAnchor-PfDyn2 complex, as well as investigating the role of the GTPase domain of PfDyn2 in IMC biogenesis.

0459

### GENETIC ABLATION OF SEX-SPECIFIC TRANSCRIPTION FACTORS IN CRYPTOSPORIDIUM: DISSECTING THE REGULATORY PATHWAYS OF SEXUAL DEVELOPMENT AND REPRODUCTION

**Katelyn A. Walzer**, Jayesh Tandel, Jessica H. Byerly, Jodi A. Gullicksrud, Elise Krespan, Daniel P. Beiting, Boris Striepen

*University of Pennsylvania, Philadelphia, PA, United States*

The parasite *Cryptosporidium* is a leading cause of diarrheal disease and infects millions of people worldwide each year, with a disproportionately high burden on children in south Asia and sub-Saharan Africa. There is no vaccine and only limited treatment. A greater understanding of *Cryptosporidium* biology is necessary to identify the stages that can be targeted by therapeutics or vaccines to block infection and transmission. The parasite life cycle begins upon ingestion of the oocyst, which releases

invasive sporozoites into the gut. These invade intestinal epithelial cells and initially propagate asexually before transitioning to male and female gametes. Sex then leads to the production of new oocysts. While these stages are clearly distinguished morphologically, the genes which define them remain largely unknown. Recently, we developed a *Cryptosporidium* single-cell atlas which documents the transcriptional changes that occur throughout the life cycle and reveals an abrupt switch to male or female development. We discovered AP2 and Myb transcription factors associated with this conversion to sexual development and initiated functional characterization. Three factors were deemed essential *in vivo*: Myb-M, AP2-M, and AP2-F, with Myb-M expressed in the earliest males and AP2-M and AP2-F expressed during later stages of male and female development, respectively. To enable genetic studies of these essential genes, we developed a conditional gene regulation system to either ablate factors or to force their expression at different phases of the life cycle. We used this approach to conditionally ablate AP2-F and observed downregulation of meiotic genes *in vitro* and a significant loss of shed oocysts *in vivo*, implicating that this gene is involved in the post-fertilization stage and may be used as a transmission-blocking target. Current work is focused on dissecting the roles of the two essential male transcription factors and their capacity to drive male fate.

### PLASMODIUM FALCIPARUM UTILIZES TWO CRITICAL BUT DISTINCT MEMBRANE FUSOGENS FOR GAMETE FERTILIZATION

**Sudhir Kumar**<sup>1</sup>, Clari Valansi<sup>2</sup>, Meseret T. Haile<sup>1</sup>, Xiaohui Li<sup>2</sup>, Biley A. Abatiyow<sup>1</sup>, Amanda S. Leeb<sup>1</sup>, Nelly M. Camargo<sup>1</sup>, Ashley M. Vaughan<sup>1</sup>, Benjamin Podbilewicz<sup>2</sup>, Stefan H. Kappe<sup>1</sup>

<sup>1</sup>Seattle Children's Research Institute, Seattle, WA, United States, <sup>2</sup>Israel Institute of Technology, Haifa, Israel

The fertilization of the female *Plasmodium* gamete by the male gamete occurs in the mosquito midgut and is the central event in sexual reproduction. Fertilization requires gamete fusion and represents a major bottleneck in the malaria life cycle. In many plant species and lower eukaryotes, the Hapless 2 (HAP2)/Generative Cell Specific 1 (GCS1) family of proteins are conserved and mediate gamete fusion. Although HAP2 is encoded by a single gene in most of these species, *Plasmodium falciparum* expresses two distinct paralogs: *PfHAP2* and *PfHAP2p*. While *PfHAP2* is expressed exclusively by the male gamete, *PfHAP2p* is expressed by both sexes. Gene deletion analyses shows that both *PfHAP2* and *PfHAP2p* are essential for zygote formation and thus for parasite infection of the mosquito. Importantly, using a mammalian cell fusion assay, we demonstrate that *PfHAP2* is a *bona fide* membrane fusogen. Furthermore, antibodies targeting a critical fusion peptide (the *cd*-loop) of *PfHAP2p* blocks parasite transmission to mosquitoes. Our results demonstrate essential roles for *PfHAP2* and *PfHAP2p* in mediating gamete fusion in *Plasmodium falciparum* and their potential as a transmission blocking target.

Globally 2.6 million stillbirths occur annually, yet there are major knowledge gaps about their causes and the circumstances associated with these events. Investigating causes of stillbirth is critical to proposing effective preventive measures. The Child Health and Mortality Prevention Surveillance (CHAMPS) Network was established to understand and track causes of stillbirths and childhood deaths in South Asia and Sub-Saharan Africa by routinely conducting postmortem minimally invasive tissue sampling (MITS). We aimed to describe the main conditions of stillbirths and their epidemiologic characteristics across 7 CHAMPS sites. Between December of 2016 and 2019, 453 stillbirths were enrolled and underwent MITS. The determination of cause of death process was completed for 433 of these stillbirths by March 2021 and an expert panel determined the main condition based on histopathology of MITS, microbiological diagnostics, clinical data abstraction, and verbal autopsies. Of these 433 cases, 415 (96%) stillbirths were delivered at a healthcare facility and 184 (42%) were macerated stillbirths. The most frequent main condition was intrauterine hypoxia (326/433; 75%), ranging from 58% in South Africa to 91% in Kenya followed by congenital infections (48/433; 11%), with *Streptococcus* species, *E. coli*/*Shigella* species and cytomegalovirus being

the most common etiologies. The majority of congenital infections were documented in macerated stillbirths (31/48, 65%). In 21% (90/433) of cases, the main maternal condition was placental complications, mostly separation of placenta. Maternal hypertension was the main maternal condition leading to stillbirth in 17% (74/433) of cases. The expert panels in each country concluded that 70% (303/433) of all stillbirths were preventable through increased access to antenatal care, intrapartum fetal monitoring, earlier C-section and improved obstetric care. Systematic monitoring and inclusion of stillbirth rate as a marker of quality maternal care is critical to generate robust evidence that can aid stakeholders in formulating feasible strategies to reduce the burden of stillbirths globally.

0462

## ETIOLOGY OF DEATH AMONG INFANTS AND CHILDREN ENROLLED THROUGH THE MULTISITE CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE (CHAMPS) NETWORK

In spite of the increasing importance of the neonatal period to overall child mortality, 2.8M deaths still occur globally each year in children aged 1-59 months (53% of all U5 deaths). Characterizing post-neonatal deaths may help to improve child survival. The Child Health and Mortality Prevention Surveillance (CHAMPS) Network conducts childhood mortality surveillance in Sub-Saharan Africa and South Asia, innovatively using postmortem minimally invasive tissue sampling (MITS). We describe the causes of post-neonatal mortality across CHAMPS sites in 7 countries. 502 MITS on child deaths (263 in infants; 239 in children 12-59 months) were completed between 2016 and 2019. Expert panels at each site determined the underlying condition and chain of events leading to death, based on histopathology, microbiological diagnostics, clinical data, and verbal autopsies. The 5 most common underlying causes of death were malnutrition (80/502; 15.9%); HIV (59, 11.8%); malaria (53, 10.6%); congenital birth defects (52, 10.4%) and lower respiratory tract infections (LRTI; 42, 8.4%). However, when considering any position (underlying, antecedent, immediate) occupied within the chain of events leading to death, LRTI (232, 46.2%) and sepsis (192; 38.3%) contributed to nearly half and one third of all deaths, respectively. Pathogens most frequently

contributing to death included *Klebsiella pneumoniae* (133; 26.5%), *Streptococcus pneumoniae* (89; 17.7%) and *Plasmodium falciparum* (88; 17.5%). Among the 5 top underlying causes of death, the median number of other conditions in the chain of events leading to death was 3 for malnutrition, 3 for HIV, 1 for malaria, 3 for congenital birth defects and 1.5 for LRTI. 76% (382/502) of all post-neonatal deaths were considered preventable by the expert panels. CHAMPS results highlight gaps and opportunities for action to effectively prevent death during infancy and childhood and reveals the common interaction of various etiologies in the path towards death. The significance of *Klebsiella Pneumoniae*, hitherto insufficiently recognized, calls for a closer focus on this particular pathogen to improve child survival.

### COST-BENEFIT ANALYSIS OF FOUR-PANEL RAPID SCREENING IN ANTENATAL CARE IN THREE COUNTRIES IN SUB-SAHARAN AFRICA

Donald S. Shepard<sup>1</sup>, Katharine R. Rowlands<sup>1</sup>, Maria Kulchyskyj<sup>1</sup>, Robert K. Basaza<sup>2</sup>, Emmanuel D. Otieno<sup>3</sup>, Simon K. Kariuki<sup>4</sup>, Sabine F. Musange<sup>5</sup>

<sup>1</sup>Brandeis University, Waltham, MA, United States, <sup>2</sup>Uganda Christian University, Mukono, Uganda, <sup>3</sup>Bugema University, Kampala, Uganda, <sup>4</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>5</sup>National University of Rwanda School of Public Health, Kigali, Rwanda

We performed an economic analysis of a new technology used in antenatal care (ANC), the ANC panel. Introduced in 2019-2020 in 5 Rwandan districts, the ANC panel screens for 4 infections (hepatitis B, HIV, malaria, and syphilis) using a blood sample from a single fingerstick. It increases the scope and sensitivity of screening. We developed an Excel-based mathematical and economic model to perform cost-effectiveness and cost-benefit analyses of this technology. We used it first for these Rwandan districts and then applied it to 2 neighboring sub-Saharan African countries (Uganda, and Kenya). Key parameters included the infant mortality rate, life expectancy, and rates of positivity (with 95% confidence intervals, CI) and treatment success of each infection. Rwanda had actual current positivity rates, compared to literature estimates for Uganda and Kenya. We calculated costs by combining the cost of the ANC panel, its administration, and follow-up treatment. We conducted a literature review of the impacts of the four infections on maternal and infant health. We used data from in-country and international sources, and expert opinion. Benefit-cost ratios (with positivity CIs) for each country were 21.9 (21.3-22.4) in Rwanda, 8.4 (8.2-8.9) in Uganda, and 10.0 (9.2-10.6) in Kenya. The ANC panel averted 76 (71-81) disability-adjusted life years (DALYs) per 1,000 women in ANC in Rwanda, 204 (181-234) in Uganda, and 121 (98-144) in Kenya. Net economic benefits per woman ranged from \$105 (\$100-\$111) in Rwanda, \$165 (\$149-\$190) in Uganda, and \$213 (\$171-\$255) in Kenya. Net healthcare costs per woman ranged from -\$40.52 to -\$43.68 in Rwanda, -\$6.01 to -\$7.71 in Uganda, and -\$0.30 to -\$2.82 in Kenya. With negative net costs, the ANC panel saved healthcare costs in all three countries. Each \$1 in ANC screening generated societal economic benefits worth \$8 to \$22. By combining literature and field data, the ANC model is applicable to other countries and technologies in sub-Saharan Africa.

0464

### DISTANCE MATTERS: BARRIERS TO ANTENATAL CARE AND SAFE CHILDBIRTH IN A MIGRANT POPULATION ON THE THAILAND-MYANMAR BORDER FROM 2007-2015, A PREGNANCY COHORT STUDY

Eric Steinbrook<sup>1</sup>, Myo Chit Min<sup>2</sup>, Ladda Kajeewiwa<sup>2</sup>, Jacher Wiladphaingern<sup>2</sup>, Moo Kho Paw<sup>2</sup>, MuPawJay Pimanpanarak<sup>2</sup>, Woranit Hiranloetthanyakit<sup>2</sup>, Aung Myat Min<sup>2</sup>, Nay Win Tun<sup>2</sup>, Mary Ellen Gilder<sup>2</sup>, Francois Nosten<sup>2</sup>, Rose McGready<sup>2</sup>, Daniel M. Parker<sup>2</sup>

<sup>1</sup>University of Michigan Medical School, Ann Arbor, MI, United States, <sup>2</sup>Shoklo Malaria Research Unit, Mae Sot, Thailand

Background: Antenatal care and professional childbirth services are important interventions to improve maternal health and lower the risk of poor pregnancy outcomes and mortality. Recent literature has shown that distance to clinics can be a disincentive towards seeking care during pregnancy. On the Thailand-Myanmar border antenatal clinics serving migrant workers have found high rates of loss to follow-up of 17.4%, but decades of civil conflict have made this difficult to study. Here we perform a comprehensive study examining the geographic, demographic, and health-related factors contributing to loss to follow-up. Methods: Using patient records we conducted an epidemiological analysis looking for predictors of loss to follow-up and pregnancy outcomes between 2007-2015. We used multivariable regressions to assess for predictors of loss to follow-up, pregnancy complications, and time of first presentation for antenatal care. Results: We found distance travelled to clinic strongly predicts loss to follow-up, miscarriage, malaria infections in pregnancy, and presentation for antenatal care after the first trimester. Women lost to follow-up travelled 45% farther than women who had a normal singleton childbirth (a ratio of distances (DR) 1.45; 95% confidence interval (CI): 1.40 – 1.51). Women with pregnancies complicated by miscarriage travelled 23% farther than those who did not have miscarriages (DR: 1.23; CI 1.14 - 1.31), and those with *Plasmodium falciparum* malaria in pregnancy travelled 62% farther than those without *P. falciparum* (DR: 1.62; CI: 1.44 – 1.82). Women who delayed antenatal care until the third trimester travelled 46% farther compared to women who attended in the first trimester (DR: 1.46; CI: 1.39 – 1.53). Conclusions: This analysis provides the first evidence of the impact of distance on access to antenatal services and pregnancy outcomes in the rural, remote, and politically complex Thailand-Myanmar border region. Our findings can be applied to other similar environments, in which increased patient support services may be required to improve continuity of care and provide for a more positive pregnancy experience.

### TWIN PREGNANCIES: HIGH RISK OF PERINATAL DEATH, PRETERM BIRTHS, AND MATERNAL COMPLICATIONS IN RURAL BANGLADESH

Kyu Han Lee<sup>1</sup>, Shahana Parveen<sup>2</sup>, Mohammad Z. Hossain<sup>2</sup>, Atique I. Chowdhury<sup>2</sup>, Solveig A. Cunningham<sup>3</sup>, Dianna Blau<sup>4</sup>, Qazi S. Rahman<sup>2</sup>, Kazi M. Islam<sup>2</sup>, Sanwarul Bari<sup>2</sup>, Shams E. Arifeen<sup>2</sup>, Emily S. Gurley<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>icddr, Dhaka, Bangladesh, <sup>3</sup>Emory University, Atlanta, GA, United States, <sup>4</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Twin pregnancy rates vary by geographic region, ranging from 8-19 per 1000 deliveries. Compared to singletons, twin pregnancies involve higher risk for adverse outcomes for babies and mothers, including premature birth, neonatal and maternal death, and severe maternal complications. In this study, we describe the risk of adverse outcomes among twin pregnancies in Baliakandi, a rural sub-district of Bangladesh. We used a health and demographic surveillance system to identify births and deaths between Sep 2017-Dec 2019. In Dec 2018, we began detailed pregnancy surveillance to collect data on pregnancy and delivery, including complications and antenatal care (ANC). Excluding miscarriages/abortions,

we identified 11547 deliveries; 102 were twin deliveries (8.8 per 1000 deliveries): 90 live birth, 4 stillbirth, and 8 discordant pairs. Compared to singletons, twins were more likely to be delivered at a health facility (79% vs 66%, 79/102 v 7608/11434;  $\chi^2$  p<0.018), preterm (57% v 20%, 58/102 v 2301/11445;  $\chi^2$  p<0.001), and stillborn (78 v 45 per 1000 births, 16/204 v 268/11445; Fisher p<0.001). Twin live births were more likely to end in early neonatal death (175 v 22 per 1000 live births, 28/160 v 245/10932; Fisher p<0.001). Compared to singletons, women with twin pregnancies in 2019 were more likely to report complications during pregnancy (62% v 42%, 28/45 v 2306/5468;  $\chi^2$  p=0.010) and delivery (51% v 31%, 23/45 v 1709/5481;  $\chi^2$  p=0.007). Statistically significant complications included hemorrhagic (16% v 7%, 7/45 v 378/5520,  $\chi^2$  p=0.032) and hypertensive disorders (14% v 5%, 6/43 v 268/5135,  $\chi^2$  p=0.023). There were no significant differences in attending  $\geq 4$  ANC visits (39% v 32%, 17/44 v 1676/5159;  $\chi^2$  p<0.481) and receiving key procedures such as blood pressure checks, urine tests, blood tests, and ultrasounds (range 48-71%, all  $\chi^2$  p>0.05). Twin pregnancies are at higher risk of adverse outcomes compared to singletons and require added preventative measures including more frequent ANC visits and maternal/fetal testing. Our findings suggest this may not be practiced in Baliakandi and emphasize a need for early detection and improved local care.

## 0466

### HIGH BURDEN OF NEURAL TUBE DEFECTS IN EASTERN HARAGHE, ETHIOPIA: INITIAL FINDINGS FROM CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE

**Haleluya Leulseged**<sup>1</sup>, Tseyon Tesfaye<sup>1</sup>, Tadesse Dufera<sup>1</sup>, Tadesse Gure<sup>1</sup>, Addisu Alemu<sup>1</sup>, Yunus Edris<sup>1</sup>, Nega Assefa<sup>1</sup>, Lola Madrid<sup>2</sup>

<sup>1</sup>College of Health and Medical Sciences, Haramaya University, Harar, Ethiopia, <sup>2</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Neural tube defects (NTDs) can result in fetal loss and severe disability in children and, most of them are related to folate deficiency in the mother. In Ethiopia, the estimate rate of neural tube birth defects is 2 cases per 1,000 live births although published data from northern Ethiopia showed up to 13 cases per 1,000 births. In spite of a lack of data from Eastern Ethiopia, a recent nutritional survey in reproductive-aged women of Ethiopia in the region found that 81% were folate deficient, almost two times the national prevalence (46%); The public health recommendation to reduce burden of NTDs is mandatory folic acid fortification, but this policy is yet to be legislated in Ethiopia. Child Health and Mortality Prevention Surveillance (CHAMPS) aims to determine causes of death (CoD) among <5 children (U5) using Minimally Invasive Tissue Sampling (MITS) and advanced diagnostic methods. Mortality surveillance was established in a demographic surveillance system (DSS) area in Eastern Ethiopia in February 2019. A notifications system was implemented to detect MITS-eligible deaths (stillbirths and U5 children who died within the last 24 hours and were DSS members). An expert panel assigned the final CoD after analysing clinical information, pictures, microbiological and histopathological findings, and verbal autopsy. From 4<sup>th</sup> February 2019 to 3<sup>rd</sup> February 2021, families of 196 (63.8%) among 307 MITS-eligible deaths were approached and consented for MITS. Of these, CoD was assigned for 129; 67 stillbirths, 42 neonates and 20 U5 infants/children. Among them, nine had a neural tube defect (7%), all identified as the underlying cause of death, 8/67 stillbirths (12%) and one neonate/42 (2%) who died within 24h of birth. The most common type of NTD was anencephaly (5/9, 60%), of which three had craniorachischisis. Mortality surveillance identified that NTDs are common among stillbirths in Eastern Ethiopia, a region with high prevalence of folate deficiency among reproductive-aged women. Due to the lethality and disability of NTDs, the role of folic acid fortification as public health intervention to prevent NTDs in Ethiopia urgently needs to be explored.

## 0467

### SUSTAINABLE PALM WEEVIL FARMING TO ADDRESS FOOD INSECURITY AND INCOME GENERATION AT MATERNITY WAITING HOMES IN LIBERIA: A PROOF-OF-CONCEPT PROJECT EVALUATION

**Jacob Paarechuga Anankware**<sup>1</sup>, Joseph E. Perosky<sup>2</sup>, Alphonso Kofa<sup>3</sup>

<sup>1</sup>University of Energy and Natural Resources, Sunyani, Ghana, <sup>2</sup>Spectrum Health, Department of Obstetrics and Gynecology, Michigan State University College of Human Medicine, East Lansing, MI, United States, <sup>3</sup>Bong County Health Team, Bong County, Liberia

Food insecurity is widespread in Liberia, with every fifth household considered food insecure. Nearly two-thirds of pregnant women in Liberia are anemic. In 2010, the University of Michigan and the Bong County Health Team established the first six maternity waiting homes (MWHs) in post-conflict Liberia where women in the late stages of pregnancy stay to await safe childbirth. In 2018, a country-wide assessment of 118 MWHs across Liberia was conducted to understand successes and barriers to scale-up. Food security at MWHs was identified as a barrier to their use. Women and community members residing at these MWHs identified indigenous insects are an acceptable food source consumed by pregnant women in rural areas. The goals of the current intervention were to: 1) educate local Liberians on the concept of rearing edible insects; 2) train participants residing at MWHs to complete two cycles of insect production; 3) evaluate insect farming as a potential income generating activity for MWHs. Training was successfully conducted for 60 participants at four MWHs in Bong County, Liberia. Participants were provided palm larvae rearing kits, starter culture of adults, larvae and a wooden structure. Three of the four sites were able to produced larvae for consumption, while two were also able to produce additional product for income generation. The three most common methods of palm weevil preparation were grilled (50%), boiled (25%), and fried (25%). In terms of production patterns, 50% of the participants indicated that the production of palm weevil larva was successful whilst 25% reported their production was limited due to challenges such as sourcing of palm yolk and cassava feed for larvae production. The intervention was able to reduce food insecurity for pregnant women awaiting delivery and served as an income generating activity at one MWH through the sale of palm weevils. Rearing palm larvae has the potential to provide a sustainable source of high protein food supplement at rural MWHs in Liberia while also serving as an income generating activity.

## 0468

### HUMAN-IMMUNE-SYSTEM HUMANIZED DRAGA MICE AS SURROGATE IN VIVO HUMAN MODEL FOR COVID-19 RESEARCH AND GENERATION OF THERAPEUTIC HUMAN MONOCLONAL ANTIBODIES

**Sofia A. Casares**<sup>1</sup>, Ahmad Karim<sup>1</sup>, Teodor Brumeanu<sup>2</sup>, Pooja Vir<sup>2</sup>, Kathleen Pratt<sup>2</sup>, Kevin Chung<sup>2</sup>, Swagata Kar<sup>3</sup>

<sup>1</sup>Naval Medical Research Center, Silver Spring, MD, United States, <sup>2</sup>Uniformed Services University of Health Sciences, Bethesda, MD, United States, <sup>3</sup>BioQual Inc, Rockville, MD, United States

There is an urgent need for generation of animal models for SARS-CoV-2 to accelerate development of vaccines and therapeutics for COVID-19. Herein, we report the first human-immune-system humanized mouse model ("DRAGA": HLA-A2.HLA-DR4.Rag1KO.IL-2RgcKO.NOD) for COVID-19 research. This mouse reconstitutes a functional human-immune-system upon infusion of HLA-matched human hematopoietic stem cells from umbilical cord blood. The DRAGA mouse also reconstitutes human epithelial and endothelial cells expressing the human ACE2 receptor for SARS-CoV-2, and TMPRSS2 serine protease co-localized on human lung epithelial cells, as demonstrated by immunofluorescence microscopy (IFA). All DRAGA mice (n=17) challenged by the intranasal route with SARS-CoV-2 (10<sup>3</sup> pfu/mouse) became infected, showing deteriorated clinical condition (5%-15% loss body weight, ruffed fur, hunched back,

reduced mobility), replicating virus in the lungs as measured by RT-qPCR, and human-like lung immunopathology including human T-cell infiltrates, microthrombi and pulmonary sequelae. Among T-cell infiltrates, lung-resident (CD103<sup>+</sup>) CD8<sup>+</sup> T cells were sequestered in epithelial (CD326<sup>+</sup>) lung niches and secreted granzyme B and perforin as measured by IFA, indicating cytotoxic potential. All SARS-CoV-2 infected DRAGA mice also developed human antibodies against the SARS-CoV-2 viral proteins at day 25 post-infection. Using human B cells from immunized DRAGA mice we have generated a panel of human monoclonal antibodies (hmAbs, n=9) against the SARS-CoV-2 spike receptor-binding-domain (RBD). The hmAbs have been re-engineered on different Ig-Fc scaffolds (IgG1 and IgG2) to investigate the role of Ig-Fc biological functions on their prophylactic and therapeutic efficacy against SARS-CoV-2. In summary, DRAGA mice proved to be a surrogate *in vivo* human model for SARS-CoV-2/COVID-19 research, and a unique research resource for generation of therapeutic hmAbs against emerging infectious diseases.

0469

### THE SARS-COV-2 SPIKE GLYCOPROTEIN INDUCES EPITHELIAL AND ENDOTHELIAL BARRIER DYSFUNCTION AND VASCULAR LEAK INDEPENDENTLY OF ACE2

**Francielle T. Gomes de Sousa**<sup>1</sup>, Scott B. Biering<sup>1</sup>, Trishna Patel<sup>1</sup>, Sophie Blanc<sup>1</sup>, Dustin Glasner<sup>2</sup>, Nicholas Lo<sup>1</sup>, Marcus Wong<sup>1</sup>, Victoria Ortega<sup>3</sup>, Charles Chiu<sup>2</sup>, Hector Aguilar<sup>3</sup>, John Pak<sup>4</sup>, Robert Beatty<sup>1</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, <sup>2</sup>Department of Laboratory Medicine, University of California, San Francisco, San Francisco, CA, United States, <sup>3</sup>Department of Microbiology and Immunology, College of Veterinary Medicine, Cornell University, Ithaca, NY, United States, <sup>4</sup>Chan Zuckerberg Biohub, San Francisco, CA, United States

SARS-CoV-2 is the causative agent of COVID-19, characterized by acute respiratory distress syndrome (ARDS) in severe cases; however, the triggers of pathogenesis are unclear. As a clinical feature of ARDS is epithelial and endothelial barrier dysfunction, we monitored endothelial (human pulmonary microvascular endothelial cells; HPMECs) and epithelial (Calu-3) hyperpermeability and endothelial glycocalyx layer (EGL) disruption induced by recombinant soluble SARS-CoV-2 trimeric Spike (S) and its receptor-binding domain (RBD), as well as vesicular stomatitis virus (VSV) particles pseudotyped with SARS-CoV-2 S (VSV-S) or VSV-glycoprotein (VSV-G) as a control. We found that SARS-CoV-2 S, RBD, and VSV-S, but not VSV-G, triggered both endothelial and epithelial hyperpermeability, measured by Transendothelial Electrical Resistance (TEER), and EGL disruption, measured by cell surface levels of sialic acid and heparan sulfate (HS). Intriguingly, SARS-CoV-1 and MERS-CoV S did not induce hyperpermeability in HPMECs comparably to SARS-CoV-2 S. Surprisingly, we observed SARS-CoV-2 S-mediated endothelial dysfunction using cells that do not express ACE2 (HPMECs), suggesting a distinct pathogenic mechanism from the ACE2-dependent inflammatory responses previously reported. Using murine models of dermal and systemic vascular leak in C57BL/6 mice, we showed that SARS-CoV-2 S was sufficient to mediate vascular leak *in vivo*, supporting that this activity is independent of human ACE2. To further characterize this pathway, we conducted RNA-Seq on HPMECs treated with SARS-CoV-2 S, revealing transcriptional signatures indicative of endothelial dysfunction and proinflammatory responses. Further, a point mutation in the SARS-CoV-2 S HS binding site abrogated the capacity of S to induce EGL disruption, indicating that S interaction with HS could be a trigger of pulmonary COVID-19 pathogenesis. Overall, our results indicate that SARS-CoV-2 S glycoprotein alone can directly mediate endothelial hyperpermeability independently of both ACE2 interaction and viral infection, serving as an additional feature of SARS-CoV-2 pathogenesis.

### GENOME-WIDE, BIDIRECTIONAL CRISPR SCREENS IDENTIFY MUCINS AS CRITICAL MODULATORS OF SARS-COV-2 INFECTION

**Scott B. Biering**<sup>1</sup>, Sylvia Sarnik<sup>2</sup>, Eleanor Wang<sup>2</sup>, Varun Sathyan<sup>2</sup>, Xammy Nguyenla<sup>1</sup>, James Zengel<sup>3</sup>, Erik Van Dis<sup>1</sup>, Livia Yamashiro<sup>1</sup>, Jinyoung Kim<sup>4</sup>, Douglas Fox<sup>1</sup>, Jan Carette<sup>3</sup>, Sarah Stanley<sup>1</sup>, Silvana Konermann<sup>5</sup>, Eva Harris<sup>1</sup>, Patrick Hsu<sup>2</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, <sup>2</sup>Department of Bioengineering, College of Engineering, University of California, Berkeley, Berkeley, CA, United States, <sup>3</sup>Department of Microbiology and Immunology, School of Medicine, Stanford University, Stanford, CA, United States, <sup>4</sup>Division of Biochemistry, Biophysics and Structural Biology, Department of Molecular and Cell Biology, University of California, Berkeley, Berkeley, CA, United States, <sup>5</sup>Department of Biochemistry, School of Medicine, Stanford University, Stanford, CA, United States

The emergence of severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2), the causative agent of COVID-19, has resulted in an unprecedented public health catastrophe for which new therapeutic strategies are desperately needed. Gaining a basic understanding of host-pathogen interactions mediating viral infection or viral control in relevant human cells is critical for identifying new host targets for therapeutic intervention. To this end, we conducted genome-wide CRISPR inhibition and activation screens in human lung epithelial (Calu-3) cells, identifying numerous factors that implicate diverse and druggable host pathways important for mediating or restricting SARS-CoV-2 infection. These include cell-cycle factors and inflammatory responses, as well as components of intercellular junctional complexes. Intriguingly, numerous mucins, a family of high-molecular weight highly-glycosylated proteoglycans and the main constituent of mucus, emerged as critical modulators of SARS-CoV-2 infection, with the membrane-anchored MUC1, 4, 13, and 21 playing an antiviral role and the gel-forming MUC5AC exhibiting proviral activity when overexpressed. Using a SARS-CoV-2 spike pseudotype entry assay, we determined that overexpression of these diverse mucins modulated viral entry in a manner consistent with their proviral or antiviral role. Our data suggest that mucins encountered by SARS-CoV-2 in the human airway may serve both to prevent virus attachment and entry into permissive lung cells, or conversely, to promote virus attachment to cells. In summary, these data provide a valuable resource for the field and generate insight into the host-pathogen interactions of SARS-CoV-2 in relevant human epithelial cells, highlighting the potential of ubiquitous mucins to serve both as predictors of patient disease progression as well as druggable host targets.

0471

### COMPARATIVE PHYLODYNAMICS OF SARS-COV-2 VARIANTS IN THE NORTHEAST UNITED STATES

**Mary Petrone**<sup>1</sup>, Mallery Breban<sup>1</sup>, Isabel Ott<sup>1</sup>, Tara Alpert<sup>1</sup>, Rebecca Earnest<sup>1</sup>, Annie Watkins<sup>1</sup>, Jessica Rothman<sup>1</sup>, Chaney Kalinich<sup>1</sup>, Anderson Brito<sup>1</sup>, Steven Murphy<sup>2</sup>, Caleb Neal<sup>2</sup>, Marie Landry<sup>3</sup>, Kaya Bilguvar<sup>4</sup>, Curt Scharfe<sup>4</sup>, Mark Adams<sup>5</sup>, Joseph Fauver<sup>1</sup>, Chantal Vogels<sup>1</sup>, Nathan Grubaugh<sup>1</sup>

<sup>1</sup>Yale School of Public Health, New Haven, CT, United States, <sup>2</sup>Murphy Medical Associates, Greenwich, CT, United States, <sup>3</sup>Yale School of Medicine, New Haven, CT, United States, <sup>4</sup>Yale Center for Genome Analysis, New Haven, CT, United States, <sup>5</sup>Jackson Laboratories, Farmington, CT, United States

In the midst of a national vaccination campaign, COVID-19 cases are rising in the United States (US). A contributing factor to this trend may be the emergence of SARS-CoV-2 variants. B.1.1.7, the variant first identified in the United Kingdom, was detected in the US in January 2021, and is classified as a Variant of Concern (VOC). This variant has rapidly risen in prevalence among globally circulating SARS-CoV-2 likely due to its increased transmissibility. To monitor the frequency of this and

other variants, we are conducting genomic surveillance in Connecticut (CT). Since November 2020, we have generated over 2,300 SARS-CoV-2 whole genomes collected across the state. We found that the prevalence of B.1.1.7 rose to 60% by April 5 in CT. Interestingly, the majority of the remaining viruses belong to the lineage B.1.526, which was first identified in New York (NY) and is not a VOC. To investigate, we combined our dataset with publicly available genomes on GISAID, selecting all B.1.526 genomes ( $n \approx 7,000$ ). Due to the large number of B.1.1.7 genomes, we included all genomes from CT and neighboring states and a random sample of genomes collected globally ( $n \approx 2,500$ ). We tabulated the number of sustained introductions of each variant into CT by constructing separate time-resolved trees, which served as a fixed topology for discrete phylogeographic trait reconstruction in BEAST. We assigned three geographic trait states: CT, NY, or other. We defined a sustained introduction as a CT clade with a non-CT common ancestor containing at least three tips. Of the 23 sustained B.1.1.7 introductions, 74% came from New York, while 68% of the 19 sustained B.1.526 introductions originated there. To ensure that these introductions have strong phylogenetic support, we will build bootstrapped maximum likelihood trees. We will next investigate the spread of these lineages within and between CT and NY using a continuous phylogeographic approach. We hypothesize that NY disproportionately influences SARS-CoV-2 dynamics in CT, which would provide a strong motivation to cultivate inter-state surveillance and control efforts as the US looks towards the end of the pandemic.

To characterize the immune response to SARS-CoV-2 infection, we have created a comprehensive Ala-scan mutation library (>1240 mutations) of the SARS-CoV-2 S protein. We are using this library to epitope map human anti-SARS-CoV-2 monoclonal antibodies (MAbs), by high-throughput, rapid screens of MAb binding to each mutant S protein. Individual mutant expression plasmids are transfected into human cells to achieve native protein expression and folding. Immunoreactivity of MAbs to each mutant S protein is then quantified by high-throughput flow cytometry, allowing us to identify the S protein epitope residues with the highest energetic contribution to MAb binding. We have mapped over 50 MAbs that target different regions of the S protein, identifying conformational epitopes in the S1 receptor binding domain (RBD) and N-terminal domain (NTD), and in S2, helping characterize MAbs that neutralize and protect in animal models of disease. To provide critical reagents for analyses of MAb or serum immune responses to SARS-CoV-2 infection, we developed a pseudotyped lentiviral system to generate SARS-CoV-2 reporter virus particles (RVPs) displaying S protein. The replication-incompetent RVPs perform one round of infectivity and enable safe (BSL-2) and reproducible virus neutralization assays with luminescent or fluorescent readout. We have produced over 30 different SARS-CoV-2 RVPs incorporating known S protein variants. We also used RVP technology to screen the S protein mutant library for infectivity, to identify residues whose mutation eliminates virus infectivity but does not impact S protein expression, antigenicity, or reporter virus budding, indicating that these residues perform critical functions for infectivity. To identify uncharacterized SARS-CoV-2 cellular binding factors we are assaying wild-type SARS-CoV-2 RVP infectivity in non-permissive cells expressing our membrane proteome array (MPA) of 6,000 unique human membrane proteins. Similar experiments with other viruses have yielded previously unidentified candidate membrane proteins that enable virus infectivity.

### ORACOV, AN ORAL, SELF-ADMINISTERED, ROOM TEMPERATURE STABLE, TRIPLE ANTIGEN SARS-COV-2 VACCINE AND AN APPROACH TO VACCINES AGAINST OTHER EMERGING INFECTIOUS DISEASES

B. Kim Lee Sim<sup>1</sup>, Ehud Inbar<sup>2</sup>, Tint T. Wai<sup>1</sup>, Sumana Chakravarty<sup>2</sup>, Minglin Li<sup>1</sup>, Lixin Gao<sup>1</sup>, Henry Huang<sup>2</sup>, Natasha KC<sup>1</sup>, Eric R. James<sup>2</sup>, Stephen L. Hoffman<sup>2</sup>

<sup>1</sup>Protein Potential, LLC., Rockville, MD, United States, <sup>2</sup>Sanaria Inc., Rockville, MD, United States

Vaccines are the optimal intervention to prevent COVID-19 and emerging infectious diseases. The goal is billions of effective immunizations. Our recombinant, attenuated *Salmonella Typhi* (Ty21a=Vivotif) vaccine platform expresses multiple SARS-CoV-2 proteins. The vaccine, OraCOV, is manufactured using methods amenable to inexpensive scale-up, is self-administered orally in 3-4 doses over 4-6 days, has an excellent safety record (<150 million Ty21a doses administered), and induces protective immunity, in large part through cellular immune responses, protective for 3-7 years against typhoid fever. Our recombinant Ty21a expresses SARS-CoV-2 proteins and, 1) is stable at room temperature, 2) is administered orally and taken up via the oral and intestinal mucosa and 3) intended to induce secretory IgA antibodies and protective T cell responses to eliminate SARS-CoV-2 at the respiratory mucosa. Our innovations depart from approaches taken by most COVID-19 vaccines: A) *Vaccine delivery and administration*: We envision immunizing in a short period huge numbers of people without congregating for inoculation, because vaccine will be shipped in envelopes at ambient temperature for oral self-administration at home over one week. B) *Induction of protective immunity*: Immunization via the oral mucosa is intended to lead to durable immunity mediated by secretory IgA antibodies and protective T cells targeting not only the spike (S), but also the membrane (M) and nucleocapsid (N) proteins. Our live vaccine candidate(s) is stabilized by foam drying and is room temperature stable. We have integrated the coding regions for the ecto-domain of S, M, and N proteins into the chromosome of Ty21a, as individual and all-in-one constructs. These multi-subunit, bi-valent vaccine candidates express SARS-CoV-2 proteins and protective O-antigen of *S. Typhi*. We will present results on induction of viral neutralizing antibodies and cellular responses against SARS-CoV-2. We anticipate success with Ty21a-SARS-CoV-2 will establish our recombinant Ty21a platform as universal for responding to many emerging, re-emerging, and current infectious diseases.

Bustos Carrillo<sup>1</sup>, Brenda Lopez Mercado<sup>2</sup>, Jairo Monterrey<sup>2</sup>, Damaris Collado<sup>2</sup>, Tatiana Miranda<sup>2</sup>, Sergio Ojeda<sup>2</sup>, Nery Sanchez<sup>2</sup>, Miguel Plazaola<sup>2</sup>, Harold Suazo Laguna<sup>2</sup>, Douglas Elizondo<sup>2</sup>, Sonia Arguello<sup>2</sup>, Saira Saborio<sup>2</sup>, Anna Gajewski<sup>2</sup>, Hannah Maier<sup>3</sup>, Krista Latta<sup>3</sup>, Bradley Carlson<sup>3</sup>, Josefina Coloma<sup>1</sup>, Leah Katzelnick<sup>1</sup>, Hugh Sturrock<sup>4</sup>, Angel Balmaseda<sup>2</sup>, Guillermina Kuan<sup>5</sup>, Aubree Gordon<sup>3</sup>, Eva Harris<sup>1</sup>

<sup>1</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, <sup>2</sup>Sustainable Sciences Institute, Managua, Nicaragua, <sup>3</sup>Department of Epidemiology, School of Public Health, University of Michigan, Ann Arbor, Ann Arbor, MI, United States, <sup>4</sup>Locational, Poole, United Kingdom, <sup>5</sup>Centro de Salud Socrates Flores Vivas, Ministry of Health, Managua, Nicaragua

Chikungunya virus, Zika virus, and severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) recently caused large epidemics across the Americas, resulting in many symptomatic and inapparent infections. Spatial analyses usually measure cases (symptomatic infections) and estimate incidence rates (cases/total population). Using data from two prospective cohort studies of children and households in Managua, Nicaragua, we separately analyzed infection risk (infections/total),

disease risk (cases/infections), and the incidence rate (cases/total), which are commonly conflated in the literature. We assessed ~3,000 initially uninfected children over two chikungunya (2014, 2015) and one Zika (2016) epidemic, as well as 1811 household members who experienced a COVID-19 epidemic (2020). We confirmed infections by ELISAs and cases by rRT-PCR and serological assays; we used spatial/spatiotemporal models, the intracluster correlation coefficient, and SaTScan to analyze the data. Across the four epidemics and all analyses, incidence rates substantially underestimated infection and disease risks. The spatial infection risk differed from the spatial disease risk, showing that areas with many infections did not necessarily have many cases and that among infections, the risk of disease varied spatially. We identified large clusters of infection outcomes, but not clusters of disease outcomes. Thus, infections but not cases were spatially modulated. Infection outcomes were poorly correlated within households. Spatiotemporal modeling of infection dynamics showed extensive month-to-month changes in infection risk across the study area. In sum, robust results across alphavirus, flavivirus, and coronavirus epidemics show when and how interpreting the incidence rate as the risk of infection or disease leads to considerable bias (e.g., missing clusters, incorrect inferences), a general finding applicable to a wide variety of pathogens that cause many inapparent infections. We argue for the expanded use of serosurveillance to overcome the inherent limitations of relying solely on case-based incidence rates during epidemics.

#### CAPPABLE-SEQ REVEALS PROLIFIC NON-CANONICAL TRANSCRIPTION START SITES IN WOLBACHIA STRAINS WMELPOP-CLA AND WALBB UNDER STRESS CONDITIONS

Yousef Suliman<sup>1</sup>, Zhiru Li<sup>2</sup>, Amit Sinha<sup>2</sup>, Philip D. Dyer<sup>1</sup>, Catherine S. Hartley<sup>1</sup>, Laurence Ettwiller<sup>2</sup>, Alistair C. Darby<sup>1</sup>, Clotilde K. Carlow<sup>2</sup>, Benjamin L. Makepeace<sup>1</sup>

<sup>1</sup>University of Liverpool, Liverpool, United Kingdom, <sup>2</sup>New England Biolabs, Ipswich, MA, United States

Symbiont-mediated control of arbovirus transmission entails the transfection of the alpha-proteobacterium *Wolbachia* into mosquito vectors, which greatly reduces vector competence. The choice of optimal *Wolbachia* strain for mosquito population replacement programmes needs to consider several factors, such as potential negative fitness effects on the mosquito host, the speed of replacement induced by cytoplasmic incompatibility, and the stability of the transinfection in the face of stressors such as heat. Mounting evidence indicates that different *Wolbachia* strains exhibit profound differences in resilience to the high temperatures that are regularly experienced in dengue-endemic countries. For instance, wMelPop-CLA (originally isolated from *Drosophila melanogaster*) is more easily lost from transinfected *Aedes aegypti* at elevated temperatures than is wAlbB (native to *Aedes albopictus*). However, very little is understood about the regulatory response to stress in *Wolbachia* at the transcriptional level. Here, we apply Cappable-Seq to unveil the primary transcriptome of these *Wolbachia* strains under low, optimal and high temperatures during mosquito cell culture. Stark differences in temperature tolerance between wMelPop-CLA and wAlbB were confirmed *in vitro*. Transcription start sites (TSS) were mapped at single-nucleotide resolution for the first time in an endosymbiotic bacterium responding to stress, demonstrating that both wMelPop-CLA and wAlbB have the capacity to utilise all four known TSS types, including a high proportion of antisense TSS. Global TSS discovery also enabled the identification of TSS promoter motifs associated with the global regulator sigma-70. Interestingly, wMelPop-CLA exhibited very high levels of expression for prophage-related TSS, whereas insertion sequence-associated TSS were more dominant in wAlbB. This study represents the first comparative transcriptomic analysis between *Wolbachia* strains in use for transinfected mosquito strategies and will facilitate experimentally guided strain choice in future.

0476

#### MATING STIMULI CAUSE DRAMATIC CHANGES IN THE FEMALE TSETSE FLY (*GLOSSINA MORSITANS*) REPRODUCTIVE TRACT AT THE LEVELS OF GENE EXPRESSION, BIOCHEMISTRY AND MORPHOLOGY

Geoffrey M. Attardo<sup>1</sup>, Irene Rossi<sup>2</sup>, Davide Carraretto<sup>2</sup>, Francesca Scolari<sup>2</sup>, Ludvik Gomulski<sup>2</sup>, Serap Aksoy<sup>3</sup>, Anna Malacrida<sup>2</sup>

<sup>1</sup>University of California, Davis, Davis, CA, United States, <sup>2</sup>University of Pavia, Pavia, Italy, <sup>3</sup>Yale University, New Haven, CT, United States

Tsetse flies (*Glossina* sp.) transmit the human and animal forms of African Trypanosomiasis, neglected diseases, which affect marginalized populations in sub-Saharan Africa. Tsetse flies have low reproductive capacity and low population numbers relative to other disease vectors as they reproduce by obligate viviparity (intrauterine larval development/nutrition and live birth). This work investigates the physiological responses by female tsetse flies to mating stimuli. Physical mating stimuli and male seminal fluid proteins, induce physiological and behavioral changes observed in mated female insects. In *Glossina*, these include reduced receptivity to remating, increased blood meal volume and initiation of ovulation. Time course analysis of the post mating response by tsetse fly females by gene expression, metabolomic and morphological analyses of female reproductive tissues reveal significant changes in gene expression patterns, metabolite abundances, and morphological shifts over a 72-hour time course after mating. The transcriptional response peaks at 24 hours post mating and is distinguished by the dramatic increase in transcripts encoding a female reproductive specific OBP, orthologs of royal jelly protein in bees (responsible for initiation of developmental programs resulting in queen development from workers), and upregulation of structural, transporter, calcium signaling and stretch reception genes. Metabolomic analyses reveal increases in phospholipid moieties likely derived from the male seminal secretions which may function as a nuptial gift. Byproducts of glycosaminoglycan degradation are also enriched and may represent the degradation of glycoprotein constituents of the spermatophore by the female. MicroCT scans reveal changes in the constitution of fat body cells between virgin and mated flies indicating that the post mating effect also induces changes in nutrient storage. These analyses reveal an array of new insights into the physiology of the post-mating response in *Glossina* which will be the focus of targeted research to identify processes with potential as targets for reproductive inhibition.

0477

#### B-TRIKETONES, A NEXT GENERATION SCABICIDE?

Nirupama Abeysekera Nammunige<sup>1</sup>, Kylie Agnew-Francis<sup>2</sup>, Deepani D. Fernando<sup>1</sup>, Sara Taylor<sup>1</sup>, Hieng Lu<sup>1</sup>, Craig Williams<sup>2</sup>, Robin Gasser<sup>3</sup>, Katja Fischer<sup>1</sup>

<sup>1</sup>Queensland Institute of Medical Research Berghofer, Herston, Australia, <sup>2</sup>University of Queensland, Queensland, Australia, <sup>3</sup>University of Melbourne, Melbourne, Australia

Scabies is a contagious human skin disease caused by the obligate parasitic mite *Sarcoptes scabiei*. It affects approximately 300 million people per year globally and is a major problem in Australian Aboriginal communities. Scabies is linked to secondary bacterial infections with life threatening sequelae. Available drugs target mainly the motile parasite stages and fail to kill eggs, hence they are suboptimal. Manuka oil (MO) has extensive bioactive properties but its scabidicidal efficacy has not been explored. Six commercially available MOs were tested *in vitro*. The MO fractionation was followed by gas chromatography and Spearman's Correlations analysis revealed the acaricidal compounds are  $\beta$ -triketones.  $\beta$ -triketones were tested on mites and eggs at different concentrations *in vitro* and LC50 values were generated. Mites and eggs were also exposed to 150mM of  $\beta$ -triketones for different durations and LT50 values were generated. Probit analysis was used to generate LC50 and LT50 values. The synergistic effects of  $\beta$ -triketones were checked using different combinations on mites and eggs and the data were analysed using Compusyn Software. Proteo-transcriptomic analyses of MO treated mites and eggs for 30 mints

versus untreated were done to assist target elucidation. A 1.2-fold cut-off value was used to identify up or down regulated proteins ( $p$ -value<0.05). KiwiHerb® showed highest ovicidal (>95%) and miticidal activity (100%). KiwiHerb® was fractionated into 17 fractions and 28 compounds. The  $\beta$ -triketones flavesone, isoleptospermone and leptospermone were identified as the active compounds against *S. scabiei*. Flavesone showed highest miticidal activity with LC50 of 57.81 mM (95% CI 53.97-61.68) at 4 h and leptospermone showed the highest ovicidal activity with LC50 of 33.59 mM (95% CI 29.23-38.04) at day 3. The lowest LT50 values for mites and eggs, 1.34 (1.24-1.45) h and 8.03 (6.30-9.70) h respectively were measured from 150mM Flavesone. There was a little or no synergism in all combination  $\beta$ -triketones tested.  $\beta$ -triketones show the potential to be a novel scabicide and broader implications on other arthropod-associated diseases.

0478

### ABAMETAPIR - A POTENTIAL SINGLE DOSE SCABICIDE WITH OVICIDAL ACTIVITY.

**Gangi R. Samarawickrama**<sup>1</sup>, Deepani D. Fernando<sup>1</sup>, Hieng C. Lu<sup>1</sup>, Sara Taylor<sup>1</sup>, Gunter Hartel<sup>2</sup>, Robin B. Gasser<sup>3</sup>, Vern M. Bowels<sup>4</sup>, Katja Fischer<sup>1</sup>

<sup>1</sup>QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>2</sup>Statistics Unit, QIMR Berghofer Medical Research Institute, Brisbane, Australia, <sup>3</sup>Faculty of Veterinary Science and Agricultural Sciences, The University of Melbourne, Melbourne, Australia, <sup>4</sup>Centre for Animal Biotechnology, The University of Melbourne, Melbourne, Australia

Scabies is a contagious skin disease in humans caused by the obligatory parasitic, burrowing mite *Sarcoptes scabiei* var *hominis*. Intense pruritus facilitates secondary bacterial infections associated with potentially life threatening sequelae. Scabies is common in overcrowded and disadvantaged communities. There is no vaccine, molecular diagnostic methods and only limited treatment options are available. Suboptimal efficacies of the existing drugs, and patient incompletion to repeat treatments, as well as emerging resistance are major concerns. Therefore, our objective is to develop a single-dose regimen targeting the entire lifecycle. Xeglyze® lotion is a FDA approved ovicidal lousicide containing 0.74% abametapir as active ingredient. Abametapir has metal chelating properties and therefore acts on multiple targets in an organism. It is capable of inhibiting multiple enzymes (including metalloproteases) and pathways that requires metal ions as co-factors. Abametapir has been shown to inhibit Meprin, a metalloprotease important in arthropod embryonic development. Considering the above facts, we hypothesized that Abametapir inhibits a range of metalloproteases in *S. scabiei* mites and eggs involved in development (moulting), metabolism and egg hatching. Proposed research will validate Abametapir as a new scabicide with novel modes of action(s) and efficacy against all developmental stages of *S. scabiei*. *In vitro* drug assays were conducted using pure abametapir. Experiments were conducted using *S. scabiei* var *suis* mites and eggs. Mites and eggs were exposed to abametapir at different exposure times. Mite mortality and egg hatchability inhibition were recorded over time compared to an untreated control. Lethal exposure time (LT) was determined by probit analysis using IBM® SPSS® Statistics 23.0. Software. LT<sub>50</sub> and LT<sub>95</sub> for 0.74% pure abametapir were 15.30 (14.00-16.75) h and 49.50 (41.20-63.00) h respectively for mites, and 1.23 (0.98-1.52) h, 9.32 (6.75-14.65) h respectively for eggs. Our results show that abametapir affects all developmental stages of *S. scabiei* and has potential as a single dose treatment for scabies.

0479

### COMPARTMENTALIZATION AND EFFECT OF TRYPANOSOMA CRUZI INFECTION ON THE GUT MICROBIOTA OF TRIATOMA DIMIDIATA

**Juan Carlos Cambronero-Heinrichs**<sup>1</sup>, Johan Alvarado-Ocampo<sup>1</sup>, Keilor Rojas-Jimenez<sup>1</sup>, Diego Rojas-Gätjens<sup>2</sup>, Max Chavarria<sup>2</sup>, Randall Loaiza<sup>2</sup>, Monica Baizan<sup>2</sup>, Olger Calderon-Arguedas<sup>1</sup>, Adriana Troyo-Rodriguez<sup>1</sup>

<sup>1</sup>University of Costa Rica, San Jose, Costa Rica, <sup>2</sup>CENIBiot, San Jose, Costa Rica

Chagas disease is an endemic zoonosis in Latin America, and it is mostly concentrated in rural and poor areas. It is considered a neglected tropical disease, and the main vector in Central America is *Triatoma dimidiata*. Given the diversity of biological factors involved in the host-parasite association, we studied the effect of *Trypanosoma cruzi* infection on the microbiota and the localization of important microbial taxa in the gut of *T. dimidiata*, which would facilitate identifying key factors associated with the interaction of endemic microbiota and *T. cruzi*. In this study, 8 insects (4 infected and 4 uninfected with *T. cruzi*) from a single site in Costa Rica were dissected, and the anterior midgut, posterior midgut, and rectum were separated. The bacterial metabarcoding of the sections was sequenced and compared between infected and uninfected insects. In addition, aerobic bacteria and yeasts were isolated in BHI medium and identified by sequencing of the genes 16S or ITS, in order to evaluate a possible effect on the replication of *T. cruzi* epimastigotes *in vitro*. We identified 3218 microbial amplicon sequence variants (ASVs) based on the 16S rRNA gene analysis. Overall, Actinobacteria was the most abundant phylum, with *Corynebacterium* and *Tsukamurella* as the most abundant genera. We determined significant changes in the microbial composition and diversity among gut sections. A higher diversity was observed in the posterior midgut, where epimastigote replication occurs. In general, insects infected with *T. cruzi* showed a higher gut bacterial diversity than insects without the parasite. Moreover, we obtained 34 different microbial isolates, including Firmicutes and Actinobacteria. Interaction assays against epimastigotes of *T. cruzi* are being conducted. Our study gives relevant ecological information on microbiota compartmentalization and microbial interactions in the gut of *T. dimidiata*. Further investigations on interactions and localization of important microbial taxa in the gut of *T. dimidiata* may help to develop new strategies and/or improve current control efforts.

### EVALUATION OF ENDEMIC AND EPIDEMIC STRAINS OF VESICULAR STOMATITIS VIRUS INFECTION IN CULICOIDES SONORENSIS MIDGES

**Paula Rozo-Lopez**<sup>1</sup>, Steve Pauszek<sup>2</sup>, Luiz L. Rodriguez<sup>2</sup>, Yoonseong Park<sup>1</sup>, Barbara S. Drolet<sup>3</sup>

<sup>1</sup>Kansas State University, Manhattan, KS, United States, <sup>2</sup>United States Department of Agriculture, Orient Point, NY, United States, <sup>3</sup>United States Department of Agriculture, Manhattan, KS, United States

Vesicular stomatitis (VS) is a viral disease primarily affecting cattle, horses, and swine. Endemic to Central and South America, VS outbreaks in the US occur sporadically every five to ten years, lasting for a single year (incurion year) and often re-emerging for a second year (expansion year). Virus spreads from animal-to-animal by direct contact but is also vector-borne. During outbreaks, especially in expansion years, *Culicoides* biting midge vectors likely play a key role in inter-herd viral spread. Earlier phylogeographic studies showed that in 2012, a VS virus (VSV) (epidemic strain) successfully spread northward out of an endemic area in southern Mexico and into the US, causing disease in horses in New Mexico and Colorado. In contrast, a genetically related strain from the same area in southern Mexico (endemic strain), did not move out of the endemic zone and into the US. It is not clear why some viral lineages escape the endemic areas and move northward into the US, and some do not. Whole-genome sequencing revealed the two strains differed in seven significant

amino acid changes. Comparative infection studies in pigs showed that the epidemic strain was more virulent than the endemic strain, possibly contributing to its overall ability to escape the endemic area and spread northward into the US. Here, we evaluated the efficiency of these two viral strains to infect *Culicoides* biting midges and to disseminate to the salivary glands for subsequent bite transmission. Our results showed that the epidemic strain had a significantly higher infection rate and a higher dissemination rate in midges, compared to the endemic strain. Thus, in addition to affecting virulence, small genetic changes also affect virus-vector interactions, which may contribute to the ability of a specific viral lineage to move out of an endemic area in Mexico and into the US.

0481

### EMERGING ENTOMOLOGICAL EVIDENCE OF INCREASED CUTANEOUS LEISHMANIASIS BURDEN IN SRI LANKA

**R.W.C. Kalpani Kumarasiri**<sup>1</sup>, S.A.S.C. Senanayaka<sup>2</sup>, D. Sunil Shantha<sup>2</sup>, B.G.D.N.K. De Silva<sup>3</sup>, N. D. Karunaweera<sup>2</sup>

<sup>1</sup>Postgraduate Institute of Medicine, University of Colombo, Colombo, Sri Lanka, <sup>2</sup>Department of Parasitology, Faculty of Medicine, University of Colombo, Sri Lanka, Colombo, Sri Lanka, <sup>3</sup>Department of Zoology, Faculty of Applied Sciences, University of Sri Jayawardanapura, Sri Lanka, Colombo, Sri Lanka

There is a sustainable rise in the global health burden of cutaneous leishmaniasis (CL), as a truly neglected tropical disease. CL has transmitted to all 25 districts in Sri Lanka with persistent hotspots in selected areas, without specific control or prevention programs. This is the first island-wide molecular-based evaluation of entomological factors contributing to the escalating burden of CL in Sri Lanka. DNA was extracted from 1520, morphologically identified, female *Phlebotomus argentipes glaucus* (*Ph. glaucus*), probable vector in Sri Lanka. Sandflies were collected through an island-wide survey and molecularly confirmed with COI and Cyt b markers. DNA was tested for the presence of *Leishmania* parasite in sandflies using a conventional PCR and confirmation as *Leishmania donovani* using specific nested PCR. Blood meal source identification was done using a light trap collected 270 blood-engorged female sandflies targeting the universal vertebrate Cyt b gene. Positive amplicons of all PCR experiments were sequenced and analyzed. Thirteen blood-fed and 2 non-fed sandflies were infected with *L. donovani* indicating an infection rate of 1% (15/1520). Eleven infected sandflies were engorged with human blood implicating humans as a possible parasitic reservoir. The presence of infected non-engorged sandflies reinforces the view of *Ph. glaucus* as *L. donovani* vector in Sri Lanka. Out of 216 positive PCR amplicons of blood-meal analysis, 153 (70%) were *Ph. glaucus* and 63 (30%) were *Sergentomyia* species. Further analysis revealed the presence of human blood in 133 (87%) out of 153 vertebrate blood-engorged *Ph. glaucus*, favoring the probable anthropophilic nature of *Ph. glaucus*. The presence of 70% *Ph. glaucus* in sandfly collection, rising infection rate (a threefold rise compared to the previous rate of 0.3%), likely anthropophilic nature of *Ph. glaucus* with human as a possible parasitic reservoir, may partly explain the rising case incidence with escalating health threat. The evidence uncovered will aid future planning and implementation of vector control strategies, required to contain the rapid spread of leishmaniasis in Sri Lanka.

0482

### INFRARED THERMAL IMAGING AS A NOVEL NON-INVASIVE POINT-OF-CARE TOOL TO ASSESS FILARIAL LYMPHOEDEMA AND THE IMPACT OF SELF-CARE INTERVENTIONS IN ENDEMIC AREAS OF BANGLADESH, ETHIOPIA, AND MALAWI

**Louise A. Kelly-Hope**<sup>1</sup>, John Chiphwanya<sup>2</sup>, Fikre Hailekiros<sup>3</sup>, Mohammad Jahirul Karim<sup>4</sup>, ASM Sultan Mahmood<sup>4</sup>, Abdullah Al Kawsar<sup>4</sup>, Abul Khair<sup>4</sup>, Mossie Tamiru<sup>5</sup>, Fikre Seife<sup>5</sup>, Dorothy E. Matipula<sup>2</sup>, Limbikani Chaponda<sup>2</sup>, Carrie Barrett<sup>1</sup>, Hannah Betts<sup>1</sup>, Janet Douglass<sup>1</sup>, Armelle Forrer<sup>1</sup>, Mark J. Taylor<sup>1</sup>

<sup>1</sup>Centre for Neglected Tropical Diseases, Department of Tropical Disease Biology, Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Ministry of Health, Lilongwe, Malawi, <sup>3</sup>National Podoconiosis Action Network, Addis Ababa, Ethiopia, <sup>4</sup>Ministry of Health and Family Welfare, Dhaka, Bangladesh, <sup>5</sup>Federal Ministry of Health, Addis Ababa, Ethiopia

Lymphatic filariasis causes disfiguring and disabling lymphoedema, which is commonly and frequently exacerbated by acute dermatolymphangioadenitis (ADLA). Affected people require long-term care and monitoring but health workers lack objective assessment tools. We assess the use of an infrared thermal imaging camera as a novel non-invasive point-of-care tool for filarial lower limb lymphoedema before and after a self-care intervention in five highly endemic areas of Bangladesh, Ethiopia and Malawi. A prospective cohort study of ~150 people in each of the five study areas was conducted over six months. Participants were surveyed at three-time points; baseline before being training in an enhanced self-care protocol (pre-intervention) and at 3- and 6 months (post-intervention). Limb temperatures were captured using the FLIR C3 Compact Thermal Imaging Camera and differences by lymphoedema stage (mild, moderate, severe) and ADLA status were visualised and quantified using descriptive statistics and regression models. Baseline results from Bangladesh found temperatures to increase by severity and highlighted subclinical differences between no lymphoedema and mild lymphoedema, and differences between moderate and severe stages. Toes and ankle temperatures detected significant differences between all stages other than between mild and moderate stages. Significantly higher temperatures, best captured by heel and calf measures, were found in participants with a history of ADLA, compared to participants who never had ADLA, regardless of the lymphoedema stage. Baseline surveys are completed with data analyses underway in Ethiopia and Malawi. All post-intervention surveys are in progress and due to be completed by August 2021. The results from three countries will be presented. This novel tool has great potential to be used by health workers in LF endemic areas to detect subclinical cases, predict progression of disease and ADLA status, and monitor pathological tissue changes and stage severity following enhanced care packages or other interventions in people affected by lymphoedema.

0483

### POPULATION PHARMACOKINETICS OF IVERMECTIN IN LYMPHATIC FILARIASIS PATIENTS AND HEALTHY INDIVIDUALS

**Abdullah M. Alshehri**<sup>1</sup>, Yashpal S. Chhonker<sup>1</sup>, Veenu Bala<sup>1</sup>, Constant Edi<sup>2</sup>, Catherine M. Bjerum<sup>3</sup>, Benjamin G. Koudou<sup>4</sup>, Christopher L. King<sup>3</sup>, Daryl J. Murry<sup>1</sup>

<sup>1</sup>Dept of Pharmacy Practice and Science, University of Nebraska Medical Center, Omaha, NE, United States, <sup>2</sup>Centre Suisse de Recherche Scientifique en Côte d'Ivoire, Abidjan, Côte D'Ivoire, <sup>3</sup>Center for Global Health and Diseases, Case Western Reserve University School of Medicine, Cleveland, OH, United States, <sup>4</sup>Université Nangui Abrogoua, Abidjan, Côte D'Ivoire

Ivermectin (IVM) combined with diethylcarbamazine (DEC) and albendazole (ALB) is part of triple-drug therapy (IDA) recommended for mass drug administration to eradicate lymphatic filariasis in certain populations. IDA had reduced efficacy for sustained suppression of microfilaremia in residents of West Africa compared to Papua New Guinea. Some of this variable efficacy may arise from differences in

population pharmacokinetics (PK) of IVM and the presence and intensity of LF infection. We have previously shown that IVM has substantial pharmacokinetic variability with systemic drug exposures (AUC) ranging over 10 fold when administered as a fixed dose. Population PK modeling of IVM was conducted to evaluate dose rationale and evaluate the impact of factors associated with observed PK variability. This study evaluated the PK of IVM following single-dose (0.2 mg/kg) oral administration in lymphatic filariasis infected subjects compared to healthy individuals. A total of 56 participants were enrolled in the study and 724 samples were collected from treatment naïve *Wuchereria bancrofti*-infected (n=32), and uninfected (n=24) adults who also received IVM as a part of triple drug therapy. Plasma samples were collected from 0-168 hours post administration and analyzed using liquid chromatography-mass spectroscopy. PK analysis was conducted with Phoenix NLME 8.0 software. A two-compartment model with mixed first and zero order absorption and linear elimination with time-lag function best described IVM disposition. IVM PK was not altered by lymphatic filariasis infection. However, gender was found to be a significant covariate on the peripheral volume of distribution (higher in women than men). The IVM PK model was suitable for predicting drug exposure in patients with lymphatic filariasis and identification of important covariates associated with pharmacokinetic variability. Additional studies evaluating the influence of body size are warranted for IVM PK. The studies will allow sparse sampling of populations to determine if PK variability of IVM may account for variability in IDA efficacy across populations and to optimize dosing.

0484

#### ILC2 CELLS MEDIATE RESISTANCE TO LITOMOSOIDES SIGMODONTIS INFECTION

Julia J. Reichwald, Anna Lena Neumann, Frederic Risch, Johanna F. Scheunemann, Alexandra Ehrens, Wiebke Strutz, Beatrix Schumak, Achim Hoerauf, **Marc P. Hübner**  
University Hospital Bonn, Bonn, Germany

The *Litomosoides sigmodontis* mouse model is a well-established model to study immune responses during filarial infection. BALB/c mice develop chronic *L. sigmodontis* infection and microfilaremia, whereas C57BL/6 mice clear the majority of filariae shortly after the molt into adult worms ~30 days after infection (dpi) and do not develop microfilaremia. In the present study we investigated group 2 innate lymphoid cells (ILC2s) during *L. sigmodontis* infection in BALB/c and C57BL/6 mice. Mice were naturally infected via the mite vector and ILC2s (CD45<sup>+</sup> Lineage<sup>-</sup> TCRβ<sup>-</sup> CD90.2<sup>+</sup> Sca-1<sup>+</sup> IL-33R<sup>+</sup> GATA-3<sup>+</sup>) were analysed in the thoracic cavity, the site of *L. sigmodontis* residence, on 9, 30 and 70 dpi. C57BL/6 mice had a significant increase in ILC2 numbers compared to BALB/c mice at 30 dpi. At this time point the ILC2 numbers positively correlated with the worm burden in both mouse strains (Spearman  $r = 0.7$ ;  $p = 0.02$ ). Additionally, C57BL/6 mice had significantly higher levels of IL-5 and IL-13 at 30 dpi in comparison to BALB/c mice, indicating a stronger type 2 immune response in C57BL/6 mice during the onset of adult worm clearance. Pleural cavity ILC2s and CD4<sup>+</sup> T cells were the dominant source of IL-5 in 30 day-*L. sigmodontis*-infected C57BL/6 mice with ILC2s showing a significantly higher IL-5 expression than CD4<sup>+</sup> T cells. In order to investigate the role of ILC2s on *L. sigmodontis* infection, we depleted ILC2s using anti-CD90.2 antibodies before the molt into adult worms (26-28 dpi) from B and T cell deficient RAG2<sup>-/-</sup> C57BL/6 mice and compared the outcome to isotype-treated RAG2<sup>-/-</sup> controls. RAG2<sup>-/-</sup> mice had lower ILC2 numbers in comparison to wildtype C57BL/6 controls and were susceptible to *L. sigmodontis* infection with the development of microfilaremia. Depletion of ILC2s in RAG2<sup>-/-</sup> C57BL/6 mice did not alter the adult worm recovery at 63 dpi, but significantly increased microfilariae numbers in comparison to isotype-treated RAG2<sup>-/-</sup> mice. In conclusion, our data reveal differences in the ILC2 subset during *L. sigmodontis* infection in susceptible and semi-susceptible mouse strains and demonstrate that ILC2s are involved in the control of microfilaremia.

#### ADJUVANTED RECOMBINANT FUSION PROTEIN VACCINE INDUCES DURABLE AND PROTECTIVE IMMUNITY TO LARVAL ONCHOCERCA VOLVULUS IN MICE

Nathan M. Ryan<sup>1</sup>, Jessica A. Hess<sup>1</sup>, Darrick Carter<sup>2</sup>, Sean A. Gray<sup>2</sup>, Erica J. Robertson<sup>1</sup>, Nikolai Petrovsky<sup>3</sup>, Bin Zhan<sup>4</sup>, Maria Elena Bottazzi<sup>4</sup>, Benjamin L. Makepeace<sup>5</sup>, Sarah Lustigman<sup>6</sup>, David Abraham<sup>1</sup>

<sup>1</sup>Thomas Jefferson University, Philadelphia, PA, United States, <sup>2</sup>PAI Life Sciences Inc., Seattle, WA, United States, <sup>3</sup>Vaxine Pty Ltd, Flinders University, Adelaide, Australia, <sup>4</sup>Baylor College of Medicine & Texas Children's Hospital Center for Vaccine Development, Houston, TX, United States, <sup>5</sup>University of Liverpool, Liverpool, United Kingdom, <sup>6</sup>New York Blood Center, New York, NY, United States

Control mechanisms for *Onchocerca volvulus* include vector control and mass drug administration. Given challenges in current control programs, further exacerbated by the COVID-19 pandemic, an effective prophylactic vaccine against *O. volvulus* is urgently needed. Previous studies demonstrated that vaccination with recombinant *O. volvulus* antigens Ov-103 and Ov-RAL-2, with the adjuvant Advax-2, induced protective immunity in mice. The current study aimed to determine: (1) whether a fusion of the two antigens (FUS-1) could replace the single antigens in the vaccine, (2) will other adjuvants optimize the induction of protective immunity and (3) how durable is the protective immunity induced by the adjuvanted FUS-1 vaccines? Mice were immunized with the fusion protein FUS-1 formulated with three different adjuvants: alum (which induces Th2 bias), Advax-2 (delta inulin with CpG oligonucleotide that induces combined Th1 and Th2 immunity) and AIT4 (alum plus a TLR-4 agonist that induces a Th1 bias). Mice were immunized 3 times and then challenged with third-stage larvae implanted subcutaneously within diffusion chambers. At 3-weeks post-final-booster immunization, mice vaccinated with either FUS-1/alum or FUS-1/Advax-2 had significantly reduced larval survival when compared to adjuvant controls, whereas mice vaccinated with FUS-1/AIT4 did not. At the 12-week time point, only mice vaccinated with FUS-1/Advax-2 exhibited significantly reduced larval survival. Flow cytometry analysis of infiltrating cells in the parasite microenvironment did not reveal differences between mice immunized with FUS-1/AIT4 versus the other adjuvants nor between cell populations at 12-weeks between FUS-1/alum and FUS-1/Advax-2. This suggests that the lack of protective immunity at 3-weeks with FUS-1/AIT4 and at 12-weeks with FUS-1/alum was not due to a deficiency in infiltrating effector cells but another immune mechanism or factor yet to be determined. The present study demonstrates that FUS-1 in combination with the adjuvant Advax-2 consistently induces a durable protective immune response against infection with *O. volvulus* in mice.

#### IMMUNIZATION WITH CO-ADMINISTERED ONCHOCERCA VOLVULUS 103 AND RAL-2 VACCINE ANTIGENS REDUCES INFECTION IN A NATURAL BOVINE ONCHOCERCA OCHENGI INFECTION MODEL

Lisa Luu<sup>1</sup>, John Graham-Brown<sup>1</sup>, Bin Zhan<sup>2</sup>, Nodde Herman Okah-Nnane<sup>3</sup>, Nicolas Bayang Houli<sup>4</sup>, Bernard Viban Tangwa<sup>3</sup>, Rene Ayiseh<sup>5</sup>, Glory MBah<sup>3</sup>, Maria Elena Bottazzi<sup>2</sup>, David Abraham<sup>6</sup>, Germanus Soh Bah<sup>3</sup>, Vincent Tanya<sup>3</sup>, Sara Lustigman<sup>7</sup>, Benjamin Makepeace<sup>1</sup>

<sup>1</sup>Institute of Infection Biology, Veterinary and Ecological Sciences, Liverpool, United Kingdom, <sup>2</sup>Baylor College of Medicine, Houston, TX, United States, <sup>3</sup>L'Institut de Recherche Agricole Pour le Développement, Yaounde, Cameroon, <sup>4</sup>L'Institut de Recherche Agricole Pour le Développement, Yaounde, Cameroon, <sup>5</sup>University of Buea, Buea, Cameroon, <sup>6</sup>Thomas Jefferson University, Philadelphia, PA, United States, <sup>7</sup>New York Blood Center, New York, NY, United States

Human onchocerciasis is a neglected tropical disease affecting 21 million sub-Saharan Africans. 30 years of elimination efforts have resulted in only

a 31% reduction in prevalence and is complicated by the restricted use of ivermectin in *Loa loa* co-endemic areas. Emerging ivermectin-resistant *Onchocerca volvulus* is also a major concern. Novel interventions, such as vaccines, are needed to complement ongoing elimination efforts. In small animal models, we've shown that *O. volvulus* 103 and RAL-2 antigens (Ov-103 and Ov-RAL-2) are the most promising vaccine candidates for clinical development for human use. Here, 24 immunologically naïve calves were split into two equal groups. One group was co-immunized (via intramuscular injection), with 103 and RAL2 antigens individually formulated with Montanide ISA 206VG adjuvant; 500µg/antigen for primary immunisation, plus two boosters at 250µg/antigen, at 4 and 8 weeks. The control group received adjuvant only. Animals were naturally exposed to infection with *O. ochengi* for 24 months. Throughout the study, calves were sampled to evaluate serum antibody titres, peripheral blood leucocyte counts and *in vitro* cellular assays. Post exposure, calves were also examined monthly for evidence of *O. ochengi* infection by palpation for female nodules and skin snips to detect microfilariae. All vaccinated calves showed strong serum IgG responses composed of IgG1 and IgG2 isotypes following primary and boost immunizations to both Ov-103 and Ov-RAL-2. These waned progressively following final immunization but were still detectable at 6 months post-exposure. All calves acquired *O. ochengi* infections following exposure. Parasitological assessments during, and at the completion of, the exposure period indicated reduction in female worm burdens and microfilarial densities in vaccinated calves, although these findings are pending statistical analysis. Immunization of *O. volvulus* 103 and RAL-2 antigens formulated with Montanide ISA 206VG in cattle elicits a strong antibody response that was associated with the protective and anti-fecundity effects to natural exposure to infection with *O. ochengi*.

### A PROMISING NEW SEROLOGIC TEST FOR EVALUATING THE SUCCESS OF ELIMINATION PROGRAMS FOR BANCROFTIAN FILARIASIS

Sarah E. Greene<sup>1</sup>, Kurt Curtis<sup>1</sup>, Christopher King<sup>2</sup>, Peter Fischer<sup>1</sup>, Gary Weil<sup>1</sup>

<sup>1</sup>Washington University in St Louis, Saint Louis, MO, United States, <sup>2</sup>Case Western Reserve University, Cleveland, OH, United States

The Global Programme to Eliminate Lymphatic Filariasis (LF) uses mass drug administration (MDA) of anti-filarial drugs to treat existing infections and interrupt transmission. New diagnostic options are needed to verify the success of MDA and identify areas at risk for ongoing transmission. The prevalence of circulating filarial antigen (CFA) and antibodies to the recombinant filarial antigens Bm14 and Wb123 decline slowly after treatments that clear microfilariae (Mf) from the blood. The Brugia Rapid Test (BRT) detects antibodies to BmR1, a *B. malayi* antigen that is expressed by Mf and gravid female worms. The BRT is a useful tool for MDA end-point decisions in areas with brugian filariasis, because antibodies to BmR1 clear fairly rapidly after successful treatment. However, the BRT has low sensitivity for *W. bancrofti* infections. We have explored the utility of a *W. bancrofti* orthologue of BmR1 (Wb-R1) for filariasis serology. An IgG4 ELISA with the Wb-R1 antigen has high sensitivity (~85%) using sera from persons with *W. bancrofti* Mf from Egypt, Sri Lanka, India and Papua New Guinea. Low amino acid sequence conservation of the Wb-R1 orthologues in *L. loa* and *O. volvulus* may account for the superior specificity of this assay relative to an IgG4 assay for antibodies to Bm14. A study of archived samples from Egypt showed that antibodies to Wb-R1 were significantly more common in treatment-naïve persons with Mf than in amicrofilaraemic persons with positive CFA tests (70% vs 53%). In addition, a study of sera from a clinical trial in Papua New Guinea showed that antibodies to Wb-R1 decreased in persons with long-term Mf clearance after treatment with the triple drug combination of ivermectin-DEC-albendazole (IDA) despite persistence of CFA. Additional studies are needed to verify these preliminary findings. However, if antibodies to Wb-R1 are better predictors of Mf persistence, this new test may prove to be a very useful surveillance tool for LF elimination programs that need to assess the potential for ongoing transmission of LF following MDA.

### POTENTIAL USE OF ANTIBODIES TO PROVIDE AN EARLIER INDICATION OF LYMPHATIC FILARIASIS RESURGENCE IN POST-MASS DRUG ADMINISTRATION SURVEILLANCE, AMERICAN SAMOA

Angela M. Cadavid Restrepo<sup>1</sup>, Katherine Gass<sup>2</sup>, Kimberly Y. Won<sup>3</sup>, Keri Robinson<sup>3</sup>, Meru Sheel<sup>4</sup>, Saipale Fuimaono<sup>5</sup>, Patricia M. Graves<sup>6</sup>, Colleen L. Lau<sup>1</sup>

<sup>1</sup>School of Public Health, Faculty of Medicine, The University of Queensland, Brisbane, QLD, Australia, <sup>2</sup>Neglected Tropical Diseases Support Center, Task Force for Global Health, Decatur, GA, United States, <sup>3</sup>Centers for Disease Control and Prevention, Division of Parasitic Diseases and Malaria, Atlanta, GA, United States, <sup>4</sup>Research School of Population Health, College of Health and Medicine, The Australian National University, Canberra, ACT, Australia, <sup>5</sup>American Samoa Department of Health, Pago Pago, American Samoa, <sup>6</sup>College of Public Health, Medical and Veterinary Sciences, James Cook University, Cairns, QLD, Australia

American Samoa conducted seven rounds of mass drug administration for lymphatic filariasis (LF) between 2000 and 2006. Subsequently, the territory passed transmission assessment surveys in February 2011 (TAS-1) and April 2015 (TAS-2) with two and one antigen (Ag)-positive children respectively, below the critical cut-offs. However, the territory failed TAS-3 in September 2016 with nine positive children and a crude prevalence of 0.8% (95% confidence interval [CI] 0.4-1.5%); a positivity rate higher than the cut-off and the recommended upper confidence limit of 1%. Anti-filarial antibodies (Ab) are detected earlier in infection than parasite antigen and thus could potentially provide an initial indication of resurgence. Earlier identification of resurgence would enable timelier control measures and optimise long-term success of elimination programs. We examined the school-level Ag status (presence/absence of Ag-positive children) and prevalence of single and combined IgG responses to Wb123, Bm14, Bm33 Ags in the three TAS to assess if Ab testing could have provided earlier signals of transmission than Ag. Pearson's chi-squared tests and univariate logistic regression were used to examine associations between school-level Ab prevalence in TAS-1 and TAS-2 and school Ag status in TAS-3. School-level Wb123 Ab prevalence in TAS-2 was significantly associated with Ag-positive status in TAS-3 ( $p = 0.02$ ). This association also provided the best balance between sensitivity (100%) and specificity (70%) of test results. Our analyses also found that schools with higher prevalence of Wb123 Ab in TAS-2 had higher odds of being Ag-positive in TAS-3 (odds ratio [OR] 24.5, 95% CI: 1.2-512.7). Similarly, schools that were positive for Ab responses in the combinations Wb123nBm14, Wb123nBm33 and Wb123nBm14nBm33 in TAS-2 also had higher odds of being Ag-positive in TAS-3 (OR 16.0-24.5). Results suggest that anti-filarial Ab provided earlier signals of LF resurgence than Ag alone. Further studies are required to determine the role of Ab testing in LF elimination programs, and how results can be used to inform programmatic decision making.

<sup>7</sup>*Servicio Navarro de Salud- Osasunbidea, Zizur Mayor, Spain*, <sup>8</sup>*Université de Montréal, Montréal, QC, Canada*, <sup>9</sup>*Instituto de Salud Global de Barcelona, Barcelona, Spain*

Cough is a landmark symptom of respiratory disease. However, its objective monitoring is challenging. Adoption of technology-enabled alternatives to clinical questionnaires is hindered by issues of privacy and portability, limiting their use in clinical practice. As part of an ongoing acoustic surveillance study, we instructed a group of participants at the University of Navarra (Spain) to monitor their night-time cough for thirty days. A smartphone application using a machine learning convolutional neural network was used to automatically detect cough events among ambient sounds. Population cough data was aggregated to construct cough time series. Cough incidence in the cohort was compared to incidence of medical consultations due to respiratory symptoms. We identified three archetype cases for which changes in cough patterns identified by the surveillance app were clear and linked to specific explanatory events. We describe (1) an evident, yet unnoticed increase in cough in a participant newly diagnosed with COVID-19; (2) a sharp reduction in cough frequency in a participant with idiopathic chronic cough newly treated with gabapentin; and (3) similar cough reductions following smoking cessation in a long-time smoker. Our results highlight the potential usefulness of artificial intelligence in the detection and monitoring of cough patterns associated with acute and chronic respiratory diseases. These systems can accurately capture the influence of clinically relevant changes in cough, representing a promising alternative to standard self-reporting methods.

0490

#### DEVELOPMENT AND EVALUATION OF MOTOMEDS: A PEDIATRIC TELEMEDICINE AND MEDICATION DELIVERY SERVICE FOR RESOURCE-LIMITED SETTINGS

Molly Klarman<sup>1</sup>, Youselfine Cajusma<sup>1</sup>, Lerby Exantus<sup>2</sup>, Katelyn E. Flaherty<sup>1</sup>, Valery Madsen Beau de Rochars<sup>1</sup>, Torben K. Becker<sup>1</sup>, Chantale Baril<sup>2</sup>, Eric J. Nelson<sup>1</sup>

<sup>1</sup>*University of Florida, Gainesville, FL, United States*, <sup>2</sup>*Faculté de Médecine et de Pharmacie - Université d'Etat d'Haïti, Port au Prince, Haïti*

Acute respiratory infection and diarrheal disease are the two leading causes of pediatric mortality between 1 month and 5 years of age globally. These, and other common childhood illnesses have well-established low-cost treatments. However, treatment is most effective when administered early, which is a challenge in resource-limited settings. MotoMeds, a pediatric telemedicine and medication delivery service, was launched in Gressier Haiti as a pre-pilot feasibility study. When a child becomes sick at night a parent calls MotoMeds to connect with a nurse who uses clinical decision-support tools that our team adapted from WHO in-person guidelines. The nurse synthesizes information relayed over the phone to triage, assess and develop a treatment plan, which may include medication delivery. To evaluate the approach, a clinical congruence study was conducted where a nurse accompanied each delivery to perform a parallel in-person exam. The primary outcome measure was congruence of illness severity between call center and household. Cohen's Kappa statistic and sensitivity and specificity measurements were calculated. From September 2019 to January 2021 394 cases were enrolled. The most common chief complaints were fever (42%), respiratory illness (17%), and skin infection/irritation (14%). At the call center, 6.8% (27) of patients were categorized as severe and sent to the hospital and 88% (348) received a nurse visit. At the household, danger signs were identified in 1.5% (6) of patients. Agreement between mild cases was substantial  $\kappa=0.63$  (95% CI 0.50-0.77) with 95.0% (95% CI 92.0%-97.1%) sensitivity and 76.7% (95% CI 57.7%-90.1%) specificity and agreement between moderate cases was moderate  $\kappa=0.60$  (95% CI 0.45-0.75) with 83.3% (95% CI 62.6%-95.3%) sensitivity and 93.8% (95% CI 91.0%-96.4%) specificity. These data indicate aspects of the information collected at the call center hold clinical value. The service was robust and remained operational despite

an unstable environment. Future analysis will evaluate congruence of all assessment components and explore rates of conversion to severe illness and seeking in-person care.

0491

#### IS E-LEARNING EFFECTIVE AT IMPROVING KNOWLEDGE OF MALARIA AMONG HEALTH WORKERS COMPARED TO TRADITIONAL TRAINING? RESULTS FROM A PRAGMATIC ASSESSMENT IN ANGOLA, 2020-2021

Jose Franco Martins<sup>1</sup>, Benjamin Nieto-Andrade<sup>2</sup>, Rukaaka Mugizi<sup>2</sup>, Sarah M. Labuda<sup>3</sup>, Joana L. Do Rosario<sup>4</sup>, Admilde Jose<sup>2</sup>, Derson Andrade<sup>5</sup>, Pedro Beirao<sup>5</sup>, Elisa Miguel<sup>1</sup>, Christopher Lourenco<sup>6</sup>, Anya Fedorova<sup>2</sup>

<sup>1</sup>*National Malaria Control Program / Angola, Luanda, Angola*, <sup>2</sup>*Population Services International / Angola, Luanda, Angola*, <sup>3</sup>*President's Malaria Initiative, Centers for Disease Control and Prevention/Angola, Luanda, Angola*, <sup>4</sup>*President's Malaria Initiative, United States Agency for International Development/Angola, Luanda, Angola*, <sup>5</sup>*Appy People, Luanda, Angola*, <sup>6</sup>*Population Services International / Washington, Washington, DC, United States*

Malaria causes 60% of hospital admissions in children in Angola, with poor quality-of-care being a driver of in-patient mortality. The Malaria Strategic Plan 2021-2025 prioritizes traditional training as an important quality of care improvement strategy; however, its effectiveness is limited by unstandardized training quality. The Ministry of Health (MOH) developed an e-learning platform (KASSAI) to enhance quality of training on Malaria Case Management (MCM). KASSAI's content is aligned with national guidelines and includes 4 modules (8 hours each): MCM in children, pregnancy, adults, and epidemiology. Each module is organized by learning objectives and interactive exercises, with a pre-test and post-test to assess knowledge improvement. Between July 2020-March 2021 KASSAI was rolled out in 4 high malaria transmission provinces. It was implemented in 45 public health units with high malaria caseloads, prioritizing health workers (HWs) from the pediatric, obstetric, and emergency departments. HWs enrolled into KASSAI using tablets, receiving support on course navigation, and troubleshooting by an MOH trainer. By mid-March 2021, 751 HWs had enrolled onto KASSAI, with a completion rate of 88.4% (n=664). Of these, the percentage who scored  $\geq 75\%$  points increased from 28.6% in the pre-test to 65.5% in the post-test (37 points increase). In contrast, 678 HWs enrolled in traditional training (July-December 2020), with a completion rate of 100.0%. The percentage who scored  $\geq 75\%$  points increased from 4.9% in the pre-test to 40.3% in the post-test (35 points increase). Importantly, KASSAI was able to identify in real-time areas with persistent knowledge gaps in the post-test: severe MCM in children (scored 47.0%) and comorbidity diagnosis (scored 51.0%). Inadequate digital literacy might be a barrier to completion of KASSAI. However, KASSAI offers the advantage of standardizing the quality of trainings across provinces. It can be used for self-learning and as part of continued medical education program in health units. It provides similar learning improvements as traditional training, becoming ideal to implement in the COVID-19 context.

0492

#### IMPACTS OF MASS NUTRITIONAL SUPPLEMENTATION ON DYNAMICS OF MEASLES: A SIMULATION STUDY

Navideh Noori<sup>1</sup>, Laura A. Skrip<sup>2</sup>, Assaf P. Oron<sup>1</sup>, Benjamin M. Althouse<sup>1</sup>, Indi Trehan<sup>3</sup>, Kevin P. Phelan<sup>4</sup>

<sup>1</sup>*Institute for Disease Modeling, Global Health, Bill & Melinda Gates Foundation, Seattle, WA, United States*, <sup>2</sup>*University of Liberia, Monrovia, Liberia*, <sup>3</sup>*University of Washington, Seattle, WA, United States*, <sup>4</sup>*Alliance for International Medical Action, Paris, France*

Undernutrition and infection interact in a bidirectional manner. Nutrient deficiencies in children stunt growth, impair immunity, and increase susceptibility to infection. Simultaneously, infections compound undernutrition by increasing metabolic demand, reducing food intake

and impairing nutrient absorption. Nutrition-specific approaches like mass supplementation of children with specially designed foods has been shown to improve growth, reduce wasting and all-cause mortality. Combined with a package of health support, including immunization, it could lead to overall improved health of children. To understand how mass nutritional supplementation and vaccination collectively affect the dynamics of a common vaccine-preventable infection, beyond providing therapeutic feeding for wasted children, we developed a population-level, dynamic model of measles transmission stratified by undernutrition status. We simulated a range of scenarios to assess the benefits of these interventions on measles morbidity and mortality. Mass nutritional supplementation was assumed to increase engagement with the health sector leading to increased proportions of children being vaccinated. We found a strong effect of mass supplementation in reducing measles infection and death, as well as measles-induced kwashiorkor mortality. In addition to treatment of wasted children, 60% mass supplementation coverage of children aged 6-23 months followed by an increase in vaccination coverage of non-wasted children from baseline of 65% to 80%, leads to a ~40-55% reduction in all three outcomes, regardless of the wasting treatment coverage. This synergy of mass nutritional supplementation and increases in vaccine coverage provides sizeable reductions in measles morbidity and mortality well above treatment of acute malnutrition or increased vaccine uptake alone. Our work highlights the need to account for nutrition in infectious disease models to prevent overestimation of impact interventions, as well as the need to collect quantitative information about how undernutrition may be associated with higher susceptibility to infection.

0493

#### IMPACT OF VACCINATION AND NON-PHARMACEUTICAL INTERVENTIONS ON SARS-COV-2 DYNAMICS IN SWITZERLAND

Andrew J. Shattock, **Epke A. Le Rutte**, Robert P. Duennen, Swapnoleena Sen, Sherrie L. Kelly, Nakul Chitnis, Melissa A. Penny  
*Swiss Tropical and Public Health Institute, Basel, Switzerland*

Having started as a zoonotic tropical infectious disease, COVID-19 quickly spread into a global pandemic. Capturing SARS-CoV-2 transmission dynamics, and more importantly preventing cases numbers, ICU admissions, and deaths, has become of utmost importance to scientists and policymakers. With this study we present a new individual-based transmission model, OpenCOVID, which has been used to support policymakers in formulating public health control strategies against COVID-19 in Switzerland. As vaccination coverage continues to increase, amidst the emergence and spread of more infectious and potentially more deadly viral variants, decisions on timing and extent of relaxing effective, but unsustainable, non-pharmaceutical interventions (NPIs) continue to need to be made. Using OpenCOVID, we estimated that even if NPIs were not relaxed and continued at high levels from March 2021 onwards, a 'third wave' would still arise with more than 1250 ICU admissions over a 6-month period even with the assumption of high vaccine coverage (100,000 vaccines being administered daily). Would NPIs be lifted quickly, combined with 50,000 vaccines administered daily, we estimated nearly 5-times more ICU admissions (>7000), over the maximum ICU capacity limit for Switzerland. However, a cautious, phased relaxation of NPIs that reaches a similarly low level but 9 weeks later, combined with 100,000 vaccines being administered daily, could offset the size of such a wave and could substantially reduce population-level morbidity and mortality leading to fewer ICU admissions (~2500), from 400,000 confirmed cases, and 3000 deaths in a population of 8.5 million. Showing that the right balance between vaccine uptake and ongoing NPIs can alleviate the size of any future wave and speed up the timing of its peak. Presenting the latest insights around SARS-CoV-2 transmission dynamics and the impact and interplay of interventions that lead to the latest COVID-19 projections for Switzerland, will highlight the importance of future tropical infectious disease outbreak preparedness.

0494

#### COVID-19 TREATMENTS SOLD ONLINE WITHOUT PRESCRIPTION REQUIREMENTS: A GLOBAL CONCERN

**Sachiko Ozawa**, Joanna Billings, Catherine Sun, Sushan Yu, Benjamin Penley

*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

The COVID-19 pandemic has increased online purchases and heightened interests in treatments. Dexamethasone, hydroxychloroquine, and lopinavir-ritonavir have been touted as potential treatments for COVID-19. We assessed the availability of these potential COVID-19 treatment options online and evaluated the safety and marketing characteristics of websites selling these products. A cross-sectional study was conducted in June-August 2020 searching the first 100 results on Google, Yahoo, and Bing. Unique websites were included if they sold targeted medicines, were in English, offered to ship to the US, and were free to access. Identified online pharmacies were categorized as rogue, unclassified or legitimate based on LegitScript classifications. We found 117 websites: 30 selling dexamethasone, 39 selling hydroxychloroquine, and 48 selling lopinavir-ritonavir. This included 89 unique online pharmacies: 62 (70%) rogue, 20 (22%) unapproved, and 7 (8%) legitimate. All rogue pharmacies selling dexamethasone (n=19) did not require a prescription. Half of the rogue online pharmacies selling hydroxychloroquine (50%, n= 11) and lopinavir-ritonavir (61%, n= 20) did not require a prescription. Rogue sites rarely offered pharmacist counseling (3-9%). Drug warnings were unavailable on 86% of unapproved dexamethasone sites. Illegitimate pharmacies were more likely to offer bulk discounts and claim price discounts; yet dexamethasone and hydroxychloroquine were more expensive online. Some websites claimed hydroxychloroquine and lopinavir-ritonavir were effective COVID-19 treatments despite lack of evidence. Only 8.5% of IP addresses matched their claimed locations, with servers located worldwide. The lack of safety measures taken by illegitimate online pharmacies endanger patients, facilitating access to medications without appropriate monitoring by healthcare providers. Health care professionals must urgently educate the public of the dangers of purchasing drugs from illegitimate websites and highlight the importance of seeking treatment through authentic avenues of care.

0495

#### EFFECTIVENESS OF SOCIAL MEDIA-BASED INTERVENTIONS FOR HEALTH BEHAVIOR CHANGE IN LOW- AND MIDDLE-INCOME COUNTRIES: A SYSTEMATIC REVIEW

**Jessie Seiler**<sup>1</sup>, Tanya Libby<sup>1</sup>, Emahlea Jackson<sup>1</sup>, Jairam Lingappa<sup>1</sup>, Sohail Agha<sup>2</sup>, W. Douglas Evans<sup>3</sup>

<sup>1</sup>University of Washington, Seattle, WA, United States, <sup>2</sup>Bill & Melinda Gates Foundation, Seattle, WA, United States, <sup>3</sup>The George Washington University, Washington, DC, DC, United States

Use of social media interventions to effect health behavior change has been well-documented to be effective in the context of high-income countries (HICs). However, there is limited information on the effectiveness when such interventions target residents of lower- and middle-income countries (LMICs). We performed a systematic review of the available literature (following the 2009 Preferred Reporting Items for Systematic Reviews and Meta-Analyses [PRISMA] guidelines) to identify interventions that have been implemented using social media in LMICs, and to characterize the evidence of their effectiveness. We searched PubMed, Embase, Elsevier, CINAHL, PsycInfo, and Global Index Medicus for studies published between January 1, 2000 and April 5, 2021 (PROSPERO # CRD42020223572). We restricted to articles available in English and required that studies evaluated interventions that were at least partly conducted on a social media platform and used the social components of the medium. Among 1,832 identified studies, 107 passed title-abstract review, and 34 passed full-text review to final data abstraction. Among these, 22 studies concluded that the social media intervention was effective, but only 13 of 22 quantified the level of social media engagement. The desired behavior change varied widely, but studies

frequently aimed to increase knowledge and prevention behaviors for viral infections, including HIV (n=5) and Dengue, Zika, and Nipah virus (one study each). Few studies identified a theoretical (n=8) or conceptual (n=5) model of behavior change. Our review of these 34 studies identified methodological gaps in settings and types of interventions, length of follow-up, evaluation techniques, and discussions of the privacy implications of the use of social media in LMICs. As social media becomes a more powerful and omnipresent factor in people's lives, its potential as a platform for public health work grows rapidly. This review highlights the need for improved methodological rigor in the planning, implementation and evaluation of health interventions for LMIC in order to increase the current, relatively small, evidence base.

0496

### SUPPLY CHAIN DATA-TO-ACTION FOR IMPROVED MALARIA COMMODITY AVAILABILITY IN LAO PDR

**Southongkham Sitthideth**<sup>1</sup>, Rose Martersteck<sup>2</sup>, Manisai Khounsombat<sup>1</sup>, Phengdavanh Inthavongtham<sup>3</sup>, Lauren Theis<sup>2</sup>, Phonephet Butphomvihane<sup>4</sup>, Garrett Young<sup>2</sup>, Chanthalone Khamkong<sup>1</sup>, Viengxay Vanisaveth<sup>1</sup>

<sup>1</sup>Center for Malaria, Parasitology and Entomology (CMPE), Vientiane, Lao People's Democratic Republic, <sup>2</sup>Clinton Health Access Initiative (CHAI), Vientiane, Lao People's Democratic Republic, <sup>3</sup>Regional Artemisinin-resistance Initiative 3 Elimination (RAI3E), Vientiane, Lao People's Democratic Republic, <sup>4</sup>World Health Organization (WHO), Vientiane, Lao People's Democratic Republic

Lao PDR seeks to eliminate all forms of malaria by 2030. To achieve elimination, the Center for Malaria, Parasitology and Entomology (CMPE) Logistics Management Unit aims to ensure that quality malaria commodities, such as rapid diagnostic tests (RDTs) and artemisinin-based combination therapies (ACTs), are continually available. Despite the wealth of data in the national health management information system (HMIS), CMPE lacked a way to quickly synthesize, interpret, and act on data to improve supply availability. Stockouts remained a challenge in five high burden provinces in southern Lao PDR, with an average of 4% health facilities (HFs) stocked out of RDTs in 2019. While only 0.1% of HFs stocked out of adult ACTs in this time, 10% of HFs were below the required minimum stock. To address these challenges, CMPE Logistics, with support from partners CHAI and WHO, designed stock dashboards in the HMIS to facilitate interpretation of stock data at provincial, district, and HF levels. The team created color-coded maps and tables to provide user-friendly outputs indicating when a HF is over-stocked, under-stocked or stocked-out of key commodities. They also built a distribution planning tool that specifies the quantities required to meet forecasted product needs at each level. By recommending these quantities per recent trends, seasonality, and stock minimums, the dashboards allow staff to identify facilities at risk of stock-out and proactively resupply to prevent service interruption. CMPE launched the stock dashboards nationally in September 2020, with focused implementation in the five high burden provinces. The dashboards have been incorporated into routine program management planning and review meetings, leading to resupply before HFs stock out of products. By March 2021, program staff succeeded in reducing the HF average monthly stock-out rates in the five high burden provinces from 4% to 2% RDTs. Below minimum ACT inventory in HFs dropped from 17% to 12%, with further improvements in the coming months. With these improved tools, CMPE expects to eliminate stock outs in 2021 and maximize availability of malaria testing and treatment.

### DIGITALLY ENABLED CLINICAL TRIALS IN SUB SAHARAN AFRICA READY TO GO

**Eric Ipnyn Nebie**<sup>1</sup>, Jürg Utzinger<sup>2</sup>, Christian Burri<sup>2</sup>

<sup>1</sup>National Institute of Public Health/Centre de Recherche en Sante de Nouna, Nouna, Burkina Faso, <sup>2</sup>Swiss TPH, University of Basel, Basel, Switzerland

Innovations in drug development approaches are needed to address its increasing complexity and the observed trends of efficiency loss. Drugs and vaccines development during the COVID-19 pandemic has proved that there is room for improvement. Novel digital health technologies application is gaining attention in drug development in the North. These new models foster trial participants' engagement through self-reporting, remote samplings to accelerate and improve clinical trials quality. The growing contribution of Sub-Saharan Africa (SSA) to clinical research calls for local investigators to become involved in this transition to digitally enabled clinical trials (DECT) in SSA. Our study aims to assess the opportunities, gaps and pitfalls for clinical trials digitalization. A qualitative study including semi-structured interviews was conducted in two clinical research centers of excellence in Burkina Faso and Mali. In addition, clinical trial procedures, site organization and level of efforts were assessed through work shadowing. Data were analyzed using a thematic approach. Overall, nineteen interviews were conducted from December 2020 to February 2021 with site leaders, principal investigators, study coordinators and Contract Research Organizations based in SSA. The investigators had on average seven years of experience in clinical research. None of the sites has been involved in a fully digitally enabled trial. Investigators consider DECT as feasible and as an opportunity for participant adherence improvement and adverse events reporting. However, the adaptation of these technologies to the sociocultural specificities is crucial. Acceptability challenges of remote participants' management, e.g. with follow-up or data collection through wearable devices are multifactorial. "Doctor to patient relationship is very important – we should not dehumanized clinical research," stressed a senior researcher. Substantial communication and investigators involvement will be important for a successful rollout of DECT in SSA. Patient to investigator relationship and mutual trust in clinical trials should be considered.

0498

### COMPARING THE ROI OF TECHNOLOGIES FOR DETECTING POOR QUALITY AMOXICILLIN: A KENYA CASE STUDY

**Colleen R. Higgins**, Betty Kobia, Sachiko Ozawa

University of North Carolina Chapel Hill, Chapel Hill, NC, United States

Substandard and falsified medicines harm patients and have economic implications for health systems. An effective post-market surveillance system involves the identification and removal of poor-quality medicines in circulation, averting them from use by patients. Cost is a barrier to conducting post-market surveillance in some low- and middle-income countries, but screening technologies exist that both speed up the identification of poor-quality samples and lower the investment by relying less on the costlier high performance liquid chromatography (HPLC). However, there is little guidance on which screening technology to implement. We calculated the return on investment of using five screening methods: Minilab, Near Infrared (NIR), Paper Analytical Devices (PADs), Raman, and HPLC alone to conduct post-market surveillance of amoxicillin in Kenya. The Examining Screening Technologies using Economic Evaluations for Medicines (ESTEEM) agent-based model was employed to simulate sampling, testing, and removal of substandard and falsified medicines from the Kenyan market. Assuming that identified poor-quality batches were removed from circulation, we analyzed the population impact of amoxicillin quality used for pediatric pneumonia. Compared to doing no post-market surveillance, screening technologies prevented 2,230 - 10,137 poor-quality treatments from reaching patients annually, averting 132 - 60 pediatric deaths. Using NIR, we estimate it costs \$12 per death averted, and \$17, \$21, \$59, and \$238 using PADs,

Minilab, Raman, and HPLC, respectively. The cost per substandard and falsified treatment averted ranged from \$0.70 (NIR) to \$14.11 (HPLC). The NIR and PADs yielded the highest ROI of \$62 and \$43 per dollar invested, respectively. PADs, Minilab, NIR, and the Raman are similar in their abilities to quickly identify substandard and falsified amoxicillin but differences in costs, usability, and country-specific capabilities affect the implementation. National medicine regulatory authorities should consider cost evidence among other factors when deciding which of these screening technologies to implement.

0499

### EXCESSIVE SEEPAGE DURING MITS PROCEDURE: AN EXPLORATIVE STUDY TO IDENTIFY THE UNDERLYING CAUSES

**Rajib Biswas<sup>1</sup>**, Mohammad Zahid Hossain<sup>1</sup>, Kazi Munisul Islam<sup>1</sup>, Mohammad Sabbir Ahmed<sup>1</sup>, Sanwarul Bari<sup>1</sup>, Shams El Arifeen<sup>1</sup>, Emily S. Gurley<sup>2</sup>

<sup>1</sup>International Centre for Diarrhoeal Disease Research, Bangladesh, Dhaka, Bangladesh, <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Minimally invasive tissue sampling (MITS) is a postmortem sample collection approach used to identify the cause of death where full diagnostic autopsy is not feasible. Under the Child Health and Mortality Prevention Surveillance (CHAMPS) Network, findings from MITS are helping to identify and analyze specific causes of stillbirth and under-5 deaths. Families, who are largely unfamiliar with this procedure, may have socio-cultural and religious concerns about consenting. Tissue sample collection, using specialized needles, sometimes causes excessive seepage from the puncture sites that may cause family dissatisfaction or give rise to community rumors leading to reduced acceptance for MITS. The objective of the study was to identify characteristics that increase the chance of excessive seepage so that additional counseling can be provided to the family before the procedure. From September 2017 to December 2020, we conducted 213 MITS in the CHAMPS Bangladesh site where 11% cases (23/213) had excessive seepage. There was no correlation with the time interval between death and MITS procedure ( $p=0.94$ ). Among the 23 with excessive seepage, 74% (17/23) were early neonatal deaths and 17% (4/23) stillbirths. We compared them with 180 early neonatal deaths (46%, 83/180) and stillbirths (54%, 97/180) undergoing MITS but without seepage to investigate characteristics associated with excessive seepage using binary logistic regression. Of the total 203 cases, 21% had spontaneous bleeding without any trauma from either the nose, mouth, or ear prior to MITS, but the incidence of bleeding was higher (48%) among the children with excessive seepage; they had 3.7 higher odds of bleeding from the nose (95% CI: 1.1-12.0,  $p<0.05$ ). Odds of seepage in stillborn children were lower (OR: 0.1, 95% CI: 0.1-0.6) compared to early neonatal deaths. None of the macerated stillbirths had excessive seepage. Preliminary findings suggest that family members of children who died within the first 7 days of birth, already having signs of bleeding prior to the MITS, should be counseled about the possibility of seepage to minimize post-MITS dissatisfaction or rumors.

### MACHINE LEARNING-BASED PREDICTION OF CLINICAL OUTCOMES FOR CHILDREN USING LINKED ELECTRONIC HEALTH RECORDS IN MANHIÇA DISTRICT, MOZAMBIQUE

**Sham Lal<sup>1</sup>**, Marta Valente<sup>2</sup>, Oliver Baerenbold<sup>1</sup>, Justina Bramugy<sup>3</sup>, Sara Ajanovic<sup>2</sup>, Teodimiro Matsena<sup>3</sup>, Chrissy H. Roberts<sup>1</sup>, Quique Bassat<sup>2</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>ISGlobal, Hospital Clínic - Universitat de Barcelona, Barcelona, Spain, <sup>3</sup>Centro de Investigação em Saúde de Manhiça (CISM), Maputo, Mozambique

The increasing availability of individual-level electronic health records (EHR) presents a major opportunity to understand the progression and

outcome of childhood illnesses in clinical settings. Recently, predictive machine learning (ML) algorithms have been used with EHRs to identify the vital clinical and laboratory information to assess individual risk and aid prognosis. ML methods result in algorithms that can identify key characteristics or patterns in large complex datasets, which may otherwise be hard to detect by traditional regression methods or by health care workers in clinical settings. However, many ML studies predicting outcomes have been conducted in high-income countries and lack detailed pre-admission health and demographic data which has constrained the development of clinical prediction algorithms suitable for these settings. We applied ML algorithms to predict child outcomes using data from; a longitudinal child morbidity surveillance study, demographic surveillance system (DSS) and a fever aetiology study (FIEBRE), for all child (under 15 years) visits to Manhica District Hospital, Mozambique. Child out-patient and inpatient data were collected for 1,384,354 hospital visits between January 1997 and October 2020. These data included; medical history, physical examination, laboratory samples, diagnosis and health outcomes. These data were linked with a unique ID to a health and a demographic surveillance site dataset that monitors a population of 201,845 bi-annually. These data include socio-economic position, immunisation history, pregnancies and use of malaria control interventions. We applied a standard set of ML classification algorithms to predict; a) admissions, b) length of stay ( $<72$  or  $\geq 72$  hours) and c) mortality. For all visits, the median age was 3 years (IQR 1-7) and 49% were female, 1,315,628 were outpatients and 68,726 were inpatients, with a median length of stay of 3 days (IQR 2-5) and 4% inpatient mortality. We will present the critical evaluation of ML algorithms to identify vital clinical, demographic and health information to predict child outcomes in resource-limited settings.

### KAP COVID CASE STUDY: MASKS, BELIEFS, AND VACCINE ACCEPTANCE - GLOBAL DISSEMINATION OF COVID BEHAVIORS

**Jeni Stolow<sup>1</sup>**, Stella Babalola<sup>2</sup>, Dean Eckles<sup>3</sup>, Tamer Farag<sup>4</sup>, Nina Gobat<sup>5</sup>, Susan Krenn<sup>6</sup>, Avichal Mahajan<sup>7</sup>, Elizabeth Serlemitsos<sup>6</sup>, Marla Shaivitz<sup>6</sup>, Dominick Shattuck<sup>6</sup>

<sup>1</sup>Temple University, Philadelphia, PA, United States, <sup>2</sup>Johns Hopkins University Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>Massachusetts Institute of Technology Sloan School of Management, Cambridge, MA, United States, <sup>4</sup>Facebook, Menlo Park, CA, United States, <sup>5</sup>University of Oxford, Oxford, United Kingdom, <sup>6</sup>Johns Hopkins Center for Communications Programming, Baltimore, MD, United States, <sup>7</sup>World Health Organization, Geneva, Switzerland

The COVID-19 pandemic challenges global health responders to continuously motivate populations to uptake and adhere to COVID-19 prevention and control behaviors. Such monumental effort requires rapid, nuanced data on populations' COVID-19 knowledge, attitudes, risk perceptions, and behaviors. Without such data, those on the COVID-19 frontlines lack the information needed to roll out COVID-19 policies, research, risk communication, health education, social mobilization, and community engagement. To fill the gap, the World Health Organization (WHO), Global Outbreak Alert and Response Network (GOARN), Massachusetts Institute of Technology (MIT), Johns Hopkins University Center for Communications Program (CCP), and Facebook teamed up to develop the KAP COVID Dashboard. Data for the dashboard were collected via a survey promoted on the Facebook platform. Thus far, 19 waves of data have been collected, yielding five dashboard visualizations: (1) Global Vaccine Acceptance, (2) Trend Analysis of 23 Countries, (3) Global and Regional Views, (4) Individual Country Views, and (5) US and India Subnational Views. These interactive dashboards display data from 67 countries, representing over 1.7 million participants. The user-centered approach is aimed at supporting the efforts of COVID-19 practitioners, decision-makers, and responders around the globe to make informed decisions related to COVID-19 policies, communication, and resource allocation. This presentation will discuss the design process as well as the benefits of such collaborative approaches to data collection, visualization, and partner engagement. Case studies will be presented to demonstrate

the range of how this dashboard has been utilized by in-country teams. With numerous outbreaks, epidemics, and pandemics on the horizon, it is imperative that global researchers and responders aim to uptake collaborative, innovative, rapid, and agile approaches to data collection, visualization, and operational research.

### A PROCESS OF SETTING UP TUBERCULOSIS RESEARCH PRIORITIES AT A NATIONAL SCALE IN ZIMBABWE THROUGH THE NATIONAL TUBERCULOSIS PROGRAM

**Nokuthula Samantha Tozivepi**<sup>1</sup>, Collins Timire<sup>2</sup>, Wietske Mushonga<sup>3</sup>, Charles Sandy<sup>2</sup>, Kudakwashe Collin Takarinda<sup>2</sup>, Elton Mugomeri<sup>3</sup>, Fadzai Naomi Mukora-Mutseyekwa<sup>1</sup>

<sup>1</sup>Africa University Clinical Research Centre, Mutare, Zimbabwe, <sup>2</sup>Ministry of Health and Child Care, National AIDS & TB Program, Harare, Zimbabwe,

<sup>3</sup>Africa University Department of Health Sciences, Mutare, Zimbabwe

Zimbabwe is a high-burden country for Tuberculosis (TB), Multi-drug resistant tuberculosis (MDR-TB) as well as Tuberculosis/ Human Immunodeficiency Virus (TB/HIV) co-infection. The Government of Zimbabwe is committed to ending TB by 2030. By 2025, the National Tuberculosis Program (NTP) aims to reduce TB incidence and mortality by 80%. To achieve these targets, one of the pillars set was the research and innovation pillar of the End TB Strategy, which promotes research along a continuum that links upstream fundamental research to discovery, new tool development and to operationalize and implement research. Thus, allowing innovative strategic approaches to be adapted to specific country needs. The process of setting up research priorities started with identifying a Tuberculosis Research Technical Working Group (TBR TWG). The TBR TWG aimed to capacitate the NTP's relevant operational research plan in conducting operations research and this followed a research prioritisation process. The research prioritisation process was conducted at a national scale through a multi-stakeholder workshop. The various stakeholders were put into 4 groups to identify research questions in the context of Zimbabwe-specific needs. A tool by Varkevisser et al (1991), was used basing on a template to categorise research questions under selected thematic areas. The template was presented as a public consultation to stakeholders. The template was presented on a Likert scale, thus prioritisation made use of a scoring system. Research questions were ranked into high, medium & low priority research questions. The research questions were then compiled together by order of priority to produce a prioritised list which was presented to stakeholders in a series of 3 stakeholder engagement meetings to facilitate review. A literature review was conducted by graduate students basing on the set-up TBR database, allowing for research questions which need further research to be identified and to refine the rationale of the prioritised list. The final TB research plan was then consolidated at the TBR TWG level to strategically include the prioritised list of research areas.

### MAJOR DEPRESSIVE DISORDER SCREENING AMONG LATIN AMERICAN IMMIGRANTS AND REFUGEES IN FLORIDA DURING COVID-19

**Norman L. Beatty**<sup>1</sup>, Rodrigo Alcalá<sup>2</sup>, Nelson A. Luque<sup>2</sup>, Laura M. Velez<sup>2</sup>, Paola A. Trejo<sup>2</sup>, Austin P. White<sup>2</sup>, Maria C. Carrasquilla<sup>2</sup>, Nicole G. Bender<sup>3</sup>, Kaci D. McCoy<sup>3</sup>, Joshua Latner<sup>4</sup>, Omkar Betageri<sup>4</sup>, Jessica Portillo<sup>4</sup>, Jonathan G. Harrell<sup>5</sup>, Colin J. Forsyth<sup>6</sup>, Rhoel R. Dinglasan<sup>3</sup>

<sup>1</sup>University of Florida College of Medicine, Department of Medicine, Division of Infectious Diseases and Global Medicine, Gainesville, FL, United States, <sup>2</sup>University of Florida College of Medicine, Gainesville, FL, United States, <sup>3</sup>University of Florida Emerging Pathogens Institute, Gainesville, FL, United States, <sup>4</sup>University of Florida College of Medicine, Department of Medicine, Gainesville, FL, United States, <sup>5</sup>University of Florida College

of Medicine, Department of Community Health & Family Medicine, Gainesville, FL, United States, <sup>6</sup>Drugs for Neglected Diseases Initiative, New York City, NY, United States

Major depressive disorder (MDD) among immigrants and refugees has significant implications for mental health wellness and integration into society after migration. We screened Latin American immigrants and refugees (N=258) originating from Mexico, and other countries found in Central and South America who had emigrated to Florida for evidence of MDD at participating medical clinics located in north Florida. Using the Patient Health Questionnaire-9 (PHQ-9) we screened participants for MDD during the COVID-19 pandemic from 11/10/20 until 04/16/21 at our medical clinics for those who were largely uninsured, and Spanish was their primary language. A total of 31% (N=80/258) scored 5 or greater using the PHQ-9, indicating risk for MDD. Median age was 40 years with 64% female, and median arrival to the United States was 2015. Participants migrating from 14 Latin American countries (Mexico, Central, and South America) were included, with greater than one-third of those screening positive migrating from Venezuela (N=28/80; 35%). Mexico (N=16/80; 20%), Colombia (N=9/80; 11%), Honduras (N=8/80; 10%), and Guatemala (N=7/80; 9%) were other regions with increased rates of MDD within this cohort. Average PHQ-9 scores among these five countries (Venezuela, Mexico, Colombia, Honduras, and Guatemala) were 11. Feeling down, depressed, or hopeless was substantial in the entire group screened, with 18% (N=46/258) expressing this occurs several days a week, 11% (N=29/258) more than half the days of week, and 4% (N=9/258) expressing these feelings occur nearly every day. Among those who screened positive for MDD, 51% (N=41/80) felt these problems were somewhat difficult to manage work, things around the home, and get along with other people, with 28% (N=22/80) stating this was very difficult. Each participant who screened positive for MDD was provided resources for further support and management in our clinic network. As demonstrated among this ongoing study, the current COVID-19 pandemic and other factors, such as political unrest among home country, are likely having a major impact on some who are immigrating to the United States from Latin America.

0504

### THE ASSOCIATION THAT GENDER ROLES HAVE WITH HEALTH SEEKING BEHAVIOR FOR WOMEN IN KENYA, TANZANIA, AND UGANDA

**Gloria N. Nabiosa**<sup>1</sup>, Sandra D. Lane<sup>2</sup>, Brittany L. Kmush<sup>1</sup>

<sup>1</sup>Syracuse University, Syracuse, NY, United States, <sup>2</sup>Laura J. & L. Douglas Meredith Professor of Public Health & Anthropology Research Professor Obstetrics & Gynecology Upstate Medical University, Syracuse, NY, United States

There are negative effects on maternal and child health outcomes in areas with greater gender inequalities, but it is not clear that there is an association between education status, control of earnings, and who makes health care decisions. Our research investigates the association between gender equality and health seeking behavior for women in Kenya, Tanzania, and Uganda. Using the 2014 Demographic Health Surveys (DHS), we examined who decides how to spend a woman's earnings, who decides on women's healthcare, and women's highest level of education. The outcomes of interest were health care seeking behaviors, including antenatal care and the place of care. We used R to conduct multivariate logistic regression to examine this association adjusting for age of head of household, age of respondent, urban or rural residence, wealth index, and age of respondent's first birth. There were 83,591, 57,906, and 37,169 women in Kenya, Uganda, and Tanzania, respectively included. We found that women were less likely to go to a government hospital if their husband controlled their earnings (Kenya OR=0.88, 95% CI:0.84 - 0.93; Uganda OR=0.77, 95% CI:0.73 - 0.81). When the husband controlled health care decisions, the women were less likely to visit a health care facility in the last 12 months (Kenya OR=0.71, 95% CI:0.70-0.72; Uganda OR= 0.87, 95% CI:0.86 - 0.88; Tanzania OR= 0.84, 95% CI:0.82 - 0.85). College educated women were more likely than those without a formal

education to seek antenatal care at government-run hospitals (Kenya OR= 1.56, 95% CI: 1.50 - 1.62; Uganda OR= 2.94, 95% CI: 2.81 - 3.07; Tanzania OR= 2.12, 95% CI: 1.96 - 4.96). For those with a primary education, the strength of the association was typically smaller and only statistically significant in Uganda and Tanzania (Kenya OR= 1.01, 95% CI: 0.97 - 1.03; Uganda OR= 1.16, 95% CI: 1.12 - 1.13; Tanzania OR= 3.14, 95% CI: 2.91 - 7.34). This study, the first to use a large sample across the three countries, showed that with more access to education and control of earnings and health care decision making, women are more likely to go to their local hospital and seek antenatal care

0505

### ANTIBIOTIC ENTANGLEMENTS. HEALTH, LABOUR AND EVERYDAY LIFE IN AN URBAN INFORMAL SETTLEMENT IN KAMPALA, UGANDA

**Christine Nabirye**<sup>1</sup>, Laurie Denyer-Willis Denyer-Willis<sup>2</sup>, Susan Nayiga<sup>1</sup>, Miriam Kayendeke<sup>1</sup>, Sarah G. Staedke<sup>3</sup>, Clare I. Chandler<sup>3</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>University of Edinburgh, Edinburgh, United Kingdom, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, London, United Kingdom

Antimicrobial resistance (AMR) is considered a global health crisis, threatening the effectiveness of all classes of antibiotics, and putting people at risk of untreatable infections. Current literature on AMR suggests low- and middle-income countries (LMICs) are at high risk for the emergence of AMR, which is depicted as a potentially catastrophic burden to already constrained health care systems. In Uganda, AMR is a growing area of concern for public health actors. A 2015 situational analysis revealed increasing trends in antimicrobial resistance to commonly used antimicrobials. To further explore the everyday use of antibiotics in Uganda, we engaged in ethnographic research, including a survey of 350 households, 16 semi-structured interviews and 2 participatory focus group discussions. Participant observation was conducted over 18 weeks among selected day-wage urban workers. We found that antibiotics were used frequently; their use intertwined with ongoing struggles with infection and a need for quick recovery to return to work. We found that significant and chronic infrastructural challenges were linked with antibiotic use – through three interconnected examples: flooding, limited toilet facilities, and water contamination. Antibiotics, we argue, have become a way to negotiate the inequalities written into the landscape; their use entangled with ongoing relations with labour, environment and bodily suffering; certain environments are overburdened with infection due to inequality and marginalisation. Attending to the structural reasons for antibiotic use in urban informal settings beset by inequality is necessary. Antibiotic use interventions often depend on theories and models of individual behaviour change, placing responsibility for action at the individual level which requires a behaviour change intervention. We propose that attention must be paid to the structural conditions that make avoiding antibiotic use nearly impossible.

0506

### PRELIMINARY FINDINGS FROM A POINT PREVALENCE SURVEY OF ANTIMICROBIAL USE AT THREE RURAL DISTRICT HOSPITALS IN RWANDA

Sandra Urusaro<sup>1</sup>, Carol Mugabo<sup>1</sup>, Mariella Munyuzangabo<sup>1</sup>, Marthe Yankurije<sup>1</sup>, Alphonse Nshimiryo<sup>1</sup>, Saidath Gato<sup>1</sup>, Regis F. Uwizeye<sup>1</sup>, Christian Mpazimpaka<sup>1</sup>, Cyprien Shyirambere<sup>1</sup>, Emmanuel Kayitare<sup>2</sup>, Jean de Dieu Gatete<sup>1</sup>, Grace Umutesi<sup>3</sup>, **Fredrick Kateera**<sup>1</sup>

<sup>1</sup>Partners In Health, Kigali, Rwanda, <sup>2</sup>Butaro District Hospital, Ministry of Health, Burera, Rwanda, <sup>3</sup>University of Washington, Seattle, WA, United States

Antimicrobials significantly mitigate the burden of communicable diseases, specifically infections. However, their misuse and overuse have resulted in antimicrobial resistance (AMR). The World Health Organization (WHO) has declared AMR one of the top ten global public health threats across

the globe. In Rwanda, AMR is not well documented due to the lack of adequate surveillance systems. Here, we assessed antimicrobial prescribing patterns among health care providers at three rural district hospitals (DHS) in Rwanda. We conducted a point prevalence survey (PPS) using a standardized study tool adapted from the WHO Methodology for PPS tool at three Rwandan district hospitals (DHS) - Butaro (BDH), Kirehe (KDH) and Rwinkwavu (RDH). Patients' and prescribers' level data was collected between March - April 2021. Data of all admitted patients and prescribed antimicrobials was recorded on the same day and analyzed using Stata v.15.1. Data collection was completed at KDH and BDH. 242 admitted patients were included in the survey as they were prescribed antimicrobials -with 147 patients from KDH and 95 patients from BDH. Antibiotics from the "Access and Watch" WHO categories were the most prescribed, with three antibiotics ranking higher -- ampicillin (30%), gentamicin (20%), and third-generation cephalosporin such as cefotaxime (12.0%). From the prescribers' survey, 30.6% of the prescribed antibiotics were based on microbiology reports. Common indications for antibiotics prescriptions in this sample were; neonatal risk of infection, C-section risk of infection, and pneumonia. Prevalence of antibiotics use per facility was 57.2% for BDH and 72.8% for KDH. Study findings show significant broad-spectrum antibiotic prescribing rates against a reported low rate of laboratory results. Prospective surveillance of antibiotic use over time and between different health facilities, promoting laboratory tests guided prescription habits, and develop site-specific data-driven antibiotic guidelines may improve rational prescribing practices which, in consequence, will support rational AMS in Rwanda.

0507

### PRENATAL ALCOHOL USE KNOWLEDGE AND OUTCOMES IN LEYTE, THE PHILIPPINES

**Spencer C. Darveau**<sup>1</sup>, Alice M. Huang<sup>1</sup>, Matthew N. Neale<sup>1</sup>, Marianne J. Sagliba<sup>2</sup>, Amabelle J. Moreno<sup>2</sup>, Maria Paz G. Urbina<sup>2</sup>, Veronica Tallo<sup>3</sup>, Emily A. McDonald<sup>4</sup>, Mario A. Jiz<sup>2</sup>, Jennifer F. Friedman<sup>5</sup>

<sup>1</sup>The Warren Alpert Medical School of Brown University, Providence, RI, United States, <sup>2</sup>Research Institute for Tropical Medicine - Palo Satellite Laboratory, Palo, Leyte, Philippines, <sup>3</sup>Research Institute for Tropical Medicine, Manila, Philippines, <sup>4</sup>Center for International Health Research at Rhode Island Hospital, Providence, RI, United States, <sup>5</sup>Department of Pediatrics, The Warren Alpert Medical School of Brown University, Providence, RI, United States

Women in resource-limited settings may be at higher risk of giving birth to babies with fetal alcohol spectrum disorder due to consumption of unregulated brews without warning labels and lack of systemic preventive education. This is a major unaddressed public health issue in Leyte, The Philippines, where tuba, a locally made palm wine, is consumed. In this study, 100 postpartum women, established subjects in a longitudinal birth cohort in Leyte, were administered surveys in the local language of Waray via interview at their scheduled visits in June-Sep. 2019. The survey examined participants' knowledge, attitudes, practices, and beliefs regarding healthy pregnancies and prenatal alcohol use. The Phosphatidylethanol (PEth) dried blood test, which measures an abnormal phospholipid formed in red blood cells 2-4 weeks post alcohol exposure, was collected at enrollment, 32 weeks gestation, and birth. Chi-square and Fisher's exact tests were used to analyze bivariate relationships. 75% of subjects answered yes to drinking tuba and/or other alcoholic beverages during their most recent pregnancy. Participants who endorsed drinking tuba while pregnant were more likely to have positive PEth results at 32 weeks gestation than participants who denied drinking tuba prenatally (18% vs. 0%;  $p < 0.05$ ). Mothers who said tuba is healthy during pregnancy were more likely to have positive PEth results at 32 weeks gestation (25.00% vs. 2.27%;  $p < 0.05$ ). Some participants who reported not drinking tuba or alcohol during pregnancy had positive PEth results at enrollment (5/21, 23.81%). Almost all surveyed (98%) indicated that they would cut back on drinking alcoholic beverages if they were told that this negatively impacted them and their unborn child. Lack of information about tuba and its risks seem to contribute to its continued

use by pregnant women in Leyte. The PEth results provide a quantitative assessment of participants' prenatal alcohol consumption. Based on our results, educating women of reproductive age in Leyte regarding prenatal tuba use would likely lead to a reduction in tuba use among this population and FASD risk among their children.

0508

### EXPERIENCE OF THAI RESIDENTS DURING THE FIRST WAVE OF THE COVID-19 PANDEMIC: A QUALITATIVE STUDY

Bhensri Naemiratch<sup>1</sup>, Tassawan Poomchaichote<sup>1</sup>, Supanat Ruangajorn<sup>1</sup>, Anne Osterrieder<sup>2</sup>, Mira Leonie Schneiders<sup>2</sup>, Wirichada Pan-ngum<sup>3</sup>, **Phaik Yeong Cheah<sup>1</sup>**

<sup>1</sup>Mahidol Oxford Tropical Medicine Research Unit, Bangkok, Thailand,

<sup>2</sup>University of Oxford, Oxford, United Kingdom, <sup>3</sup>Mahidol University, Bangkok, Thailand

The impact of COVID-19 is being mitigated using non-pharmaceutical interventions (NPIs). Here we report a qualitative study in Thailand, which was part of a mixed-methods study, 'Social, ethical and behavioural aspects of COVID-19' (SEBCOV) in Thailand, Malaysia, UK, Slovenia and Italy. A total of 28 online in-depth interviews (18-74 years old) were conducted between 8<sup>th</sup> May and 21<sup>st</sup> July 2020 in Thailand. This represents the period in which the number of cases in the country was steadily decreasing and the government was relaxing its NPIs. At the time of the interviews, all participants had already experienced the strictest NPIs in Thailand, which was from 26<sup>th</sup> March to 3<sup>rd</sup> May 2020. Participants were selected using purposive sampling to gain a maximum variation sample, based on six characteristics: age, gender, educational level, household size, location, and risk of contracting COVID-19 due to their occupation and living conditions. Our results describe how Thai residents conceptualised and made sense of COVID-19. Some participants attributed the cause of COVID-19 to nature's revenge, eating "exotic" meat or acts of God. Most participants viewed COVID-19 as a serious disease, appeared to understand the rationale for strict public health measures, and reported complying with them. The challenges participants faced during the COVID-19 pandemic included economic, social and emotional challenges. Among participants most negatively impacted were those who worked in or with the tourism industry. Despite these challenges, some saw silver linings of COVID and NPIs, such as an opportunity to rethink their future life plans and not taking things for granted. This study also highlighted some coping strategies that individuals adopted, which included practicing self-care, limiting exposure to news, practicing acceptance, and turning to religion. Those who were financially able said they helped others by "making merit" (*tum bun*) such as organising "sharing pantries" (*tu pan suk*). The findings of this study are important to inform future policies in order to minimize their negative impacts on people's lives in the current pandemic and in the future.

### EFFECTS OF CORONAVIRUS PANDEMIC ON HEALTH SEEKING BEHAVIORS OF YOUNG ADULTS IN UGANDA

Judith Nalukwago<sup>1</sup>, Bolanle Olapeju<sup>1</sup>, Pallen Mugabe<sup>1</sup>, Anna Passaniti<sup>1</sup>, Isaac Musoke<sup>1</sup>, Musa Kimbowa<sup>1</sup>, Brian Asiimwe<sup>1</sup>, Emmanuel Kayongo<sup>1</sup>, Ruth Musekura<sup>1</sup>, Lyndsey Mitchum<sup>1</sup>, Arzum Ciloglu<sup>1</sup>, Leanne Wolfe<sup>1</sup>, Glory Mkandawire<sup>1</sup>, Richard Kabanda<sup>2</sup>, Joel Kisubi<sup>3</sup>, Frank Kaharuzza<sup>4</sup>, Sheila Nyakwezi<sup>4</sup>, Douglas Storey<sup>1</sup>

<sup>1</sup>Johns Hopkins Center for Communication Programs, Baltimore, MD, United States, <sup>2</sup>Ministry of Health, Uganda, Kampala, Uganda, <sup>3</sup>US President's Malaria Initiative, United States Agency for International Development (USAID), Uganda, Kampala, Uganda, <sup>4</sup>United States Agency for International Development Uganda, Kampala, Uganda

Background: The widespread social and economic effects of the COVID-19 pandemic in Uganda has likely affected access to, and perceptions of, health care services at large, yet there is still limited attention on young adults as key contributors to its spread. We sought to understand the effects of COVID-19 on health seeking behaviors of young adults

aged 18-29 in Uganda. Methods: A national population-based mobile phone survey of men and women was conducted in December 2020. Multivariable regression analyses were used to explore the associated effect of COVID-19 pandemic on access to health care services among young adults aged 18-29. Control variables included region, education level, parity, and source of health information. Results: The majority (98%) of the participants perceived COVID-19 as a serious threat to Ugandans. Although the majority reported taking action on handwashing (96%) and masking (91%), fewer participants avoided shaking hands (38%), ensured physical distancing (56%), avoided groups of more than 4 people (43%), and stayed home most of the days (30%), avoided touching eyes, nose and mouth (13%), and sneezing/coughing in the inside of the elbow (7%). Participants noted that the COVID-19 pandemic affected their access to family planning (40%), HIV (49%), maternal health (55%), child health (56%), and Malaria (63%) services. The perceived effect of the COVID-19 pandemic on services was higher among participants in the Northern region (OR= 2.00, 95% CI 1.00-4.02), higher education OR= 2.26, 95% CI 1.28-3.99), having five or more children (OR= 2.05, 95% CI 0.92-4.56) or trust in radio as a source of COVID-19 information (OR= 1.65, 95% CI 1.01-2.67). Conclusion: Young adults are a priority target audience and there is a need to intensify social and behavior change interventions that promote COVID-19 preventive measures and address challenges to accessing health services.

### KNOWLEDGE, ATTITUDE AND PRACTICE OF COMMUNITY-ORIENTED RESOURCE PERSONS ON COVID 19 IN NIGER AND KEBBI STATES, NIGERIA: A RAPID ASSESSMENT

**Emmanuel I. Taribo**

*Malaria Consortium, Minna, Nigeria*

Integrated Community Case Management (iCCM) is an equity-focused strategy that extends the reach of public health services by providing timely and effective treatment of malaria, pneumonia and diarrhoea to children under 5 years in hard-to-reach populations. During the COVID-19 pandemic, global technical guidance on infection prevention and control protocols among community health workers was issued by WHO and UNICEF and then adapted by countries. We assessed the effect of the COVID-19 pandemic on service provision and evaluated the knowledge, attitudes, and practices (KAP) of community oriented resource persons (CORPs) in an existing iCCM program in two states (Niger and Kebbi) in Nigeria from August 2021 to October 2021. 341 CORPs were randomly selected from the two states and a rapid assessment of commodities, clients' patronage, community awareness and KAP of CORPs regarding COVID-19 was done. Telephone interviews were carried out by trained data collectors using structured questionnaires and appropriate KAP regarding COVID-19 among CORPs as well as possible influencing factors were analyzed. Response rate for the study was 100% and all CORPs had received information about COVID-19, majority through the radio (82.9%). Majority of CORPs (95.9%) reported they observed no significant changes in number of caregivers seeking iCCM services compared to the pre-COVID-19 era. However, 10.3% and 13.2% of the CORPs reported stock-out of malaria rapid diagnostic tests and artemisinin-based combination therapies respectively, lasting more than 3 months. Most CORPs interviewed knew signs and symptoms of COVID-19 (83.6%) and 95.9% knew how to prevent the disease. Also, 80.1% of CORPs reported they did not avoid patients with symptoms indicative of COVID-19 in previous week before the study and 96.2% wore face masks while attending to patients. In conclusion, the pandemic did not adversely affect iCCM service provision and CORPs demonstrated satisfactory knowledge, attitudes and practices in delivering safe and effective iCCM services in the context of COVID-19.

### HANDS-ONLY CPR TRAINING PROGRAM OF SECONDARY SCHOOL STUDENTS IN IBADAN, NIGERIA: PILOTING COMBINATION VIRTUAL AND IN-PERSON LEARNING

Bolanle Akinyele<sup>1</sup>, Oluwaseyi Bolorunduro<sup>2</sup>, Olufunso Odunukan<sup>3</sup>, William R. Brieger<sup>1</sup>

<sup>1</sup>The Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Revolving Hearts Foundation, Atlanta, GA, United States, <sup>3</sup>Revolving Hearts Foundation, Atlanta, GA, United States

Out-of-hospital cardiac arrest (OHCA) has an estimated average global incidence of 55 adults per 100,000 person-years. Despite advances in medical care and technology, survival to hospital discharge remains abysmally low at 8-10%. In low to middle income countries like Nigeria, where cardiovascular disease is rising but emergency response systems are poor, the rate of survival after OHCA is lower. Bystander cardiopulmonary resuscitation (CPR) training is effective, scalable, and low-cost interventions that can reduce the OHCA mortality. Training schoolchildren to perform Hands-only CPR (HOCPR) has been shown to increase bystander CPR. CPR Peer Educator's Program (CPEP) is a community-based program in Ibadan, Nigeria, designed to enhance understanding of OHCA and CPR in secondary school students. The American Heart Association's CPR in Schools module was adapted. The training was run jointly by the Revolving Hearts Foundation, Atlanta, and Issachar Generation, Nigeria. The training had in-person and virtual components due to COVID-19 travel restrictions. We present results of training on knowledge, comfort level, and perceived barriers of performing HOCPR. Convenience sampling was used to recruit participants. Pre- and post-training surveys were conducted in February 2021. Participant responses were matched to assess changes and analyzed using Stata 16.1 software. A paired t-test analysis was conducted. The primary outcome was percentage change in mean knowledge scores and secondary outcome was change in comfort level and perceived barriers pre- and post- training. A total of 45 secondary school students from 4 schools completed the survey. Females comprised 31.1% of students and the average age was 15.02 + 0.18 years. Paired t-test showed a significant change of 44.6% ( $p < 0.0001$ ) in the mean knowledge score. There was also an increase in comfort level in performing HOCPR, and a decrease in perceived barriers. Trainees then disseminated their knowledge in schools via skits. Follow-up evaluation and longitudinal expansion to other schools and states is planned.

### MAKING THE CONNECTIONS: ORGANIZATIONAL NETWORK MAPPING TO SUPPORT IMPLEMENTATION OF AN EVIDENCE-BASED CONTROL INTERVENTION FOR CYSTICERCOSIS IN NORTHERN PERU

Angela G. Spencer<sup>1</sup>, Lisset Dumet Poma<sup>1</sup>, Ruth Atto<sup>2</sup>, Vanessa Cruz<sup>2</sup>, Percy Vilchez<sup>2</sup>, Brenda Beltran<sup>1</sup>, Javier Bustos<sup>2</sup>, Hector H. Garcia<sup>3</sup>, Sarah Gimbel<sup>4</sup>, Patricia J. Garcia<sup>5</sup>, Seth E. O'Neal<sup>6</sup>

<sup>1</sup>School of Public Health, Oregon Health & Science University - Portland State University, Portland, OR, United States, <sup>2</sup>Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>3</sup>Center for Global Health - Tumbes and Department of Microbiology, Universidad Peruana Cayetano Heredia, and Cysticercosis Unit, Instituto Nacional de Ciencias Neurológicas, Lima, Peru, <sup>4</sup>Department of Global Health, University of Washington, Seattle, WA, USA and Department of Child, Family & Population Health Nursing, University of Washington, Seattle, WA, United States, <sup>5</sup>School of Public Health, Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>6</sup>School of Public Health, Oregon Health & Science University - Portland State University, Portland, OR, USA and Center for Global Health Tumbes, Universidad Peruana Cayetano Heredia, Lima, Perú, Portland, OR, United States

We are working with community members and the health system in Northern Peru to implement ring treatment - an evidence-based focal control strategy for cysticercosis - as a government-administered program. Successful implementation requires health personnel to work across teams

and alongside animal health agencies to deliver the intervention. As part of the formative evaluation phase of this 5-year project, we are creating a map to describe the organizational network of the health system involved in implementation of ring treatment. Using questionnaires based on the Consolidated Framework for Implementation Research (CFIR), we have completed 258 interviews, of an expected 423, with key stakeholders and staff at 18 health posts and centers, in four rural districts, about their intra- and inter-organizational networks and communications. Stakeholders also identify which people or organizations should be responsible for implementing specific steps in ring treatment. We are using R and UCINET software to visualize supervision networks, team networks, and inter-organizational networks, and calculate network centrality and cohesion. We will present the current intra- and inter-organizational networks of health staff who have an essential role to play in implementing ring treatment. We will also share a comparison of the current networks to the networks described by participants as ideal for successful implementation, and recommendations for network modifications and linkages to support implementation and scaling ring treatment. The study of organizational and community networks provides important information to support implementation and scaling ring treatment to regional and national levels, across heterogeneous settings.

### TRENDS IN MORTALITY AND PERCEIVED CAUSE OF DEATH IN KERSA HEALTH AND DEMOGRAPHIC SURVEILLANCE SYSTEM, 2008-2019, EASTERN ETHIOPIA

Nega A. Kassa<sup>1</sup>, Gezahegn Mengesha<sup>1</sup>, Merga Dheresa<sup>1</sup>, Solveig A. Cunningham<sup>2</sup>

<sup>1</sup>Haramaya University, Harar, Ethiopia, <sup>2</sup>Emory Global Health Institute, Emory University, Atlanta, GA, United States

Demographic transition and population aging are health issues this days. Attached to this, epidemiological transition is concomitantly changing disease and mortality patterns. These changes in patterns have been observed in some urban areas of Ethiopia. We examine health and demographic trends in rural Ethiopia using data from a demographic surveillance (Kersa HDSS), established in 2007. We used life table to calculate population death rates (CDR), age specific death rates, and life expectancy at birth. Neonatal, infant, and under-five mortality have also been calculated. The perceived causes of death as reported by a close relative of the deceased were analyzed using the global burden of disease classification as Group I (communicable, perinatal, maternal and nutritional deficiency diseases), Group II (non-communicable diseases), Group III (injuries and accidents). Jaundice and Sudden Death were treated separately as they don't fall in any of the groups. The overall CDR dropped from 11.19 per 1000 population in 2008 to 5.53 in 2019. The consistent reduction in mortality yielded a 13.3-year average gain in life expectancy between 2008 and 2019 increased from 4.6 in 2008 to 17.4 in 2019 for age 85+ years. There was a drop in under-five mortality from 147.4 per 1000 births in 2008 to 85.4 in 2019. Thought overall the primary causes of death were Group I causes, over the twelve-year period in this rural population, there is a slight shift from Group I causes to Group II causes.. The CDR has dropped yielding a significant gain in life expectancy, although the under-five mortality remains above the national average (78 per 1000 live birth). Interventions targeting communicable diseases, maternal and child deaths should be intensified to avert the tall of burden of mortality from these causes.

## NEW CONFIRMED EBOLA OUTBREAK IN NORD KIVU, DEMOCRATIC REPUBLIC OF CONGO, FEBRUARY 2021

Eddy Kinganda Lusamaki<sup>1</sup>, Catherine B. Pratt<sup>2</sup>, Daniel B. Mukadi<sup>3</sup>, Adrienne Aziza Amuri<sup>1</sup>, Shannon Whitmer<sup>4</sup>, Emmanuel Lofiko Lokilo<sup>1</sup>, Jean-Claude Cigolo Makangara<sup>1</sup>, Francisca Muyembe Mawete<sup>1</sup>, Osee Yibayiri<sup>4</sup>, Michael Wiley<sup>2</sup>, Placide Mbala Kingebeni<sup>1</sup>, John Klena<sup>4</sup>, Steve AHUKA MUNDEKE<sup>1</sup>, Joel Montgomery<sup>4</sup>, Jean Jacques Tamfum Muyembe<sup>1</sup>, Stuart Nichol<sup>4</sup>

<sup>1</sup>Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>University of Nebraska Medical Center, Omaha, NE, United States, <sup>3</sup>Institut National de Recherche Biomedicale, Goma, Democratic Republic of the Congo, <sup>4</sup>Viral Special Pathogens Branch, Centers for Diseases Control and Prevention, Atlanta, GA, United States

INRB received a new Ebola-positive sample from Nord Kivu on February 9, 2021. The individual was a 42-year-old patient and the wife of a recovered EVD survivor from the previous Ebola virus disease (EVD) outbreak 2018-2020. She resided in the Biena health zone and her symptoms began on January 25, 2021. She first visited the Ngubi health post where she remained under observation for 4 days. Then, she consulted the Masoya reference health center where she remained in hospital until February 03, 2021. A blood sample was taken the same day for suspicion of EVD due to the onset of hallucinations, diarrhea, melaena, epistaxis. She was transferred the same day to Matanda Hospital in Butembo where she died on February 04, 2021. The blood sample, along with historical samples from her husband, were subjected to sequencing. Four genomes with high coverage were obtained and compared to other genomes from the 2018-2020 Nord Kivu/Ituri EVD outbreak. The new case could have been caused by 1) a new spillover event, meaning a new separate EVD outbreak; 2) a transmission chain from the Nord Kivu EVD outbreak that continued unnoticed since the end of the outbreak, or 3) an infection from a persistent source, either from a survivor of the Nord Kivu outbreak or a relapse of her own prior infection (although she was not known to have had EVD). The new case is descended from the Ituri variant and therefore does not represent a new spillover event, but indicates this variant is from the 2018-2020 EVD outbreak. The new case clusters with samples from Mandima and Mabalako collected around October 2019, including the samples from her husband. It has 5 more mutations than the nearest genome. This is indicative of a slowed substitution rate which is a hallmark of infection from a persistent source.

Maryland School of Medicine, Baltimore, MD, United States, <sup>12</sup>Centro de Investigação em Saúde de Manhiça, Maputo, Mozambique, <sup>13</sup>Crown Agents, Freetown, Sierra Leone, <sup>14</sup>Vaccine and Infectious Diseases Analytics, Johannesburg, South Africa

Despite reductions in the global rate of stillbirths and under-five (U5) mortality, geographic disparities persist. Child Health and Mortality Prevention Surveillance (CHAMPS) collects standardized, population-based data on stillbirths and U5 deaths in Bangladesh, Ethiopia, Kenya, Mali, Mozambique, Sierra Leone, and South Africa. Laboratory analyses are performed on post-mortem biopsies from key organs and body fluids obtained through minimally invasive tissue sampling (MITS). However, not all deaths are eligible or consent for MITS; some families only consent to collection of antemortem clinical and verbal autopsy (VA) data. In-country expert panels use all available data to deduce the most plausible causes of death (CoD). Crude calculations of mortality fractions using only deaths consented for MITS may be biased due to selective non-response. Using the Horvitz-Thompson strategy, this analysis estimated unadjusted and adjusted mortality fractions for the top five CoD anywhere in the causal chain (immediate, underlying, other comorbid conditions) in each age group (stillbirths, neonates, infants and children) and country from 2017 to 2019; selection probabilities were estimated based on subgroup membership of all CHAMPS cases. Subgrouping variables identified *a priori* included season and location of death, maternal education, caretaker's religion, sex of child, and VA CoD; those statistically significantly associated with MITS conducted were selected for adjustment. Across all sites, CHAMPS enrolled 1,346 stillbirths, 1,585 neonatal and 1,337 infant and child deaths; on average (SD), 57% (19%), 50% (23%) and 59% (31%) declined to consent for MITS, respectively. Of 103 cause-specific mortality fractions estimated, 27 were meaningfully different (>10%) from the crude after adjustment; the mean (SD) change was 13% (15%). For example, the mortality fraction (95% CI) due to HIV among infants and children in Mozambique, increased 57% from 0.15 (0.07, 0.23) to 0.24 (0.15, 0.33). Adjusted mortality fractions more accurately represent the true distribution of CoD in the population, which may help target prevention efforts.

0516

## YEAST-LIKE FUNGI ASSOCIATED WITH CHILD DEATH AND ILLNESS IN BANGLADESH: FINDINGS FROM CHILD HEALTH AND MORTALITY PREVENTION SURVEILLANCE STUDY

Shafina Jahan<sup>1</sup>, M Ishrat Jahan<sup>1</sup>, Mustafizur Rahman<sup>1</sup>, Afruna Rahman<sup>1</sup>, Sanwarul Bari<sup>1</sup>, Kyu Han Lee<sup>2</sup>, Emily S. Gurley<sup>2</sup>, Shams El Arifeen<sup>1</sup>, Muntasir Alam<sup>1</sup>

<sup>1</sup>icddr, Dhaka, Bangladesh, <sup>2</sup>Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

In the United States, yeast like fungi accounts for about 1-4% of nosocomial infections in neonatal intensive care units, which result in 20-30% mortality. Data on these infections in Bangladesh are rare. The aim of this analysis is to understand the contribution of yeast like fungal infections in child death and illness from the Child Health and Mortality Prevention Surveillance (CHAMPS) site in Bangladesh. Laboratory results (post-mortem specimens - blood, cerebrospinal fluid, nasopharyngeal swabs, rectal brush, liver, lungs and brain and tissue specimens), clinical, demographic and verbal autopsy data are presented to a panel of experts for determination of cause of death (DeCoDe). From August 2017 to March 2020, specimens were collected utilizing minimally invasive tissue sampling method from the 178 cases from stillbirths and under-5 deaths from Faridpur and Rajbari districts. In addition, blood specimens were collected for microbial culture from 110 under-5 children hospitalized with suspected sepsis. Among post-mortem cases and living suspected sepsis cases, 126/178 (70%) and 86/110 (78%) were positive for any microorganism in different testing platforms, respectively. Among these cases, *Candida* spp. were detected from 4/126 (3%) post-mortem cases and 5/86 (6%) suspected sepsis cases. All deceased children were early neonates aged 1 to 3.5 days from delivery who were born and died in hospital, and organisms were detected from blood. The DeCoDe panel

determined *Candida albicans* as the cause of death from 1 of 4 (25%) post-mortem cases. This case was a neonate born at 30 weeks gestation who also tested positive for *Klebsiella pneumoniae*, *Pseudomonas aeruginosa* and *Staphylococcus aureus*. Our initial analysis showed that yeast-like fungi is important in hospital related neonatal deaths and illness in Bangladesh. More extensive investigation covering species level identification and species-specific antifungal susceptibility patterns will help to better understand the real situation of yeast like fungal infection and trigger necessary infection control measures to prevent its spread in health-care settings.

0517

## COVID-19 SURVEILLANCE IN THE SOUTHERN PROVINCE OF SRI LANKA

**W. M. D. G. B. Wijayarathne<sup>1</sup>**, S. Gunasena<sup>1</sup>, A. de S. Nagahawatte<sup>1</sup>, N. P. Weerasinghe<sup>1</sup>, L. G. Tillekeratne<sup>2</sup>, B. Nicholson<sup>3</sup>, C. Woods<sup>2</sup>, N. Danthanarayana<sup>4</sup>, D. T. Mahaliyanage<sup>1</sup>, S. S. Wickramasinghe<sup>1</sup>, H. H. P. M. J. Thabrew<sup>1</sup>, D. L. B. Piyasiri<sup>4</sup>, D. Priyanthi<sup>5</sup>, R. Lewkebandara<sup>6</sup>, H. A. Ubeysekara<sup>4</sup>, C. K. Bodinayake<sup>1</sup>, I. V. Devasiri<sup>1</sup>, T. S. D. Amarasena<sup>1</sup>

<sup>1</sup>University of Ruhuna, Sri Lanka, Galle, Sri Lanka, <sup>2</sup>Duke University, Durham, NC, United States, <sup>3</sup>VA Medical Center, Durham, NC, United States, <sup>4</sup>Teaching Hospital Karapitiya, Galle, Sri Lanka, <sup>5</sup>District General Hospital, Matara, Sri Lanka, <sup>6</sup>District General Hospital, Hambantota, Sri Lanka

Since identification of the first case of COVID-19 in Sri Lanka in January 2020, surveillance PCR testing was implemented across the country. The Department of Microbiology, Faculty of Medicine, University of Ruhuna volunteered to survey the Southern Province of the country. The purpose of this study was to determine the prevalence of COVID-19 in the Southern Province during the early stages of the pandemic. A prospective observational study conducted among a sample of outpatients obtaining medical care at the three tertiary care hospitals in the Southern Province. Patients' demographic data, clinical information, and potential exposure to COVID-19 was documented. In all patients, a nasopharyngeal and an oropharyngeal swab was tested for COVID-19 using RT-PCR (CDC protocol). A total of 859 persons were tested from 19<sup>th</sup> June to 20<sup>th</sup> November 2020. The participants were from Galle (44.8%) Matara (28.1%) and Hambantota (27.1%) Districts. The majority were adults of 19-59 years (736/820, 89.8%) and male (474/833, 56.9%), and 12.8% (37/290) were frontline workers involve in combating COVID-19. Symptoms suggestive of COVID-19 at the time of testing included fever (14.5%, 99/685), cough (25.5%, 175/686), common cold (7.8%, 47/603), sore throat (24.3%, 165/680), shortness of breath (5.4%, 35/651) and diarrhea (0.8%, 5/602). Total of 253 persons (29.5%) had at least one feature suggestive of influenza like illness (ILI). None of the participants had been previously positive for COVID-19, admitted to a COVID-19 ward, or quarantined in isolation camps. Potential exposure to COVID-19 was identified in 9.1% (78/859) of participants. Only one person (0.1%, 1/859) tested positive for COVID-19 by RT-PCR. This patient had a sore throat and had been exposed to a COVID-19 positive patient at work. COVID-19 prevalence was 3.9/1000 in those having symptoms suggestive of ILI (1/253) and zero in the non-ILI group (0/606). During the latter half of 2020, the prevalence of COVID-19 in the community of the Southern Province of Sri Lanka was low (1.2/1000 population) with no evidence of infection among the asymptomatic population; but continued surveillance is needed.

0518

## PHYSICAL ACCESSIBILITY TO COVID-19 RELATED HEALTH SERVICES ANALYSIS IN BANGLADESH

**Richard J. Maude<sup>1</sup>**, Afrida Asad<sup>1</sup>, Izay Pantanilla<sup>2</sup>, Md Nurullah<sup>1</sup>, Obaidur Rahman<sup>1</sup>, Sazid Ibna Zaman<sup>1</sup>, Steeve Ebener<sup>2</sup>

<sup>1</sup>Mahidol-Oxford Tropical Medicine Research Unit, Bangkok, Thailand, <sup>2</sup>Health GeoLab Collaborative, Manila, Philippines

Ensuring the population has equitable access to COVID-19 testing and treatment facilities is a key component of the response to the COVID-19 pandemic. This study aimed to identify the proportion of the population that can reach testing, treatment and intensive care unit (ICU) health services within a given travel time (1, 2, 3 hours) in Bangladesh and, as such, support planning and decision making. The analysis was done for wet and dry seasons using AccessMod 5.6.0 and used geospatial and statistical data that was compiled, checked, cleaned and, when necessary, improved before analysis. The estimates of travel time represent a best case scenario. Delays due to unavailability of a vehicle, disruptions to transport networks, waiting times for, or interruptions to health services at the destination were not considered due to wide variation and a lack of data on these factors. At the national level, 65.7% of the total population could reach a testing facility within 1 hour of travel time during the dry season, 85.7% for treatment facilities and 56% for ICU. There was substantial variability in these results between different administrative units. During the wet season, physical accessibility was reduced in the subdivisions experiencing flooding by up to 85% for testing facilities and 11% for treatment facilities and ICU facilities. While all results presented are dependent on the quality of the data and the validity of the travel scenarios that were considered, the findings to date allow for the identification of potential areas for which the government might require more in-depth analyses. These results should be regularly updated to account for the changes of the COVID-19 health services delivery network put in place by the government to respond to the evolution of the pandemic. Travel times to health services for COVID-19 testing, treatment and ICU care were estimated and found to vary widely across the country. The analyses presented can also be extended to examine access to other health services such as COVID-19 vaccination, provided the relevant data are available on the locations of service providers.

0519

## DETECTION OF SARS-COV-2 CASES IN A PHILIPPINE MILITARY HOSPITAL

**Paula Corazon Diones<sup>1</sup>**, John Mark Velasco<sup>2</sup>, Valderama Maria Theresa<sup>1</sup>, Susie Leonardia<sup>1</sup>, Vicente Vila II<sup>3</sup>, Chermane Ugalino<sup>3</sup>, Ruzzelle Mae Paras<sup>3</sup>, Stefan Fernandez<sup>2</sup>, Anthony Jones<sup>2</sup>, Fatima Claire Navarro<sup>3</sup>, Henry Tabinas Jr.<sup>3</sup>, Maria Theresa Alera<sup>4</sup>

<sup>1</sup>Philippines-AFRIMS Virology Research Unit, Quezon City, Philippines, <sup>2</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>3</sup>Victoriano Luna Medical Center, Quezon City, Philippines, <sup>4</sup>Philippines-AFRIMS Virology Research Unit, Cebu City, Philippines

The unique capabilities of the military such as expertise in command and control, coordination and collaboration are vital in the Philippine COVID-19 outbreak response where >900,000 cases and >15,000 deaths have been recorded from the initial detection of SARS-CoV-2 on 30 Jan 2020. The Philippine military serve as frontliners that support the implementation of SARS-CoV-2 strategic approaches in the Philippines through the transport of food, people, medical supplies and equipment that are needed in communities, clinics and hospitals. Implementation of community quarantine measures by the Philippine government also allows the deployment of Philippine military personnel to high density areas with high concentrations of COVID-19 such as checkpoints and local government areas. Such military movements can increase the risk of acquiring SARS-CoV-2 infection which can lead to morbidity and mortality among the soldiers. Therefore, early detection and management plays a vital role in controlling the spread of COVID-19 in the military and decreasing casualties among these frontliners. As part of a collaboration

between the Armed Forces of the Philippines (AFP) and the Armed Forces Research Institute of Medical Sciences (AFRIMS), the COVID molecular laboratory was established for the early detection and control of SARS-CoV-2 cases via RT-PCR testing of military personnel, dependents and authorized civilians. From 14 April 2020 to 31 March 2021, a total of 59,632 oropharyngeal and nasopharyngeal specimens were tested for SARS-CoV-2 with 3,668 (6%) positive and 55,964 (94%) negative cases. Cases were highest among the active military age group (21-50 years old) with 2,885 cases (78%) and males with 38,495 cases (65%). Typical symptoms were fever, cough and sore throat. Aside from early detection and rapid isolation of positive cases, COVID-19 transmission control strategies include: contact tracing; screening of hospital and non-hospital staff; control of entry and exit points, and information and education strategies. These assets were also leveraged for the Philippines COVID-19 vaccine rollout, which was initiated in early March of 2021.

## 0520

### IMPACT OF THE COVID-19 PANDEMIC AND ASSOCIATED RESTRICTIONS DURING THE FIRST WAVE ON MATERNAL AND CHILD HEALTHCARE PROVIDED AT FACILITIES IN RURAL BALIAKANDI, BANGLADESH

**Kazi Munisul Islam**<sup>1</sup>, Mohammad Zahid Hossain<sup>1</sup>, Mohammad Sabbir Ahmed<sup>1</sup>, S A M Safiur Rahman<sup>1</sup>, Fahamida N. Zebin<sup>1</sup>, Sanwarul Bari<sup>1</sup>, Shams El Arifeen<sup>1</sup>, Emily S. Gurley<sup>2</sup>

<sup>1</sup>International Center for Diarrhoeal Disease Research Bangladesh, Dhaka, Bangladesh, <sup>2</sup>John Hopkins University, USA, Baltimore, MD, United States

According to UNICEF, 2.4 million babies and mothers in Bangladesh had restricted access to health during enforced movement restrictions from 26th March to 31st May 2020 due to the COVID-19 pandemic. The Child Health and Mortality Prevention Surveillance (CHAMPS) project has maintained mortality surveillance in Baliakandi, a rural area in Bangladesh, allowing CHAMPS staff to conduct this study to identify healthcare facility closures and reductions maternal and childcare services received. We contacted the 16 facilities (6 hospitals, 4 clinics, 3 health centers, and 3 private chambers) that provided the greatest proportion of maternal and child healthcare to inquire about closures and the number of women and children receiving care during August 2020 compared to February 2020, before the pandemic. The public health facilities (8/16) provided limited scheduled and routine immunization, antenatal care, and patient admissions in April 2020, and 85% (6/7) of clinics and doctor's chambers were closed during the restrictions. The pediatric ward in the largest public tertiary care hospital was converted to a COVID-19 ward from the 1st of April 2020, resulting in the referral of children to other facilities through October 2020. In August 2020, there were 15-68% fewer outpatient visits, including wellness visits, ANC, and malnutrition follow-ups compared to February 2020, and 14-174% fewer inpatient admissions in hospitals (6/16). Eight out of 11 facilities that conduct deliveries had 11-37% fewer in August, but the three private facilities conducting deliveries experience an increase. Hospitals and health centers reported shortages in vaccines, PPE, lab equipment, reagents, and oxygen starting in March 2020, which was resolved by August 2020. COVID-19 among staff was a major concern, and at one hospital, 33% (28/84) of staff were infected during April and May 2020. The imposed restrictions in movement and closure of public facilities had a negative impact on healthcare access in Baliakandi. Future directives need to mitigate the rural health care delivery system.

## 0521

### USING EMERGENCY OPERATIONS CENTERS TO SUPPORT THE COVID-19 RESPONSE: CREATION OF AN ONLINE RESOURCE FOR SELF-DIRECTED TRAINING AND TECHNICAL ASSISTANCE

**Claire J. Standley**, James A. Banaski, Brenna Means, Ileana Vélaz Alvarado, Ryan Rimmel

*Georgetown University, Washington, DC, United States*

The rapid spread and severity of the novel coronavirus 2019 (COVID-19) pandemic prompted countries around the world to pursue strategies to manage transmission and protect their healthcare systems. The fundamental approaches for responding to the COVID-19 pandemic remain the tried and tested tools of public health response: identify affected individuals, monitor them (and isolate or quarantine as necessary, depending on the context), and trace and monitor their contacts. However, the scale of the pandemic has required most countries to adopt substantial additional measures to prevent community transmission, including stay-at-home orders, closing public spaces and recreation areas, reducing or closing public transport, and suspending schools and universities. With the advent of safe and effective vaccines, countries have also developed, and begun to deploy, strategies to deliver vaccines at large-scale, starting with highest priority groups such as the elderly and healthcare workers. These efforts require close operational coordination across multiple sectors, and operational response efforts also need to be coordinated with broader policy decision-making processes, managed by national and sub-national political leaders. In all these ways, COVID-19 response efforts can benefit from application of the principles of emergency management, including coordination through structures like emergency operations centers. To this end, we present here a newly developed website, developed with input from international subject matter experts, containing training materials, checklists, country case studies, and other resources for development and strengthening of public health emergency management capacities, with an emphasis on emergency operations centers. Since its launch in June 2020, the website has garnered substantial international interest, and positive feedback on its utility from end-users, highlighting the potential for online tools and resources to complement more traditional technical assistance for delivering public health emergency management capacity strengthening in the future.

## 0522

### A NOVEL APPROACH TO PUBLIC HEALTH PREPAREDNESS FOR SARS-COV-2: A STATEWIDE REPRESENTATIVE SAMPLING

**Lidia Gual Gonzalez**<sup>1</sup>, Virginie Daguise<sup>2</sup>, Windsor Westbrook Sherrill<sup>3</sup>, Alain H. Litwin<sup>4</sup>, Mufaro Kanyangarara<sup>1</sup>, Mary K. Lynn<sup>1</sup>, Jeffrey Korte<sup>5</sup>, Connor H. Ross<sup>2</sup>, Melissa S. Nolan<sup>1</sup>

<sup>1</sup>University of South Carolina, Columbia, SC, United States, <sup>2</sup>South Carolina Department of Health and Environmental Control, Columbia, SC, United States, <sup>3</sup>Clemson University, Clemson, SC, United States, <sup>4</sup>Prisma Health, Greenville, SC, United States, <sup>5</sup>Medical University of South Carolina, Charleston, SC, United States

The global SARS-CoV-2 pandemic has had devastating effects on public health systems worldwide, and emergency preparedness agencies require timely information on current representative prevalence, vaccination status and neutralizing antibody kinetics post-infection. An evidence based representative sample at state-wide level for SARS-CoV-2 is lacking in most of the US. For this reason, a collaborative effort between academic, medical, and public health partners created the SC Strong COVID-19 Project, a yearlong randomly selected surveillance initiative to attain this goal. The South Carolina Department of Health and Environmental Control together with the University of South Carolina contacted &gt; 449,000 residents from November 2020 to May 2021. In conjunction with clinical community partners, participants were offered free viral and antibody testing, and asked to complete an online health survey to evaluate symptomatology, perception of the public health response, social distancing and other preventive measure compliance, and mental health status of participants during the pandemic. A project website,

email and hotline phone number were available to gain the public's trust, address concerns, and facilitate participation. This presentation will cover the design, implementation, and response to a large-scale surveillance project to enhance understanding of SARS-CoV-2 at the state level over 4 distinct time points. An overview of the infrastructure that allowed for this large prospective cohort, a time series analysis of participant's behaviors and attitudes, and results of this project will further be addressed. To our knowledge, South Carolina is the only state to implement a year-long statewide representative sampling as part of the state's public health response to the SARS-CoV-2. This program can be used as template for other states, attempting to meet their respective populations' needs and to strengthen public health preparedness for this and future pandemics. This talk will provide a timely pandemic response example and provide guidance for the development of similar infrastructures at other health departments.

0523

### LESSONS LEARNED: OCCUPATIONAL HEALTH SUPPORT TO GLOBAL PROJECTS FOR SAFETY AND BUSINESS CONTINUITY DURING COVID-19 PANDEMIC

**Kees de Rooij**<sup>1</sup>, Susan Ngunjiri<sup>2</sup>

<sup>1</sup>*ExxonMobil, Centraal Kantoor Benelux, Breda, Netherlands*, <sup>2</sup>*ExxonMobil, Houston, TX, United States*

The nature of global projects is that they utilize resources and workforce in multiple countries. This presents an unprecedented challenge during the COVID-19 pandemic due to the asynchronous nature of response not only at a national level but also regional and global scale. Global projects have adopted an agile strategy whilst balancing both economic and health risk to ensure continuity. We use an occupational health support lens to review lessons learned and share opportunities that when considered would improve efficiency in future pandemics or outbreaks with pandemic potential. The focus areas of occupational health support in global projects during a pandemic were to ensure 1) we protect people's health 2) pursue multi-lateral partnerships and 3) medical infrastructural assessment including care of workers not just for COVID-19 but other diseases in a stretched system. Due to the scale of the pandemic, vulnerabilities emerged. We outline the critical lessons of the pandemic's impact including the successes in managing health especially in remote set up while navigating new business environment, providing travel, occupational & mental health guidance that is scalable (one size does not fit all) and rapidly developing procedures with focus on protective preventive equipment and mitigation measures. Opportunities were realized by risk analysis and mitigated by developing strategies and tactical restructuring to minimize impact and likelihood of poor health outcomes. There is need for alignment in the international guidelines, and whilst this may take time, effort can be channeled internally to update pandemic plans, preposition supplies, and enhance design of outbreak response to be robust and outlast long health crisis. Global projects in oil and gas help provide critical products and work on a structured limited timeline and challenging environment. Providing support during a pandemic needs a comprehensive beyond traditional health plans. There is need to be intentional and exponentially flexible, to not only protect the health of workers but also to ensure business continuity not just for the energy we need today but also tomorrow.

0524

### SEROPREVALENCE OF SARS-COV-2 AMONG MEDICAL UNDERGRADUATES IN A STATE UNIVERSITY OF SRI LANKA

**N. P. Weerasinghe**<sup>1</sup>, S. Gunasena<sup>1</sup>, W. M. D. G. B. Wijayaratne<sup>1</sup>, A. de S. Nagahawatte<sup>1</sup>, L. G. Tillekeratne<sup>2</sup>, B. Nicholson<sup>3</sup>, S. S. Wickramasinghe<sup>1</sup>, H. M. M. Herath<sup>1</sup>, C. Woods<sup>2</sup>, M. D. Pathirana<sup>1</sup>, D. Mahaliyanage<sup>1</sup>, H. A. Ubeysekara<sup>4</sup>, H. H. P. M. J. Thabrew<sup>1</sup>, R. Handunnetti<sup>1</sup>, C. K. Bodinayake<sup>1</sup>, I. V. Devasiri<sup>1</sup>, T. S. D. Amarasena<sup>1</sup>

<sup>1</sup>*Faculty of Medicine, University of Ruhuna, Sri Lanka, Galle, Sri Lanka*, <sup>2</sup>*Duke University, Durham, NC, United States*, <sup>3</sup>*VA Medical Center, Durham, NC, United States*, <sup>4</sup>*Teaching Hospital Karapitiya, Galle, Sri Lanka*

In Sri Lanka's state universities, medical undergraduates are recruited from throughout the country and can provide an estimate of COVID-19 seroprevalence across many geographic regions. A repeated cross-sectional study was conducted to estimate the prevalence of SARS-CoV-2 antibodies among medical undergraduates during the two waves of the COVID-19 pandemic in Sri Lanka. Demographic and clinical data and blood samples were collected during September-November 2020 and January-February 2021. COVID-19 antibodies were tested by ELISA. Of 279 collected samples, 175 (62.7%) were just after the students returned to the university following the first wave of COVID-19 and balance after the onset of second wave. Median age of both groups was 25 years (IQR 24-27). One-fifth of each group were residents of the local Galle district. Recent (within last 3 months) febrile illness was reported by 2.3% and 8.8% in the two groups respectively. One-third of the second group reported staying in a COVID-19 quarantine center for possible COVID-19 exposure, but none in the first group. Over 95% in both groups did not report close contact with overseas returnees or security personnel, but close contact with healthcare staff was seen in 32.6% and 63.5% in groups 1 and 2, respectively. Proportion of students who reported about undergoing PCR testing has increased from <1% to 94.2%. PCR positive cases were detected only in second group (n=5, 4.8%). Frequencies of contact with a confirmed or suspected patient or an identified contact were negligible in the first group while in second group 34.3%, 14.4% and 13.5% Prevalence of SARS-CoV-2 antibodies were detected only during second wave 6.7% (n=7) and asymptomatic infection in 1.9% (n=2) were detected during routine surveillance. Serological evidence of COVID-19 was not seen in November 2020. But two months later antibodies were detected. Surveillance at regular intervals, targeting individuals from diverse geographic regions is important for tracking the spread of SARS-CoV-2 in Sri Lanka.

0525

### RAPID IDENTIFICATION OF INFECTIOUS AGENTS IN HUMAN PLASMA WITH LASER-BASED DIAGNOSTICS

**Carolyn Fisher**<sup>1</sup>, Rosalie Multari<sup>2</sup>, David Cremers<sup>2</sup>, Ann Nelson<sup>2</sup>, Robert Duncan<sup>1</sup>

<sup>1</sup>*FDA Center for Biologics Evaluation and Research, Silver Spring, MD, United States*, <sup>2</sup>*Creative LIBS Solutions LLC, Bernalillo, NM, United States*

Rapid detection of pathogens within minutes on-site, with simple specimen preparation, no requirement for highly skilled personnel, and the ability to expand for detecting emerging pathogens is needed to reduce blood donor screening time and risk of transfusion-transmission disease. Laser-induced breakdown spectroscopy (LIBS), a detection method utilizing optical emissions from a sample interrogated by a laser beam, then resolved by spectrometry and processed by programmed analysis, has been effectively used with bloodborne pathogens spiked in blood. There is potential to build a device that is compact and affordable for use in low resource settings. To investigate laser-based technology for the rapid identification of infectious agents in plasma specimens, donor plasma spiked with HCV and HIV-1 and clinical specimens were tested. Virus stocks for spiking were FDA CBER reference vials with validated copies per ml. Pathogens were spiked as low as 100 copies/ml in healthy volunteer plasma. Clinical donor plasma was identified by approved tests

as negative, HCV positive, or HIV-1 positive. The pathogen-spiked plasma, negative controls, and clinical plasma were applied to paper filters, air dried, wrapped, baked, and analyzed with a benchtop assembled LIBS device. Detection algorithms were developed for two studies; study one had 65 samples including 20 clinical specimens and study two had 69 samples including 20 clinical specimens. The LIBS system with detection algorithms was 100% correct in differentiating spiked plasma from unspiked plasma and infected clinical plasma from uninfected clinical plasma with identification of HCV or HIV-1. There were no false positives nor false negatives. Our advances with LIBS analysis allow for effective and rapid differentiation of infected clinical plasma from uninfected and identifying the type of infection. Advantages are rapid and minimal specimen preparation, simultaneous analytical processing, and flexibility to add new algorithms for emerging pathogens. This laser-based study for multiplex pathogen detection suggests LIBS has potential for use as a blood safety diagnostic.

### DEPLOYMENT OF A REMOTE FIELD SEQUENCING LABORATORY IN NORD KIVU: A PREPAREDNESS STRATEGY FOR BETTER MANAGEMENT OF FUTURE OUTBREAKS IN THE DEMOCRATIC REPUBLIC OF CONGO

**Jean Claude C. Makangara**<sup>1</sup>, Adrienne A. Amuri<sup>1</sup>, Eddy L. Kinganda<sup>1</sup>, Emmanuel L. Lokilo<sup>1</sup>, Francisca M. Muyembe<sup>1</sup>, Shannon Whitmer<sup>2</sup>, John Klena<sup>2</sup>, Christopher Mores<sup>3</sup>, Yibayiri O. Sanogo<sup>2</sup>, Joel M. Montgomery<sup>2</sup>, Catherine Pratt<sup>4</sup>, Michael Wiley<sup>4</sup>, Nichol T. Stuart<sup>2</sup>, Bill & Melinda Gates Foundation<sup>5</sup>, Daniel B. Mukadi<sup>1</sup>, Placide K. Mbala<sup>1</sup>, Steve Ahuka-Mundeki<sup>1</sup>, Jean Jacques T. Muyembe<sup>1</sup>

<sup>1</sup>National Institute for Biomedical Research, INRB, KINSHASA, Democratic Republic of the Congo, <sup>2</sup>Viral Special Pathogens Branch, Centers for Diseases Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Georges Washington University, Washington, WA, United States, <sup>4</sup>University of Nebraska Medical Center, Omaha, NE, United States, <sup>5</sup>Bill & Melinda Gate Foundation, Seattle, WA, United States

Since the recent large Ebola Virus Disease, EVD, outbreaks in West Africa, 2013-2016 and Democratic Republic of Congo, DRC, 2018-2021, real-time pathogen sequencing has been an effective tool for assisting with field epidemiology. In DRC, sample shipment is challenging and delays the sequencing results, with the risk of sample degradation. The EVD outbreak in Equateur Province 11<sup>th</sup> outbreak and EVD re-emergence in North Kivu 12<sup>th</sup>, highlighted the need to deploy tools for rapid results and to enable adequate responses as seen during the 10<sup>th</sup> EVD outbreak. In April 2021, we used a blueprint developed with a collaboration of scientists from CDC, UNMC, GWU, and Gates Foundation to gather the minimal equipment and supplies required to perform viral sequencing in a resource-limited environment. With minimal power requirements, the equipment allows robust implementation of viral genomic sequencing in hours, rather than days. In order to field test the final iteration of the portable sequencing lab, a trained team of scientists from the National laboratory in Kinshasa, DRC, were deployed with the portable laboratory to Goma. After visiting the Goma INRB facility, it took 2 hours to set up the lab and get it ready to start sequencing. Local Goma staff, unfamiliar with MinION sequencing, were trained to use this laboratory and workflow over a 6 day period. During 48h, RNA from 23 EVD patients were processed, including 11 RNA extracts from the 12<sup>th</sup> EVD outbreak, and a library with 12 samples was prepared and loaded onto the MinION. Local staff trainers generated 7 genomes with coverage above 70% and 5 above 90%. The local Goma staff also performed SARS-CoV2 sequencing and the laboratory is continuing to operate in Goma and provides SARS-CoV2 sequencing support for the pandemic surveillance. The equipment and workflow have proven to be robust, portable, and trainable, enabling effective implementation of MinION sequencing in resource-limited settings. This experience is included in the response preparedness of the country to face future outbreaks by improving and increasing detection capacity and genomic surveillance

0527

### FINANCIAL ANALYSIS TO INFORM PROGRAMMATIC DECISION MAKING AND DOMESTIC RESOURCE MOBILIZATION FOR NEGLECTED TROPICS DISEASES

**Justin Tine**<sup>1</sup>, Marie Sy<sup>2</sup>, Margot Feroletto<sup>2</sup>

<sup>1</sup>FHI 360, Accra, Ghana, <sup>2</sup>Deloitte Consulting, Arlington, VA, United States

With the elimination and control of certain Neglected Tropics Diseases (NTDs) increasingly within reach, effective, sustainable programs to prevent disease reemergence are of paramount importance. In fact, NTD programs have made substantial progress over the last decade leading to global declines in the burden of five NTDs responsive to Preventive Chemotherapy (PC): lymphatic filariasis, trachoma, onchocerciasis, schistosomiasis, and soil-transmitted helminths. Many endemic countries have substantially reduced their prevalence, and subsequently disease burden and morbidity, with the support of global initiatives and significant donor and national financing. Act to End NTDs | West is a USAID-funded project supporting 11 countries in West Africa to achieve elimination and control goals for all five PC-NTDs. As national NTD programs (NTDPs) near elimination targets, sustaining gains may be challenging as Ministries of Health prioritize other high-prevalence diseases (e.g., HIV, malaria) with higher visibility and mortality. If programs are unable to secure sufficient national support, NTD gains may be threatened, leading to the reemergence of "eliminated" NTDs and erasing the success achieved thus far through coordinated action and sustained investments. NTDPs use the Tool for Integrated Planning and Costing (TIPAC), a Microsoft Excel-based program that helps NTDPs accurately estimate their program's costs and funding gaps. TIPAC is important for programmatic decision making as the tool can be used in conjunction with existing national NTD strategic plans and budgets to effectively plan and coordinate future program resources. Additionally, TIPAC data is a key driver for advocacy and resource mobilization activities. This poster presentation will illustrate how TIPAC data is used by Act | West programs to inform budgeting, planning, and costing and is an essential factor for resource mobilization and NTD elimination. Such activities contribute to country ownership, a key pillar of the WHO 2030 Roadmap.

0528

### INTRODUCING A SPATIAL SYNDROMIC SURVEILLANCE APPROACH TO IDENTIFY EMERGENT CLUSTERS OF COVID 19

**Andrew Curtis**, Jayakrishnan Ajayakumar, Jacqueline Curtis

Case Western Reserve University, Cleveland, OH, United States

Identifying emergent patterns of coronavirus disease 2019 (COVID-19) at the local level presents a geographic challenge. The need is to identify meaningful spatial patterns, especially in vulnerable settings where even small numbers and low rates are vital for the targeting of early intervention. This presentation identifies a gap in current spatial analytical approaches that tend to rely on maps describing broader patterns of disease rather than a near-real time assessment of emerging situations. This new technique, Geographic Monitoring for Early Disease Detection (GeoMEDD), is either used as a stand-alone analysis or part of an "enterprise" solution integrating a spatial database, by providing multiple spatial and temporal perspectives on an ever-changing disease landscape by connecting cases using different spatial and temporal thresholds. GeoMEDD, has proven effective in revealing different cluster sizes, as well as the influencers and accelerators that give insight as to why a cluster exists where it does, and why it evolves. In this paper we will show how the technique was developed at the beginning of the pandemic to support a single hospital system, but soon evolved into the syndromic surveillance tool for the entire US state of Ohio. We will go on to show how it can be used to sort through spatial noise in periods of surge, or for identifying flare-ups when cases recede. In this regards it has also proven useful for the spatial targeting of vaccine deployment. The technique had been developed for maximum flexibility for different data environments, making

it ideal for any global setting including locations with limited resources. We will end this presentation with an example of how GeoMEDD can be used to address other health situations beyond the current pandemic.

0529

### **BUILDING CAPACITY ON INFECTION, PREVENTION AND CONTROL (IPC) IN HEALTHCARE SETTINGS DURING THE COVID-19 PANDEMIC IN BANGLADESH**

**Mst. Farhana Akter**, Jebun Nessa Rahman, Amany Ayub

*Management Sciences for Health, Dhaka, Bangladesh*

The COVID-19 pandemic underscored the lack of capacity in infection, prevention and control (IPC) among frontline health care workers (HCWs) in Bangladesh. Upon request of the Communicable Disease Control of the Directorate General of Health Services, USAID Medicines, Technologies, and Pharmaceutical Services (MTaPS) program provided IPC training to 4,250 HCWs from 259 health facilities across the country between March and December 2020. Capacity building activities included training on IPC knowledge and practices, how to practice IPC along with triage, and hands-on demonstrations on safety measures while treating COVID-19 patients in health care settings. In February 2021, MTAps evaluated the effectiveness of its COVID-19 IPC capacity building efforts through a cross-sectional study using a mixed-method design. Ninety-seven doctors and 30 nurses from a random sample of trainees from 12 COVID-19 health facilities in Dhaka were surveyed on IPC knowledge and practices. Key informant interviews were also conducted with 6 doctors and nurses to help contextualize the survey findings. The findings showed that the IPC knowledge retention rate among the doctors and nurses was high; over 80% of the respondents correctly answered the IPC knowledge assessment survey questions. Key informants explained that the training improved their IPC knowledge and encouraged them to practice IPC. Nearly all study participants agreed on the relevance and necessity of the training program and its contribution to proper management of COVID-19 patients at health facilities. Doctors (50%) and nurses (60%) reported that they were able to use all their learnings from the IPC training in their practice during COVID-19 pandemic. The findings demonstrate that the training improved reported IPC knowledge and practices of the trainees. However, the findings also underscore the need to invest in more sustained IPC capacity building of HCWs, invest in behavioral change and functional IPC committees to ensure implementation of IPC activities at the facilities as IPC is a key component in effectively managing the COVID-19 pandemic and other public health emergencies.

0530

### **A CONTINUOUS, SCALABLE SEROSURVEILLANCE PLATFORM TO MONITOR EXPOSURE TO PATHOGENS AND IDENTIFY HEALTH DISPARITIES USING ELECTRONIC HEALTH RECORDS**

**Isobel Routledge**, Adrienne Epstein, Saki Takahashi, Owen Janson, Jill Hakim, Elias Duarte, Keirstine Turcios, Joanna Vinden, Jesus Rangel, Marcelina Coh, Lee Besana, Wai-Kit Ho, Ching-Ying Oon, Chui Mei Ong, Cassandra Yun, Kara Lynch, Alan H. Wu, Wesley Wu, Edward Thornborrow, William Karlon, John Pak, Michael Peluso, Timothy Henrich, Jessica Briggs, Bryan Greenhouse, Isabel Rodriguez-Barranquer

*University of California San Francisco, San Francisco, CA, United States*

Serosurveillance provides a unique opportunity to quantify the proportion of the population that has been exposed to pathogens. However, "gold standard" (probabilistic) population-based serological surveys are often too expensive and time consuming to quickly and frequently implement in response to an emerging epidemic. We developed and piloted *Serosurveillance for Continuous, Actionable Epidemiologic Intelligence of Transmission* (SCALE-IT), a platform through which we systematically selected and tested remnant samples from routine blood draws in two major health networks in San Francisco for SARS-CoV-2 antibodies from March to June 2020 and during February 2021. Importantly, these remnant samples were linked to detailed electronic health records,

enabling careful algorithmic selection based on demographic, geographic and clinical variables, improving their representativeness to the general population. Between March 28 and June 26 2020, we collected a total of 5,244 samples and calculated raw and adjusted seroprevalence estimates stratified by space, time, and socio-demographic indicators including age, health insurance status, gender, homelessness status and race/ethnicity. These data provide estimates of the overall population-weighted seroprevalence in San Francisco during the initial phase of the SARS-CoV-2 outbreak (4.2%, 95% Credible Interval: 2.1% - 6.3%) and highlight important heterogeneities in transmission by neighborhood, homelessness status, gender and race/ethnicity. We will also present updated results that incorporate additional sampling efforts, providing a picture of how seroprevalence and the health disparities we identified varied as the pandemic progressed. Serosurveillance efforts globally will be fundamental to monitor transmission rates of emerging infectious diseases, including SARS-CoV-2, and evaluate the impact of interventions. Due to the ease and low cost of implementation, this hybrid serosurveillance approach has strong potential for scaling its application beyond this local context and for diseases other than SARS-CoV-2.

0531

### **EPIDEMIOLOGY OF INFLUENZA IN GHANA: 2011-2019**

**Terrel Sanders<sup>1</sup>**, Ivy Asante<sup>1</sup>, Anne Fox<sup>1</sup>, Eric Behene<sup>1</sup>, Naiki Attram<sup>1</sup>, Shirley Nimo-Paintsil<sup>1</sup>, Andrew Letizia<sup>1</sup>, Chaselynn Watters<sup>1</sup>, William Ampofo<sup>2</sup>

<sup>1</sup>NAMRU-3, Marion, SC, United States, <sup>2</sup>NMIMR, Marion, SC, United States

The earliest reports of influenza in Ghana date back to the 1918-1919 global pandemic. Influenza data from Africa was limited for multiple decades after this pandemic until an outbreak of highly pathogenic influenza A H5N1 among poultry in 2007, which led to the initiation of a national surveillance program. Here we present influenza surveillance data in Ghana from 2011-2019. Systematic data on influenza was collected at the population level to describe the epidemiology of influenza as an etiology for influenza like illness (ILI) and severe acute respiratory infection (SARI) in Ghana from 2011-2019 as part of the Integrated Disease Surveillance and Response (IDSR) system. The IDSR utilized modified WHO case definitions for ILI and SARI, including individuals with measured fever or history of fever with cough or sore throat, with symptom onset within the prior 10 days for outpatients (ILI) and inpatients (SARI). A maximum of five ILI and all SARI samples were analyzed weekly for seasonal influenza A and B lineages (A[H1], A[H3], A[H1] pdm, B Yamagata and B Victoria). A total of 25,176 samples were collected from patients who met the case definitions of ILI (21,747) and SARI (3,429). Of those meeting ILI criteria, 14% were positive for influenza with the peak incidence of 21% occurring in the 5-14-year-old group. The observations for both ILI and SARI surveillance show that in Ghana, influenza is most prevalent in children 5-14 years old. Based on global influenza data, extremes of age tend to be most affected resulting in a U-shaped incidence curve, but this pattern is not evident in the surveillance data. There are years where Ghana mirrors the global and/or West African case peaks and influenza lineages, but many years with significant variability. This unpredictability limits the generalizability of global and West African data in predicting influenza trends within Ghana, highlights the need for multiple surveillance sites, potentially has significant implications for vaccine strain selection and effectiveness, and impacts public health preparedness and military force health protection.

## A SYSTEMATIC LITERATURE REVIEW AND META-ANALYSIS OF THE SEROPREVALENCE AND SPATIAL DISTRIBUTION OF MEDICALLY IMPORTANT TICK-BORNE DISEASES IN EAST AFRICA (1901-2020)

**Fatima Jaradat**<sup>1</sup>, Arisa Kano<sup>1</sup>, Alexander Potter<sup>2</sup>, David B. Pecor<sup>2</sup>, Michael von Fricken<sup>1</sup>, Dawn Zimmerman<sup>3</sup>, Katherine Mertes<sup>4</sup>, Yvonne-Marie Linton<sup>2</sup>

<sup>1</sup>George Mason University, Fairfax, VA, United States, <sup>2</sup>Walter Reed Biosystematics Unit (WRBU), Smithsonian Institution Museum Support Center, Suitland, MD, United States, <sup>3</sup>Global Health Program, Smithsonian's National Zoological Park and Conservation Biology Institute, Washington, DC, United States, <sup>4</sup>Conservation Ecology Center, Smithsonian's National Zoological Park and Conservation Biology Institute, Front Royal, VA, United States

Tick-borne diseases (TBDs), including anaplasmosis, babesiosis, and East Coast fever, pose a significant threat to livestock production and both human and animal health in East Africa. Despite their importance, remarkably little is known on the seroprevalence and spatial distribution of TBDs in this region. This study represents the most comprehensive regional meta-analyses to date on the prevalence of TBDs impacting populations in Chad, Djibouti, Ethiopia, Kenya, and Uganda. A systematic literature review was conducted to identify peer-reviewed articles reporting tick collection findings, including pathogen screening results and TBD seroprevalence data. Over 6,000 manuscripts were screened, of which more than 200 contained high-quality occurrence data regarding TBD seroprevalence. Surveillance data were georeferenced and assigned a spatial resolution. These findings will be linked with additional datasets detailing the spatial distribution of tick vector species and the pathogens they carry. Using this approach, we can characterize the prevalence, geographic distribution, and temporal trends of TBD exposure among wildlife, livestock, and human populations across East Africa. The resultant dataset reflects a significant improvement to our regional knowledge of TBD prevalence and provides a valuable platform for future TBD risk assessment, prevention, and mitigation in this region. Such data further allows us to identify and address associated gaps in disease surveillance.

## DOCUMENTING TICK AND TICK-BORNE DISEASE DISTRIBUTIONS IN EAST AFRICA THROUGH ADVANCED SYSTEMATIC LITERATURE SEARCHES

Ticks pose a significant risk to human health across the globe. To diminish these risks, high quality tick and tick-borne disease surveillance data is needed to develop accurate risk assessments and effective mitigation plans. However, despite the large quantity of tick research performed in East Africa, no standardized, comprehensive, review has been conducted for this region. Our goal was to produce a comprehensive review of historic tick and tick-borne disease studies conducted in five countries in East Africa—Chad, Djibouti, Ethiopia, Kenya, and Uganda. Eligible reports were those that contained mappable tick collection data such as detailed locality descriptions, GPS coordinates, and map-displayed data. To generate our review, we searched for original research articles, published in English, between 1901 and August 2020. We searched four databases (PubMed, Web of Science, Scopus, and CABI VetMed Resource) using 19 search terms related to ticks and tick-borne diseases in each library, with the corresponding MeSH terms used in PubMed. Over 6,000 articles were initially captured in our search, yet after scrutiny, nearly 300 met our eligibility criteria. Tick collection records gleaned from these articles were subsequently georeferenced using point-radius method to standardize the locality data, and then combined with historic collection records from the Walter Reed Biosystematics Unit (WRBU) VectorMap platform (vectormap.si.edu), which includes our current surveillance records. The result was a comprehensive, novel dataset comprised of high-quality collection events from over 1300 unique point locations representing over 100 tick species in the five countries. These data were used to map tick and tick-borne disease presence in these countries, providing regional oversight and detailed risk maps for tick-borne diseases in East Africa.

## TICKS AND TICK-BORNE DISEASE THREATS OF KENYA

There are several documented tick-borne disease (TBD) risks in Kenya, impacting both humans and livestock. Despite the persistence of these threats, there are few data resources available for assessing TBD risk. A comprehensive understanding of the tick vector threats in this country is essential. Kenya-specific data from our ongoing surveillance and a systematic literature review of over 6000 tick and tick-borne disease research papers in East Africa were sourced and over 120 met our inclusion criteria for Kenya. This effort revealed over 70 tick species, spanning 8 genera, were reported from Kenya between 1901 and August 2020. Additionally, over 50 disease-causing parasitic, bacterial, and viral agents were detected across these species. *Coxiella burnetii* and *Rickettsia* spp. were some of the most frequently detected agents. Preliminary results indicate vast distribution of several tick species such as *Amblyomma variegatum* (Fabricius, 1794), *Rhipicephalus decoloratus* Koch, 1844, R.

*eversti* Neumann, 1897, and *R. appendiculatus* Neumann, 1901. Further investigation of this rich dataset will contribute to a more complete understanding of the tick vector threats of Kenya and will drive future tick surveillance and tick-borne disease mitigation efforts.

**FIRST RECORD OF THE GENUS *CULICOIDES* (DIPTERA: CERATOPOGONIDAE) IN CHIHUAHUA, NORTHWEST MEXICO: A STUDY OF DNA BARCODE, HUMAN-LANDING RATE, ARBOVIRUS DETECTION, AND PUBLIC HEALTH IMPORTANCE OF *CULICOIDES FURENS***

Javier A. Garza-Hernandez<sup>1</sup>, Stephanie V. Laredo-Tiscareao<sup>2</sup>, Carlos A. Rodríguez-Alarcen<sup>1</sup>, Jaime R. Adame-Gallegos<sup>3</sup>, Rodolfo Gonzalez-Peta<sup>3</sup>, Ezequiel Rubio-Tabarez<sup>1</sup>, Bradley J. Blitvich<sup>2</sup>

<sup>1</sup>Universidad Autónoma de Ciudad Juárez, Cd. Juárez, Mexico, <sup>2</sup>Iowa State University, Ames, IA, United States, <sup>3</sup>Universidad Autónoma de Chihuahua, Chihuahua, Mexico

The genus *Culicoides* (Fam. Ceratopogonidae), commonly named biting midges, are the smallest hematophagous dipterans with public health importance worldwide. *Culicoides* transmit multiple pathogens to humans and animals, but as vectors of arboviruses, they achieve their principal importance; more than 50 viruses have been isolated from *Culicoides* species. From the almost 1400 morphospecies identified, Mexico has 84 morphospecies. However, some regions of Mexico are still scantily studied. This is the case of Chihuahua, located in Northwest Mexico, where does not have any record for *Culicoides* species. In the present study, DNA barcode, bionomic parameters, and arboviral diagnosis of *Culicoides* from San Buenaventura, Chihuahua, Mexico were estimated. Here, collections of *Culicoides* were carried out from April through September 2020 in San Buenaventura, Chihuahua, by using the human-landing-collection (HLC) method, CDC, and mosquito magnet traps. Morphological keys and corroborated by DNA barcoding were performed to *Culicoides* identification. The daily pattern of total landing activity of *Culicoides* was estimated. Also, pools of *Culicoides* were achieved for the screening of viruses by metagenomic analyses. In this research, *Culicoides furens* was identified as unique species. DNA barcode reveals a possible complex compared with those in DNA databases. Host-seeking females of *C. furens* showed a unimodal human-landing activity pattern between 4-8 pm. The human daily landing rate was directly proportional to temperature and solar radiation, but there was a significant negative association with wind speed. Overall, a daily landing rate (DLR) of 88 lands/person/day was estimated. Several sequences of possible arbovirus associated with *C. furens* were detected. We conclude that *Culicoides furens* is the first species reported in Chihuahua, northwest Mexico. Also, this is the first study of metagenomics analyses in *Culicoides* in Mexico. The data offer insights into the ecology of *C. furens*, a potential vector of arbovirus in Mexico.

**SPOTLIGHT REPORT: TICK VECTOR THREATS OF DJIBOUTI**

Graham Matulis<sup>1</sup>, Mary F. Kearney<sup>2</sup>, David B. Pecor<sup>3</sup>, Alexander Potter<sup>3</sup>, Alec G. Richardson<sup>3</sup>, Michael von Fricken<sup>1</sup>, Dawn Zimmerman<sup>4</sup>, Yvonne-Marie Linton<sup>3</sup>

<sup>1</sup>George Mason University, Fairfax, VA, United States, <sup>2</sup>University of Michigan, Ann Arbor, MI, United States, <sup>3</sup>Walter Reed Biosystematics Unit, Suitland, MD, United States, <sup>4</sup>Smithsonian's National Zoological Park and Conservation Biology Institute, Washington, DC, United States

VectorMap is the largest online repository for global arthropod disease vector distribution data. In an effort to improve tick surveillance coverage in East Africa, a systematic literature review was conducted, targeting publications from 1901-2020. This study supports an ongoing regional effort to better characterize the distribution of ticks and the pathogens they carry in Djibouti. Scientific literature was compiled from PubMed, Scopus, WOS, and CABI search engines. Over 6,000 manuscripts were screened for relevance according to title and abstract, of which 7 met

inclusion criteria. Information captured included tick species, collection locality, collection method and pathogen detections. Thirty-two species/subspecies of ticks from 5 different genera were reported in Djibouti. Pathogens detected include *Rickettsia africae* and Crimean-Congo hemorrhagic fever virus. Most ticks reported were removed from animals and in many instances, these animals had migrated into Djibouti from neighboring countries. Considering this trend, and the role Hajj plays in human and animal movement through this region, enhanced surveillance is recommended for early detection and monitoring of select agents. Findings from this study highlight major gaps in our understanding of tick-borne diseases within Djibouti that warrants further investigation.

0537

**GENETIC DIVERSITY AND POPULATION STRUCTURE OF PHLEBOTOMUS ARGENTIPES, THE VECTOR OF LEISHMANIASIS IN SRI LANKA**

Dulani Ruwanika Pathirage<sup>1</sup>, Thilini Chathurika Weeraratne<sup>2</sup>, S H P Parakrama Karunaratne<sup>2</sup>, Nadira D. Karunaweera<sup>1</sup>

<sup>1</sup>Faculty of Medicine, Colombo, Colombo 08, Sri Lanka, <sup>2</sup>Faculty of Science, University of Peradeniya, Peradeniya, Sri Lanka

Vector of leishmaniasis in Sri Lanka is *Phlebotomus argentipes* which transmit *Leishmania donovani* and the disease is a growing health problem. A proper understanding of the population genetic structure of sand fly vectors is considered important prior to planning and implementation of a successful vector control program. Thus, the present study was conducted to determine the population genetic structure of sand fly vectors in Sri Lanka. Two mitochondrial genes viz. *Cytochrome c oxidase subunit 1 (CO1)* and *Cytochrome b oxidase (Cytb)*, and the internal transcribed spacer 2 (ITS2) region from the nuclear ribosomal DNA were used for molecular characterization. Analysis was done using maximum likelihood method, Network analysis and DNA polymorphisms. The analysis revealed unique sequences of all genomic regions studied except the *CO1* region in 21 flies that aligned with those from Kerala, India and *Cytb* region of 4 flies that aligned with those isolated earlier from Sri Lanka and 3 from Madagascar. *CO1* and ITS 2 region analyses revealed gene flow between the study sites whereas *Cytb* gene region analysis indicated genetically distinct populations of *P. argentipes* in each of the study sites. Populations of *P. argentipes* in Sri Lanka are in most part distinct when compared to sand flies from elsewhere. Gene flow with lack of population differentiation of *P. argentipes*, even between geographically distant sites is likely to pose future challenges for leishmaniasis control due to the likelihood of gene transfer between locations. Such occurrences affecting functionally important genes such as those which confer insecticide resistance can facilitate the spread, of insecticide resistance across the country, which in turn will make vector control difficult.

**QUANTUM CASCADE LASERS FOR MOSQUITO SURVEILLANCE**

Mauro Pazmino Betancourth<sup>1</sup>, Francesco Baldini<sup>1</sup>, David Childs<sup>2</sup>

<sup>1</sup>University of Glasgow, Glasgow, United Kingdom, <sup>2</sup>Vector Photonics, Glasgow, United Kingdom

Fourier Transform Infrared (FTIR) spectroscopy has shown a great potential as a tool for mosquito surveillance. Mid-Infrared spectroscopy coupled with machine learning analysis allow us to identify mosquito age and species. However, current FTIR technology has various limitations: very expensive and bulky equipment, low signal-to-noise ratio and low speed. These limitations make them unsuitable for on-site measurements in remotes areas where surveillance is needed. New technologies in the field of semiconductor lasers have emerged in the last decade with the potential of overcome these limitations. Quantum Cascade lasers (QCLs) can emit infrared radiation with high power over a broad spectral range with a size of no more than a few millimetres. QCLs have been applied mainly in the development of portable system for biomedical diagnosis and monitoring, gas sensing and analysis of pharmaceutical formulations.

Here we present a portable system using QCLs for mid-IR spectroscopy measurements in mosquitoes. Our set up consists of a single QCL 3 mm in size chip mounted in an external cavity. The laser chip can be tuned using a scanning galvanometer from 950 to 1150  $\text{cm}^{-1}$ . This set up can scan samples with speeds up to 125 Hz (~100 scans per second). Our set up successfully measure mid-infrared spectra from mosquitoes in KBr pellets. Currently, we are working on non-destructive methods to measure mid-IR spectra on other mosquito tissues. Our results highlight the potential of QCLs for a cheaper, compact option for current tools for spectroscopy. Moreover, this technology can be expanded to other areas such as malaria diagnosis.

**CULTURE-DEPENDENT AND -INDEPENDENT METAGENOMIC ASSEMBLIES FROM MALAYSIAN CTENOCEPHALIDES SPP. FLEAS UNCOVER NEW COMPLETE GENOMES FOR BARTONELLA CLARRIDGEIAE, RICKETTSIA ASEMBONENSIS AND MULTIPLE CLADES OF WOLBACHIA**

Alexandra Beliavskaia<sup>1</sup>, Jing Jing Khoo<sup>2</sup>, Kim-Kee Tan<sup>2</sup>, Amit Sinha<sup>3</sup>, Shih-Keng Loong<sup>2</sup>, Clotilde K. Carlow<sup>3</sup>, Lesley Bell-Sakyi<sup>1</sup>, Sazaly Abubakar<sup>2</sup>, Alistair C. Darby<sup>1</sup>, **Benjamin L. Makepeace<sup>1</sup>**

<sup>1</sup>University of Liverpool, Liverpool, United Kingdom, <sup>2</sup>University of Malaya, Kuala Lumpur, Malaysia, <sup>3</sup>New England Biolabs, Ipswich, MA, United States

*Ctenocephalides* spp. fleas are recognised as globally distributed vectors of human diseases including cat-scratch disease (bartonellosis), dipylidiasis, and several rickettsioses, such as murine typhus (*Rickettsia typhi*) and flea-borne spotted fever (*Rickettsia felis*). They may also harbour other microorganisms, including arthropod-specific bacterial symbionts, which remain poorly characterised. Scant information exists on the geographical variation of pathogen and symbiont carriage in *Ctenocephalides* spp. fleas, especially outside Western countries, and the risk these vectors pose for disease transmission in the tropics. In this study, fleas were collected from cats and dogs in an Orang Asli (aboriginal) community in Peninsular Malaysia. Cat flea tissues were cultured with IDE8 tick cells to isolate bacterial symbionts and positive cultures were sequenced on the Oxford Nanopore MinION platform. Fleas from dogs (*Ctenocephalides orientis*) were subjected to culture-independent metagenomics on the same sequencing platform. Two *Wolbachia* strains from cat fleas were successfully isolated in IDE8 cells and genomic analysis demonstrated these constituted a novel supergroup F symbiont closely related to *wCfe* from bedbugs, and a strain highly similar to *wCfeJ*, recently sequenced from *C. felis* in the USA. From *C. orientis*, complete genomes were obtained for *Bartonella clarridgeiae*, *Rickettsia asembonensis*, and a third *Wolbachia* strain that resembled *wCfeT* from North American cat fleas. The *B. clarridgeiae* genome was highly similar to Western cat-scratch disease isolates except for polymorphisms in flagellin genes. For *R. asembonensis*, which has been previously associated with a human clinical case in Malaysia, our assembly represents the first circularised genome obtained worldwide and was accompanied by a distinct plasmid with low similarity to the published sequence for this species. Taken together, our data highlight the complexity and knowledge gaps pertaining to *Wolbachia* symbionts in *Ctenocephalides* spp. and the potential for these vectors to transmit bacterial pathogens in aboriginal communities.

**ALERTACHIRIMACHA: SHIFTING COMMUNITY-BASED VECTOR SURVEILLANCE TO SOCIAL MEDIA DURING COVID-19**

Laura D. Tamayo<sup>1</sup>, Valerie Paz-Soldan<sup>2</sup>, Carlos Condori-Pino<sup>1</sup>, Ricardo Castillo-Neyra<sup>3</sup>, Michael Z. Levy<sup>3</sup>

<sup>1</sup>Zoonotic Disease Research Lab (LIEZ), One Health Unit, School of Public Health and Administration, Universidad Peruana Cayetano Heredia, Arequipa, Peru, <sup>2</sup>Department of Global Community Health and Behavioral Sciences, Tulane School of Public Health and Tropical Medicine, New

Orleans, LA, United States, <sup>3</sup>Department of Biostatistics, Epidemiology and Informatics, Perelman School of Medicine at University of Pennsylvania, Philadelphia, PA, United States

COVID-19 pandemics have brought new challenges for the surveillance and control of many other infectious diseases. The social distancing measures and the social immobilization imposed by the national government to avoid the transmission of SARS-CoV-2 virus in Arequipa-Peru have greatly affected the entomological surveillance of kissing bugs, the vectors of the etiological agent of Chagas disease: *Trypanosoma cruzi*. As a way to maintain surveillance activities, we created "AlertaChirimacha" a new system of communication and reporting that educates the contact between the community and vector control staff. We have used facebook advertising to promote this new reporting system via phone calls and WhatsApp messages. If an infested house is detected, we delimit a risk area around it and distribute fliers requesting householders to check their homes for the presence of triatomines and report it through the phone line. After the two paid posts and promotion around an infested dwelling, we have received 82 reports of insects that people considered to be kissing bugs, two of which resulted in the uncovering of 2 new infestation foci--a substantial finding in a city where the insects are very near elimination. Compared to the 7 months prior to the launch of "AlertaChirimacha" the number of reports had increased by 575%. Reports received came from all across the city. These preliminary results demonstrate the possibility of using social media to keep disease surveillance active in situations where physical contact must be reduced.

**RESULTS: SYSTEMATIC LITERATURE SEARCH TARGETING TICK AND TICK-BORNE DISEASES IN FIVE COUNTRIES IN EAST AFRICA**

Rachel Wofford<sup>1</sup>, Mary Kearney<sup>2</sup>, Graham Matulis<sup>1</sup>, Stephanie Mitchell<sup>3</sup>, Fatima Jaradat<sup>1</sup>, Arisa Kano<sup>1</sup>, David Pecor<sup>4</sup>, Alexander Potter<sup>4</sup>, Alec Richardson<sup>4</sup>, Dawn Zimmerman<sup>3</sup>, Katherine Mertes<sup>5</sup>, James Hassel<sup>3</sup>, Yvonne-Marie Linton<sup>4</sup>, Michael von Fricken<sup>1</sup>

<sup>1</sup>George Mason University, Fairfax, VA, United States, <sup>2</sup>University of Michigan, Ann Arbor, MI, United States, <sup>3</sup>Smithsonian's National Zoological Park and Conservation Biology Institute, Washington, DC, United States, <sup>4</sup>Walter Reed Biosystematics Unit (WRBU), Suitland, MD, United States, <sup>5</sup>Smithsonian's National Zoological Park and Conservation Biology Institute, Front Royal, VA, United States

As part of an ongoing Armed Forces Health Surveillance Division-Global Emerging Infections Surveillance (AFHSB-GEIS) regional East Africa project, a large systematic review of ticks and their associated pathogens in five countries (Chad, Djibouti, Ethiopia, Kenya, and Uganda) was undertaken to augment current field data and recover maximal verified data points for mapping and risk modelling purposes. Over 6,000 peer-reviewed articles were screened for reports of tick and tick-borne pathogen surveillance published between 1901 and 2020. Articles containing surveillance data were mined and collection data geo-referenced and combined into a single database. The findings from the database are presented in a large matrix of identified tick species and pathogens for the five countries of interest. While over one hundred articles each were sourced for Ethiopian and Kenyan, few articles were available for tick studies in Chad, Djibouti and Uganda, highlighting the need for increased surveillance efforts in these under sampled countries. With data now readily available on vector - pathogen associations and their geographic occurrences, highly specific tick-borne disease maps and models can be created for a variety of study types using a single database. The longitudinal data accumulated in this study provides a digital, mappable, and relatable database of tick collections across 5 neighboring countries in East Africa that can immediately inform tick-borne disease risks and surveillance priorities at both country and regional levels.

0542

### THE FIRST PROSPECTION FOR VECTOR BREEDING SITES OF ONCHOCERCIASIS IN LIBERIA: IDENTIFYING PRODUCTIVE SITES OF *SIMULIUM DAMNOSUM* S.L. SPECIES IN 2018

Sonnie Zياما Gbewo<sup>1</sup>, Daniel Boakye<sup>2</sup>, Isaac Gbewo<sup>3</sup>

<sup>1</sup>Ministry of Health, Paynesville, Liberia, <sup>2</sup>Noguchi Memorial Institute for Medical Research, Legon, Ghana, <sup>3</sup>WASH Commission, Monrovia, Liberia

Onchocerciasis has been earmarked as one of the five neglected tropical diseases (Onchocerciasis, Lymphatic Filariasis, Trachoma, Schistosomiasis and STH) amenable to preventive chemotherapy targeted for elimination. Unlike the other diseases where the target is elimination as a public health problem, onchocerciasis has a goal to eliminate transmission. Towards this goal, the World Health Organization (WHO) has come out with a verification of onchocerciasis elimination guideline. The guideline places emphasis for verifying the elimination of onchocerciasis on transmission assessment (Entomology), infection prevalence (Epidemiology) and transmission zone. Liberia began treatment for onchocerciasis in 2000, however, due to the civil unrest (2001-2003) and the Ebola outbreak (2014-2015), the program experience interruption in the treatment round. After 12 rounds of Mass Drug Administration (MDA), the country along with experts decided to identify vector productive breeding sites, vector *Simulium* species, first line communities and the development of a breeding sites map for Liberia. The survey was completed in 10 counties constituting two regions (northwest & southwest) showing possible transmission zones in Liberia. The research was undertaken in the dry season when most rivers especially the smaller ones were dry while larvae collected were processed involving an initial sorting of the samples into members of the *S. damnosum* complex. During the research, 17 breeding sites were identified, 4 different species seen, 204 samples (larvae) collected and the percent of forest cytospecies predominate with only a few sites having savannah species. *Simulium yahense* was observed to be the most widespread species in Liberia. The research results have generated valuable data to support the onchocerciasis control and elimination programme in Liberia. It shows the classification of species found in Liberia and have guided the program to the next step of conducting impact assessment for communities' dwellers living within 5km of a productive breeding site.

0543

### EVALUATING THE EFFECTS OF BREEDING WATER BACTERIA ON THE LIFE HISTORY OF MALE *Aedes aegypti* MOSQUITOES

Brendan J. Kelly, Sarah M. Short

The Ohio State University, Columbus, OH, United States

The yellow fever mosquito *Aedes aegypti* presents a threat to human health around the globe, making the development of sustainable and effective methods of mosquito population control necessary. One such strategy is the sterile insect technique (SIT), in which sterile males are released into the environment to compete for mates, ultimately reducing the population. Boosting the fitness of these sterile males would improve the efficacy of SIT strategies. Our work seeks to evaluate the role that different larval microbes play in the development and life history of male mosquitoes. During development, *Ae. aegypti* larvae regularly ingest bacteria and bacteria from breeding water are also found in adult mosquitoes. These bacteria support development, provide nutritional benefits, and impact female mosquito physiology in many ways. We hypothesize that bacteria species will differ in the effects they have on larval and adult physiology, leading to differences in overall male fitness. We are rearing larvae in the presence of a single bacterial species. From here, we are measuring the development time, adult longevity, and wing length (as a proxy for body size) of single individuals. The effects of larval bacteria on male longevity and body size will be discussed, as these data may be used to identify specific bacteria species that could enhance the current mass rearing practices employed for SIT. These data will also be

compared to data collected from female individuals resulting from the same treatments to investigate the possibility of sex-specific effects of larval bacterial presence.

0544

### VECTORS TAKING FLIGHT; THE INFLUENCE OF INVASIVE TICK SPECIES, BIRD MIGRATION AND CLIMATE CHANGE ON SOUTH CAROLINA'S COASTAL ZONES

Connor Ross<sup>1</sup>, Kyndall Dye-Braumuller<sup>1</sup>, Chris Evans<sup>2</sup>, Melissa S. Nolan<sup>1</sup>

<sup>1</sup>University of South Carolina, Columbia, SC, United States, <sup>2</sup>South Carolina Department of Health and Environmental Control, Columbia, SC, United States

Climate change is having a profound impact globally, including changes in migratory bird patterns. Along the eastern North American coastline, a substantial number of migratory birds have expanded their ranges to adapt to more southern latitudes, increasing their exposure to novel tick vectors in tropical regions. Further, certain species have created new geographic routes altogether, allowing for a second pathway of potential exotic tick introduction into new environments. Recent state-wide tick surveillance in collaboration between the University of South Carolina and the South Carolina Department of Health and Environmental Control has identified invasive and exotic avian-feeding tick species within the state. This presentation will review the public health importance of *Haemaphysalis longicornis*, *Haemaphysalis leporispalustris*, *Ixodes scapularis*, *Ixodes brunneus*, and *Ixodes affinis*. *H. longicornis* is a recently invasive species, and the others are native but have been documented as moving into new ranges. These four tick species were recently identified in South Carolina, and all four are known causes of clinical or veterinary disease and can be geographically displaced by migratory birds. Understanding the relationship between these tick vectors and changing migratory bird patterns due to climate change can serve to inform vector surveillance and public health officials on possible new trends in vector-borne disease spread.

0545

### GRADIENT OF ONCHOCERCIASIS ENTOMOLOGIC INDICES FROM RIVERSIDES TO THE CENTRE OF TWO FIRST LINE COMMUNITIES IN THE MBAM VALLEY: IMPLICATION FOR OPTIMAL VECTOR CONTROL USING TRAPS

André Domche<sup>1</sup>, Hugues Clotaire Nana Djeunga<sup>2</sup>, Philippe Bienvenu Nwane<sup>2</sup>, Sébastien Pion<sup>3</sup>, Guy-Roger Njitchouang<sup>2</sup>, Flobert Njikou<sup>4</sup>, Joseph Kamgno<sup>2</sup>

<sup>1</sup>Centre for Research on Filariasis, Yaounde, Cameroon, <sup>2</sup>Centre for Research on Filariasis and other Tropical Diseases, Yaounde, Cameroon, <sup>3</sup>Institut de Recherche pour le Développement, Montpellier, France, <sup>4</sup>Parasitology and Ecology Laboratory, Department of Animal Biology and Physiology, Faculty of Science, University of Yaounde 1, Yaounde, Cameroon

The reduction of human-blackfly contact can interrupt onchocerciasis transmission. Esperanza window trap (EWT) has been shown to be effective in reducing blackfly densities. Several shape-based improvements to this trap have been made to optimize its performance. However, its placement within a community generally only meets the criteria of high-density areas and the presence of humans without taking into account blackfly transmission potentials (MTP and ATP, monthly and annual transmission potentials) and parity rates (PR). We investigated entomological indices at different points within the communities for optimal use of the EWT. Monthly blackfly collection was carried out for one year using human landing method at three catch points along a transect from riverside toward the center of two first-line communities (Biatsota and Bayomen) in Cameroon. Collected blackflies were counted and dissected, and entomologic indicators (MBR and ABR, monthly and annual biting rates, PR, MTP and ATP) were computed and compared using Kruskal Wallis test. A total of 80,732 blackflies (37,242 at Biatsota and 43,490 at Bayomen) were caught, of which 57,517 (71.2%) were

dissected (27,508 at Biatsota and 30,008 at Bayomen). A total of 2,743 (4.8%) were parous and 44 (1.6%) were infective, with a total of 51 infective larvae (Li) in the head. Regarding the distance to the river, we observed a decreasing vector density gradient, with the highest ABRs recorded at the two riversides (489,009 bites/human/year). The highest ATPs were also recorded at the two riversides (420 Li/man/year). The comparison of MBRs between the three catching points in each village revealed a significant difference ( $p$ : 0.0001 and 0.001 for Bayomen and Biatsota respectively). Globally, the highest PR was recorded at the riverside in Biatsota (5.1%) where various human activities take place all day long, while in Bayomen it was recorded in the centre of community (6.36%). This study showed that entomologic parameters were highest at riversides and indicates that EWT or other traps should be set up in priority on the riverside for optimal performance in onchocerciasis control.

0546

### FIRST REPORT OF N1575Y MUTATION IN PYRETHROID RESISTANT ANOPHELES GAMBIAE S.L. IN NIGERIA

Tolulope Amos Oyeniyi

Nigerian Institute of Medical Research, Lagos, Nigeria

In view of recent findings that codon 1575 mutation increases the L1014F-mediated resistance in *Anopheles* mosquitoes, we investigated the presence of this mutation in four States with intense pyrethroid resistance in Nigeria. Permethrin and deltamethrin susceptibility tests were carried out using 2-3 day old adult female *Anopheles* from larval collections. Based on the susceptibility test results, intensity tests with 5x and 10x concentrations were carried out at sites with high resistance (% mortality >85). Resistant specimens were identified by PCR and screened for the presence of L1014F and N1575Y mutations using allele specific PCR and Taqman assay respectively. The frequency of *kdr* mutation for permethrin varied from 0.71-0.75 for 5x and 0.73-0.75 for 10x. The *kdr* frequency for deltamethrin was not significantly different ( $P=0.157$ ): 0.54-0.60 for 5x and 0.66-0.71 for 10x. Percentage increase in *kdr* frequency between 1x and 5x permethrin doses ranges from 1.4% to 11.9% in all sites except Edo and Anambra; while only Lagos had percentage increase of 1.4% between 5x and 10x. For deltamethrin, Lagos and Niger had the same (3.8%) percentage increase in *kdr* frequency between 1x and 5x, while 5x and 10x gave 23.6% and 31.5% respectively. Resistant *Anopheles gambiae* at 5x and 10x concentrations of permethrin showed the presence of homozygous (Y) and heterozygous (NY) mutant allele in two sites. From this study, the mutation has no significant association with resistance intensity ( $\chi^2=0.8$ ,  $P=0.3711$ ). There is need for frequent monitoring to forestall the effect this may have on national malaria control programs.

<sup>2</sup>Faculty of Infectious and Tropical Diseases, Disease Control Department, London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>3</sup>Medical Research Council (MRC) Tropical International Statistics and Epidemiology Group, London School of Hygiene & Tropical Medicine, London, United Kingdom

This study provides detailed characteristics of vector populations in preparation for a cluster randomized controlled trial aiming to compare the impact of dual active-ingredient long-lasting insecticidal nets (LLINs)

that combine two novel insecticide classes - chlorfenapyr or pyriproxyfen - with alpha-cypermethrin to improve the prevention of malaria transmitted by insecticide-resistant vectors compared to standard pyrethroid LLINs. The study was carried out in 60 villages across three districts, south Benin. Mosquito collections were performed using human landing catches. After morphological identification, a sub-sample of *Anopheles gambiae* s.l. were analyzed by PCR for species and presence of L1014F *kdr* mutation and by ELISA to identify *Plasmodium falciparum* sporozoite infection. WHO susceptibility tube tests were performed by exposing adult *An. gambiae* s.l., collected as larvae from each district, to 0.05% alpha-cypermethrin, 0.75% permethrin, 0.1% bendiocarb and 0.25% pirimiphos-methyl. Synergist assays were conducted with exposure first to 4% piperonyl butoxide followed by alpha-cypermethrin. Overall, *An. gambiae* s.l. was the main malaria vector complex. It was comprised of *An. coluzzii* (53.9%) and *An. gambiae* s.s. (46.1%), both displaying a frequency of the L1014F *kdr* mutation >80%. Human biting rate in *An. gambiae* s.l. was higher indoors [26.5 bite/person/night (95% CI: 25.2-27.9)] than outdoors [18.5 b/p/n (95% CI: 17.4-19.6)], as were the trends for sporozoite rate [2.9% (95% CI: 1.7-4.8) vs 1.8% (95% CI: 0.6-3.8)] and entomological inoculation rate [21.6 infected bites/person/month (95% CI: 20.4 - 22.8) vs 5.4 (95% CI: 4.8-6.0)]. *An. gambiae* s.l. was resistant to alpha-cypermethrin and permethrin but, fully susceptible to bendiocarb and pirimiphos-methyl. Synergist assays induced a higher 24 hour mortality compared to alpha-cypermethrin alone. The intense malaria transmission and high pyrethroid resistance with involvement of multiple mechanisms (L1014F *kdr* and mixed function oxidases) suggest that novel insecticide classes are required to tackle issues of pyrethroid resistance in the study area.

### PERSONAL PROTECTION WITH PBO-PYRETHROID SYNERGIST TREATED NETS AFTER TWO YEARS OF HOUSEHOLD USE AGAINST PYRETHROID-RESISTANT ANOPHELES IN TANZANIA

Jackline L. Martin

NIMR Mwanza, Mwanza, United Republic of Tanzania

Jackline L Martin<sup>1,2\*</sup>, Franklin W Mosh<sup>1</sup>, Eliud Lukole<sup>1</sup>, Mark Rowland<sup>3</sup>, Jim Todd<sup>2,3</sup>, Jacques D Charwood<sup>3</sup>, Jacklin F Mosh<sup>2</sup> and Natacha Protopopoff<sup>3</sup> <sup>1</sup>Kilimanjaro Christian Medical University College, Moshi, <sup>2</sup>United Republic of Tanzania<sup>2</sup>National Institute for Medical Research-Mwanza center, United Republic of Tanzania<sup>3</sup>London School of Hygiene and Tropical, London, United Kingdom

Synergist nets combine pyrethroid and piperonyl-butoxide (PBO) to enhance potency against resistance mediated by mono-oxygenase mechanisms. We assessed personal protection of Olyset Plus versus standard Olyset net against pyrethroid resistant malaria vectors in North West Tanzania after 20 months of household use. From household survey, 39 standard Olyset net and 39 Olyset Plus houses were selected, physical integrity and hole index (HI) of nets assessed, resting mosquitoes collected from inside nets and room walls, indoor abundance estimated using CDC light traps and species identified using PCR. Bioefficacy of PBO and standard LLINs against wild *Anopheles* was assessed using 30 minutes cylinder bioassays. Of 2397 *Anopheles* collected, 8.9% (n=213) were resting inside standard Olyset nets while none were found inside Olyset Plus of any HI category. Resting density of blood-fed mosquitoes was higher on walls of sleeping rooms with Olyset net compared to Olyset Plus (0.62 vs 0.10, density ratio: 0.03, 95% CI: 0.01-0.13,  $p<0.001$ ). Mosquitoes were found inside Olyset nets of all WHO HI categories, but more were collected inside the more damaged nets (HI $\geq$  643) than in less damaged (HI 0-64) nets (DR: 6.4, 95% CI: 1.1-36.0,  $p=0.037$ ). In bioassay, mortality of *An. gambiae* s.l. was higher with Olyset Plus than with Olyset net for new nets (76.8% vs 27.5%) and 20 months' nets (56.8% vs 12.8%); similar trends were observed with *An. funestus*. The Olyset Plus provided improved protection after 20 months of household use irrespective of hole index category, as compared to Olyset nets.

### RESISTANCE TO PYRETHROID INSECTICIDES IN ANOPHELES GAMBIAE S.S AND AN. ARABIENSIS IN UGANDA

Henry D. Mawejje<sup>1</sup>, Brian Leetakubulidde<sup>1</sup>, Francis Nyagabakye<sup>1</sup>, Lilian N. Kayondo<sup>1</sup>, Adrienne Epstein<sup>2</sup>, Moses Kanya<sup>1</sup>, Jo Lines<sup>3</sup>, Grant Dorsey<sup>2</sup>, Martin Donnelly<sup>4</sup>, Sarah Staedke<sup>3</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>University of California, San Francisco, California, San Francisco, CA, United States,

<sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom,

<sup>4</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

The effectiveness of malaria control interventions is threatened by widespread insecticide resistance. The World Health Organization (WHO) advocates resistance management through use of combinations of insecticides. In Uganda, long lasting insecticidal nets (LLINs) with pyrethroids have been distributed nationwide every 3-4 years, and indoor residual spraying (IRS) with bendiocarb or pirimiphos-methyl implemented in selected districts. We assessed if different vector control combinations were associated with resistance patterns in *An. gambiae* s.s and *Anopheles arabiensis* raised from larvae collected from 11 districts in Uganda, including those with no IRS history (3 districts), where IRS was conducted in 2014-17 then discontinued (4 districts), and where IRS has been sustained since 2014 (4 districts). All sites received two rounds of LLINs (2013-14 and 2017). Susceptibility to permethrin and deltamethrin was assessed using the standard WHO tube test; analyses were stratified by IRS status. Overall, 1971 *Anopheles* mosquitoes were assessed; 773 *An. gambiae* s.s. (240 No IRS, 525 IRS stopped, 8 IRS active) and 1198 *An. arabiensis* (249 No IRS, 254 IRS stopped, 695 IRS active). Mortality to pyrethroids was significantly lower for *An. gambiae* s.s. than *An. arabiensis* in sites with no history of IRS (permethrin 16.3% vs 69.0%,  $p < 0.0001$ ; deltamethrin 23.1% vs 83.8%,  $p < 0.0001$ ), and in sites where IRS was discontinued (permethrin 11.1% vs 69.4%,  $p < 0.0001$ ; deltamethrin 24.9% vs 88.6%,  $p < 0.0001$ ). In IRS active sites, nearly all *Anopheles* were *An. arabiensis* (98.9%); mortality to permethrin and deltamethrin was 63.4% and 88.6%, respectively. Comparing mortality for *An. gambiae* s.s. across different IRS site categories, no statistically significant differences were observed for permethrin or deltamethrin. The same was true for *An. arabiensis*. Overall, resistance to pyrethroids was widespread, particularly in *An. gambiae* s.s. In sites with active IRS, *An. arabiensis* predominated. There was no evidence that resistance patterns varied with different vector control combinations once data were stratified by species, but larger studies are needed.

### INTERACTION BETWEEN INSECTICIDE RESISTANCE ASSOCIATED MARKERS AND MALARIA TRANSMISSION PATTERNS IN ANOPHELES GAMBIAE S. L. POPULATION AROUND BOUAKÉ, CÔTE D'IVOIRE.

Rosine Z. Wolie<sup>1</sup>, Alphonsine A. Koffi<sup>1</sup>, Ludovic P. Ahoua Alou<sup>1</sup>, Eleanore D. Sternberg<sup>2</sup>, Oulo N'Nan-Alla<sup>3</sup>, Amal Dahounto<sup>1</sup>, Michael K. Kanh<sup>3</sup>, Soromane Camara<sup>1</sup>, Welbeck A. Oumbouke<sup>4</sup>, Innocent Z. Tia<sup>1</sup>, Prof Simon-Pierre A. Nguetta<sup>3</sup>, Prof Matthew B. Thomas<sup>5</sup>, Raphael K. NGuessan<sup>6</sup>

<sup>1</sup>Institut Pierre Richet, Bouaké, Côte D'Ivoire, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>3</sup>Université Félix Houphouët-Boigny, Abidjan, Côte D'Ivoire, <sup>4</sup>Innovative Vector Control Consortium, Liverpool, United Kingdom, <sup>5</sup>The Pennsylvania State University, University Park, PA, Pennsylvania, PA, United States, <sup>6</sup>London School of Hygiene & Tropical Medicine, Bouaké, Côte D'Ivoire

There is evidence that the Kdr L1014F and G119S Ace-1<sup>R</sup> mutations involved in pyrethroids and carbamates resistance in *Anopheles gambiae* in sub Saharan Africa influence malaria transmission. Such influence is likely due to changes in behavior, life history, vectorial competence and vectorial capacity. In the present study, we investigated the distribution of insecticide target site mutations and their association with the infection status in wild *Anopheles gambiae* s.l populations. Mosquitoes

were captured indoor and outdoor in 40 villages around Bouaké by human landing catches (HLC), from May 2017 to April 2019. Sample of 1,392 mosquitoes collected (686 infected with *Plasmodium* sp. And 706 uninfected randomly selected) were identified to species and then genotyped for the L1014F Kdr and G119S Ace-1<sup>R</sup> mutations using quantitative polymerase chain reaction (qPCR) assays. The frequencies of the two alleles were compared between *An. coluzzii* and *An. gambiae* and then between infected and uninfected groups for each species. The presence of *An. gambiae* (49 %) and *An. coluzzii* (51 %) was confirmed in Bouaké. There was significant difference in the allelic and genotypic frequencies of Kdr L1014F and Ace-1<sup>R</sup> G119S mutations between *An.gambiae* and *An. coluzzii* ( $p < 0.05$ ). The probability of the Kdr L1014F resistance allele (R) to occur in *An. gambiae* was 56 times higher than in *An. coluzzii* population. The two mutations showed no significant association with *Plasmodium* infection status in wild population. Further studies should consider more complex interactions between resistance and other aspects of the mosquito biology to assess the impact of insecticide resistance markers on malaria transmission in wild population of *An. gambiae* s.l targeted by vector control interventions.

### "TRICK OR TREAT": DEVELOPMENT OF A FIELD-FRIENDLY IVERMECTIN BIO-EFFICACY ASSAY BY EXPLOITING SWITCHING MECHANISMS IN MOSQUITO FEEDING

Jonathan K. Karisa<sup>1</sup>, Kelly M. Ominde<sup>1</sup>, Yvonne Kamau<sup>1</sup>, Martha N. Muturi<sup>1</sup>, Caroline Kiuru<sup>2</sup>, Carlos Chaccour<sup>2</sup>, Marta Maia<sup>1</sup>

<sup>1</sup>Kenya Medical Research Institute-Wellcome Trust Research Programme, Kilifi, Kenya, <sup>2</sup>ISGlobal, Hospital Clinic - Universitat de Barcelona, Barcelona, Spain

Ivermectin is currently being considered as a novel malaria vector control tool due to its endectocidal properties. Several trials are ongoing to evaluate the efficacy of ivermectin mass drug administration (MDA) at reducing malaria transmission. Malaria transmission is expected to be disrupted through reduction in mosquito survival and fitness post feeding on ivermectin-treated hosts. Monitoring of ivermectin bio-efficacy is necessary to evaluate the effect of the intervention on local vector populations. Endectocides are taken up in blood meals, thus requiring wild-caught mosquitoes to either feed directly on a treated host's skin, raising ethical issues; or feed on blood through a membrane which is unfeasible due to low feeding rates. In this experiment, ivermectin bio-efficacy was compared when administered in glucose solution using soaked filter paper; spiked blood fed through a membrane; and in glucose solution laced with blood soaked in filter paper. Insectary-reared *Anopheles gambiae* (Kilifi strain) were exposed to five ivermectin concentrations in the different solution types: 85 ng/ml, 64 ng/ml, 43 ng/ml, 21 ng/ml, 11 ng/ml and control (0 ng/ml). Mosquito survival was monitored for 28 days and three replicates were carried out per treatment and solution type. Survival rates were presented using Kaplan-Meier curves and compared across groups using Log-rank tests. It was observed that when ivermectin was ingested in a sugar meal, survival rates were significantly different to when ingested in blood, suggesting that the digestion process plays a determinant role in ivermectin's bio-efficacy. By adding blood to the sugar solution mortality rates resembled those observed in spiked blood, suggesting that the presence of blood in the sugar solution may have "tricked" the mosquito to divert the meal to the midgut rather than the diverticula through a "switching mechanism". This study presents the development of a field-friendly assay to monitor ivermectin bio-efficacy and will inform programmes on how to best monitor the effect of ivermectin MDA on malaria vectors in the field.

## SEASONAL ABUNDANCE AND INSECTICIDE RESISTANCE STATUS OF Aedes MOSQUITOES IN GHANA

Christopher Mfum Owusu-Asenso<sup>1</sup>, Julius A. Mingle<sup>1</sup>, David Weetman<sup>2</sup>, Yaw A. Afrane<sup>1</sup>

<sup>1</sup>University of Ghana, Accra, Ghana, <sup>2</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Vector control is the main intervention for arboviral diseases transmitted by *Aedes* mosquitoes, because for most there are no effective vaccines or treatment. Vector control relies heavily on the use of insecticides, effectiveness of which may be impacted by resistance in the vector. This study investigated the spatio-temporal distribution and insecticide resistance status of *Ae. aegypti* in seven study sites (Ada Foah, Tema, Accra, Konongo, Larabanga, Navrongo and Paga) from across ecological extremes of Ghana. Indoor and outdoor adult sampling were done using BG traps, human landing catch, and prokopack aspirator during the dry and rainy seasons of 2017/2018. Distributions of immatures and adult *Aedes* mosquitoes were determined indoors and outdoors during dry and rainy seasons at all sites. Phenotypic resistance status of *Aedes* mosquitoes to insecticides was determined using WHO bioassays. A total of 16,711 *Aedes* immatures were sampled from car tires (73.9%), discarded containers (18.8%), air-condition saucers (4.4%), buckets (1.4%), tanks (1.3%) and drums (0.3%). There were more positive habitats during the rainy season 50 (61.73%) compared to the dry season 31 (38.27%) (df = 5;  $\chi^2 = 19.4435$ ;  $p = 0.001$ ). A total of 1,895 adult *Aedes* mosquitoes were collected consisting of *Ae. aegypti* (97.8%), *Ae. africanus* (2.1%) and *Ae. luteocephalus* (0.1%). Adult *Aedes* mosquitoes were more abundant during the rainy season 1,257 (66.3%) compared to the dry season 638 (33.7%) ( $z = -1.433$ ;  $p = 0.1519$ ). *Aedes aegypti* populations were resistant to DDT at all study sites (0-88%). Vectors showed suspected resistance to bendiocarb (96-97%), permethrin (90-96%) and deltamethrin (91-96%) and were susceptible to the organophosphate malathion at all study sites. About 90% of vectors had taken a blood meal from humans. *Aedes* mosquitoes were found at high densities in all ecological zones of Ghana. Resistance to pyrethroids and carbamates may limit the efficacy of current vector control tools and requires constant monitoring.

## MAKING THE CASE FOR METHOD VALIDATION IN VECTOR CONTROL

Natalie Lissenden, Rosemary Susan Lees, Angus Spiers

Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Next generation insecticide treated nets (ITN) are vital to malaria control. Multiple ITNs with differing product specifications are now PQ listed, and many are being evaluated in RCTs and pilot deployment schemes. However, the introduction of new AIs and product classes is exacerbating the methodological shortcomings that already exist in evaluation of vector control tools. Several products that are currently undergoing evaluation rely on entomological effects that differ from the pyrethroids' fast acting knockdown. There is little consensus on the methods used to monitor performance of these entomological effects, and although a lot of data is being generated, a lack of validated methodologies to provide comparable data could delay evaluation of these tools. Using durability monitoring methods for next generation nets as a worked example, we demonstrate a pipeline used to collate and interrogate current methods to produce a 'consensus SOP', and how data will be used to validate the method before it is made available for use. Overall, a renewed focus on developing, updating or validating testing methodologies is needed to efficiently evaluate novel tools, streamline access and monitor performance.

## ANALYSIS OF METABOLIC RESISTANCE AGAINST INSECTICIDES IN Culex QUINQUEFASCIATUS IN HOUSTON, TEXAS

Xinyue Huang<sup>1</sup>, Kendra Dagg<sup>2</sup>, Chris Fredregill<sup>2</sup>, Michel Slotman<sup>1</sup>

<sup>1</sup>TAMU, College Station, TX, United States, <sup>2</sup>Harris County Public Health, Houston, TX, United States

Resistance against insecticides is widely reported in mosquitoes around the world, including in the West Nile vector *Culex quinquefasciatus*. In Houston, Texas, this mosquito is subjected to extensive insecticide-based control by the Harris County Public Health Department. In order to assess to what extent *Culex quinquefasciatus* has developed metabolic resistance against insecticides we conducted a gene expression analyses of detoxification gene families between susceptible and resistant mosquitoes. *Culex quinquefasciatus* were sampled from Harris County in 2019. Mosquitoes were classified into 'malathion resistant' and 'malathion susceptible' groups based on a standard WHO bottle assay. RNAseq data was obtained for five pools of 10 mosquitoes for each group. In addition, RNAseq data was obtained for five pools of 10 field collected *C. quinquefasciatus* and susceptible Sebring colony samples. Differential gene expression in EdgeR found 1,339 differential expressed genes in comparison between insecticide resistant and susceptible groups, and 1,915 differential expressed genes in comparison between wild and susceptible groups in *Culex* mosquito. Within these, we identified 16 candidates from the three gene families (P450, GST and esterase) known to be associated with metabolic resistance. Several of these candidate genes were implicated in insecticide resistance previously. For others we will validate their role in metabolic resistance using RNAi. This work will assist in planning future vector control work.

## YEAST RNAI-BASED ATTRACTIVE TARGETED SUGAR BAITS FOR CONTROL OF ANOPHELES MOSQUITOES

Keshava Mysore, Longhua Sun, Limb K. Hapairai, Joseph B. Roethele, Ping Li, Molly Duman-Scheel

Indiana University School of Medicine, South Bend, IN, United States

The development of transformative, environmentally friendly, cost-effective new mosquito control tools is critical for preventing the spread of malaria parasites. Attractive targeted sugar baits (ATSBs), a new paradigm for vector mosquito control, exploit the sugar feeding behavior of female and male mosquitoes that are lured to feed on a sugar source containing an insecticide. The mosquito-specific interfering RNA pesticides (IRPs) identified by our investigative team are a novel class of insecticides that can overcome rising incidences in pesticide resistance, significantly enhance existing ATSB technology, and reduce outdoor residual transmission. Recent high-throughput screens in the Scheel laboratory identified hundreds of IRPs, a subset of which have 25 bp target sites that are conserved in many species of disease vector mosquitoes, but that are not found in humans or other non-target organisms. We are developing an ATSB target product with IRP(s) as the mosquitocidal agent. To this end, we have generated yeast strains which can be used for economical IRP production and are developing yeast formulations that can be delivered to mosquitoes in sugar baits. Laboratory trials confirmed the activity of five different yeast IRPs in sucrose-based ATSB trials conducted on *Anopheles gambiae* females. Target gene silencing and a mode of action was confirmed for each of the five IRPs in the adult *A. gambiae* brain. Although the yeast-based ATSBs were toxic to *A. gambiae*, the insecticides, which lack known target sites outside of mosquitoes, were not found to be toxic in assays conducted on select non-target arthropods. The results of these studies suggest that yeast IRP-ATSBs could one day be a beneficial addition to integrated mosquito control programs. Future studies will include evaluation of these broad-based mosquito adulticides in additional *Anopheles* species, outdoor semi-field trials, efforts to scale yeast production, and development of commercial formulations.

### FIGHT THE BITE: APPLYING REMOTE SENSING TECHNOLOGIES TO DETECT MOSQUITO BREEDING HABITATS OF IMPORTANCE

Sarah M. Gunter<sup>1</sup>, Abiodun Oluyomi<sup>1</sup>, Huixuan Li<sup>2</sup>, Chris Fredregill<sup>3</sup>, Jerry Helfand<sup>1</sup>, Melissa Nolan<sup>2</sup>

<sup>1</sup>Baylor college of Medicine, Houston, TX, United States, <sup>2</sup>University of South Carolina, Columbia, SC, United States, <sup>3</sup>Harris County Public Health, Houston, TX, United States

Mosquitoes are the world's most deadly animal. The arboviruses they transmit result in an estimated 300 million infections and 500,000 deaths annually. With few effective therapeutics or preventative vaccine available, public health officials rely on targeted mosquito abatement efforts to reduce the burden of disease. Effective insecticides have been developed to reduce the mosquito population and therefore reduce disease transmission. However, widespread insecticide application is inhibited by limited budgets for mosquito control and the fear of inducing insecticide resistance in the mosquito population. Targeted mosquito abatement efforts are critical to effectively reducing the burden of disease in affected areas. Our current collaborative project built a predictive geospatial model to detect mosquito breeding habitats in Harris County, Texas. Our models focused on *Culex sp.* mosquitoes, the known vectors for West Nile virus in the southern US. We have built a series of models using low (Landsat-8), medium (Sentinel-2), and high (WorldView-2/3) resolution imagery to conduct a comparative analysis. For each image type, we derived variables using remote sensing techniques in ArcGIS Pro 2.6. Our models were constructed using 8 different machine learning techniques and the optimal technique was determined based on overall accuracy and major error analysis. Finally, we conducted a comparative analysis to determine the optimal imagery type and model building technique for implementation for vector control. We hope this innovative approach to mosquito control will be employed to develop targeted abatement efforts that will reduce the burden of mosquito-borne disease not only in the US but globally.

### ANOPHELES PRODUCTIVITY OF AQUATIC HABITATS CREATED THROUGH ARTISANAL CAPTURE FISHING ON MAGETA ISLAND IN WESTERN KENYA

Millicent Sifuna

The University of Nairobi, Nairobi, Kenya

The effect of physicochemical characteristics of mosquito larval habitats on *Anopheles* productivity is not well known. To fill this knowledge gap, a cross-sectional survey was carried out on Mageta Island, western Kenya. Habitats were classified either as those created by or associated with artisanal capture fishing (ACF) activities on the Island or non-ACF. Physicochemical parameters and *Anopheles* mosquito larval density were recorded for each habitat type. The degree of association between *Anopheles* larvae/pupae and the physicochemical factors was tested using generalized linear models. High numbers of *Anopheles* pupae and larvae were found in habitats associated with ACF activities. Habitats with wooden bottom surfaces had more larvae than mud and rock bottom surfaces. Perimeter, TSS, temperature, and conductivity influenced larval abundance significantly. Other factors interacted resulting in significant associations with *Anopheles* larval abundance. These were TDS with conductivity, TSS with DO, and TSS with temperature. Even though individual physicochemical characteristics could be linked to the density of *Anopheles* larvae and productivity of mosquito habitats, the results indicate that certain variables interact to regulate mosquito abundance. Malaria control measures tailored towards manipulating physicochemical characteristics in mosquito breeding sites should be adopted in integrated mosquito control programmes.

### UPWARDLY MOBILE: MICROCLIMATE AND THE VERTICAL STRATIFICATION OF POTENTIAL VECTORS OF MOSQUITO-BORNE VIRUSES IN A CENTRAL AMAZONIAN FOREST BORDERING MANAUS, BRAZIL

Adam Hendy<sup>1</sup>, Danielle Valério<sup>2</sup>, Nelson Ferreira Fé<sup>2</sup>, Eduardo Hernandez-Acosta<sup>3</sup>, Claudia Mendonça<sup>2</sup>, Eloane Andrade<sup>2</sup>, Igor Pedrosa<sup>4</sup>, Edson Rodrigues Costa<sup>4</sup>, Bárbara Aparecida Chaves<sup>2</sup>, Vera Margarete Scarpassa<sup>5</sup>, Marcelo Gordo<sup>4</sup>, Michaela Buenemann<sup>3</sup>, Marcus Vinícius Guimarães de Lacerda<sup>2</sup>, Kathryn A. Hanley<sup>3</sup>, Nikos Vasilakis<sup>1</sup>

<sup>1</sup>University of Texas Medical Branch, Galveston, TX, United States, <sup>2</sup>Fundação de Medicina Tropical Doutor Heitor Vieira Dourado, Manaus, Brazil, <sup>3</sup>New Mexico State University, Las Cruces, NM, United States, <sup>4</sup>Universidade Federal do Amazonas, Manaus, Brazil, <sup>5</sup>Instituto Nacional de Pesquisas da Amazônia, Manaus, Brazil

The emergence and resurgence of Zika, chikungunya, and dengue viruses in Latin America brings with it the threat of arbovirus spillback into neotropical forests. To discern which mosquito species may bridge urban and sylvatic transmission cycles, we investigated the vertical stratification of mosquitoes and their relationships with microclimate in a rainforest reserve bordering Manaus, Brazil. We collected mosquitoes at heights of 0, 5, and 9 m using handheld nets in a tower constructed at the edge of a treefall gap and compared our findings with BG-Sentinel trap collections previously made in the same area. Mosquito taxa sampled with each method were broadly similar and included *Psorophora*, *Haemagogus*, and *Sabethes* species. Net collections were dominated by *Haemagogus janthinomys* and *Psorophora amazonica*, which were detected more frequently when 7-day cumulative rainfall was higher at one week prior to collection, and at one and four weeks prior to collection for respective species, supporting our earlier findings. *Hg. janthinomys* was significantly more abundant above ground (Kruskal-Wallis test,  $P = 0.007$ ), whereas *Ps. amazonica* showed no significant vertical stratification. The mean temperature when *Hg. janthinomys* was collected in nets was 29.9°C at each height, which was greater than the mean daily temperature at ground level (29.0°C). Nominal logistic regressions revealed that the occurrence of this species increased with increasing temperature at 0 m ( $DF = 1$ ,  $\chi^2 = 13.9$ ,  $P = 0.0002$ ) and 5 m ( $DF = 1$ ,  $\chi^2 = 17.0$ ,  $P < 0.0001$ ), but not at 9 m ( $DF = 1$ ,  $\chi^2 = 2.0$ ,  $P = 0.157$ ). Our results show that *Hg. janthinomys* prefers warm temperatures, such as those associated with forest clearings, while the high relative abundance of both *Hg. janthinomys* and *Ps. amazonica* at each height sampled suggests that both are potential bridge vectors in this setting.

0559

### A DIVERSE GROUP OF ANOPHELINES FORAGE INDOORS AND OUTDOORS BEFORE 22:00 IN A HOLOENDEMIC SETTING IN NCHELENGE DISTRICT, ZAMBIA

Mary E. Gebhardt<sup>1</sup>, David Mbewe<sup>2</sup>, Francis Kapasa Mulenga<sup>2</sup>, James Sichivula Lupiya<sup>3</sup>, Rachel S. Krizek<sup>1</sup>, Jack T. Dorman<sup>4</sup>, Mbanga Muleba<sup>2</sup>, Mike Chaponda<sup>2</sup>, William J. Moss<sup>1</sup>, Jennifer C. Stevenson<sup>5</sup>, Giovanna Carpi<sup>4</sup>, Douglas E. Norris<sup>1</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Tropical Diseases Research Centre, Ndola, Zambia, <sup>3</sup>Tropical Disease Research Centre, Ndola, Zambia, <sup>4</sup>Purdue University, West Lafayette, IN, United States, <sup>5</sup>Macha Research Trust, Choma, Zambia

In Nchelenge District, Zambia, malaria is transmitted year-round, with 50-80% of individuals parasitemic at any given time despite a decade of intensive annual indoor residual spraying (IRS) and insecticide-treated bed net (ITN) distributions. The limited effectiveness of these primarily indoor vector-targeted interventions has cast doubt on our understanding of the foraging behaviors of the major vector, *Anopheles funestus*, and led to a concerning hypothesis that this vector may be feeding outdoors and before people go to sleep. We performed mosquito collections over eight weeks in 2019 in Nchelenge District during the *An. funestus* s.s.

population peak in the dry season, by setting CDC light traps indoors, outdoors where people gather, and near animal pens from 16:00-22:00. We also assessed human risk by performing surveys to collect information about evening behaviors, and household and environmental data to identify other covariates associated with high numbers of early-evening foraging mosquitoes. Human surveys revealed that before 22:00, 78% of people were not asleep, leaving them unprotected by their bed nets. At least nine species of *Anopheles* were identified foraging outdoors and indoors during this time, including a large proportion of *An. gambiae* - a species not previously described in this region of Zambia. 1% of samples were positive for *P. falciparum* sporozoites by CSP ELISA, and were composed of *An. gambiae* s.s. and *An. funestus* s.l. Positive specimens were captured indoors, in outdoor gathering spaces, and animal pens, indicating that infection risk may not be limited to indoor exposure. These data underscore the necessity for further evaluation of outdoor vector surveillance and control tools that are effective outside net use and independent of IRS.

### COMPARISON OF AEDES AEGYPTI AND ANOPHELES DIRUS FEEDING SUCCESS AND PREFERENCE USING AN IN VITRO BLOOD-FEEDING SYSTEM

Siriporn Phasomkusolsil

Armed Forces Research Institute of Medical Sciences (AFRIMS), Bangkok, Thailand

Blood-feeding of female mosquitoes is a basic part of laboratory colonization since blood it is required for female egg production. Artificial membrane feeding is the standard for mass rearing of colony mosquitoes. In this study, *Aedes aegypti* and *Anopheles dirus* were allowed access to human blood via three natural membranes (pig intestine, cow intestine, and fresh frog skin) and two synthetic membranes (Parafilm M and latex condom). This study was designed under two different test conditions, namely no-choice and choice tests to determine 1) feeding success and 2) membrane preference. In the no-choice test, pig intestine proved to be the most effective membrane (92.4%) for blood-feeding *Ae. aegypti*, while, *An. dirus* displayed no significant differences in the feeding rate between pig intestine (80.0%) and cow intestine (72.4%). In the preference experiment by choice test, feeding rates of both *Ae. aegypti* and *An. dirus* females that fed on pig intestine and cow intestine were greater than the other pair membranes. In conclusion, the rates of feeding were higher when using natural membranes of pig intestine, cow intestine and fresh frog skin perhaps due to mosquito preference. These data thus demonstrate the efficiency of the artificial feeder, especially if combined with natural membranes and human blood.

### SEASONALITY AND ABUNDANCE OF ANOPHELES STEPHENSI IN DJIBOUTI

Alia Zayed<sup>1</sup>, Reham Tageldin<sup>1</sup>, James f. Harwood<sup>2</sup>

<sup>1</sup>US Naval Medical Research Unit 3, Cairo, Egypt, <sup>2</sup>US Naval Medical Research Unit 3, Sigonella, Italy

The presence of the invasive malaria vector, *Anopheles stephensi*, in Djibouti has been a significant concern to health authorities over the past 5 years. Urban malaria cases are expected to increase in the overall human population due to the introduction of this vector. The increased malaria risk also threatens the health of military personnel at the Camp Lemonnier, Djibouti. Vector control measures have been initiated on the installation, with control efforts mandating regular monitoring of vector populations to identify areas on the installation with the highest vector densities. Mosquito were collected weekly using CDC Light and Mosquito Magnet® traps from October 2019 to July 2020 across 32 sites on the installation. Mosquito collection data were analyzed and correlated with metrological records monitored at the geographic position of latitude 11.54733 and longitude 43.15948. In 2019 and 2020 mean temperature ranged between 24-38 degree centigrade and precipitation rates were between

0 to 155 mm<sup>2</sup>. Temperature and rain fall records have been separated into categories based on the weekly temperatures and precipitation rates. Analysis of trap collection rates found Mosquito Magnet® Traps were significantly more effective (P=0.02) in collecting *An. stephensi* than CDC traps (5.0 ±5.8; 3.4 ±3.5). The vector numbers were negatively correlated (R=-0.5; P=0.004) with temperature ranges (24-38°C), whereas the rainfall did not affect the numbers of *An. stephensi*. Conversely, the populations of other mosquito species increased significantly in the weeks after heavy rains. The insignificant role of rain fall on *An. stephensi* populations is likely due to its presence in human dwellings and modified environments, which may provide the vector an independent niche to breed in and adapt to the conditions in Djibouti. The presented updates on *An. stephensi* data at Camp Lemonnier is of profound interest to the Djiboutian health authorities due its proximity to Djibouti airport and to Camp Lemonnier in informing their vector control operations. Continuing efforts are ongoing to expand the surveillance to cover Djibouti City and other districts.

### MATING COMPETITIVENESS IS REDUCED IN ANOPHELES GAMBIAE MALES MARKED WITH RHODAMINE B IN LABORATORY TRIALS

Ilse A. Ortega Eguia<sup>1</sup>, Katelyn Cavender<sup>1</sup>, Keri Oxendine Harp<sup>1</sup>, Priscila Bascunan<sup>1</sup>, Mark Q. Benedict<sup>1</sup>, Ellen M. Dotson<sup>2</sup>

<sup>1</sup>CDC Foundation, Atlanta, GA, United States, <sup>2</sup>Centers for disease control and prevention (CDC), Atlanta, GA, United States

Mosquito marking can be a valuable tool to study physiological and behavioral traits in field and laboratory settings. One of the most common techniques for marking mosquitoes is fluorescent dust; however, it can increase mortality, decrease mobility, and affect sensory organs. Rhodamine B, a thiol-reactive fluorescent dye, has been shown to successfully mark mosquito sperm, among other tissues, with a red-violet and fluorescent stain after providing males with a sugar meal containing rhodamine B. Rhodamine B has been used to study mating by dissecting and observing the presence/absence of fluorescence in spermathecae of females exposed to rhodamine-marked males. However, the effect of the dye on the capacity of males to compete for mates remains uncertain. We tested whether rhodamine B impacted the mating competitiveness of *Anopheles gambiae* (G3) males when exposed to virgin females for three nights. Rhodamine B's effect was assessed according to cage size (24cm<sup>3</sup> versus 50cm<sup>3</sup>) and ratios of unmarked males: rhodamine-marked males: females of 50:50:50 versus 50:50:100, respectively. Approximately 35% of mated females mated with rhodamine-marked males whereas approximately 65% mated with unmarked males. These percentages were consistent regardless of cage size or male: female ratio, suggesting that rhodamine-marked males are less competitive than unmarked males. Interestingly, we did not find higher mortality of rhodamine-marked males compared to unmarked males during the mating period. Further studies addressing other variables, such as the effect of rhodamine B concentration on male mating competitiveness, are underway and will be reported.

### AN ECOLOGICAL NICHE MODEL TO PREDICT THE GEOGRAPHIC DISTRIBUTION OF THE YELLOW FEVER AND MAYARO VIRUS VECTOR, HAEMAGOGUS JANATHINOMYS, IN SOUTH AMERICA

Michael Celone<sup>1</sup>, David Pecor<sup>2</sup>, Alexander Potter<sup>2</sup>, Alec Richardson<sup>2</sup>, James Dunford<sup>1</sup>, Simon Pollett<sup>1</sup>

<sup>1</sup>Uniformed Services University of the Health Sciences, Bethesda, MD, United States, <sup>2</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States

Yellow fever virus (YFV) has a long history of impacting human health in Latin America. Mayaro virus (MAYV) is an emerging arbovirus and its full impact to the region is yet unknown. Both YFV and MAYV are maintained via a sylvatic transmission cycle and both can be transmitted to humans

opportunistically, by forest dwelling *Haemagogus janthinomys* mosquitoes. To understand the potential risk of YFV more fully and MAYV transmissions to human populations, a more detailed estimation of this vector species' distribution is needed. This study compiled a comprehensive database of *Hg. janthinomys* collection records from published literature, museum specimens and publicly accessible mosquito surveillance data. A covariate analysis was performed to optimize a selection of climatic variables associated with predicting habitat suitability. Using a maximum entropy approach, collection data was used to model this species distribution across South America. Our results indicate that suitable habitat for this species can be found across all countries in the region and that more surveillance is needed to better define where this species is most likely to encounter humans.

### EFFECTS OF LARVAL EXPOSURE TO SUBLETHAL DOSES OF IVERMECTIN ON ADULT FITNESS AND SUSCEPTIBILITY TO IVERMECTIN IN ANOPHELES GAMBIAE

Caroline Kiuru<sup>1</sup>, Kelly Ominde<sup>2</sup>, Martha Muturi<sup>2</sup>, Carlos Chaccour<sup>1</sup>, Marta Maia<sup>2</sup>

<sup>1</sup>Barcelona Institute for Global Health (ISGlobal), Barcelona, Spain, <sup>2</sup>KEMRI Wellcome Trust Research Programme, Kilifi, Kenya

Since its discovery in 1987, ivermectin has been widely used as a parasiticide both in veterinary and human medicine. The last 30 years have seen a scale up in ivermectin coverage through mass drug administration (MDA) for the control of onchocerciasis and lymphatic filariasis. In addition, the effects of ivermectin on adult mosquito survival have prompted it to be considered as a potential malaria control tool. The current considerations for malaria control are based on ivermectin's ability to reduce adult mosquito survival and in turn alter malaria transmission. However, the effects of ivermectin to the malaria vector larval stages are not properly understood. The increased use of ivermectin could cause increased exposure of larval habitats to ivermectin either directly through livestock excreta or indirectly through leaching or run-off from contaminated soil. Therefore, it is important to understand how exposure to ivermectin during the aquatic larval stages affects both the larvae and the emerging adults. Herein we evaluated the effects of exposure to sublethal doses of ivermectin during the larval stages of *Anopheles gambiae* on larval survival and development. We subsequently assessed the fitness of the emerging adults by evaluating their survival and fecundity. To identify the sublethal doses, we first subjected larvae to five concentrations of ivermectin; 100ng/ml, 10ng/ml, 1ng/ml, 0.1ng/ml and 0.01ng/ml and monitored larvae survival. The concentrations producing about 20% mortality (LC20) were 0.1ng/ml and 0.01ng/ml were selected as the sublethal doses. Larvae were exposed to these sublethal doses at either the first instar stage or third instar stage. Larval development was assessed as well as oviposition rate, number of eggs laid and egg hatch rate for the emerging female adults. Additionally, the susceptibility of the emerging adults to ivermectin was evaluated by blood feeding females on ivermectin spiked blood.

<sup>1</sup>Ministry of Health Zanzibar, Zanzibar, United Republic of Tanzania, <sup>2</sup>USAID-Okoa Maisha Dhibiti Malaria Project, RTI International, Dar es Salaam, Tanzania; <sup>3</sup>US President's Malaria Initiative, USAID, Dar es Salaam, United Republic of Tanzania, <sup>4</sup>US President's Malaria Initiative, USAID, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>4Centers for Disease Control and

Prevention and President's Malaria Initiative, CDC, Atlanta, GA, United States, <sup>6</sup>4Centers for Disease Control and Prevention and President's Malaria Initiative, CDC, Atlanta, GA, United States, <sup>7</sup>USAID-Okoa Maisha Dhibiti Malaria Project, RTI International, Dar es Salaam, United Republic of Tanzania, <sup>8</sup>RTI International, Washington, DC, WA, United States

Understanding mosquito behavior is key in implementing an effective malaria vector control intervention. The present work highlights the important malaria vectors species present in Zanzibar, their host-seeking behavior, and their role in malaria transmission. Monthly adult *Anopheles* sampling was conducted from October 2018 to September 2019 using human landing catch (HLC), CDC light-trap, pyrethrum spray catch (PSC), and pit trap collection methods. Collected female mosquitoes were identified based on morphology and categorized according to their physiological status. Members of *Anopheles gambiae* s.l. and *An. funestus* were separated using PCR-based methods. *Plasmodium falciparum* sporozoites were detected by enzyme-linked immunosorbent assay (ELISA). Overall, 2754 female *Anopheles* mosquitoes were collected. Of these, 65.5% were collected using HLC. Morphological identification showed catches comprised *Anopheles gambiae* s.l. (86.7%), *Anopheles funestus* (12.2%), and the remaining 1.1% were *An. maculipalpis*, *An. coustani*, *An. nili*, and *An. ziemanni*. *Anopheles gambiae* s.l. were trapped more abundantly outdoors (69.2%) than indoors using HLC. *Anopheles gambiae* s.l. demonstrated high outdoor biting activity which peaked during the night between 2200-2300 hours whilst the indoor biting activity remained at low levels throughout the night. The majority of the *An. gambiae* s.l. were *An. arabiensis* (96.4%) followed by *An. merus* (2.9%), *An. gambiae* s.s. (0.7%) and *An. quadriannulatus* (0.1%). The *An. funestus* group comprised *An. leesonii* (68.5%), *An. funestus* s.s. (2.8%), *An. parensis* (1.2%) and *An. rivolorum* (27.5%). The *P. falciparum* sporozoite rate was 0% (n=2712). We observed increased exophilic and exophagic behavior of the local malaria vectors in Zanzibar. Before the introduction of insecticide treated nets (ITNs) and indoor residual spraying (IRS) in 2006, malaria vectors were highly endophilic and endophagic. This change might be attributed to the high coverage of ITNs and IRS. Using supplementary outdoor vector control interventions with ITNs and IRS might reduce the exophilic and exophagic mosquitoes in Zanzibar.

0566

### BLOOD-MEAL SOURCES OF MALARIA VECTORS FOUND IN ENDEMIC AREAS OF ZIMBABWE

Charmaine C. Matimba

Africa University, Mutare, Zimbabwe

Understanding vector behaviour is critical to informing effective vector control decisions. Zimbabwe has a comprehensive vector control programme spanning seven decades, based on mainstay indoor residual spraying (IRS) and, more recently long lasting insecticidal nets (LLINs). Long term exposure to IRS insecticides and LLINs can lead to shifts in the biting or resting behaviour of mosquitoes. The present study examined the blood meal preferences of mosquitoes in endemic areas of Zimbabwe where vector control methods are implemented. A total of 428 mosquitoes were collected in 2019 and 2020 in Vumba (no vector control), Dendera, Arcturus, Burma Valley where IRS is done, and Makarara where LLINs are used. Mosquito collection methods used were CDC light traps, pit shelter and PSC. The samples were identified morphologically followed by PCR confirmation prior to blood meal PCR assay. 32% of the anophelines were collected indoors and 67% collected outdoors. *An. funestus* s.s. constituted 57% of the samples collected indoors with a human blood index (HBI) of 36% observed on Vumba mosquitoes. The most common species found outdoors were *An. pretoriensis* (27%) and *An. parensis* (20%) and the primary vectors were found in low proportions. 37% of the anophelines captured outdoors mostly fed on cow blood while those indoors had fed on humans. It was also observed that other anophelines found outdoors, especially *An. parensis*, fed on multiple hosts, exhibiting combinations of human and animal/s blood meals (25%). Multiple feeding was not observed in *Anopheles* species found indoors. *An. funestus* s.s. predominantly biting humans may reflect the effects of having no vector

control in Vumba, indicating that there is need for vector control in that area. The abundance in the cow blood meal for exophilic anophelines might be influenced by availability of cattle in Zimbabwe. Vector control in potential malaria vector species like *An. parensis* feeding on multiple hosts may prove to be a challenge in the control of malaria vectors. More studies are recommended to ascertain timing and feeding behaviour patterns that can be exploited to guide malaria control interventions.

### MALARIA VECTOR ECOLOGY ON THE LIHIR GROUP OF ISLANDS, PAPUA NEW GUINEA, WITH A FOCUS ON THE IMPACT OF A LARGE-SCALE MINING OPERATION

Michelle Katusele<sup>1</sup>, Elias Omera<sup>1</sup>, Peter Kaman<sup>1</sup>, Absalom Dau<sup>1</sup>, Esther Jamea<sup>1</sup>, Muker Sakur<sup>1</sup>, Lemen Kilepak<sup>1</sup>, Siub Yabu<sup>1</sup>, Barbara Baro<sup>2</sup>, Pere Millat<sup>2</sup>, Russel Supit<sup>3</sup>, William Pomat<sup>4</sup>, Quique Bassat<sup>2</sup>, Quique Bassat<sup>5</sup>, Quique Bassat<sup>6</sup>, Quique Bassat<sup>7</sup>, Stephan Karl<sup>8</sup>

<sup>1</sup>Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, <sup>2</sup>ISGlobal, Hospital Clinic - Universitat de Barcelona, Barcelona, Spain, <sup>3</sup>Lihir Malaria Elimination Programme, Londolovit, Papua New Guinea, <sup>4</sup>Papua New Guinea Institute of Medical Research, Goroka, Papua New Guinea, <sup>5</sup>Centro de Investigação em Saúde de Manhiça, Barcelona, Spain, <sup>6</sup>ICREA, Barcelona, Spain, <sup>7</sup>Hospital Sant Joan de Déu, Universitat de Barcelona, Esplugues, Barcelona, Spain, <sup>8</sup>Australian Institute of Tropical Health and Medicine, James Cook University, Cairns, Australia

There is ongoing efforts control and eliminate malaria in the Lihirian communities of Papua New Guinea, a country that accounts for 79% of the malaria cases in the Western Pacific region. Aniolum, the main island of the Lihir group of islands, New Ireland Province, hosts one of the largest global gold mining operations with clear demarcation of development and different vector control interventions between mine impacted and non-impacted communities. This study provides insights into the vector ecology and transmission dynamics in Lihir to guide future elimination strategies. A comprehensive larval and adult mosquito survey including standard insecticide resistance tests was conducted in 2019. All mosquito samples were identified to morphospecies level using standard identification keys. Species typing and *Plasmodium* infection will be done by PCR-RFLP and quantitative PCR. In Aniolum, *An. farauti* was the predominant vector in the mine impacted area, while *An. punctulatus* was the main species outside it, with the exception of one outer island that was also colonized by *An. farauti*. Both species showed exophagic behavior with peak biting periods from 9-10PM at a biting rate of 0.24bites per person/hour (p/h) by *An. farauti* within impact areas and 6-7PM outside of it (2.5bites p/h). *An. punctulatus* was biting mostly at 0.45bites p/h around 9-10PM. Both species were fully susceptible to deltamethrin and bendiocarb (100% mortality) but showed low grade DDT resistance in vector populations outside the impact area (95% mortality). *An. farauti* and *An. punctulatus* are the main vector species found in Lihir Islands with different biting profiles and distribution. Vector control could be improved by using alternative outdoor interventions and by expanding larval source management strategies across communities outside the mine impacted area. Future experiments to quantify risks of malaria transmission between mine impacted and on-impacted areas will provide further insights to individualize malaria control strategies to accelerate malaria elimination.

### SUSTAINING EFFICIENT MALARIA VECTOR CONTROL WHILE ACCOUNTING FOR BREEDING SITE STAGES: A PREDICTIVE MODELLING APPROACH

Toheeb Babatunde Ibrahim<sup>1</sup>, Martin Eichner<sup>2</sup>, Kristan A. Schneider<sup>1</sup>

<sup>1</sup>Hochschule Mittweida University of Applied Sciences, Mittweida, Germany, <sup>2</sup>University of Tuebingen, Tuebingen, Germany

Malaria is one of the three biggest infectious diseases amidst tuberculosis and HIV/AIDS terrorising the world and has been a global concern for

decades. In an effort to reducing malaria incidence, the malaria vector is one of the cornerstones its contribution needs to be controlled. Targeting entomological features distinguishing malaria vector species is crucial in vector control interventions and a key component in malaria control that need to be considered appropriately. In fact, breeding habits and choice of breeding sites vary among mosquito species, hence understanding the breeding habits of targeted species can facilitate cost-efficient and optimal vector control measures. Additionally, unlike *Aedes* mosquitoes, *Anopheles* (An.) are less tolerant to desiccation and drought. Mosquitoes breed in water puddles formed when rain falls. Over time, predating organisms such as fish or tadpoles cohabit the breeding site with the mosquito juvenile stage and contribute to the depletion of nutrients and the mortality of mosquitoes in the larval stage. Typically, these critical breeding habits are overlooked or not adequately addressed in predictive models. Here, we introduce an extended SEIR model that incorporates the dynamics in the breeding site of the An. mosquito accounting for (i) larvae competition resulting in a reduction in the number of emerging late-stage larvae, (ii) effect of larvivorous fish as a predator on the late-stage larvae, (iii) effect of insecticide-treated bednets as an adult-stage control intervention, and (iv) the implication of introducing genetically modified mosquitoes to the wild. In our model, it is supposed that gravid mosquitoes find a suitable breeding site to oviposit. We derive the basic reproduction number in the mosquito population and study the effect of different mosquito control interventions. The model was exemplified by parameters from the literature.

0569

### HABITAT MICROBIOTA SHAPES HETEROGENEITY IN MOSQUITO POP DYNAMICS IN THE FIELD

Serena Y. Zhao<sup>1</sup>, John Hausbeck<sup>2</sup>, Kerri Coon<sup>1</sup>

<sup>1</sup>University of Wisconsin-Madison, Madison, WI, United States, <sup>2</sup>Public Health Madison and Dane County, Madison, WI, United States

Mosquito population dynamics play a fundamental role in the chain of vector-borne disease transmission, and these dynamics are rooted in conditions during the aquatic larval stage. Larval development is shaped by gut microbiota recruited from the environment, and many surveys of environmental microbiota associated with mosquitoes are available. However, to understand the implications of patterns of microbial diversity for vector-borne disease, it is necessary to connect patterns of microbial diversity to mosquito population dynamics. Here, we combine 16S-rRNA gene amplicon sequencing-based characterization of bacterial communities from mosquito larval habitats with monitoring of larval productivity through time, analyzing local variation in the Madison, WI, USA area. Our results highlight a dominant role for the community composition of habitat microbiota in shaping larval productivity in the field. These findings underscore the importance of future work to identify the mechanisms of microbiota action on mosquito populations and physiology under natural conditions.

0570

### SPATIOTEMPORAL DYNAMICS OF CULEX SPECIES ON AN URBAN TO RURAL GRADIENT IN GREATER WASHINGTON DC

Arielle Arsenault-Benoit, Megan Fritz

University of Maryland, College Park, MD, United States

In the mid-Atlantic region of North America, a community assemblage of *Culex* species, including *Cx. pipiens*, *Cx. restuans*, and *Cx. quinquefasciatus* transmits West Nile Virus among vertebrate hosts. In this study, we described the influence of both seasonality and environment on the *Culex* community in the greater Washington DC region along an urban to rural gradient. Because mosquitoes with diverse life-history traits and feeding patterns can sustain, amplify, and transmit the virus between hosts and vectors across the landscape, species distributions in a heterogeneous environment can have a strong impact on disease transmission. In 2019, we collected over 6,000 mosquitoes using gravid traps at 5 urban, 5 suburban, and 5 rural site classes in Washington DC

and Maryland across eight occasions per site. A subset of cryptic *Culex* mosquitoes were identified to species using molecular methods (N=788). Species distributions differed by site class (Pearson's  $\chi^2=126.44$ ,  $df=4$ ,  $p<0.001$ ) and season (Pearson's  $\chi^2=51.901$ ,  $df=4$ ,  $p<0.001$ ), according to a contingency table analysis. *Culex quinquefasciatus* associated with urban environments, whereas *Cx. restuans* associated with rural environments, most strongly in the early season. Furthermore, both season and site class predicted differences in the relative frequency of *Cx. pipiens* according to analysis by generalized linear model. There was considerable by-site variation within each of our urban, suburban, and rural site classes, which motivated us to use redundancy analysis (RDA) to explore the environmental factors that contribute to this variation. Normalized difference vegetation index (NDVI), distance to city center, and site class explained 58% of the variance in species distribution ( $p=0.021$ ). As observed in our contingency analysis, our RDA indicated that *Cx. quinquefasciatus* was associated with urban environments. *Cx. restuans* was associated with increasing NDVI and increasing distance to city center. *Cx. pipiens* did not have strong relationships to any of these variables. This may be due to the consistently high relative frequency of *Cx. pipiens* spatially and phenologically.

0571

### INNOVATIVE METHODS AND SOFTWARE FOR THE ANALYSIS OF MOLECULAR XENOMONITORING SURVEYS AND OTHER POOL-TESTED DATA

Angus McLure<sup>1</sup>, Ben O'Neill<sup>1</sup>, Helen Mayfield<sup>2</sup>, Colleen Lau<sup>2</sup>, Brady McPherson<sup>3</sup>

<sup>1</sup>Australian National University, Canberra, Australia, <sup>2</sup>University of Queensland, Brisbane, Australia, <sup>3</sup>Australian Defence Force Malaria and Infectious Disease Institute, Brisbane, Australia

Pooled specimen testing has a long history of use in public health surveillance and screening where prevalence of the condition is low and the cost of the diagnostic tests are prohibitive, e.g., pooled stool samples for soil-transmitted helminths, and recently in COVID-19 testing. Pooled-testing is often part of molecular xenomonitoring (MX) surveys, where surveillance of vector-borne diseases is conducted by capturing, pooling, and testing large numbers of vectors. MX can be used to map disease prevalence, evaluate the efficacy of interventions, and identify locations with residual transmission in the endgame of elimination campaigns. MX surveys often include hierarchical sampling designs, with vector traps placed at locations around the study area of interest. We have developed an R package, PoolTestR, to meet the needs of large and complex MX surveys and other data involving pooled testing. PoolTestR includes user-friendly and flexible tools to estimate prevalence and fit a range of regression models for pooled data in frequentist and Bayesian frameworks, including fixed- and mixed-effect models and Gaussian process models. Mixed-effect models can be used to account for the hierarchical sampling designs in surveys. The regression modelling capabilities allow for the identification of trends and variables associated with high or low infection prevalence (using odds ratios), while extensions for Gaussian process modelling enable Bayesian geostatistical modelling. This presentation will illustrate the key features of the PoolTestR package and its benefits compared to existing software and methods, including application to real and simulated data from MX surveys. We show that failing to adjust for the hierarchical nature of MX surveys leads to overly confident estimates of infection prevalence with confidence intervals that often may not include the true value. We show that using a regression framework for estimating infection prevalence for different vector species and primary sampling units can improve the precision of prevalence estimates even when sample sizes are small.

### COMPLEMENT-FIXING ANTIBODIES ARE PRODUCED IN RESPONSE TO A TETRAVALENT DENGUE VACCINE

Eduardo J. M. Nascimento, Brooke Norwood, Eloi Kpamegan, Allan Parker, Isamu Tsuji, David Dominguez, Hansi J. Dean  
Takeda Vaccines, Brookline, MA, United States

The complement system is an arm of innate immunity that functions as an effector mechanism of the humoral response. Mechanisms of viral neutralization mediated by antibodies are highly dependent upon complement activation, which involves aggregation, opsonization, lysis and phagocytosis. The classical pathway of the complement system has been demonstrated to contribute to protection against flaviviruses through virus opsonization, B-cell activation, antibody production and inhibition of antibody-dependent enhancement of infection. Takeda's attenuated tetraivalent dengue vaccine candidate TAK-003 demonstrated 80% efficacy against virologically-confirmed dengue due to any serotype in an ongoing phase 3 study (ClinicalTrials.gov NCT02747927). TAK-003 elicits neutralizing antibodies against all four dengue viruses (DENV). We investigated the ability of antibodies produced in response to TAK-003 to bind complement as an indicator for activation of the complement system. Samples were collected from baseline seronegative and seropositive study participants from two phase 2 clinical trials (DEN-203, NCT01511250 and DEN-204, NCT02302066), before and after vaccination with two doses of TAK-003 at months 0 and 3. The sera were evaluated for the presence of complement-fixing antibodies against all four DENV serotypes using a Luminex multiplex platform-based assay. In both trials, TAK-003 elicited complement-fixing antibodies against all four DENV serotypes which persisted for up to one year post-vaccination, irrespective of baseline serostatus. In general complement-fixing antibody levels were correlated with neutralizing antibody titers, as well as virus-specific IgG concentrations and avidity. Taken together, these results indicate that antibodies produced after vaccination can fix complement system components of the classical pathway and may contribute to protection mediated by TAK-003.

0573

### VALIDATION OF A MICRONEUTRALIZATION TEST TO QUANTIFY DENGUE VIRUS NEUTRALIZING ANTIBODIES AFTER VACCINATION WITH THE TAK-003 TETRAVALENT DENGUE VACCINE CANDIDATE

Tim Powell<sup>1</sup>, Jasdeep Nanra<sup>2</sup>, Kelley Moss<sup>1</sup>, Tina Green<sup>3</sup>, Brent Seaton<sup>4</sup>, Hansi Dean<sup>1</sup>, Eric Shaw<sup>1</sup>

<sup>1</sup>Takeda Vaccines, Cambridge, MA, United States, <sup>2</sup>Affinivax, Cambridge, MA, United States, <sup>3</sup>PPD, Wayne, PA, United States, <sup>4</sup>Q2 Solutions, San Juan Capistrano, CA, United States

Reliable assays to measure functional antibody responses to the four dengue virus serotypes (DENV-1–4) are essential for dengue research and vaccine development. The gold standard plaque-reduction neutralization test (PRNT) is the method most commonly used to measure neutralizing antibody responses to each of the four DENV serotypes. The dengue microneutralization test (MNT) was developed based on WHO PRNT guidelines and is essentially a miniaturized PRNT conducted in 96-well cell culture plates to increase sample throughput when measuring neutralizing antibodies to DENV-1–4 in human sera. The MNT was validated for intra- and inter-assay precision, accuracy/linearity, limits of quantitation, and specificity using serum samples containing a wide range of anti-dengue antibody levels. The assay met the pre-specified acceptance criteria for intra-assay (percent geometric coefficient of variation [%GCV] < 30) and inter-assay precision ( $\geq 91\%$  of the samples with median neutralizing titers within the limits of quantitation had %GCV < 60). The MNT also met the prespecified acceptance criteria for accuracy (the predicted bias between the geometric mean and expected titers was 0.62–1.88-fold for  $\geq 80\%$  of samples) and dilutional linearity (the overall fold-decrease in titer per 2-fold dilution increase was 2.03–2.16-fold for DENV-1–4). Specificity for the presence or absence of dengue antibodies was demonstrated.

Possible cross-reactivity was observed in samples positive for antibodies to Japanese encephalitis, West Nile, and yellow fever viruses. The assay has been validated for quantitating DENV-1–4 neutralizing antibodies and has been used to measure immune responses to the tetravalent DENV vaccine candidate TAK-003.

0574

### ADRENAL DYSFUNCTION IN PATIENTS WITH DENGUE: A HOSPITAL BASED STUDY FROM JODHPUR, INDIA

**Prakrati Yadav**, Bharat Kumar, Ravindra Kumar Gayaprasad Shukla, Maya Gopalakrishnan, Mahendra Kumar Garg

*All India Institute Of Medical Sciences, Jodhpur, Jodhpur, India*

Stress response during dengue fever usually results in secretion of cortisol mediated by cytokines like interleukin-6, interleukin-1, tumour necrosis factor- $\alpha$ . It is hypothesized that the adrenal gland may be affected either due to hemorrhage or functional insufficiency due to cytokine effects on hypothalamic-pituitary-adrenal axis. We did a cross-sectional study in which all patients >18 years of age attending the in-patient services at our centre with diagnosis of dengue fever were included. Basal and stimulated cortisol were measured in all patients. We used the following criteria for diagnosis of adrenal insufficiency: Post-ACTH stimulated serum cortisol < 18 mcg/dl, basal cortisol <3 mcg/dl or increment during ACTH stimulation < 7 mcg/dl. Total 50 patients were enrolled in the study out of which 44 were male and 6 were female. Median age of patient was 29.5 ( $\pm$ 12.75) years. Thirty-eight patients had dengue without warning signs and twelve had dengue with warning signs. All patients survived. Eight out of 50 (16%) patients had adrenal insufficiency according to definition; out of which 7 had stimulated cortisol < 18 mcg/dl. The median basal cortisol value in dengue without warning signs cohort was 9 mcg/dl and the median stimulated cortisol was 22 mcg/dl. The median basal cortisol value in dengue with warning sign cohort was 6.5 mcg/dl and the median stimulated cortisol was 25 mcg/dl. The median value was significantly reduced in dengue fever with warning signs (6.5 + 2.75 mcg/dl) compared with those without warning signs (9.0  $\pm$  4.0 mcg/dl) [ $p = 0.04$ , Mann Whitney U test]. However, there was no significant difference in post-ACTH stimulated cortisol between the two groups. Our results suggest that adrenal insufficiency is more common than previously reported in dengue fever. Lower serum cortisol values are associated with dengue with warning signs suggesting an imbalance in the stress response and may be an important predictor of severity. However, lower levels of stimulated cortisol in adrenal insufficiency suggest a direct viral mediated suppression on adrenal gland than a hypothalamic-pituitary-adrenal axis mediated effect.

### Aedes-borne virus immune profiles in a pediatric population in Merida, Yucatan, Mexico: A baseline serologic analysis of the TIRS trial

**James Thomas Earnest**<sup>1</sup>, Henry Puerta-Guardo<sup>2</sup>, Oscar D. Kirstein<sup>1</sup>, Gloria A. Barrera<sup>2</sup>, Azael Che-Mendoza<sup>2</sup>, Pablo Manrique-Saide<sup>3</sup>, Hector Gomez-Dantes<sup>3</sup>, Norma Pavia-Ruz<sup>2</sup>, Salha Villanueva-Jorge<sup>4</sup>, Pilar Granja-Perez<sup>4</sup>, Guadalupe Ayora-Talavera<sup>2</sup>, Matthew C. Collins<sup>1</sup>, Gonzalo Vazquez-Prokopec<sup>1</sup>

<sup>1</sup>Emory University, Atlanta, GA, United States, <sup>2</sup>Universidad Autonoma de Yucatan, Merida, Mexico, <sup>3</sup>National Institute of Public Health, Cuernavaca, Mexico, <sup>4</sup>Secretaria de Salud de Yucatan, Merida, Mexico

Aedes-borne viruses (ABVs) like dengue (DENV), Zika (ZIKV) and Chikungunya (CHIKV) viruses are mosquito vector-borne diseases responsible for substantial health burden in many tropical areas. While DENV infection can be controlled by robust antibody (Ab) responses, the presence of four serotypes of DENV, the potential for co-transmission of the related flavivirus Zika virus, and cross-reactivity of neutralizing and non-neutralizing Abs complicates infection control among individuals and populations. Indeed, cross-reactive but weakly neutralizing Abs may lead to worse disease outcomes due to Ab dependent enhancement of DENV

infection. We characterized the immune state of a cohort of children in Merida, Yucatan, Mexico, participating in the TIRS trial and living in 50 clusters located in an area identified as high risk for ABV transmission. Children were categorized as naïve or previously infected by DENV, ZIKV, and/or CHIKV according to flavivirus IgG ELISA and neutralization or CHIKV IgG ELISA tests. We analyzed binding affinity and virus neutralization across four DENV serotypes and ZIKV in a subset of samples. Following reported infections among the participants, we analyzed newly collected serum samples. Finally, by collecting socio-economic data and spatial statistics, we generated a heatmap of risk for DENV and ZIKV prevalence by serotype. The map indicates areas of high susceptibility to both DENV and ZIKV, which may inform future infection control efforts.

### VIRAL PARKINSONISM: AN UNDERDIAGNOSED NEUROLOGICAL COMPLICATION OF DENGUE VIRUS INFECTION

**Hannah K. Hopkins**<sup>1</sup>, Elizabeth Traverse<sup>1</sup>, Vedana Vaidhyathan<sup>2</sup>, Kelli L. Barr<sup>1</sup>

<sup>1</sup>University of South Florida, Tampa, FL, United States, <sup>2</sup>Baylor University, Waco, TX, United States

Dengue virus (DENV) is a flavivirus that is a significant cause of human disease. It is spread by the mosquito *Aedes aegypti*, and humans are crucial to the viral life cycle. Up to 20% of patients with DENV infections exhibit neurological symptoms, including encephalitis and encephalopathy. DENV infection has also caused the rare complication of viral-parkinsonism. Viral-parkinsonism occurs when infection of the brain causes degeneration of neurons. Approximately 11% of DENV encephalitis cases have a movement disorder associated with their condition. One of these is the lesser-known condition of post-DENV parkinsonism or DENV-parkinsonism. For viral-parkinsonism to be considered as a diagnosis, the patient must exhibit at least two of the following symptoms: tremor, bradykinesia, rigidity, and postural instability. Little is known about the condition, and current knowledge is confined to case reports. We examined the indexed knowledge from Pubmed, Scopus, CINAHL, Embase, LILACS, Google Scholar, and gray literature from medical and governmental agencies. We also included DENV cases with an encephalitis diagnosis containing at least 2 symptoms of parkinsonism occurring during or immediately following acute infection but without a diagnosis of parkinsonism. We performed logistic regression analysis to obtain odds ratios of specific clinical features to determine which specific symptoms prompted an official diagnosis of DENV-parkinsonism. The data show that a specific serotype could not be linked to any manifestation of parkinsonism. Cases of DENV-parkinsonism were almost exclusively reported in southern Asia, specifically in India, Sri Lanka, and Malaysia. Men were significantly more likely to develop viral-parkinsonism, and age was not associated with disease. Expressionless face, speech problems, and slow movements were significantly associated with patients acquiring an official DENV-parkinsonism diagnosis. The diagnosis of dengue encephalitis is vague, considering the broad range of symptoms exhibited by patients. DENV-parkinsonism is likely more prevalent than reported due to misdiagnosis as encephalitis.

### THE RESURGENCE OF DENGUE VIRUS AFTER THE ZIKA EPIDEMIC IN BRAZIL

**Anderson F. Brito**<sup>1</sup>, Lais C. Machado<sup>2</sup>, Marcio J. Siconelli<sup>3</sup>, Rachel J. Oidtman<sup>4</sup>, Joseph R. Fauver<sup>1</sup>, Rafael F. Franca<sup>2</sup>, T. Alex Perkins<sup>4</sup>, Benedito A. Fonseca<sup>3</sup>, Gabriel L. Wallau<sup>2</sup>, Nathan D. Grubaugh<sup>1</sup>

<sup>1</sup>Yale University, New Haven, CT, United States, <sup>2</sup>Fiocruz, Recife, PE, Brazil, <sup>3</sup>University of Sao Paulo, Ribeiro Preto, SP, Brazil, <sup>4</sup>University of Notre Dame, Notre Dame, IN, United States

After Zika virus (ZIKV) was introduced in the Americas, it caused major outbreaks in 2016, and the number of reported dengue cases in Brazil dropped in 2017-2018. However, in 2019, dengue resurged, reaching

high incidence across the country. In this study we investigate the causes of dengue decline, and uncover the dynamics and origins of dengue virus 1 (DENV-1, genotype V) and DENV-2 (genotype AA) causing recent outbreaks in the country. To investigate dengue dynamics in recent years we used distinct data types. Based on epidemiological data, we modelled the annual force of infection of dengue from 2002 to 2019. Using ecological data, we estimated the level of environmental suitability for mosquito populations, in distinct regions. Finally, by sequencing 69 dengue virus genomes, we performed phylogeographic analyses to uncover the evolutionary history of DENV-1 and -2 in Brazil. Estimates of force of infection revealed that dengue transmission was very low in 2017 and 2018. This likely indicates the population immunity acquired in prior ZIKV and/or DENV infections likely played a role determining the dengue decline. Furthermore, environmental conditions in 2017/2018 did not change in comparison to other years, and were favourable for mosquito reproduction. Phylogenetic analyses revealed that the 2018-2019 dengue outbreaks were mainly caused by local DENV lineages, circulating and causing recurrent outbreaks in Brazil since 2012 (DENV-1, BR5) and 2013 (DENV-2, BR4). We revealed the dynamics of DENV before and after the major 2016 Zika outbreaks in Brazil and uncovered the causes of dengue decline and resurgence. The 2018-2019 DENV outbreaks in the country were caused by viruses circulating locally prior to (and despite) the Zika outbreaks. Dengue transmission in 2017/2018 was low, likely due to a decline in the number of susceptible individuals because of population immunity from years of high dengue incidence. Moreover, public health interventions in response to ZIKV may have also impacted the transmission of other arboviruses. Thus, the dengue decline in 2017-2018 is more likely explained by immunological and anthropological factors.

0578

#### GLYCOSYLATION ON PREMATURE AND ENVELOPE PROTEIN DETERMINE DENGUE VIRUS MATURATION

**Stephanie Dong**, Longping V. Tse, Ralph S. Baric

*University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Dengue virus (DENV) is a vector-borne, single-stranded positive-sense RNA virus with four distinct serotypes (DENV1-4). While DENV maturation affects both the intrinsic viral infectivity and antibody neutralization extrinsically, the generation and evolution consequences of DENV maturation are largely unknown. The lack of reagents hinders our understanding of DENV maturation and the only known maturation determinant is the furin cleavage site of the premature (prM) protein. Given the major structural conformational change between the immature and mature DENV, we hypothesize post-translational structural modification, such as N-linked glycosylation could affect DENV maturation. The prM and Envelope (E) region possess three highly conserved surface exposed N-glycosylation sites, prM-N69, E-N67, and E-N153. To investigate the impact of prM and E glycosylation on viral maturation, we systematically ablated the three glycosylation sites in DENV4. We identified prM-N69 as a lethal mutation and prevented viral growth while E-N67 and N153 did not. Subsequently, we were able to rescue the prM-N69 ablated mutant by adding a prM-N57 glycosylation site proximally near the prM-N69 region. All our variants exhibited attenuated phenotype in tissue culture compared to the wildtype DENV4 strain (WT), but the degree of attenuation is species dependent. Importantly, compared to WT, the E-N153K variant is more mature while E-N67Q and prM-N69D-V57N variants generate immature viruses. Our result suggests surface glycosylation determines DENV maturation and viral fitness. Our attenuated DENV viruses have the potential to serve as live attenuated vaccine candidates and our genetically encoded mature and immature DENVs are great tools to delineate DENV maturation.

0579

#### DENGUE SEROTYPE 4 -2 ENVELOPE DOMAIN CHIMERIC VIRUSES: DESIGN, RECOVERY, AND ANTIBODY MAPPING

**Deanna R. Zhu**, Ellen Young, Jennifer Munt, Rita Meganck, Victor Tse, Aravinda de Silva, Ralph Baric

*UNC Chapel Hill School of Public Health, Chapel Hill, NC, United States*

Dengue is the most prevalent vector-borne virus plaguing our world. In 2010, there were an estimated 390 million infections worldwide, 25% of which were symptomatic. Properties of antibodies that correlate to protection after natural infection or vaccination have not been fully described, which hinders our ability to measure vaccine efficacy. Only two human type-specific neutralizing antibodies against dengue serotype 2 (DENV2) have been mapped. In an attempt to identify additional type-specific neutralizing DENV2 epitopes, we have developed three chimeric viruses with envelope domain I, II, and III (EDI, EDII, and EDIII) transplants from DENV2 in a DENV4 backbone. Full-length viral RNA of each construct was electroporated into C636 cells and serially passaged in C636, Vero 81, and furin-overexpressing Vero 81 cell lines to compare maturation status and viral titers. Sanger-sequencing confirmed preservation of the DENV2 EDI, EDII, and EDIII footprint, respectively, on the DENV4 backbone. Neutralization assays by DENV2-specific, DENV4-specific, and cross-reactive antibodies showed phenotypic preservation of each DENV2 envelope domain as well. Our DENV4-2 chimeric viruses were then used to identify domain-specific epitopes of unmapped monoclonal antibodies. In the future, this panel of reagents can be used to identify viral targets by type-specific and polyclonal human sera.

#### MAJORITY OF PEDIATRIC DENGUE VIRUS INFECTIONS IN KENYA DO NOT MEET THE 2009 WHO CRITERIA FOR DENGUE DIAGNOSIS

**Aslam Khan**<sup>1</sup>, Bryson Ndenga<sup>2</sup>, Francis Mutuku<sup>3</sup>, Charles Ronga<sup>2</sup>, Laura Mwambingu<sup>2</sup>, Victoria Okuta<sup>2</sup>, Zainab Jembe<sup>4</sup>, Priscilla Maina<sup>4</sup>, Philip Chebii<sup>4</sup>, Desiree LaBeaud<sup>1</sup>

<sup>1</sup>*Department of Pediatrics, Division of Infectious Diseases, Stanford University, Stanford, CA, United States*, <sup>2</sup>*Centre for Global Health Research, Kenya Medical Research Institute, Kisumu, Kenya*, <sup>3</sup>*Department of Environment and Health Sciences, Technical University of Mombasa, Mombasa, Kenya*, <sup>4</sup>*Vector borne Disease control Unit, Msambweni County Referral hospital, Msambweni, Kenya*

From 1975-2009, the WHO guidelines classified symptomatic dengue virus infections as dengue fever, dengue hemorrhagic fever, and dengue shock syndrome. In 2009 the case definition was changed to a clinical classification after concern the original criteria was challenging to apply in resource-limited settings and not inclusive of a substantial proportion of severe dengue cases. More recently, the 2009 clinical classification has been criticized for being overly inclusive and non-specific, different from our experience in Kenya. Between 2014 and 2019 as part of a child cohort study of febrile illness in our four clinical study sites (Ukunda, Kisumu, Msambweni, Chulaimbo) we identified 369 dengue-PCR positive symptomatic cases and characterized whether they met the 2009 revised WHO diagnostic criteria for dengue with and without warning signs and severe dengue. Of the 369 identified cases, we found 7% met criteria for dengue without warning signs, 29% met criteria for dengue with warning signs, 2% met criteria for severe dengue, and 62% did not meet criteria for diagnosis. The mean ages were 4.99, 4.47, 4.7, and 5.5 years, respectively and the most common warning signs were lethargy paired with aches/pains and nausea/vomiting. For severe dengue all cases had impaired consciousness but none were notable for hemorrhagic symptoms. This correlates with our experience that dengue disease in children in Kenya is less severe as reported in other parts of the world. These findings also suggest the 2009 WHO dengue case definition may miss more than 50% of symptomatic infections in Kenya and may require further modification to include the African experience.

### TISSUE SPECIFICITY OF FLAVIVIRUS NS1 BINDING AND NS1-INDUCED ENDOTHELIAL PERMEABILITY IS MEDIATED BY DISTINCT PROTEIN DOMAINS

Nicholas T. Lo, Scott B. Biering, Nicole Tin, Eva Harris

*Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States*

Vascular leak is a hallmark of severe dengue caused by the positive-sense RNA flavivirus, dengue virus (DENV). DENV non-structural protein 1 (NS1) is a secreted glycoprotein that causes endothelial hyperpermeability directly by disrupting the endothelial glycocalyx-like layer (EGL) *in vitro*, as well as inducing vascular leak *in vivo*. We have shown that NS1 proteins from different flaviviruses bind to human endothelial cells (EC) and induce vascular leak in a tissue-specific manner, consistent with their respective disease tropism. For example, DENV NS1, but not West Nile virus (WNV) NS1, binds to human pulmonary microvascular endothelial cells (HPMEC), as DENV but not WNV induces leakage in the lungs. However, the molecular determinants of NS1 driving differential EC tissue specificity remain unknown. Using chimeric NS1 proteins, we exchanged the wing and  $\beta$ -ladder domains between DENV and WNV NS1. The DENV NS1 with WNV wing domain (D-W<sup>Wing</sup>) chimera lost the capacity to bind to HPMEC, whereas its counterpart, WNV NS1 with DENV wing domain (W-D<sup>Wing</sup>) chimera exhibited gain-of-function HPMEC binding. Interestingly, the DENV NS1 with WNV  $\beta$ -ladder domain (D-W <sup>$\beta$ -ladder</sup>) chimera was able to bind to HPMEC like DENV NS1 but was unable to induce endothelial permeability. Conversely, the W-D <sup>$\beta$ -ladder</sup> chimera ablated binding but could induce endothelial hyperpermeability in HPMEC. Taken together, these results suggest that the wing domain of DENV NS1 drives its capacity to bind to HPMEC, while the  $\beta$ -ladder domain mediates its ability to induce endothelial permeability. Further mutational analysis to identify specific residues responsible for these characteristics is underway, as well as work to elucidate the implications in relation to viral infection.

### SAFETY, TOLERABILITY AND PHARMACOKINETICS OF A NOVEL PAN-SEROTYPE DENGUE ANTIVIRAL SMALL MOLECULE IN A PHASE 1, DOUBLE-BLIND, RANDOMIZED, DOSE-ESCALATION STUDY

Oliver Ackaert<sup>1</sup>, Fredric Vanhoutte<sup>2</sup>, Nathalie Verpoorten<sup>3</sup>, Annemie Buelens<sup>1</sup>, Sophie Lachau-Durand<sup>4</sup>, Lieve Lammens<sup>4</sup>, Marnix Van Loock<sup>3</sup>, Guillermo Herrera-Taracena<sup>5</sup>

<sup>1</sup>Janssen Quantitative Sciences, Janssen Pharmaceutica NV, Beerse, Belgium, <sup>2</sup>SGS Clinical Pharmacology Unit, Antwerp, Belgium, <sup>3</sup>Janssen Global Public Health, Janssen Pharmaceutica NV, Beerse, Belgium, <sup>4</sup>Janssen Discovery Sciences, Janssen Pharmaceutica NV, Beerse, Belgium, <sup>5</sup>Janssen Global Public Health, Janssen Research & Development, Horsham, PA, United States

Dengue is a growing global health threat. JNJ-1802 is a novel pan-serotype dengue antiviral small molecule that blocks the formation of the viral replication complex. Preclinical results demonstrated promising safety data and excellent efficacy against dengue virus infection in murine and non-human primate models. This first-in-human, double-blind, randomized, placebo-controlled study aimed to examine the safety, tolerability and pharmacokinetics of increasing single and multiple oral doses of JNJ-1802. Eligible healthy participants 18-55 years of age were randomized to receive oral JNJ-1802 in fasted conditions as: 1) single doses (50 to 1200 mg; n=29) or placebo (polyethylene glycol 400; n=10); or 2) once daily doses (50 to 560 mg for 10 consecutive days or 400 mg for 31 days; n=38), or placebo (n=9). Safety and tolerability were evaluated throughout the study. Plasma (all cohorts) and urine (selected cohorts) samples were collected at pre-determined timepoints to characterize the pharmacokinetics of JNJ-1802. No deaths, serious adverse events (SAEs), or AEs leading to JNJ-1802 discontinuation were reported. No clinically relevant changes were observed in electrocardiograms, laboratory tests or vital signs. Two grade 2 events of rash, which were considered very likely related to JNJ-1802 by

the investigator, occurred and resolved. JNJ-1802 exposure after single or multiple dose increased dose-proportionally from 50 to 150 mg and less than dose-proportionally for higher doses. The terminal half-life was 6.3 to 9.2 days and the accumulation factor varied from 4.3 to 7.3 after 10 days and 14.6 after 31 days. Renal elimination of JNJ-1802 was very limited as low amounts of unchanged compound were excreted via urine. Oral JNJ-1802 administered as single or multiple doses was generally well tolerated and no safety concerns were identified, supporting its further clinical development for the treatment and/or prevention of dengue. To our knowledge, JNJ-1802 is the first dengue-specific antiviral small molecule to complete a first-in-human study.

### ASSOCIATION BETWEEN MAGNITUDE OF ANTI-DENGUE VIRUS ANTIBODY AVIDITY AND PROTECTION AGAINST SYMPTOMATIC DENGUE VIRUS INFECTION

Isamu Tsuji<sup>1</sup>, David Dominguez<sup>1</sup>, Magelda Montoya<sup>2</sup>, Jonathan Hernandez<sup>1</sup>, Josefina Coloma<sup>2</sup>, Guillermina Kuan<sup>3</sup>, Angel Balmaseda<sup>3</sup>, Ralph Braun<sup>1</sup>, Eva Harris<sup>2</sup>, Hansi Dean<sup>1</sup>

<sup>1</sup>Vaccines Business Unit, Takeda Pharmaceutical Inc, Cambridge, MA, United States, <sup>2</sup>Division of Infectious Diseases and Vaccinology, School of Public Health, University of California, Berkeley, Berkeley, CA, United States, <sup>3</sup>Sustainable Sciences Institute, Managua, Nicaragua

Dengue is a mosquito-borne disease caused by four dengue virus serotypes (DENV-1, DENV-2, DENV-3, and DENV-4) with an estimated 390 million infections annually, of which approximately 96 million are symptomatic. The degree of antibody affinity maturation driven by vaccination or natural infection is one measure of the overall evolution of the polyclonal antibody repertoire. Previously, we reported the development of a novel avidity assay employing bio-layer interferometry and dengue virus-like particles to assess the affinity maturation of antibodies in sera from naturally infected individuals and recipients of the Takeda tetravalent dengue vaccine candidate (TAK-003). The avidity index measured by the assay increased after infection and after vaccination and remained high through one-year post-vaccination. The Nicaraguan Pediatric Dengue Cohort Study (2004 to present) is a community-based study with an average active cohort of ~3,700 children aged 2–14 years old in Managua, Nicaragua. Blood samples are collected from all participants each year, and symptomatic DENV infections are confirmed by molecular, virological, and serological assays. Sera were selected from 40 study participants prior to a secondary DENV-3 infection (20 symptomatic and 20 asymptomatic infections) and analyzed for polyclonal antibody avidity and neutralizing antibody titers. The DENV-3 avidity index and neutralization titers were higher in asymptomatic compared with symptomatic study participants. Study participants with a high avidity index were more likely to have experienced a subsequent inapparent infection, regardless of neutralizing antibody titer. Study participants with both a low avidity index and low neutralizing antibody titer were more likely to have experienced a subsequent symptomatic infection. These results suggest that the magnitude of the avidity index, a measure of the degree of polyclonal antibody affinity maturation, is associated with prevention of symptomatic DENV-3 infection.

### DETECTION OF SPATIO-TEMPORAL HETEROGENEITY OF DENGUE IN COLOMBO CITY, SRI LANKA: AN ASSESSMENT OF URBAN RISK FACTORS AND DRIVERS USING POINT PROCESS SPATIAL MODELLING

Nayantara Wijayanandana<sup>1</sup>, Jorge Cano<sup>1</sup>, Ruwan Wijayamuni<sup>2</sup>, Hasitha Tissera<sup>3</sup>, Christian Bottomley<sup>1</sup>, Neal Alexander<sup>1</sup>, Henrik Salje<sup>4</sup>

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Public Health Department, Colombo Municipal Council, Colombo, United Kingdom, <sup>3</sup>Ministry of Health, Colombo, Sri Lanka, <sup>4</sup>Cambridge University, Cambridge, United Kingdom

Colombo, the capital of Sri Lanka, is a highly dense area with a heterogeneous residential land use pattern. Endemic for dengue transmission, it has the highest yearly burden of dengue in the country and dengue clustering persists in certain areas of the city. As part of their surveillance system, the Colombo Municipal Council records the location of dengue cases in Colombo city to pinpoint areas of high incidence and to administer vector control measures. The aim of this research was to confirm the spatio-temporal heterogeneity of dengue within the city at a high resolution of 100x100m grids and relate these to ecological risk covariates of population density, type of residential area and residential density, land use, and proximity to known vector breeding risk sites such as construction, markets, and schools. Particular focus was how the built environment and land use changes relate to dengue incidence. Spatial analysis of individual confirmed geolocated dengue cases was done for the period 2000-2016 using point pattern analysis methods to develop a spatially continuous map of disease risk. Bayesian inference was used to estimate the model parameters using Integrated nested Laplace approximation (INLA) and a Poisson process. The model estimated dengue incidence at 100m x month adjusted for spatial effects. The analysis highlighted the clustering and risk present in certain areas of the city. These findings help the dengue control program target its activities and inform control.

0585

### ARBOVIRUS SURVEILLANCE AND JAPANESE ENCEPHALITIS VIRUS GENOTYPE IV ISOLATION FROM CULEX VISHNUI MOSQUITOES COLLECTED ON BALI ISLAND, INDONESIA

Astri Nur Faizah<sup>1</sup>, Daisuke Kobayashi<sup>2</sup>, Maekawa Yoshihide<sup>2</sup>, Michael Amoa-Bosompem<sup>3</sup>, Shifa Fauziyah<sup>4</sup>, Kris Cahyo Mulyatno<sup>4</sup>, Sri Subekti<sup>4</sup>, Etik Ainun Rohmah<sup>4</sup>, Maria Inge Lusida<sup>4</sup>, Yasuko Mori<sup>5</sup>, Kozue Miura<sup>1</sup>, Kazuhiro Hirayama<sup>1</sup>, Haruhiko Isawa<sup>2</sup>, Kyoko Sawabe<sup>2</sup>

<sup>1</sup>The University of Tokyo, Tokyo, Japan, <sup>2</sup>National Institute of Infectious Diseases, Tokyo, Japan, <sup>3</sup>Kyushu University, Kyushu, Japan, <sup>4</sup>Airlangga University, Surabaya, Indonesia, <sup>5</sup>Kobe University, Kobe, Japan

Japanese encephalitis virus (JEV) remains to be the leading cause of children's encephalitis in its endemic countries in Asia, including Indonesia. Indonesia is the only country with the most diversity of Japanese encephalitis virus (JEV) genotypes, with the detection of four out of five genotypes available in the world. That being the case, knowledge on the arthropod-borne virus (arbovirus) disease surveillance in Indonesia may be crucial in elucidating the mechanism behind the JEV genotypes' evolution and spread, and ancient arboviruses' spread in general. Nonetheless, a limited number of studies in the country indicated that we are still far from understanding the arbovirus evolution. In this study, we conducted cross-sectional arbovirus surveillance by collecting mosquitoes in four sites in Tabanan Regency, Bali Island, Indonesia in 2019. An extensive approach of high-throughput RNA-sequencing combined with virus isolation in mosquito cells was utilized to determine viruses harbored in the mosquitoes. Subsequently, the results were verified by PCR and followed by phylogenetic analysis. We successfully identified 35 putative and known viral genomes, including one JEV isolate. Some novel viruses belonged to divergent families, notably Reoviridae and Rhabdoviridae. The JEV isolated

belonged to Genotype IV based on its envelope (E) gene sequences and was closely related to JEV identified from swine in Bali in 2018 and human patient in Queensland in 2020. We are currently further characterizing viruses in the mosquitoes and also determining their correlation with the most restricted JEV genotype in the world, i.e. JEV GIV, if any. This study not only adds up the knowledge pool of arbovirus studies on Bali Island, Indonesia, but also supports the evidence of JEV GIV active transmission currently occurring on the island. Established national surveillance and vaccination in Indonesia, Bali Island in particular, is greatly encouraged.

0586

### URINE AS A POSSIBLE RESOURCE FOR YELLOW FEVER DIAGNOSIS

Izabela M. Rezende<sup>1</sup>, Leonardo S. Pereira<sup>2</sup>, Aslam Khan<sup>1</sup>, Gabriela Fernanda G. Oliveira<sup>2</sup>, Thais Alkifeles<sup>2</sup>, Andreza P. Gonçalves<sup>3</sup>, Pedro A. Alves<sup>3</sup>, Olindo A. Martins-Filho<sup>4</sup>, Andréa Teixeira-Carvalho<sup>4</sup>, A. Desiree LaBeaud<sup>1</sup>, Betânia P. Drumond<sup>2</sup>

<sup>1</sup>Department of Pediatrics, Division of Infectious Disease, Stanford University School of Medicine, Stanford, CA, United States, <sup>2</sup>Laboratório de Vírus, Microbiology Department, Biological Sciences Institute, Federal University of Minas Gerais, Belo Horizonte, Brazil, <sup>3</sup>Imunologia de Doenças Virais, René Rachou Institute, Oswaldo Cruz Foundation FIOCRUZ MG, Belo Horizonte, Brazil, <sup>4</sup>Grupo Integrado de Pesquisas em Biomarcadores, René Rachou Institute, Oswaldo Cruz Foundation FIOCRUZ MG, Belo Horizonte, Brazil

From 2016 to 2018, a huge yellow fever (YF) outbreak was detected in Southern Brazil, causing 2166 confirmed human cases and 752 deaths. Laboratory molecular diagnosis of YF is usually based on RT-qPCR to detect YFV RNA in sera within ten days post symptoms (DPS) onset. The presence of YFV RNA has already been demonstrated in urine of patients. To investigate the presence of RNA in urine from YF naturally infected patients, we tested urine samples collected during the last YF outbreak in Brazil from patients in Minas Gerais state. A total of 74 urine samples, from 74 patients, were collected (55 from acute phase and 19 from convalescent phase of YF infection). A total of 140 µL from each urine sample was used for total RNA extraction followed by RT-qPCR targeting part of the YFV NS5 gene. Fifteen urine samples from different patients from the acute phase (from 2 to 21 DPS) and two urine samples from the convalescent phase (66- and 68- DPS) were YFV positive. Although international guidelines advocate using molecular tests in sera until ten DPS, the limited window of detection with serum may be extended with evaluation of urine for molecular tests, as demonstrated in our case, where YFV RNA was detected in urine up to 68 DPS onset. Whereas the two positive samples from the convalescent phase of YF were from patients who vaccinated against YF 10 days before symptoms, we genotyped the samples. They grouped with YF-SAI genotype, indicating the presence and persistence of WT YFV for a longer time in urine. To our knowledge, this is the first report of WT-YFV-RNA detected in the urine this far out from symptom onset. Other studies previously detected the RNA of YFV WT in urine, but in a smallest window (up to 45 DPS). With a prolonged period of detection beyond the viremic phase, we recommend using urine as an alternative for YF diagnosis. The use of urine samples after YF acute phase, altogether serology tests, epidemiology inquiry, and clinical assessment could provide a longer assertive YF diagnosis, especially in lower-resourced communities or remote areas, where blood collection can be problematic and in situations where trained personnel or proper facilities are unavailable.

### NON-CONSERVATIVE MUTATIONS AT THE HIGHLY CONSERVED ALA54 RESIDUE OF YELLOW FEVER VIRUS ENVELOPE PROTEIN MODULATES THE YIELD OF INFECTIOUS VIRUSES IN CELL CULTURE

Bailey E. Maloney<sup>1</sup>, Danielle R. Saunders<sup>1</sup>, Ashley N. Bilyeu<sup>1</sup>, Alan D. Barrett<sup>2</sup>, Stephen Higgs<sup>1</sup>, Dana L. Vanlandingham<sup>1</sup>, Yan-Jang S. Huang<sup>1</sup>

<sup>1</sup>Kansas State University, Manhattan, KS, United States, <sup>2</sup>University of Texas Medical Branch, Galveston, TX, United States

Yellow fever virus (YFV) is the prototypic flavivirus, that can cause a fatal viscerotropic disease in humans. The disease is prevented by live attenuated vaccines. Infection of cells with YFV is initiated after viral and cellular membrane fusion followed by the release of positive-sense RNA genome into the cytoplasm. Membrane fusion involves conformational changes of the envelope (E) protein from a dimer to a trimer in the acidic environment of endosomes. This is achieved through the coordination of the EDI-EDII hinge region. Three amino acids with small hydrophobic side chains are highly conserved in the EDI-EDII hinge region of YFV and other pathogenic flaviviruses: Ala<sup>54</sup>, Gly<sup>260</sup>, and Gly<sup>279</sup> of YFV. The Ala<sup>54</sup> residue has been shown to tolerate genetic mutations; whereas, substitutions of the Gly<sup>260</sup> and Gly<sup>279</sup> residues cause lethal phenotypes or compensatory mutations in the E protein of related flaviviruses. The live-attenuated French neurotropic vaccine (FNV) was derived from wild-type (WT) strain French Viscerotropic virus (FVV) and was used in the vaccination campaign in French-speaking Africa until 1982. Intriguingly, FNV contains a stable E-A54V mutation. The objective of this study is to determine the phenotypic changes caused by the substitutions of the Ala<sup>54</sup> residue in YFV E protein. Seven mutations including: A54S, A54V, A54D, A54G, A54K, A54P and A54Y were tolerated by WT YFV. The non-conservative A54D and A54K mutations with electrostatically charged side chains reduced the yield of infectious virus and prevented the formation of plaques in Vero cells, resembling the phenotypes associated with the A54V mutation found in FNV. The substitution of the Ala<sup>54</sup> residue with amino acids with hydrophobic or neutral side chains had no demonstrable differences in the yield of infectious viruses in electroporated BHK-21 cells. Whilst the A54V mutation in FNV is a conservative mutation, its impacts on the phenotype of WT YFV are similar to those caused by other non-conservative mutations. Reduced viral yield suggests that the A54V mutation in the E protein is a candidate attenuation determinant responsible for the loss of virulence in FNV.

### SUBSTITUTIONS OF CONSERVED HYDROPHOBIC AMINO ACIDS IN THE ENVELOPE PROTEIN DOMAIN I AND DOMAIN II HINGE REGION IMPAIR THE REPLICATION OF YELLOW FEVER VIRUS IN CELL CULTURE

Danielle R. Saunders<sup>1</sup>, Bailey E. Maloney<sup>1</sup>, Ashley N. Bilyeu<sup>1</sup>, Stephen Higgs<sup>1</sup>, Alan D. Barrett<sup>2</sup>, Dana L. Vanlandingham<sup>1</sup>, Yan-Jang S. Huang<sup>1</sup>

<sup>1</sup>Biosecurity Research Institute and Department of Diagnostic Medicine/ Pathobiology, College of Veterinary Medicine, Kansas State University, Manhattan, KS, United States, <sup>2</sup>Sealy Institute for Vaccine Sciences and Department of Pathology, University of Texas Medical Branch, Galveston, TX, United States

Flaviviruses are a group of small, enveloped RNA viruses with diverse tissue tropisms and pathogenic mechanisms. All flaviviruses have evolved to utilize the same pH-driven viral membrane fusion mechanism that releases the positive-sense RNA genome into susceptible cells. In the acidic environment of endosomes, the fusion loop (FL) structure located in domain II of the envelope protein (EDII) is exposed and inserted into the host cell membrane to initiate viral membrane fusion. This process requires the relative movement between envelope domain I (EDI) and EDII and is coordinated by the EDI-EDII hinge region that consists of four linear chains of amino acids. As a functionally important element, the EDI-EDII

hinge region contains several conserved residues, the majority of which are hydrophobic amino acids. We hypothesized that the substitutions of conserved hydrophobic residues in the EDI-EDII hinge region will interfere with the infection process of flaviviruses and produce mutants with attenuated phenotypes. To test this hypothesis, eight conserved hydrophobic residues, Ala<sup>54</sup>, Val<sup>130</sup>, Ile<sup>135</sup>, Val<sup>188</sup>, Ala<sup>261</sup>, Val<sup>264</sup>, Leu<sup>273</sup>, and Leu<sup>276</sup>, in the EDI-EDII hinge region of wild-type yellow fever virus Asibi strain were substituted with amino acid residues with polar side chains. Four single-site mutations, A54S, V188T, V264T and L273N, produced genetically stable mutants that did not contain compensatory mutations in the E protein. Multiplication curve experiments conducted in Vero and BHK-21 cells demonstrated that the E-V264T mutant produced significantly lower infectivity titers than the parental Asibi virus. Our findings suggest that substitution of conserved hydrophobic amino acids in the EDI-EDII hinge region is an effective strategy in generating genetically stable attenuated YFV mutants. Current studies are evaluating virulence of the mutants in mouse models.

### REEMERGENCE OF POWASSAN VIRUS LINEAGE 1 IN NEW YORK STATE

Rachel E. Lange<sup>1</sup>, Kiet Ngo<sup>2</sup>, Joseph G. Maffei<sup>2</sup>, Cheri A. Koetzner<sup>2</sup>, Alan P. Dupuis II<sup>2</sup>, Laura D. Kramer<sup>2</sup>, Alexander T. Ciota<sup>2</sup>

<sup>1</sup>SUNY University at Albany School of Public Health, Albany, NY, United States, <sup>2</sup>The Arbovirus Laboratory, Wadsworth Center, New York State Department of Health, Albany, NY, United States

*Ixodes scapularis*, the black-legged tick, is an important vector in the northeastern United States able to transmit up to seven human pathogens including Powassan virus (POWV). POWV was first isolated in 1958 in Ontario, Canada from a young boy with encephalitis. In 1997, a POWV-like agent was isolated from *I. scapularis* ticks in New England and determined to be genetically distinct from the original POWV isolate. This discovery revealed the existence of two lineages: lineage 1, prototype POWV (POWV-1) and lineage II, deer tick virus (DTV). It is suggested that POWV-1 is maintained in a cycle between *I. cookei* and groundhogs and *I. marxi* and arboreal squirrels, while DTV is found in an *I. scapularis* and small mammal host cycle similar to that of *Borrelia burgdorferi*. This distinction in nature suggests an evolutionary progression of POWV-1 into the *I. scapularis* transmission cycle and subsequent evolution into DTV. A majority of tick and mammalian host isolates from New York State are identified as DTV; however, for the first time in 30 years three new POWV-1 isolates were detected in both *I. scapularis* and *I. cookei*. This study aimed to understand the genetic differences between historic POWV isolates (POWV-1 and DTV) and our recent New York POWV-1 isolates and further investigate genetic determinants of host-specificity in both lineages. POWV-1 isolates LB (Ontario, Canada 1958) and 64-7062 (New York, 1964) were compared to our recent POWV-1 isolates through sequence analysis and replication kinetics in mammalian and *Ixodes spp.* cell lines. Our sequencing data revealed genetic distinctions between the New York POWV-1 isolates from both *I. scapularis* and *I. cookei* compared to the historic POWV-1 isolates. Additionally, the recent POWV-1 isolates showed a decrease in viral growth in mammalian cells compared to historic POWV-1 and DTV isolates. Of note, a new POWV-1 isolate from *I. cookei* displayed significantly decreased viral growth in mammalian cells but reached the highest titers in tick cell lines. These data suggest a reemergence of unique POWV-1 isolates in New York State that may display fitness costs due to host-specific adaptations.

## PREVALENCE OF SELECTED INFECTIONS IN PREGNANT WOMEN AND LIVEBORN INFANTS IN THE ZIKA EN EMBARAZADAS Y NIÑOS (ZEN) PROSPECTIVE COHORT IN COLOMBIA

Angelica Rico<sup>1</sup>, Laura Divens Zambrano<sup>2</sup>, Maritza Gonzalez<sup>1</sup>, **Ayzsa F. Tannis**<sup>3</sup>, Mónica Benavides<sup>4</sup>, Jessica N. Ricaldi Camahual<sup>5</sup>, Helena Rodriguez<sup>1</sup>, Suzanne Newton<sup>6</sup>, Marcela Daza<sup>4</sup>, Jennifer D. Thomas<sup>5</sup>, Jacqueline Acosta<sup>4</sup>, Panagiotis Maniatis<sup>2</sup>, Jonathan Daniels<sup>7</sup>, Veronica Burkel<sup>8</sup>, Elizabeth Ailes<sup>6</sup>, Diana Valencia<sup>6</sup>, Van T. Tong<sup>6</sup>, Suzanne M. Gilboa<sup>6</sup>, Denise J. Jamieson<sup>9</sup>, Marcela Mercado<sup>1</sup>, Julie Villanueva<sup>5</sup>, Martha L. Ospina<sup>1</sup>, Margaret Honein<sup>6</sup>

<sup>1</sup>National Institute of Health, Bogota, Colombia, <sup>2</sup>National Center for Immunization and Respiratory Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>3</sup>Oak Ridge Institution for Science and Research, Oak Ridge, TN, United States, <sup>4</sup>Research Division, Vynova Partners, Bethesda, MD, United States, <sup>5</sup>National Center for Emerging and Zoonotic Infectious Diseases, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>6</sup>National Center on Birth Defects and Developmental Disabilities, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>7</sup>Center for Preparedness and Response, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>8</sup>Eagle Medical Services, LLC, San Antonio, TX, United States, <sup>9</sup>Emory University School of Medicine, Department of Gynecology & Obstetrics,, Atlanta, GA, United States

Some maternal and fetal infections are associated with adverse pregnancy and infant outcomes. However, little data exist on the frequency of these infections and their impact on birth outcomes in Colombia. The Colombian *Instituto Nacional de Salud* (INS) in collaboration with the U.S. Centers for Disease Control and Prevention (CDC) conducted a prospective cohort study in three regions in Colombia to study the prevalence of congenital infections and characterize adverse pregnancy and infant outcomes related to Zika virus (ZIKV) and other infectious agents. Between January 2017 and February 2018, pregnant women in their first trimester were recruited from 13 participating prenatal care clinics. All samples were processed to detect arbovirus RNA (dengue [DENV], ZIKV, and chikungunya) using CDC's Trioplex assay. Maternal serum samples collected at study enrollment and delivery were also tested to determine the presence of ZIKV IgM and serologic response indicating recent cytomegalovirus (CMV) infection, rubella, toxoplasmosis, and syphilis. Available samples from fetuses and liveborn infants were tested by Trioplex and for ZIKV IgM. Presumptive ZIKV positive samples were determined by the presence of seroreactivity against ZIKV and the absence of seroreactivity against DENV. A total of 1,519 pregnant women and 1,108 liveborn infants were enrolled. Evidence of confirmed or presumptive ZIKV infection was present for 95/1,519 (6.3%) pregnant women and 42/1,108 (3.8%) liveborn infants. Evidence of active syphilis and possible acute toxoplasmosis infection was present in 16/1,519 (1.1%) and 3/1,519 (0.2%) pregnant women, respectively. Recent rubella and CMV infection was present in 2/1,519 (0.1%) and 12/1,519 (0.8%) pregnant women, respectively. Clinical review of adverse birth and infant outcomes is ongoing. This study provides epidemiologic data on the prevalence of congenital infections during the waning ZIKV outbreak in Colombia, which can be used to implement health interventions to mitigate their impact at individual and population levels.

<sup>1</sup>Biosecurity Research Institute, Kansas State University, Manhattan, KS, United States, <sup>2</sup>School of Veterinary Medicine and Biomedical Sciences, University of Nebraska-Lincoln, Lincoln, NE, United States, <sup>3</sup>Arthropod-Borne Animal Diseases Research Unit, Center for Grain and Animal Health Research, Agricultural Research Service, United States Department of Agriculture, Manhattan, KS, United States, <sup>4</sup>National Agricultural Biosecurity Center, Kansas State University, Manhattan, KS, United States, <sup>5</sup>Department of Statistics, College of Arts and Sciences, Kansas State University, Manhattan, KS, United States

Japanese encephalitis virus (JEV), a neurotropic flavivirus, is primarily transmitted through the bite of infected *Culex* species mosquitoes. During blood feeding, JEV-infected mosquitoes inoculate virus with salivary components into the vertebrate hosts. Mosquito saliva has been widely recognized to modulate the host's hemostatic, inflammatory, and immune responses. In comparison with needle inoculation, when arboviruses are delivered with mosquito saliva, this modulatory activity can result in differences in the severity and pathogenesis of the arbovirus infection. Whilst the modulation of flavivirus infections by mosquito saliva has been studied in various laboratory models, the majority of challenge studies involved in the pathogenesis of JEV have been conducted through virus-only needle inoculations. Using weanling pigs as a model for human Japanese encephalitis and immune response, the impact of mosquito saliva in JEV infection was investigated through the simultaneous co-injection of the virus and mosquito salivary gland extract (SGE), an established method to mimic mosquito feeding. Fever kinetics and duration of viral nasal shedding were altered by the presence of SGE. Interestingly, while general trends suggest the co-injection of JEV and SGE led to a lower viral load among tissues in the central nervous system, viremia, clinical signs, and tissue dissemination patterns were not affected. Our results provide us a better understanding of how mosquito saliva modulate the pathogenesis of JEV in its enzootic hosts.

## HUMAN NEURON INFECTION WITH ZIKA VIRUS AND HYBRID IGG4 ANTIBODY RESPONSE TO Aedes Aegypti SALIVARY PROTEINS

**Shanice L'Nae Harris**<sup>1</sup>, Berlin Londono-Renteria<sup>2</sup>

<sup>1</sup>Kansas State University College of Veterinary Medicine, Manhattan, KS, United States, <sup>2</sup>Kansas State University College of Agriculture, Department of Entomology, Manhattan, KS, United States

Zika virus (ZIKV) and Dengue virus (DENV) are arboviruses transmitted by aedes mosquitoes including *Aedes aegypti*. ZIKV has been linked to the development of microcephaly in fetuses of infected pregnant women, along with other serious neurological complications. DENV is endemic in many of the regions affected by ZIKV, and it has been suggested that prior immunity against DENV may have an impact on ZIKV infection. The aim of this study is to determine whether pre-existing DENV antibodies bispecific for viral particles and *Ae. aegypti* salivary proteins act to decrease ZIKV infection of human neuron cells by activating anti-inflammatory pathways or increase infection through antibody dependent enhancement. Our results have shown that IgG antibodies against total *Ae. aegypti* salivary gland extract are much higher in exposed individuals living in DENV endemic areas than in non-exposed samples. In addition, there were fewer antibodies expressing  $\lambda$  light chain in exposed patients, indicating a bias in the immune response that is different than that seen in non-exposed individuals. Neuroblastoma cells infected with ZIKV strain MR-766 (original African strain) in the presence or absence of IgG4 antibodies were used to determine antibody effect on viral entry and replication. We found that

ATP levels were significantly greater in ZIKV infected neurons incubated with IgG antibodies, which correlates with previous studies suggesting that ATP production is increased during ZIKV replication. Thus, our preliminary data suggest there is a role of pre-existing DENV immunity in ZIKV neuronal infection through hybrid antibodies and establish a better understanding of the neurological pathology of this disease.

### MEASUREMENT OF ZIKA VIRUS-SPECIFIC ANTIBODIES USING A MICROSPHERE-BASED COMPETITIVE IMMUNOASSAY

**Erick Perez-Guzman**, Mayuri Sharma, Ralph Braun

*Takeda Vaccines, Inc., Cambridge, MA, United States*

Zika virus (ZIKV) re-emergence and spread into flavivirus (FV) endemic regions have caused sero-diagnostic challenges due to antibody cross-reactivity among the FVs. Currently there are no viral envelope protein-based assays available to quantitatively measure ZIKV-specific antibody responses in individuals with prior FV exposure. Here, we describe the development of a ZIKV-specific competitive microsphere-based immunoassay to support ongoing clinical trials of Takeda's purified inactivated ZIKV vaccine (PIZV) candidate. The assay design allows ZIKV-specific antibodies present in plasma or serum samples to compete with the binding of an anti-ZIKV EDIII monoclonal antibody to a specific epitope on ZIKV virus-like particles that are coupled to Luminex magnetic microspheres. ZIKV-specific antibody levels in the presence or absence of antibodies to other FVs can then be determined in the samples. Human and non-human primate (NHP) sample panels with exposure to different FVs including ZIKV, dengue virus (all 4 serotypes), Yellow Fever virus, Saint Louis Encephalitis virus, West Nile virus, Japanese Encephalitis virus, and Tick-Borne Encephalitis virus were assessed using this assay. The assay quantified ZIKV-specific antibodies in all presumptive or confirmed ZIKV or PIZV-immune samples, while all other FV-immune samples were negative in the assay. Of note, the assay was also able to quantify PIZV-elicited ZIKV-specific antibodies in the presence of cross-reactive antibodies from prior FV vaccination. Collectively, our data suggest that the assay can differentiate ZIKV-specific antibodies from antibodies to other FVs elicited by natural infection or vaccination. Availability of a ZIKV-specific antibody-based immunoassay will improve differential diagnosis, serosurveillance and support development and implementation of ZIKV vaccines in FV endemic regions.

### IMPORTATION OF STAMARIL VACCINE PREVENTED A YELLOW FEVER VACCINE SHORTAGE IN THE UNITED STATES, 2017-2021

**Wayne Hachey<sup>1</sup>**, Gurpreet Kaur<sup>1</sup>, Joanna Korejwo<sup>2</sup>, Andrey Rojas<sup>3</sup>, **Riyadh Muhammad<sup>1</sup>**

<sup>1</sup>*Sanofi Pasteur, Swiftwater, PA, United States*, <sup>2</sup>*Sanofi Pasteur, Lyon, France*, <sup>3</sup>*Sanofi Pasteur, Bogota, Colombia*

In 2017, Sanofi Pasteur experienced an interruption in YF-VAX (Yellow Fever Vaccine) manufacturing, causing a stock-out in the United States (US). Sanofi Pasteur, FDA and CDC agreed to importation of STAMARIL (Yellow Fever Vaccine [Live]), through an Expanded Access IND Program (EAP), to ensure continued availability of yellow fever (YF) vaccine. STAMARIL is prepared by culturing the 17D-204 strain of YF virus in chicken eggs. It is approved in > 100 countries and has a long history of safety and effectiveness with over 600 million doses distributed since 1986. Travel clinics with YF vaccine-certified providers were invited to join the EAP based on location and prior YF-VAX usage. Participation required completion of training, IRB approvals and adherence to protocol requirements, including obtaining informed consent and reporting the following: doses administered, demographic information, suspected adverse reactions, serious adverse events, vaccination during pregnancy and vaccination of women who breastfed infants during the 14 days after vaccination. The EAP began in June 2017, enrolling > 250 US civilian travel clinics as EAP sites. As of June 2020, a total of 609,010 STAMARIL

doses were administered. There have been seven cases of YF vaccine-associated acute neurotropic disease (YEL-AND) and two cases of YF vaccine-associated acute viscerotropic disease reported (reporting rate: 1.1 and 0.3/100,000 vaccinees, respectively), which, with the exception of one case of YEL-AND, all occurred in individuals at increased risk. One vaccinee developed an anaphylactic reaction. No safety concerns were identified from inadvertent vaccine exposure during pregnancy or potential neonatal exposure via breast milk. No case of YF disease has been reported in a returning US traveler during the EAP. The EAP supported the public health need for YF vaccination by making STAMARIL available to travelers during a complete stock-out of the US-licensed YF-VAX. With over 600,000 doses administered, no new safety concerns were identified. Serious adverse reactions remain very rare and consistent with the known safety profile of STAMARIL.

### EVALUATION AND APPLICATION OF NOVEL SEROLOGIC TOOLS FOR ASSESSING ZIKA VIRUS SPECIFIC IMMUNITY FOR SURVEILLANCE AND TRANSLATIONAL RESEARCH

**Teresa C. Smith<sup>1</sup>**, Daniel O. Espinoza<sup>2</sup>, Yerun Zhu<sup>2</sup>, Sylvia Becker-Dreps<sup>3</sup>, Natalie M. Bowman<sup>4</sup>, Srilatha Edupuganti<sup>2</sup>, Alfonso J. Rodriguez-Morales<sup>5</sup>, Jaime A. Cardona-Ospina<sup>5</sup>, Filemon Bucardo<sup>6</sup>, Aravinda M. de Silva<sup>7</sup>, Matthew H. Collins<sup>2</sup>

<sup>1</sup>*Rollins School of Public Health, Emory University, Atlanta, GA, United States*, <sup>2</sup>*The Hope Clinic of the Emory Vaccine Center, Division of Infectious Diseases, Emory University, Decatur, GA, United States*, <sup>3</sup>*Department of Family Medicine and Epidemiology, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*, <sup>4</sup>*Division of Infectious Diseases, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*, <sup>5</sup>*Facultad de Medicina, Fundación Universitaria Autónoma de Las Américas, Pereira, Risaralda, Colombia*, <sup>6</sup>*Department of Microbiology, Faculty of Medical Science, National Autonomous University of Nicaragua, León (UNAN-León), León, Nicaragua*, <sup>7</sup>*Department of Microbiology and Immunology, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States*

Since the Zika epidemic first recognized in Brazil in 2015, transmission of Zika virus (ZIKV) continues to be a global public health threat. Although most ZIKV infections are mild, there is the risk of developing Guillain-Barré syndrome and adverse fetal outcomes from congenital infection. Although RT-PCR testing is available, ZIKV RNA is detectable during a narrow window. Serology can detect recent or remote infections, but traditional assays are complicated by cross-reactive antibodies elicited by other co-circulating flaviviruses like dengue virus (DENV). Thus, there is a critical need for serologic tools for reliable diagnosis and surveillance of ZIKV infection and to better understand protective immunity for vaccine development. We developed a blockade-of-binding (BOB) ELISA using A9E and G9E, two ZIKV envelope protein-binding monoclonal antibodies (mAbs), which are strongly and specifically neutralizing against ZIKV. We assessed BOB diagnostic performance by ROC curve analysis after running a panel of positive and negative control sera, classified by RT-PCR and/or neutralization assays. The A9E BOB ELISA has a sensitivity of 93.5% (95% CI: 79.3,98.9) and specificity 97.8 (95% CI: 92.2,99.6). The G9E BOB ELISA has a sensitivity and specificity of 100% (95% CI: 89.0,100.0) and 100% (95% CI: 95.9,100). We applied these assays to test samples from a cohort in Risaralda, Colombia and found that the assay sensitivity was similar, but specificity was notably reduced (A9E spec: 86%, G9E spec: 66%) due to a high proportion of multitypic DENV immunity. Finally, the assay was applied to samples from participants in a phase 1 RCT for a ZIKV DNA vaccine. Serum samples collected 30-day post-vaccination exhibited significantly less A9E and G9E BOB than those with natural ZIKV immunity (mean BOB % reduction: A9E: -90%, G9E: -94%). We are further testing the hypothesis that A9E and G9E BOB assays may identify a quality of neutralizing antibody response that will correlate with protective immunity against ZIKV and mapping BOB activity for additional ZIKV-neutralizing mAb in these sample sets and sera from an additional ZIKV vaccine trial.

0596

### TRANSFER AND DECAY OF MATERNAL ZIKA EDIII ANTIBODIES IN A BIRTH COHORT FROM NICARAGUA

Omar Zepeda<sup>1</sup>, Daniel Espinoza<sup>2</sup>, Evelin Martinez<sup>1</sup>, Sylvia Becker-Dreps<sup>3</sup>, Elizabeth Stringer<sup>4</sup>, Matthew H. Collins<sup>3</sup>, Filemon Bucardo<sup>1</sup>

<sup>1</sup>Department of Microbiology, Faculty of Medical Science, National Autonomous University of Nicaragua, León UNAN-León, León, Nicaragua, <sup>2</sup>Hope Clinic of the Emory Vaccine Center, Division of Infectious Diseases, Department of Medicine, School of Medicine, Emory University, Decatur, GA, United States, <sup>3</sup>Department of Family Medicine and Epidemiology, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States, <sup>4</sup>Department of Obstetrics and Gynecology, School of Medicine, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

Zika virus (ZIKV) exposure in utero is a cause of birth defects and neurodevelopmental disorders and incident ZIKV infection may also be detrimental to children. The role of antibodies induced upon in-uterus exposure or transferred from mothers to children in early life protection have been barely explored. A longitudinal cohort of 512 pregnant women was established in León, Nicaragua following Zika virus emergence in this country. A proportion of 253 of these women were pregnant mainly during the high Zika circulation (cohort 1) and 259 during low or no Zika circulation (cohort 2). Blood and umbilical cord samples were taken from mothers and their children during delivery. Subsequently, the children were followed up every 3 months up to 12 months. Serological tests based on ELISA to detect anti-ZIKV IgG and anti-ZIKV envelope domain III (Z-EDIII) were performed to investigate antibody transfer and decay over time. A 2-fold OD increased between 3 and 6 and between 6 and 9 months were defined as incident ZIKV infection. There was strong correlation between the maternal blood and cord blood anti-ZIKV and Z-EDIII IgG antibodies ( $p < 0.0001$ ). Also, Z-EDIII IgG is specific for ZIKV, and dengue-elicited antibodies do not bind Z-EDIII. A higher frequency of children (78.8%) from cohort 1 have Z-EDIII antibodies in their cord-blood as compared with 64.7% of children from cohort 2 (OD geometric mean 0.820 vs 0.480,  $p < 0.0001$ ). In cord blood, Z-EDIII IgG OD mean declined from 1.070 in cohort 1 to 0.700 in cohort 2 and from 0.470 and 0.390 in the first three months of life. In the group of children with no Z-EDIII antibodies 22 from cohort 1 and 18 from cohort 2. Incidental ZIKV infections were observed in 27.3% (6/22) of the children in cohort 2 between 6 to 9 month of life, as compared 5.5% (1/18) in the children from cohort 1 between 3 – 6 month of life. This study shows the transplacental transfer of specific antibodies against Zika during the epidemic in Leon, in addition to the decay of these antibodies at 3 months and the increase at 6 to 9 months in almost 1/3 in children with no Z-EDIII antibodies.

0597

### CHARACTERIZING THE IMMUNE RESPONSE TO ZIKA VIRUS USING EPIOTOPE MAPPING, REPORTER VIRUS PARTICLES, AND ANTI-ZIKV ANTIBODIES

Edgar Davidson<sup>1</sup>, J. Charles Whitbeck<sup>1</sup>, Anu Thomas<sup>1</sup>, J. Tabb Sullivan<sup>1</sup>, Ariadna Grinyo<sup>1</sup>, Lewis J. Stafford<sup>1</sup>, Ross Chambers<sup>1</sup>, Aravinda M. de Silva<sup>2</sup>, James E. Crowe<sup>3</sup>, Benjamin J. Doranz<sup>1</sup>

<sup>1</sup>Integral Molecular, Inc., Philadelphia, PA, United States, <sup>2</sup>Department of Microbiology and Immunology, University of North Carolina, Chapel Hill, NC, United States, <sup>3</sup>Vanderbilt Vaccine Center, Vanderbilt University, Nashville, TN, United States

We have characterized the immune response to ZIKV infection and vaccines by epitope mapping over 90 anti-ZIKV MAbs at amino acid-resolution, using a comprehensive ZIKV prM/E library of 672 single alanine mutants expressed in human cells. Published studies include epitopes of MAbs isolated from a Brazilian patient, with a highly neutralizing MAb protective in animal models of ZIKV fetal disease. Epitope locations suggest that some MAbs act by binding across adjacent E proteins, preventing rearrangements necessary for ZIKV infectivity. Mapping also reveals epitopes specific for ZIKV or common to DENV, information that can help

create better vaccines and therapeutics. To provide critical reagents, we developed ZIKV reporter virus particles (RVPs) capable of one round of infectivity, with luminescent or fluorescent readout, and demonstrated reproducible neutralization titer data ( $NT_{50}$  values) across different RVP production lots, volumes, time frames, and laboratories. We have also identified mutations that increased ZIKV RVP budding, which may aid the design and production of anti-ZIKV vaccines, by screening each individual ZIKV library prM/E variant for ZIKV particle budding and infectivity. We also isolated anti-ZIKV MAbs for ZIKV-specific immunodetection, diagnostic applications, and ZIKV neutralization studies. After immunization with DNA and sub-viral particles, and phage library panning with RVPs, we isolated 48 ZIKV-specific conformational MAbs against prM/E, including one that potently neutralized ZIKV RVPs ( $IC_{50}$  45 ng/ml) with a quaternary epitope spanning adjacent E proteins. We have also used ZIKV RVPs to identify cellular receptors and attachment factors that enable ZIKV entry. ZIKV RVPs were tested on our Membrane Proteome Array (MPA), comprising 6,000 unique human membrane proteins individually expressed in live human cells. Known receptors and attachment factors were identified (validating the approach), as well as a number of membrane proteins not previously known to enable ZIKV entry. These newly identified proteins help explain viral tropism and pathogenesis, and may be useful as therapeutic targets.

0598

### ZIKA VIRUS EFFECTS ON CREB3L1 NEUROPROTECTION

Joaris Soto-Hernandez

Ponce Research Institute-Ponce Health Sciences University, Ponce, Puerto Rico, PR, United States

Zika virus (ZIKV) flavivirus can be vertically transmitted and cause congenital Zika syndrome. It reduces the ability of human fetal nerve cells to survive or trigger self-repair mechanisms. Human neural progenitor cells' (hNPCs) ability to induce neuroprotective effects may be affected due to its permissiveness to ZIKV. Up-regulated cAMP responsive element binding protein 3-like 1 (CREB3L1) have been reported in hNPCs, suggesting this neuroprotective pathway is altered in nerve cell survival processes during an infection. CREB3L1 is synthesized endogenously as a membrane-bound precursor outside the nucleus. Later on, gets translocated into the nucleus where it activates transcription of genes encoding cell cycle inhibitors to block proliferation of the cells infected by ZIKV. The objective of our study is to determine the effects a ZIKV infection has on CREB3L1 by evaluating its protein and gene expression levels depending on the cellular compartment location and viability state. SHSY-5Y neuroblastoma cells were infected with ZIKV at a multiplicity of infection (MOI) of 0.1 for 48 hours (h). The gene expression of CREB3L1 pathway was assessed using qRT-PCR and western blot to assess the protein levels. The main mediators of CREB3L1 showed differences in protein expression in the nucleus/cytoplasm compared to controls and no alterations in their RNA levels. However, no alterations were observed in viable cells compared to apoptotic cells in any sample. Preliminary results indicate that a ZIKV infection alters CREB3L1 pathway at a protein level depending on the cellular compartment in ZIKV infected SH-SY5Y cells 48 h post infection. Analyses on protein and RNA levels will be optimized to assess the alteration of the CREB3L1 pathway in a time dependent manner. We will further evaluate CREB3L1 role in SH-SY5Y cells during a ZIKV infection.

### UNIQUE INTERACTIONS BETWEEN VIRAL GENOTYPE AND MOSQUITO POPULATION DETERMINE REGIONAL VARIABILITY IN THE EFFECT OF INCREASED TEMPERATURE ON VECTORIAL CAPACITY OF *CX. PIPPIENS* FOR WEST NILE VIRUS

Rachel L. Fay<sup>1</sup>, Elyse M. Banker<sup>2</sup>, Sean M. Bialosuknia<sup>2</sup>, Kiet A. Ngo<sup>2</sup>, Jessica L. Stout<sup>2</sup>, Laura D. Kramer<sup>2</sup>, Alexander T. Ciota<sup>2</sup>

<sup>1</sup>School of Public Health, University at Albany, Albany, NY, United States,

<sup>2</sup>Wadsworth Center, New York State Department of Health, Albany, NY, United States

Arthropod-borne viruses are associated with over 140 human diseases. The most common arboviruses vectored by mosquitoes are those which belong to the *Flaviviridae* family, including West Nile virus (WNV), Zika virus (ZIKV) and dengue virus. Global temperatures are increasing, which directly impacts arboviruses vectored by ectothermic organisms. There is a correlation between increases in WNV prevalence and increased temperature in New York State, but the extent to which this effect varies among populations and regions is not fully understood. Temperature has been shown to influence blood feeding, fecundity, development, survival and vector competence, yet this influence is variable among *Culex* spp. populations. This variation suggests that there is a genetic basis that drives a heterogeneous relationship among temperature and flavivirus prevalence and that temperature sensitivity will likely be subject to evolutionary pressures with changing environments. The purpose of this study is to assess complex interplay among population-by-genotype-by-environment interactions in NYS. To test that variability in temperature sensitivity exists in naturally occurring populations and among viral strains, two unique *Culex pipiens* populations from upstate and downstate NYS were reared at mean temperatures of 22, 25 or 30°C, mimicking current and future regional means. Life history traits were monitored at each temperature for both populations and vector competence was assessed using representative historic and contemporary WNV strains. This data was used to calculate vectorial capacity of these unique *Cx. pipiens* populations at varying temperatures. Overall, *Culex* populations were found to be unique in their capacity to vector WNV at increased temperature. Accelerated development time and decreased survival were identified at higher temperatures, yet the extent of this effect was population-dependent. Temperature effects on vector competence were also found to be both strain and population-dependent. These differences will likely contribute to regional differences in transmissibility under climate change.

### FLAVIVIRUS SEROPREVALENCE AND CONTINUOUS TRANSMISSION OF WEST NILE VIRUS AMONG FEMALE SEX WORKERS IN SENEGAL BETWEEN 1991 AND 1999

Samantha Gabrielle Morgan<sup>1</sup>, Wen-Yang Tsai<sup>1</sup>, Szu-Chia Hsieh<sup>1</sup>, Donald J. Hamel<sup>2</sup>, Phyllis Kanki<sup>2</sup>, Wei-Kung Wang<sup>1</sup>

<sup>1</sup>Department of Tropical Medicine, Medical Microbiology and Pharmacology, John A. Burns School of Medicine, University of Hawaii at Manoa, Honolulu, HI, United States, <sup>2</sup>Department of Immunology and Infectious Diseases, Harvard T.H. Chan School of Public Health, Boston, MA, United States

West Nile Virus (WNV) is a flavivirus known to circulate in the African continent, including the West African country of Senegal. Seroprevalence studies of WNV have been reported in various animal species, however, the seroprevalence and transmission of WNV in humans remains elusive. We recently used Western blot (WB) analysis containing antigens of 6 flaviviruses (dengue virus serotypes 1 to 4 [DENV1-4], WNV and Zika virus [ZIKV]) to study antibody responses following confirmed flavivirus infections. We found that anti-premembrane (prM) antibodies can discriminate WNV, DENV and ZIKV infections with a sensitivity/specificity of 88.9/96.5%, 89.5/100% and 100/98.6%, respectively (Hsieh et al. submitted). In this current research we employed WB analysis to investigate the seroprevalence of WNV in a previously described female

sex worker cohort in Dakar, Senegal between 1992 and 2004. After initial DENV WB screening of the latest 236 samples, we identified 109 samples that were positive for the cross-reactive flavivirus envelope protein. Further WB analysis with 6 flavivirus antigens revealed 24 WNV infections (21 WNV and 3 WNV/DENV infections), 32 DENV infections, 5 ZIKV infections, and 3 DENV/ZIKV infections. From those 24 WNV infections, previous blood draws 6 to 36 months prior to the latest samples were tested by both WB and WNV virion-IgG ELISA. WB analysis identified 2 seroconversions between 1991 and 1999, which was further confirmed by ELISA. The seroprevalence of WNV in this cohort was 11.0%, and the seroconversion rate was 0.8%. We also noted one possible reinfection with WNV, further implicated by a four-fold increase in WNV antibodies from an endpoint titer experiment. The seroprevalence of DENV and ZIKV were 16.1% and 3.4%, respectively. These findings demonstrate continuous transmission of WNV in humans in Senegal. We intend to test the rest of the samples from each individual for seroconversions and reinfections with other flaviviruses as well.

### EXPERIMENTAL FITNESS EVALUATION OF THE MAIN WEST NILE VIRUS GENOTYPES IN THE UNITED STATES USING REVERSE GENETICS

Chantal Vogels<sup>1</sup>, Joseph Fauver<sup>1</sup>, Anderson Brito<sup>1</sup>, Cole Jensen<sup>1</sup>, Nicholas Huston<sup>2</sup>, James Weger-Lucarelli<sup>3</sup>, Ryan Smith<sup>4</sup>, Marc Suchard<sup>5</sup>, Nathaniel Matteson<sup>6</sup>, Karthik Gangavarapu<sup>6</sup>, Kristian Andersen<sup>6</sup>, Rohit Sharma<sup>7</sup>, Doug Brackney<sup>7</sup>, Philip Armstrong<sup>7</sup>, Nathan Grubaugh<sup>1</sup>

<sup>1</sup>Yale School of Public Health, New Haven, CT, United States, <sup>2</sup>Yale University, New Haven, CT, United States, <sup>3</sup>Virginia Polytechnic Institute and State University, Blacksburg, VA, United States, <sup>4</sup>Iowa State University, Ames, IA, United States, <sup>5</sup>University of California, Los Angeles, CA, United States, <sup>6</sup>The Scripps Research Institute, La Jolla, CA, United States, <sup>7</sup>The Connecticut Agricultural Experiment Station, New Haven, CT, United States

Following the initial introduction of West Nile virus in New York in 1999, the virus rapidly emerged and spread across the United States. Evolution may be at least partially responsible for the rapid expansion and subsequent outbreaks, but this process is not well defined. Even the strongest current evidence for West Nile virus adaptation, the displacement of the original genotype (NY99) by locally derived genotypes (WN02 and SW03), requires further investigation. Here, we aimed to investigate if the West Nile virus genotypes WN02 and SW03 may have displaced the original NY99 genotype due to vector- or host-specific transmission advantages. The commonly cited hypothesis is that the emergence and spread of West Nile virus in the United States was facilitated by adaptation to local mosquito vectors. A key reason why there is a discrepancy in comparing the mosquito transmission potential between NY99 and WN02 is likely because previous studies have used different West Nile virus isolates. While all of these studies provided valuable information about West Nile virus fitness, it is difficult to discern the impact of any single amino acid substitution. Therefore, our approach was to use reverse genetics to engineer the genotype-defining amino acid substitutions (WN02: E-V159A; SW03: NS4A-A85T and NS5-K314R) into a NY99 West Nile virus infectious clone to examine their phenotypic impacts in *in vitro* and *in vivo* transmission models. Examining transmission phenotypes within mosquito and avian model systems allows us to understand the role of evolution during spread and establishment of West Nile virus.

### FORECASTING MUTATIONS OF CONCERN: A SURVEY OF SARS-COV-2 INTRA-HOST VIRAL DIVERSITY ACROSS THE NCBI SEQUENCE READ ARCHIVE DATA

Matthew A. Conte<sup>1</sup>, Ashley Thommana<sup>2</sup>, Irina Maljkovic Berry<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States,

<sup>2</sup>Montgomery Blair High School, Silver Spring, MD, United States

Despite increased sequencing and surveillance of SARS-CoV-2 across the world, timely prediction of the emergence and spread of novel variants of concern remains a great challenge. Thus, development of tools that can give an early warning of sudden increases in variant prevalence remains a high priority. The amount of publicly available SARS-CoV-2 raw whole genome sequencing datasets has become extremely large. As of April 2021, over 500,000 raw genome sequencing runs are publicly available in the NCBI SRA repository. We sought to survey these data for intra-host mutations of concern and explore if any patterns may predict emerging mutations of concern. We developed a bioinformatics pipeline using kmer methods to relatively quickly and efficiently screen the large number of samples in the NCBI SRA to retrieve samples that contained intra-host mutations belonging to the lineages of concern. Comparing across months revealed that certain mutations of concern surge in frequency as intra-host variants just prior to or while lineages of concern arose. For instance, we detected that the N501Y mutation that is nearly fixed in the B.1.1.7, P.1, and B.1.351 lineages of concern was present as a minor variant in a high number of samples in October 2020 (834 samples). This coincides with timing of the first detected samples within the B.1.1.7 and B.1.351 lineages. Our analysis detected another mutation, L452R, which is nearly fixed in the B.1.429 and B.1.427 lineages of concern was present as a minor variant in 68 samples in September 2020 prior to the rise of the B.1.429 and B.1.427 lineages in late 2020. Other clinically important mutations such as E484K, were not detected as minor variants prior to the emergence of this mutation in several lineages of concern. Detecting increases in intra-host minor variant prevalence prior to their increase on the consensus global levels might provide an early forecast, thus giving additional time to adjust public health policies and control measures prior to variant spread, as well as providing additional time for testing of phenotypic/functional changes these mutations might induce.

### VALIDATION OF MACHINE LEARNING MODELS FOR OUTCOME PREDICTION IN LASSA FEVER PATIENTS USING THE LARGEST RETROSPECTIVE CLINICAL DATASET AVAILABLE TO DATE

Kelsey M. Butler<sup>1</sup>, Christopher Iruolagbe<sup>2</sup>, Kelly Iraoyah<sup>2</sup>, Mercy Dic-Ijiewere<sup>2</sup>, Alexander Okonkwo<sup>2</sup>, Mojeed Rafiu<sup>2</sup>, Peter Akhiden<sup>2</sup>, Cyril Eramah<sup>2</sup>, Ephraim Ogbaini<sup>3</sup>, Bridget Chak<sup>4</sup>, Ikponmwosa Odiya<sup>3</sup>, Sylvanus Okogbenin<sup>5</sup>, Meike Pahlman<sup>6</sup>, Beate Becker-Ziaja<sup>6</sup>, Danny Asogun<sup>3</sup>, Christian Happi<sup>7</sup>, George Akpede<sup>8</sup>, Stephan Günther<sup>6</sup>, Pardis Sabeti<sup>9</sup>, Peter Okokhere<sup>2</sup>, Andres Colubri<sup>1</sup>

<sup>1</sup>University of Massachusetts Medical School, Worcester, MA, United States, <sup>2</sup>Department of Medicine, Irrua Specialist Teaching Hospital, Irrua, Nigeria, <sup>3</sup>Institute of Lassa fever Research and Control, Irrua Specialist Teaching Hospital, Irrua, Nigeria, <sup>4</sup>Broad Institute of MIT and Harvard, Cambridge, MA, United States, <sup>5</sup>Department of Obstetrics and Gynaecology, Irrua Specialist Teaching Hospital, Irrua, Nigeria, <sup>6</sup>Bernhard Nocht Institute for Tropical Medicine, Hamburg, Germany, <sup>7</sup>Department of Biological Sciences, Redeemer's University, Ede, Nigeria, <sup>8</sup>Department of Paediatrics, Irrua Specialist Teaching Hospital, Irrua, Nigeria, <sup>9</sup>Harvard University, Department of Organismic and Evolutionary Biology, Cambridge, MA, United States

Recent Lassa fever (LF) outbreaks of increasing severity in Nigeria highlight the need for reproducible data-driven methods to inform better control and treatment. We present a retrospective, observational cohort study that validates prognostic models using the largest LF patient dataset to

date, collected at the Irrua Specialist Teaching Hospital (ISTH), in Edo State, Nigeria, during standard clinical care. Data includes demographic information, clinical symptoms, vital signs, laboratory results, and treatment interventions for patients who tested positive for LASV with RT-PCR and were admitted to ISTH from 2016 to 2020. Of 727 patients enrolled in the study, 620 patients with known outcome (died or survived) were included in the analysis. The median age was 30 years and 39.19% (243/620) were female. The overall case-fatality rate was 18.54% (115/620). Age was strongly predictive of mortality, with a 1.42 increase in risk for each 10 years of age ( $p < 10^{-5}$ ). The complications most associated with adverse outcome were bleeding (odds ratio [OR] 10.16,  $p < 10^{-5}$ ) and renal failure (OR 3.36,  $p < 10^{-5}$ ). We trained several models on data collected at ISTH between 2011 and 2013, comprising 284 cases with known outcome. Predictor variables in these models were selected under the premise that physicians order laboratory tests to investigate two distinct clinical scenarios: (1) inflammation and end organ damage and (2) electrolyte imbalances. The two best performing models use age, severe central nervous system symptoms, and bleeding as clinical predictors together with creatinine and aspartate aminotransferase in model 1, and creatinine and potassium in model 2. The accuracy on the new 2016-2020 validation data is comparable to the accuracy on the 2011-13 training data: 87% vs 83% for model 1 and 83% vs 82% for model 2. Other performance measures (AUC, sensitivity, specificity) show a similar trend. The prediction threshold can be adjusted according to the clinical requirements for sensitivity and specificity. Our results support the use of these models as validated tools for risk stratification and could be further improved by recalibration on the new data.

0604

### GETTING READY FOR THE NEXT EBOLA OUTBREAK: A PREPAREDNESS TOOL TO PREDICT THE EFFECTS OF CONTACT TRACING, CASE ISOLATION, AND SAFE BURIAL CEREMONIES

Aliou Boubou<sup>1</sup>, Henri Christian Obama<sup>2</sup>, Kristina Barbara Helle<sup>3</sup>, Kristan Alexander Schneider<sup>2</sup>

<sup>1</sup>AIMS-Cameroon, Limbe, Cameroon, <sup>2</sup>Hochschule Mittweida University of Applied sciences, Mittweida, Germany, <sup>3</sup>Merseburg University of Applied Sciences, Merseburg, Germany

Ebola outbreaks in West Africa in 2014 followed by those Uganda and DRC in 2016 challenged the global health community. Ebola virus disease (EVD) is a severe zoonotic filovirus infection caused by viruses of the genus Ebolavirus, with the Zaire Ebola Virus (ZEBV) being the deadliest species. EVD is one of the deadliest known viral infections, with a fatality rate that varied between 25%-90% in the past outbreaks. Ebola spreads by smear infections and is most contagious in the late stage of the infections, the corps of deceased individuals remain highly infectious. During the initial phase of an epidemic, public health-emergency management needs to respond swiftly, in the absence of reliable epidemiological data and adequate treatment and vaccination infrastructure. Preparedness tools such as predictive models help to support decision-making by assessing the impact of potential control interventions. In the case of EVD, contact tracing and systemic isolation of infected individuals from the general population have been the cornerstone of the surveillance strategies with the aim to curtail its spread at the early stage of the epidemic. Since the major outbreak of 2014, different models have been developed to predict the impact of different control interventions, e.g., case isolation, contact tracing, assuming different transmission scenarios, e.g., safe and unsafe burial ceremonies. However, the combination of these interventions and scenarios has not been comprehensively studied. Here, we use an extended SEIR model to study the effect on the spread of EVD accounting for combinations of different control interventions and transmission scenarios. Novel to the model is its realistic response dynamics, that eliminates the naïve exponentially-distributed waiting times that typically lead to inaccurate quantitative predictions. We illustrate the model using parameters obtained from the literature (from the West African and DRC outbreaks), for a range of intervention scenarios. The results suggest that the effect of case isolation is substantially improved by combining isolation with contact tracing and safe funeral ceremonies.

## IMMUNOLOGICAL EVALUATION AND COMPARISON OF DIFFERENT CACHE VALLEY VIRUS VACCINE CANDIDATES

Victoria B. Ayers<sup>1</sup>, Yan-Jang S. Huang<sup>1</sup>, Alain Kohl<sup>2</sup>, James I. Dunlop<sup>2</sup>, So Lee Park<sup>1</sup>, Stephen Higgs<sup>3</sup>, Dana L. Vanlandingham<sup>1</sup>

<sup>1</sup>Department of Diagnostic Medicine and Pathobiology, College of Veterinary Medicine, Kansas State University, Manhattan, KS, United States, <sup>2</sup>MRC-University of Glasgow Centre for Virus Research, Glasgow G12 8QQ, United Kingdom, <sup>3</sup>Biosecurity Research Institute, Kansas State University, Manhattan, KS, United States

Cache Valley virus (CVV; genus *Orthobunyavirus*, family *Peribunyaviridae*), first isolated in Cache Valley, Utah in 1956, is now enzootic throughout the New World. Although transmission of CVV occurs through an enzootic cycle including more than 30 species of competent arthropod vectors, serological evidence has indicated white-tailed deer as the amplification host for the virus in nature. Whilst CVV is primarily known to cause severe disease in pregnant ruminants resulting in abortions, fetal malformations, and embryonic lethality, it has also been recently recognized for its expansion as a zoonotic pathogen. Other viruses in the bunyamwera serogroup are thought to be of minimal concern. However, during an outbreak of Rift Valley fever virus, Ngari virus was found to have infected some of the goats being tested, and Oropouche virus, has been responsible for febrile disease outbreaks in Central and South America. With this increased emergence of bunyaviruses with human and veterinary health importance, there have been significant efforts dedicated to the development of bunyavirus vaccines. In this study, immunogenicity of a CVV vaccine candidate based on the deletion of NSs and NSm genes was evaluated and compared to a vaccine candidate created through the inactivation of CVV using binary ethylenimine with the addition of an aluminum hydroxide adjuvant in sheep. Immunization of 20 sheep with one of the two vaccine candidates was performed followed by two booster immunizations. Plaque reduction neutralization test was then used to monitor the development of neutralizing antibodies elicited by each vaccine candidate. The development of a vaccine for ruminants could lead to less human exposure and a platform for CVV and other emerging bunyaviruses that have already or could potentially cause future outbreaks.

## ENSEMBLE MACHINE LEARNING METHOD AS A HIGH ACCURACY APPROACH TO COVID-19 SIMULATION

Dmytro Chumachenko<sup>1</sup>, Ievgen Meniailov<sup>1</sup>, Megan W. Howard<sup>2</sup>, Kseniia Bazilevych<sup>1</sup>, Lyubov Makhota<sup>3</sup>, Tetyana Chumachenko<sup>4</sup>

<sup>1</sup>National Aerospace University Kharkiv Aviation Institute, Kharkiv, Ukraine, <sup>2</sup>Battelle, Columbus, OH, United States, <sup>3</sup>Kharkiv Regional Laboratory Center of the Ministry of Health of Ukraine, Kharkiv, Ukraine, <sup>4</sup>Kharkiv National Medical University, Kharkiv, Ukraine

The COVID-19 pandemic shows that only timely implemented scientifically based measures can stop it. Mathematical modeling is an effective tool for studying the epidemic process. However, models suffer from low accuracy and are short-term in nature. Ensemble machine learning methods help optimize predictive models by combining several base models of epidemic processes. Different modeling approaches have different disadvantages, but their combined use makes it possible to eliminate these drawbacks. We used ensemble machine learning models to see if we could improve the accuracy of COVID-19 morbidity forecasting using data provided by the Coronavirus Resource Center of John Hopkins University & Medicine. The result was a cluster analysis method grouping countries based on similar COVID-19 morbidity characteristics, forecasting COVID-19 morbidity for each group using neural network, and combining the results into one country database. For clusterization we developed a neural network with 60 input neurons, 100 hidden neurons with Fermi activation function, and 4 output neurons. For forecasting, a neural network was built with 6 pairs of layers Dense with an activation function ReLu and 64 neurons, a layer Dropout and the last layer Dense with one output, RMSProp method as optimizer and Mean Squared Error as error function.

The final ensemble machine learning model was realized using Python programming. Employing ensemble machine learning model, we improved the accuracy of the forecast of COVID-19 morbidity to 98.11% compared to other models with accuracy of 85.12% (compartment models) or 87.30% (machine learning based models). High accuracy forecasting will improve the investigation of short-term dynamics and long-term trends of COVID-19 epidemic processes. In turn, this will allow for timely implementation of scientifically grounded measures to decrease COVID-19 dynamics. These results indicate that ensemble machine learning is useful tool for understanding the main drivers of COVID-19 dynamics and may better inform decision-making processes to prevent new waves of morbidity and deterioration of the epidemic situation.

## COVID-19 SEROSURVEYS IN MASSACHUSETTS: CALL FOR ACTION

Raquel A. Binder<sup>1</sup>, Catherine S. Forconi<sup>1</sup>, Gavin F. Fujimori<sup>1</sup>, Amanda Higgins<sup>1</sup>, Virginia Mangolds<sup>1</sup>, Thomas Nixon<sup>1</sup>, Leandro DeSouza Silva<sup>1</sup>, Priya Saikumar Lakshmi<sup>1</sup>, Quishi Tang<sup>1</sup>, Boaz Odwar<sup>1</sup>, Stephanie Fischinger<sup>2</sup>, Caroline Atyeo<sup>2</sup>, Lisa Cavacini<sup>3</sup>, John Haran<sup>1</sup>, Galit Alter<sup>4</sup>, Ann M. Moormann<sup>1</sup>

<sup>1</sup>UMass Medical School, Worcester, MA, United States, <sup>2</sup>Ragon Institute of MGH, MIT, and Harvard, Cambridge, MA, United States, <sup>3</sup>MassBiologics at UMass Medical School, Worcester, MA, United States, <sup>4</sup>Ragon Institute of MGH, MIT, and Harvard, Cambridge, MA, United States

Seroprevalence studies (i.e. serosurveys) are essential public health tools that help determine the extent of an infectious disease outbreak and map its distribution among specific populations. COVID-19 serosurveys are particularly important, because (i) they capture asymptomatic infections, which are thought to account for 40-45% of all SARS-CoV-2 infections, and (ii) they indicate the level of existing immunity among affected populations. We implemented a laboratory developed test (LDT) that measures IgM, IgG and IgA antibodies by ELISA against the SARS-CoV-2 Spike Receptor Binding Domain (RBD) to determine the seroprevalence among health care workers (HCW) and return-to-work employees (RTW) at the University of Massachusetts Medical School. We enrolled and collected blood from 553 HCWs between April 27 and June 4, 2020 and 335 RTWs between Aug 3 and Aug 6, 2020. Our initial findings based on RBD IgG antibody levels, which is the most specific compared to PCR-confirmed cases, found a 14.1 % and 5.3 % seropositivity among HCWs and RTWs, respectively. The correlation between IgG and IgA levels was modest ( $r=0.4$ , Spearman Correlation,  $p<0.0001$ ), supporting other studies that have shown divergent development of IgA in lieu of IgG for this respiratory infection. In contrast, IgM was the least sensitive and specific as a serosurveillance metric. As expected, we found that the overall positivity was higher among HCWs who were at higher risk of SARS-CoV-2 exposure as compared to employees who had been working remotely. This LDT ELISA has also been adapted for nucleocapsid and spike trimer protein in order to compare the sensitivity and specificity of each antigen and isotype, alone and in combination. In summary, we found that most of the HCWs and RTWs who enrolled in our study did not have antibodies to RBD, emphasizing the need for vaccines in order to reach population-wide immunity. This study shows that it is possible for academic medical centers to rapidly deploy LDTs and contribute to public health surveillance strategies for COVID-19.

0608

### UTILIZATION OF A PRIMER-TEMPLATE MISMATCH APPROACH FOR PCR-BASED IDENTIFICATION OF TWO CRITICAL SPIKE MUTATIONS IN THE SARS-COV-2 VARIANT B.1.1.7

Qiuying Cheng, Ivy Hurwitz, Alexandra V. Yingling, Amber Castillo, Douglas J. Perkins

Center for Global Health, Department of Internal Medicine, University of New Mexico Health Sciences Center, Albuquerque, NM, United States

Severe acute respiratory syndrome coronavirus 2 (SARS-CoV-2) is the pathogenic agent for coronavirus disease 2019 (COVID-19), an acute respiratory disease that threatens human health and public safety. The spike protein on the virus surface plays a key role in the pathogenesis of COVID-19. During the COVID-19 pandemic, SARS-CoV-2 viruses have acquired mutations in the spike protein gene and other parts of its genome, giving rise to many new lineages/variants. The B.1.1.7 variant was first identified in the United Kingdom and is currently reported in 94 countries, as well as being dominant in the US due to its 59~74% increase of transmissibility. Among nine mutations (two deletions and seven non-synonymous mutations) in the spike gene of B.1.1.7, del HV 69-70, N501Y, and P681H impact the 3D structure of the protein and its interaction with the host receptor, ACE2, and neutralizing antibodies. Like del YY 144-145, A570D, T716I, S982A and D1118H, del HV 69-70 has not been detected in any other SARS-CoV-2 variants. Using a primer-template mismatch approach, we developed PCR assays (conventional PCR and SYBR Green-based quantitative PCR) that effectively identify del HV 69-70 and N501Y, two critical spike mutations in B.1.1.7. Further optimization of reverse transcriptase quantitative PCR (RT-qPCR) conditions will enable us to detect B.1.1.7 variants without the need for Next Generation Sequencing (NGS). Although NGS is recognized as the gold standard for identifying new SARS-CoV-2 variants, this platform may not be readily available and practical for enhanced temporal monitoring to detect new variants, especially in resource-challenged settings. Therefore, application of the RT-qPCR assays for clinical samples can greatly facilitate the detection of B.1.1.7 variants.

0609

### IDENTIFICATION OF SARS-COV-2 RNA IN STILLBIRTHS AND NEONATAL DEATH CASES IN BANGLADESH

Mustafizur Rahman<sup>1</sup>, Muntasir Alam<sup>1</sup>, M Ishrat Jahan<sup>1</sup>, Afruna Rahman<sup>1</sup>, Kyu Han Lee<sup>2</sup>, Shafina Jahan<sup>1</sup>, Sanwarul Bari<sup>1</sup>, Emily S. Gurley<sup>2</sup>, Shams El Arifeen<sup>1</sup>

<sup>1</sup>icddr, Dhaka, Bangladesh, <sup>2</sup>Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States

Since the COVID-19 pandemic began, the toll of SARS-CoV-2 in human lives has been extraordinary. Studies reveal that age is by far the strongest predictor of the risk of dying- with older adults at the highest risk and children usually spared from severe disease. Knowledge regarding the effects of SARS-CoV-2 infection on fetuses and neonates is very limited. Child Health and Mortality Prevention Surveillance (CHAMPS) aims to understand the causes of stillbirths and under-five deaths in sub-Saharan Africa and South Asia. Laboratory diagnosis (post-mortem specimen - blood, CSF, nasopharyngeal swabs, lung tissue), verbal autopsy, and clinical data from each death are reviewed by an expert panel (DeCoDe) to determine the cause of death. From September 2020 to March 2021, a total of 62 cases from stillbirths and deceased neonates were retrospectively tested using real-time RT-PCR for SARS-CoV-2 N- and RdRp-genes. Of those, four nasopharyngeal swabs were positive, including three early neonates (2-4 days) and one late neonate (8 days). Among other specimens, three blood, two CSF, and one lung tissue were positive. Overall, 6 (9.7% of 62 with all specimens tested) cases had at least one specimen positive. Five of the six positive cases were detected during January-February 2021. Positive cases included two stillbirths, three early neonatal and one late neonatal death. Most of the positive specimens showed Ct values >30, indicating a very low viral load. However, the late

neonate was positive for all specimens tested, and the NPOP sample had the lowest Ct value (Ct=14.1). The spike gene sequence analysis revealed its similarity with the Wuhan D614G variant. One of the cases had gone through the DeCoDe, and SARS-CoV-2 was decided to be the co-morbid factor. CHAMPS project has a unique opportunity to relate microbiological findings with histopathological changes and thus explore the association of SARS-CoV-2 with child death and manage COVID-19 infected children during the early days of life.

0610

### THE PRESENTATION OF INFLUENZA AND CLINICAL SEVERITY IN KAMPHAENG PHET HOSPITAL, THAILAND

Darunee Buddhari<sup>1</sup>, Kanyarat Phutthasopit<sup>1</sup>, Sopon Iamsirithaworn<sup>2</sup>, Pornsopit Nuansalee<sup>3</sup>, Krotchakorn Surangkamaneesin<sup>3</sup>, Chonticha Klungthong<sup>1</sup>, Aaron R. Farmer<sup>1</sup>, Anthony R. Jones<sup>1</sup>, Stefan Fernandez<sup>1</sup>

<sup>1</sup>Department of Virology, USAMD-AFRIMS, Bangkok, Thailand,

<sup>2</sup>Department of Disease Control, Ministry of Public Health, Nonthaburi,

Thailand, <sup>3</sup>Kamphaeng Phet provincial hospital, Kamphaeng Phet, Thailand

Influenza is clinically indistinguishable from other respiratory viruses. The department of Virology, USAMD-AFRIMS has conducted influenza surveillance from April 2012 to present. The demographic and clinical data then nasal and throat swabs were collected to identify Flu A (pdmH1 and H3) and Flu B influenza subtypes and measured by cycle-to-threshold (Ct) value. This presentation analyzed the clinical and laboratory findings of different severities of influenza. We enrolled 2,136 subjects, of which 906 (42.4%) tested positive for influenza by RT-PCR from April 2012 to March 2021. Among these, the median age was 8.6 years (range from 6 months-72 years), 53.5% were male. Fever duration from onset until presentation at hospital was 1.9 days (range from 0 to 5 days). Influenza severity is classified into upper (URI) and lower (LRI) respiratory infection by either chest x-ray findings or clinical diagnosis; 89.1% of subjects were diagnosed with an URI. RT-PCR those samples: 36.7% were Flu B, 32.2% were Flu A/H3, 30.7% were Flu A/pdmH1, and 0.4% were Flu A and Flu B co-infections. The data were analyzed and compared between groups by non-parametric statistics. The baseline age and gender did not differ between groups ( $p = 0.116$  and  $0.089$ ). The fever duration was significantly different ( $p < 0.05$ ) at 1.9 days in URI and 2.4 days in LRI. The overall Ct values of upper and lower respiratory diagnosis were significantly different ( $p < 0.05$ ) at 20.5 [8.4, 36.7] and 23.7 [14.3, 35.6] respectively. Specifically, the URI and LRI Ct values of Flu B were 18.4 [8.4, 34.9] and 21.6 [14.3, 32.7], Flu A/H3 were 19.2 [10.1, 34.0] and 22.3 [14.3, 33.6], and Flu A/pdm H1 were 24.5 [15.9, 36.7] and 26.5 [19.6, 35.6] respectively. There were significant Ct value differences between the URI and LRI for each subtype at  $p < 0.05$ . URIs had significantly shorter fever duration and lower Ct values in all subtypes than LRIs, which suggests that nasal and throat swabs may be more appropriate to measure upper respiratory tract viral infection than the lower ones. These findings could potentially be utilized in formulating control strategies for emerging disease such as SARS-CoV-2 in the near future.

### CHARACTERIZING THE HUMORAL RESPONSE OF A RECOMBINANT SUBUNIT EBOLA VIRUS VACCINE IN NON-HUMAN PRIMATES

Aquena Ball, Teri Wong, Chih-Yun Lai, Albert To, Axel Lehrer

University of Hawaii at Manoa, Honolulu, HI, United States

Ebola virus (EBOV) causes lethal hemorrhagic fevers with case fatality rates of up to 90%. Outbreaks are sporadic and unpredictable and vaccination has been a much awaited tool to controlling spread of disease. However, due to limited stocks of approved vaccines and requirement of stringent and ultra-cold cold-chain storage, there is a need to continue developing new, more practical vaccine candidates. Although all vaccine candidates use the surface glycoprotein as the main antigen, the modality by which protection is induced by the EBOV glycoprotein remains unclear. We have

developed a recombinant subunit vaccine that combines an increased safety profile with excellent thermostability, allowing easier deployment in endemic regions. Our vaccine has shown full protection in non-human primates, however, we have yet to fully characterize the immune responses elicited by our vaccine with a focus on identifying correlates of protection. Subunits of the EBOV glycoprotein (GP) have been produced in *Drosophila* S2 cells including full length GP, GP $\Delta$ mucin-like domain, GP1, GP1 and sGP. These subdomains were used to characterize the binding fractions of antibodies elicited by our GP subunit vaccine. The various Ebola GP subunits were used in a multiplex immunoassay format and detect antibody populations from non-human primate sera. Approximate concentrations of antibody fractions in sera binding to individual subunits were calculated. We found more consistent humoral responses in NHPs receiving 3 doses over 2 as well as a shift towards stronger binding of the GP $\Delta$ mucin-like domain one year after immunization. Ongoing analysis focuses on samples from NHPs immunized with EBOV GP + adjuvant that will be analyzed to differentiate the pre-challenge antibody binding patterns to the different EBOV subdomains. These binding patterns will be compared to neutralization titers and survival data to reveal subdomains that are more protective. This can be used to guide further vaccine development and provide insights into correlates of protection that are still unknown for filoviruses.

### RESOURCE CONSTRAINTS IN AN EPIDEMIC: A GOAL PROGRAMMING AND MATHEMATICAL MODELLING FRAMEWORK FOR OPTIMAL RESOURCE SHIFTING IN SOUTH AFRICA

Saadiyah Mayet, Ian Durbach, Sheetal Silal  
*University of Cape Town, Cape Town, South Africa*

The COVID-19 pandemic has had devastating consequences across the globe, and has led many governments into completely new decision making territory. As such, developing models which are capable of producing realistic projections of disease spread under extreme uncertainty has been paramount for supporting decision making on many levels of government. In South Africa, this role has been fulfilled by the South African COVID-19 Modelling Consortium's generalised Susceptible-Exposed-Infectious-Removed compartmental model, known as the National COVID-19 Epi Model. This project adapts and contributes to the Model; its primary contribution has been to incorporate the notion of limited capacity, which allows for a more holistic and accurate picture of the resource-scarce context of a pandemic. This project further designs and implements a goal programming framework to shift ICU beds amongst districts in a way that aims to minimise deaths caused by the non-availability of ICU beds. The results showed a drastic decrease in lives lost when ICU beds were shifted under various scenarios. Although there are limitations to the scope and assumptions of this study, it demonstrates that it is possible to combine mathematical modelling with optimisation in a way that may save lives through optimal resource allocation.

### PREDOMINANCE OF SARS-COV-2 B.1.1.7 AND B.1.351 VARIANTS IN METRO MANILA, PHILIPPINES

John Mark S. Velasco<sup>1</sup>, Ma. Theresa Valderama<sup>2</sup>, Paula Corazon Diones<sup>2</sup>, Susie Leonardia<sup>2</sup>, Chonticha Klungthong<sup>1</sup>, Khajohn Joonlasak<sup>1</sup>, Wudtichai Manasatienkij<sup>1</sup>, Piyawan Chinnawirotpisan<sup>1</sup>, Angkana Huang<sup>1</sup>, Anthony Jones<sup>1</sup>, Stefan Fernandez<sup>1</sup>  
<sup>1</sup>USAMD-AFRIMS, Bangkok, Thailand, <sup>2</sup>USAMD-AFRIMS, Manila, Philippines

The first case of the SARS-CoV-2 B.1.1.7 variant was detected from a returning Filipino who arrived at the Philippines on 7 January 2021 and y March 2021, B.1.1.7, B.1.351, and P.1 variants were detected with local transmission of the B.1.1.7 and B.1.351 variants. Here, we report the molecular evolution of SARS-CoV-2 in the Philippines and document viral lineages and introductions events into the country. NP/OP swabs

were collected at the V Luna Medical Center from April 2020-April 2021. PCR testing was done at the VLMC Molecular Laboratory or the AFP-AFRIMS Collaborative Molecular Laboratory. SARS-CoV-2 positive samples were sequenced at the AFP-AFRIMS Collaborative Molecular Laboratory and at the Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand using Illumina Iseq100 or MiSeq. Reference mapping was performed by BWA-MEM aligner using Wuhan-Hu-1 genome sequence (NC\_045512.2) as the reference sequence. Primer regions trimming and call variants (Q  $\geq$ 25) were performed using iVar v.1.2.2 and samtools, respectively. Consensus sequences were generated by iVar v.1.2.2 (Q  $\geq$ 25 and depth of coverage  $\geq$ 10). Gaps, deletion, and ambiguous bases were identified and confirmed by genome-guided assembly with the reference sequence using Trinity v2.8.5 and Sanger sequencing. Lineage and clade were determined using Pangolin v.2.3.8, GISAID clade nomenclature, and phylogenetic analysis. We used MEGA 7.0 to examine nucleotide and amino acid substitutions. All tools were run with default parameters. A total of 77 SARS-CoV-2 genome sequences were generated. Our data shows multiple introduction events into the country. All of the sequenced samples from March-April 2021, were either B.1.1.7 or B.1.351 variants which provides evidence of sustained community transmission of these variants. The surge of COVID-19 cases starting early March in the National Capital Region and surrounding provinces may be explained by the increasing prevalence of these variants in addition to the relaxation of quarantine measures, increased mobility of the population and lower compliance with health standards concurrent with the opening up of the economy.

Sensitive diagnostic tests and the identification of targets for vaccine development are fundamental to fight against infections. The significance of humoral responses is multi-faceted. Antibodies do not only play an important role in combating a wide range of infectious diseases but can also be utilized for serology. Hence, a comprehensive analysis of humoral responses can ultimately uncover novel target antigens of protective immune responses and disease-specific biomarkers for the development of innovative serological tests. High-density peptide arrays can display large numbers of antigen proteins translated into overlapping peptides. Antibody responses to linear and conformational epitopes can rapidly be analyzed yielding high and low immunogenic specific epitopes. As examples, we chose SARS-CoV-2, HEV and *Plasmodium* infections to conduct extensive epitope mappings for antigen characterization and biomarker discovery. Profiling epitope-specific antibody responses of COVID-19 patients with mild versus life-threatening disease progression revealed significant epitope reactivities associated with severe COVID-19.

The herein identified epitopes may serve as serological markers able to discriminate severe from mild disease courses. In case of *Plasmodium* infections, we analyzed the antibody responses of individuals from malaria-endemic areas to better characterize epitopes associated with naturally acquired immunity. The results show distinct antibody patterns according to immune status of infected individuals. For HEV, we discovered common immunogenic regions in patients that clearly distinguish infected from non-infected individuals. The corresponding peptide epitopes can potentially serve as starting points for peptide based diagnostic tests. In conclusion, high content peptide microarrays are an ideal tool for the identification of reliable epitope-based biomarkers for infectious diseases. The discovery of novel linear or conformational epitopes can lead to the development of future multiplex serological assays and novel vaccine candidates.

### GENOMIC SURVEILLANCE OF HUMAN CORONAVIRUSES SARS-COV-2 AND 229E AT THE UNIVERSITY OF MARYLAND CAMPUS

**Irina Maljkovic Berry**<sup>1</sup>, Filbert Hong<sup>2</sup>, Hye Kyung Chung<sup>1</sup>, Sheldon Tai<sup>2</sup>, Marcus Chibucos<sup>1</sup>, Jennifer German<sup>2</sup>, Christian Fung<sup>1</sup>, Oluwasanmi Adenaiye<sup>2</sup>, Yu Yang<sup>1</sup>, Jianyu Lai<sup>3</sup>, Jun Hang<sup>1</sup>, Barbara Albert<sup>2</sup>, Donald K. Milton<sup>2</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States, <sup>2</sup>University of Maryland School of Public Health, Institute of Applied Environmental Health, College Park, MD, United States, <sup>3</sup>University of Maryland School of Public Health, Department of Epidemiology and Biostatistics, College Park, MD, United States

SARS-CoV-2 pandemic has led to a renewed interest in the spread of seasonal human coronaviruses, as the latter may give insights into the patterns of SARS-CoV-2 transmission. We investigated genomic epidemiology of human coronavirus 229e collected from cohorts of students on the University of Maryland College Park (UMD) campus two consecutive years prior to the SARS-CoV-2 pandemic, in 2018 and 2019, as well as genomic epidemiology of SARS-CoV-2, collected June-October 2020 from students, faculty, staff and members of surrounding communities. We performed phylogenetic analyses of the UMD SARS-CoV-2 and 229e full genomes, and the S gene for 229e, in combination with reference genomes. Coronavirus 229e analyses indicated at least two separate introductions of the virus, all resulting in successful spread to three or more individuals within the student cohorts. Epidemiological information revealed eight contacts, confirming all 2018 genomic connections, and confirming five connections in 2019. Genomic clustering indicated that the six remaining individuals also belonged to the same 2019 cluster, thus pointing to missing epidemiological links. SARS-CoV-2 analyses indicated five separate introductions, with two of the introductions resulting in clusters of four or more individuals. A major cluster comprising of nine individuals sampled in Sept-Oct 2020 also contained a Maryland reference genome sampled in early November. The genetic and spatiotemporal proximity of these genomes would suggest that the single additional genome may be a previously unreported case belonging to the same epidemiological cluster. Our analyses show that both 229e and SARS-CoV-2 coronaviruses are continuously introduced onto the UMD campus. Furthermore, we show how genomic epidemiology may aid in identification of missing epidemiological links.

### IMPACT OF THE COVID-19 PANDEMIC ON THE INCIDENCE OF DENGUE IN PERU

**Virgilio E. Failoc-Rojas**<sup>1</sup>, Rubi Plasencia-Dueñas<sup>2</sup>, Jorge G. Cordova-Hernandez<sup>1</sup>

<sup>1</sup>Universidad Peruana Cayetano Heredia, Lima, Peru, <sup>2</sup>Universidad Nacional Pedro Ruiz Gallo, Lambayeque, Peru

Dengue is a mosquito-borne viral infection endemic in our country. The world is currently mobilizing to respond to the 2019 coronavirus

pandemic (COVID19) caused by Severe Acute Respiratory Syndrome type 2 coronavirus (SARSCoV2). Both viruses coexist in dengue-endemic countries, so it is important to take the necessary preventive measures to control the spread of both diseases. This study aims to compare the temporal pattern of dengue incidences before and during the COVID-19 pandemic in Peru. An ecological study was undertaken. Time series analysis was performed. Incidence was estimated by t-student with variance correction. Poisson regression was applied to obtain dengue incidence rates before and during the COVID-19 pandemic. Dengue cases increases during the COVID-19 pandemic in all of Peru. Higher incidence rates in Huánuco (IRR= 58.3), Ica (IRR= 53.93) and Ucayali (IRR= 30.66), except in Piura (IRR=0.7). The highest increase in dengue cases per million population was in Ucayali (393.38), Tumbes (233.19), Ica (166.08), and Loreto (129.93). The slope of dengue cases was positive in all endemic regions during the COVID19 pandemic in Peru. In conclusion, the number of dengue cases per million increased during the COVID19 pandemic throughout Peru and in several of the endemic regions, except in Piura, where it was found to have decreased. The dengue incidence rate has increased during the COVID19 pandemic in all dengue-endemic regions in Peru.

### EVALUATION OF FTA CARDS FOR THE PRESERVATION OF YELLOW FEVER VIRAL RNA FOR ENHANCED MOLECULAR DIAGNOSTICS

**Emily Davis**, Jason Velez, Brandy Russel, Amy Lambert, Aaron Brault, Holly Hughes

Centers for Disease Control and Prevention, Fort Collins, CO, United States

Yellow fever virus (YFV) is a flavivirus that frequently causes outbreaks of hemorrhagic fever in Africa and South America and is considered a reemerging public health threat. Accurate diagnosis of YFV is critical as one confirmed case constitutes an outbreak and results in the initiation of mass vaccination campaigns. Highly sensitive and specific molecular diagnostics have been developed; however, these assays require cold chain transport to prevent the degradation of viral RNA. Maintaining a cold chain can be problematic in YFV endemic regions. In this study, we investigated FTA cards as an alternative stabilization method of YFV RNA for use with molecular diagnosis. These cards are an attractive addition to clinical diagnostic protocols as RNA is extracted from punches made in the sample area leaving the unpunched area for replicate testing. Although RNA yield from a single 9mm FTA card punch was significantly less than the gold standard of RNA extracted directly from a contrived specimen, pooling RNA extracted from two FTA punches improved the limit of detection to a level comparable to that of the gold standard. In experiments addressing the ability of FTA cards to stabilize YFV RNA over time, RNA was stable on cards held at room temperature for up to four weeks. Even more promising, YFV RNA was detectable on cards held at 37°C from 2.1 days to over three weeks depending on viral input. These results support that utilization of FTA cards, which are cost effective and easy to use, could improve YFV molecular diagnostics by preserving viral RNA in situations where cold chain is not available.

### HEMOGLOBINOPATHIES AND MEROZOITE SURFACE PROTEIN-2 GENE POLYMORPHISMS ARE NOT ASSOCIATED WITH ACQUISITION OF EPSTEIN BARR VIRUS IN CHILDREN BELOW THREE YEARS OF AGE IN WESTERN KENYA

**Perez Kola**<sup>1</sup>, Shehu Awandu<sup>1</sup>, Elly O. Munde<sup>2</sup>, Samuel B. Anyona<sup>3</sup>, Evans Raballah<sup>4</sup>, Asito S. Amolo<sup>5</sup>, Sidney Ogolla<sup>5</sup>, Caroline Ndege<sup>7</sup>, Clinton Onyango<sup>7</sup>, Douglas J. Perkins<sup>8</sup>, Collins Ouma<sup>9</sup>

<sup>1</sup>Department of Biomedical Sciences, School of Health Sciences, Jaramogi Oginga Odinga University of Science and Technology, Bondo, Kenya, <sup>2</sup>Department of Clinical Medicine, School of Health Science, Kirinyaga University, Kerugoya, Kenya, <sup>3</sup>Department of Medical Biochemistry, School of Medicine, Maseno University, Maseno, Kenya, <sup>4</sup>Department of

Medical Laboratory Sciences, School of Public Health Biomedical Sciences and Technology, Masinde Muliro University of Science and Technology, Kakamega, Kenya, <sup>5</sup>Department of Biological Sciences School of Biological, Physical, Mathematics and Actuarial Sciences, Jaramogi Oginga Odinga University of Science and Technology, Bondo, Kenya, <sup>6</sup>CASE Western University, Kenya, Kenya Medical Research Institute, Kisumu, Kenya, <sup>7</sup>University of New Mexico-Kenya Global Health Programs, Kisumu and Siaya, Kenya, <sup>8</sup>Center for Global Health, University of New Mexico, Albuquerque, NM, United States, <sup>9</sup>Department of Biomedical Sciences and Technology, School of Public Health and Community Development, Maseno University, Maseno, Kenya

Endemic Burkitt's Lymphoma (eBL) is a pediatric cancer associated with morbidity and mortality among children resident in holoendemic *Plasmodium falciparum* regions, such as western Kenya. *P. falciparum* infections share a causal link with Epstein Barr virus (EBV) infection. Moreover, *P. falciparum* has exerted a strong selection pressure on sickle cell trait, alpha ( $\alpha$ )-thalassemia, glucose-6-phosphate dehydrogenase (G6PD), and merozoite surface protein 2 (MSP-2) genes to confer reduced malarial disease severity. The current study investigated the impact of polymorphisms in those genes on susceptibility to EBV in children (aged 0-36 months, n=81) resident in western Kenya enrolled into a longitudinal study. Clinical, demographic, and sample collection was performed at enrolment and 6 mos. post-enrollment. Bivariate regression analyses revealed that carriage of sickle cell trait (SCT, HbAA),  $\alpha$ -thalassemia heterozygosity, and G6PD mutations [Mahidol (487G>A)/Coimbr (C592T), the Viangchan (871G>A)/Chinese (1024C>T) and the Canton (1376G>T)/Kaiping (1388G>A)] were not associated with acquisition of EBV either before or after 6 mos. of age. Additional bivariate analysis of infants <6 mos. of age illustrated that exposure to either 3D7 ( $p=0.921$ ) or FC27 ( $p=0.914$ ) MSP-2 alleles was not protective against EBV acquisition. Exposure to the MSP-2 alleles (3D7, FC27, or both) in children aged  $\geq 6$  months also had no impact on EBV acquisition ( $p=0.108$ ;  $p=0.754$ ;  $p=0.357$ , respectively). In conclusion, results presented here show that variation in SCT,  $\alpha$ -thalassemia, G6PD variants, and exposure to MSP-2 (FC27, 3D7) had no impact on susceptibility to EBV in children from this holoendemic region of western Kenya.

0619

#### DIAGNOSIS OF MALARIA IN CAMEROON: A NEED FOR ADDRESSING NON-FALCIPARUM MALARIA!

Loick Pradel Kojom Foko<sup>1</sup>, Francine Dorgelesse Kouemo Motse<sup>2</sup>, Lugarde Kamgain Mawabo<sup>3</sup>, Veena Pande<sup>4</sup>, Vineeta Singh<sup>1</sup>

<sup>1</sup>ICMR-National Institute of Malaria Research, New Delhi, India,

<sup>2</sup>Department of Medical Laboratory Sciences, Faculty of Health Sciences, University of Buea, Buea, Cameroon, <sup>3</sup>Laboratoire Sainte Therese, Douala, Cameroon, <sup>4</sup>Department of Biotechnology, Faculty of Sciences, Kumaun University, Bhimtal, India

*Plasmodium falciparum* (Pf) is commonly thought as the dominant malaria species in sub-Saharan Africa (sSA) countries. However, recent studies reported high prevalence of yet neglected non-falciparum species in Cameroon, which are still largely understudied in the country. The performances of a commonly used Pf-detecting rapid diagnostic test (RDT) were determined in 355 symptomatic individuals aged 1-65 years living in the town of Douala. The RDT reliability was evaluated using light microscopy (LM) as gold standard method. Polymerase chain reaction (PCR) of the *Plasmodium* 18S gene was performed for samples for which results between LM and RDT were discordant (i.e., False negative-RDT-/LM+, and False positive-RDT+/LM-). The PCR amplicons of non-falciparum species were sequenced and BLASTed. The sensitivity and specificity of Pf-detecting RDT was 94.0 % and 66.7 %, respectively. Thirty discordant results between LM and RDT were found viz. 25 LM+/RDT-, and 5 LM- / RDT+. The 18S PCR analysis for the 25 RDT-/LM+ samples revealed that 5 and 20 were positive for *P. ovale curtisi* (PoC) and Pf, respectively. All PoC cases were found in children below five years as mono-infections. Regarding the five RDT+/LM- samples, PCR was negative for all human

malaria species. PoC sequences were found to be phylogenetically closer to sequences reported from China-Myanmar border and Malaysia. This is the first report on molecular characterization of *P. ovale* subspecies in Cameroon. The study also outlines the good diagnostic performances of the Pf-detecting RDT. However, the presence of PoC in false negative RDT results highlights a need to pay attention non-falciparum species for a better management of malarious patients in Cameroon.

0620

#### HIGH PREVALENCE OF SUBMICROSCOPIC MALARIA INFECTION IN PEOPLE LIVING WITH HIV/AIDS ON ART AND COTRIMOXAZOLE PROPHYLAXIS IN FAKO DIVISION, SOUTH WEST REGION OF CAMEROON

Kwenti Emmanuel Tebit, Fru G. Mbah-Mbole, Ntasin V. Nyuybini, Mbigha G. Ghogomu

University of Buea, Buea, Cameroon

Malaria and HIV coinfection is common in sub-Saharan Africa (SSA). However, epidemiological surveys using light microscopic detection of the malaria parasites frequently report prevalence lower than that of the general population. Studies suggest that the lower prevalence of malaria among people living with HIV/AIDS (PLHIV) could be attributed to the ART and cotrimoxazole prophylaxis they are routinely on. However, studies using molecular diagnostic methods to detect malaria parasites in PLHIV are also not readily available. This study was designed to compare light microscopy and PCR in the detection of malaria parasites in PLHIV and on ART and cotrimoxazole prophylaxis in Fako Division of Cameroon. PLHIV were enrolled from selected HIV treatment centers in Fako Division, Southwest region of Cameroon. Screening for malaria parasites was done using microscopic examination of Giemsa-stained blood films. And the results were confirmed by multiplex PCR. In all, 404 samples were analyzed, from 315 (78.0%) females and 89 (22.0%) males. A majority (84.2%) of the participant were on first line ART and all (100%) were on cotrimoxazole prophylaxis. Of the 404 participants, 7 (1.7%) and 82 (20.3%) were positive for malaria parasites by light microscopy and multiplex PCR respectively. The mean ( $\pm$ SD) parasite density was 191.57 $\pm$ 159.51 parasites/ $\mu$ l. The prevalence of submicroscopic malaria parasites was therefore 19.1% (77/404). All (100%) the positive cases by light microscopy and confirmed by PCR, were *Plasmodium falciparum*. Meanwhile PCR detected 51 (62.2%) *P. falciparum*, 9 (11.0%) *P. malariae* and 13 (15.9%) *P. falciparum* + *P. malariae* coinfection. This study revealed a high prevalence of submicroscopic malaria parasites in the target population. The findings have significant epidemiological implications and warrants the need for the evaluation of current malaria diagnostic protocols in PLHIV and on treatment

0621

#### DETECTION OF MALARIA AS A MAJOR CAUSE OF ACUTE FEBRILE ILLNESS: FINDINGS FROM AN ACUTE FEBRILE ILLNESS SURVEILLANCE ACTIVITY IN TWO URBAN HEALTH FACILITIES IN LIBERIA

Madeline R. Farron<sup>1</sup>, Elijah Paa Edu-Quansah<sup>2</sup>, Amanda Balish<sup>1</sup>, G. Burgess Gbelee Jr<sup>3</sup>, Terrence Lo<sup>1</sup>, Daniel W. Martin<sup>1</sup>, Gulu Gwesa<sup>4</sup>, Denise Roth Allen<sup>4</sup>, Maame P. Amo-Addae<sup>2</sup>, Ashaba Davis<sup>5</sup>, John B. Dogba<sup>3</sup>, Fahn M. Taweh<sup>3</sup>, Lekilay Tehmeh<sup>6</sup>, Thelma V. Nelson<sup>7</sup>, Diabe Dore<sup>8</sup>, Williamatta S. Williams-Gibson<sup>9</sup>, Michael Aidoo<sup>1</sup>, Darwin J. Operario<sup>10</sup>, Jie Liu<sup>10</sup>, Eric Houpt<sup>10</sup>, Adam L. Cohen<sup>1</sup>, Marta A. Guerra<sup>1</sup>, Mamadou O. Diallo<sup>4</sup>, Desmond Williams<sup>4</sup>

<sup>1</sup>US Centers for Disease Control & Prevention, Atlanta, GA, United States,

<sup>2</sup>African Field Epidemiology Network, Monrovia, Liberia, <sup>3</sup>National Public Health Reference Laboratory of Liberia, Charlesville, Liberia, <sup>4</sup>US Centers for Disease Control & Prevention, Monrovia, Liberia, <sup>5</sup>African Field Epidemiology Network, Kampala, Uganda, <sup>6</sup>Ministry of Health of Liberia, Monrovia, Liberia, <sup>7</sup>National Public Health Institute of Liberia, Monrovia,

Liberia, <sup>8</sup>Star of the Sea Health Centre, Monrovia, Liberia, <sup>9</sup>Redemption Hospital, Monrovia, Liberia, <sup>10</sup>University of Virginia, Charlottesville, VA, United States

Malaria is endemic in Liberia and transmission occurs year-round. We sought to understand the contribution of malaria as a cause of Acute Febrile Illness (AFI) through expanded laboratory testing for *Plasmodium* species in an AFI surveillance program at two health facilities in Monrovia, Liberia. We recruited patients with measured temperature of  $\geq 37.5^{\circ}\text{C}$  or self-reported fever within the past seven days. Malaria Rapid Diagnostic Tests (RDTs) or microscopy were performed on suspicion of malaria. We collected blood samples for analysis using real-time polymerase chain reactions in the TaqMan Array Card (TAC) format at Liberia's National Public Health Reference Laboratory. We enrolled 1,506 patients (12/2018-3/2020), including 398 (26%) pregnant women. 1,039 (69%) patients were assessed by RDT, 276 (18%) by microscopy, and 191 (13%) were not tested for malaria at the clinical site. No patients received both RDT and microscopy. All patients' samples were tested via TAC. In total, 987 (65%) patients were positive for malaria by any test (RDT, microscopy, or TAC): 602 had a positive RDT, 178 had positive microscopy results, and TAC detected *Plasmodium* in 670 patients. Among the TAC-detected cases, *P. falciparum* represented 93% (622/670). TAC detected 95 cases of *Plasmodium* that were RDT negative, 35 cases that were microscopy negative, and 68 cases among patients who did not receive RDT or microscopy. 338 (85%) pregnant patients were positive for malaria by any test. In conclusion, malaria was a common cause of AFI in two urban health facilities in Monrovia, Liberia. The use of TAC led to the identification of an additional 198 cases of malaria, which were missed in clinical care. The high detection of malaria among pregnant women points to the need for additional prevention efforts, especially given the potential adverse effect of infection on pregnancy and outcomes of pregnancy. Finally, in areas with known malaria circulation, implementation of an AFI surveillance program with PCR testing of all acutely febrile patients can complement ongoing surveillance efforts and clinical testing to provide a better understanding of the full burden of malaria.

0622

#### MORPHOLOGY-BASED AUTOMATED MICROSCOPY MALARIA TEST TO OVERCOME THE LIMITATION OF HRP2 RDT IN THE REGION OF A HIGH PREVALENCE OF HRP2 DELETION IN ETHIOPIA, GONDAR

Hyemi Park<sup>1</sup>, Lise Carlier<sup>1</sup>, Wossenseged Lemma<sup>2</sup>, Hans-Peter Beck<sup>1</sup>, Cristian Koepfli<sup>3</sup>, Dongyoung Lee<sup>1</sup>

<sup>1</sup>Noul, Yongin-si, Republic of Korea, <sup>2</sup>Gondar University, Gondar, Ethiopia, <sup>3</sup>University of Notre Dame, Notre Dame, IN, United States

HRP2-based malaria rapid diagnostics tests (mRDTs) are widely used due to their accessibility, short time consuming, and straightforward interpretation in resource-poor settings. On the other hand, microscopic diagnosis has been relatively less used than mRDTs in these settings mostly because it requires skillful technicians, laboratory facility and local quality control. A high prevalence of parasites with *pfhrp2/3* deletion has been observed in many malaria-endemic countries leading to false-negative test results when using HRP2 based RDTs. These deletions raise concerns that patients will not be given appropriate medication and treatment on time. According to the world malaria report 2020, *Pfhrp2/3* deletions were confirmed in 11 countries, including Ethiopia. Particularly in these regions, mRDTs may have limitations to detect *Plasmodium falciparum* with the mutation. Therefore, examination of morphology is needed for accurate diagnosis and appropriate medication. Here, we suggest miLab, an automated sample preparation with an artificial intelligence image analyzing platform, with the result of the study conducted in Ethiopia. We recently (December 2019 to January 2020) undertook a malaria diagnostic study comparing different diagnostic methods in an area of a high risk of malaria transmission in Gondar, Ethiopia. Samples were collected at Maraki Health Clinic. A total of 157 patients were screened, and 104 were enrolled during the given period of time. 18 samples were *P. falciparum* positive, and 86 were negative. As a result, mRDTs showed

61.11% of sensitivity, while miLab showed 94.44%. This result illustrates the possibility of a high prevalence of *Pfhrp2/3* deletion in Gondar region. Thus, there is a limitation of using mRDTs in these settings. Unlike mRDTs, miLab diagnostic platform identifies *Plasmodium* species based on cell morphology, just like standard microscopy which is the gold standard. Therefore, it allows accurate diagnosis of *P. falciparum* parasite regardless genetic mutation such as *Pfhrp2/3* deletion. This research provide a useful insight into the paradigm shift in our understanding of malaria elimination.

0623

#### CASE REPORT: IDENTIFICATION OF PLASMODIUM VIVAX INFECTION IN RWANDA

Jessica N. McCaffery<sup>1</sup>, Douglas Nace<sup>1</sup>, Aline Uwimana<sup>2</sup>, Naomi Lucchi<sup>1</sup>, Eric S. Halsey<sup>1</sup>, Eric Rogier<sup>1</sup>

<sup>1</sup>Malaria Branch, Division of Parasitic Diseases and Malaria, Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Malaria and Other Parasitic Diseases Division, Rwanda Biomedical Center, Kigali, Rwanda

Although all four human malaria *Plasmodium* species are present in Africa, the World Health Organization estimates that *Plasmodium falciparum* accounts for approximately 99% of symptomatic infections on the continent. *Plasmodium vivax* is commonly found in the Horn of Africa and Madagascar but has not been reported in Rwanda since a single case was confirmed in a traveler returning to Japan in 2005. This current study reports a PCR-confirmed case of *P. vivax* in a 49-month old boy from Masaka, Rwanda. The child was initially recruited as part of an antimalarial therapeutic efficacy study conducted in 2018 after presenting to his community health center with symptomatic malaria. He had a hemoglobin level of 10.2 mg/dL and was diagnosed with *P. falciparum* malaria with a parasite density of 14,200 p/μl by microscopy. He was administered antimalarial treatment with artemether-lumefantrine, and a dried blood spot was collected at enrollment and later sent to the US Centers for Disease Control and Prevention for laboratory analysis. Multiplex malaria antigen detection assay revealed the sample to have no HRP2 present but a positive signal for *P. vivax* lactate dehydrogenase. DNA was extracted from this sample and subjected to photo-induced electron transfer-PCR and Snounou nested PCR assays to verify *Plasmodium* species. Both PCR assays revealed the sample to be positive for *Plasmodium* genus and *P. vivax*, but no amplification was observed for *P. falciparum*, *P. malariae*, or *P. ovale*. Current malaria surveillance efforts in Rwanda are mainly focused on detecting *P. falciparum*, *P. malariae*, and *P. ovale* since *P. vivax* has not been considered a possibility due to the high proportion of Duffy negative individuals in the country. Because *P. vivax* infection requires radical cure with an 8-aminoquinoline such as primaquine to prevent relapse, additional evaluations to determine if *P. vivax* is being transmitted in Rwanda should be considered.

0624

#### PRELIMINARY VALIDATION OF A NOVEL POINT-OF-CARE HAEMOZOIN ASSAY (GAZELLE™) FOR RAPID DETECTION OF PLASMODIUM KNOWLESI MALARIA IN SABAH, EAST MALAYSIA

Angelica F. Tan<sup>1</sup>, Priyaleela Thota<sup>2</sup>, Sitti Saimah B. Sakam<sup>3</sup>, Timothy William<sup>4</sup>, Bridget E. Barber<sup>5</sup>, Giri S. Rajahram<sup>3</sup>, Nicholas M. Anstey<sup>1</sup>, Anne Rocheleau<sup>2</sup>, David Bell<sup>2</sup>, Matthew J. Grigg<sup>1</sup>

<sup>1</sup>Menzies School of Health Research, Global Tropical Health Division, Casuarina, Australia, <sup>2</sup>Hemex Health, Portland, OR, United States, <sup>3</sup>Infectious Diseases Society Kota Kinabalu, Sabah, Malaysia, <sup>4</sup>Clinical Research Centre, Queen Elizabeth Hospital, Ministry of Health, Sabah, Malaysia, <sup>5</sup>Menzies School of Health Research, Charles Darwin University, Casuarina, Australia

The zoonotic parasite, *Plasmodium knowlesi*, is the dominant cause of human malaria in Sabah, Malaysia. Rapid and accurate diagnosis allows for effective clinical management. In Malaysia, microscopy is the first-line point-of-care (POC) malaria detection method, however misidentification

of *P. knowlesi* with other endemic species occurs. The Gazelle™ (Hemex Health, USA) is a rapid and innovative POC malaria diagnostic device utilising Magneto-Optical Detection for hemozoin, a pigment by-product found in all *Plasmodium* species infections. A pilot phase enrolled 40 patients with positive *P. knowlesi* microscopy to refine the Gazelle™ detection algorithm. The main analysis of diagnostic accuracy will include a further 100 cases and 50 febrile malaria-negative controls. All samples will have *Plasmodium* species PCR conducted. A limit of detection (LoD) analysis will be conducted on a subset of samples serially diluted with non-infected whole blood. The completed pilot phase demonstrated a sensitivity of 95% (38/40; 95% CI 83.1 - 99.4). Ongoing main analysis has enrolled 58 *P. knowlesi* microscopy-positive patients and 16 febrile controls. The median age is 43 years (range 4 - 87) with a geometric mean parasitaemia of 1078/μL (95% CI 694 - 1673). The sensitivity and specificity of the Gazelle™ against reference microscopy was 94.8% (55/58; 95% CI 85.6 - 98.9) and 100% (95% CI 81.5 - 100) respectively. Overall test accuracy (area under receiver operating curve) is 97.4% (95% CI 94.5 - 100). Positive and negative predictive values were 100% (95% CI 93.5 - 100), and 85.7% (95% CI 63.7 - 97.0) respectively. Of those tested prior to antimalarial treatment ( $n=31$ ; 53%), test sensitivity was 100% (95% CI 88.8 - 100). Sensitivity for samples tested with parasitaemia of  $<500/\mu\text{L}$  ( $n=16$ ) was 81.3% (95% CI 54.4 - 96.0), with the lowest parasitaemia detected of 34/μL. The average calculated LoD is 77 parasites/μL ( $n=7$ ; range 4 - 267). Updated results from main analysis will be presented at the ASTMH meeting. The Gazelle™ is a potential *in situ* alternative tool for rapid and sensitive detection of *P. knowlesi* by healthcare workers in remote endemic areas.

0625

#### DELETIONS IN HRP2 GENE IN PLASMODIUM FALCIPARUM ISOLATES IN BENIN

<sup>1</sup>UMR261 MERIT, IRD, Cotonou, Benin, <sup>2</sup>Centre d'Etude et de Recherche sur le Paludisme Associé à la Grossesse et à l'Enfance (CERPAGE), Faculté des Sciences de la Santé (FSS), Cotonou, Benin

Malaria Rapid Diagnosis Tests (RDTs) are specific, sensitive, easy to use and affordable. As a result, RDTs became a major tool for detection of *P. falciparum* infections. Most of the RDTs are based on the immune-detection of PfHRP2, a parasitic protein detectable in host's blood samples. If any deletion appears in *pfhrp2* gene, then, PfHRP2 protein is not expressed and so the infection is not detected using PfHRP2 based RDTs (false negative). To our knowledge, no data have been published on *pfhrp2* deletions in Benin, a West African country where malaria accounts for 40% of outpatient consultations and 25% of all hospital admissions. In this study, we have investigated *pfhrp2* deletions in isolates from a rural village in the south of Benin collected from February to March 2020. Out of 471 samples positive by PCR for *P. falciparum*, 241 have shown discordances between RDTs and PCR results (RDT-/PCR+). Discordance can be explained by a higher sensitivity of the PCR compare to RDT or by the absence of PfHRP2 expression by the parasites. Twenty-one of the 471 *P. falciparum* isolates (4.5%) had at least one deletion in *pfhrp2* gene representing 8.7% of the discordant samples. A majority (95.2% (20/21)) of the deletions were detected during submicroscopic infections whereas submicroscopic infections represented only 55% (259/471) among all infections. This study describes, for the first time, the presence of *pfhrp2* deletions in *P. falciparum* isolates in Benin. Not detected, those infections would not be treated and probably contribute to a large dissemination of the deletion. Isolates presenting deletions in *pfhrp2* gene may therefore represent a reservoir of infection not documented up to now in Benin. It has been described in the literature that the prevalence of *pfhrp2* deletions can vary depending on the geographical area. We will complete this work performing similar studies in other locations in Benin. Documenting the

distribution of *pfhrp2* deletions and the dynamic of its expansion is a priority until new tools for *P. falciparum* diagnostic are accessible in the field.

#### DELETIONS OF THE PFHRP2 AND PFHRP3 GENES IN A HIGH PERCENTAGE OF PLASMODIUM FALCIPARUM INFECTIONS: DJIBOUTI CITY, DECEMBER 2019 TO MARCH 2020

Eric Rogier<sup>1</sup>, Jessica McCaffery<sup>1</sup>, Mohamed Ali<sup>2</sup>, Camelia Herman<sup>1</sup>, Doug Nace<sup>1</sup>, Sophie Jones<sup>1</sup>, Ira Goldman<sup>1</sup>, Michael Aidoo<sup>1</sup>, Ghasem Zamani<sup>3</sup>, Venkatachalam Udhayakumar Udhayakumar<sup>1</sup>, Jane Cunningham<sup>4</sup>

<sup>1</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>Hôpital Général Peltier, Djibouti City, Djibouti, <sup>3</sup>World Health Organization, Djibouti City, Djibouti, <sup>4</sup>World Health Organization, Geneva, Switzerland

Malaria rapid diagnostic tests (RDTs) detecting the *Plasmodium falciparum* histidine-rich protein 2 (HRP2) antigen have been instrumental in expanding access to appropriate malaria diagnosis in many countries throughout the world. Reports on deletions of the *pfhrp2* (and parologue *pfhrp3*) genes have caused great concern in the African continent where *P. falciparum* causes significant morbidity and mortality. Recently, *pfhrp2* deletions have been reported in the horn of Africa including Eritrea, Ethiopia, Somalia, Sudan, and Djibouti. This current study examined 1,002 dried blood spot (DBS) samples collected as part of WHO investigation of possible *pfhrp2* deleted parasites in Djibouti city. DBS from persons presenting with malaria-like illness to Hôpital Général Peltier in Djibouti City from December 2019-March 2020 were evaluated for *Plasmodium* antigens by multiplex bead assay and for presence of *P. falciparum* infection by PCRs. Of all DBS, 44 (4.4%) were found to be *P. vivax* single-species infections, and 311 (31.0%) were from persons infected with *P. falciparum*. All 311 *P. falciparum* DNA positive (Pf+) samples had *pfhrp2* and *pfhrp3* (*pfhrp2/3*) genotyping performed to identify presence or absence of these two genes. The *pfmsp1* and *pfmsp2* single-copy control genes were amplified from 291 (95.7%) of the Pf+ samples and *pfhrp2/3* genotypes reported: 37 (12.5%) a genotype of *pfhrp2+/pfhrp3+*, 51 (17.2%) a genotype of *pfhrp2+/pfhrp3-*, 5 (1.7%) a genotype of *pfhrp2-/pfhrp3+*, and 203 (68.6%) a double-deletion genotype of *pfhrp2-/pfhrp3-*. Reductions in concentration of HRP2/3 antigens were seen in DBS samples with corresponding deletions in the *pfhrp2* and/or *pfhrp3* genes. Analysis of microsatellite markers to determine parasite relatedness with *P. falciparum* in surrounding countries is ongoing. *P. falciparum* with deletions in both *pfhrp2* and *pfhrp3* genes are highly prevalent in Djibouti City; this finding has recently led to a change in national malaria diagnostic strategy.

#### VALIDATION STUDY OF A NEW POINT-OF-CARE HEMOZOIN BASED MALARIA DIAGNOSTIC DEVICE GAZELLE™ IN INDIA

Anil Kumar Verma<sup>1</sup>, Priyaleela Thota<sup>2</sup>, Madhav Patel<sup>1</sup>, Digvijay Shah<sup>1</sup>, Shweta Srivas<sup>1</sup>, Praveen K. Bharti<sup>1</sup>

<sup>1</sup>National Institute of Research in Tribal Health, Jabalpur, India, <sup>2</sup>Hemex Health, Portland, OR, United States

Malaria diagnosis is a challenge in resource poor settings. The current field diagnostic tools such as microscopy and RDT have limitations. Although inexpensive, microscopy is labor intensive, time consuming, requires skilled personnel and has poor sensitivity and specificity in routine use, especially for low parasitemia. While RDTs provide quick results, easy handling and storage, they cannot reliably detect low density parasitemia and sensitivity is variable by malaria species and *hrp2* deletion. Previously, we tested the performance of a hemozoin based point-of-care malaria diagnostic device Gazelle, in comparison to microscopy, RDT and PCR. The performance of the device was on par with microscopy and showed higher specificity than RDTs. The device is rapid, rugged, battery operated, easy-to-use and can be employed in regions with malaria parasites with *hrp2/3* deletion. However, it has been limited by its ability to detect only

malaria positive versus malaria negative cases. This creates an extra burden wherein both *Plasmodium falciparum* and *P. vivax* are prevalent and require different treatment regimens. To further improve and validate the algorithm to identify the presence of *P. falciparum* and *P. vivax* species, we are conducting a validation study at three study sites in India: Sheopor (Madhya Pradesh), Jagdalpur (Chhattisgarh) and Udaipur (Rajasthan). To date, screening of 11,322 febrile patients has resulted in enrolment of 1,699 patients. Of the 1,699 febrile patients, a total of 345 patients were malaria positive by both microscopy and RDT. The PCR analysis of 1,373 samples yielded 509 malaria positive cases. Most of the malaria cases were caused by *P. falciparum* (63%) followed by *P. vivax* (18%), *P. falciparum* + *P. vivax* (14.5%), *P. falciparum* + *P. malariae* (2%), other mixed (1.7%) and *P. malariae* (0.4%). The comparative analysis with PCR as gold standard and improvisation in algorithm is currently ongoing, and the results will be presented at the conference.

### IMPROVING THE COMPETENCE OF MALARIA MICROSCOPISTS THROUGH BASIC MALARIA DIAGNOSTIC REFRESHER TRAINING, MADAGASCAR, 2019-2021

**Omega Raobela**<sup>1</sup>, Renion Saye<sup>2</sup>, Pharath Lim<sup>2</sup>, Sandy M. Ralisata<sup>1</sup>, Daouda Ndiaye<sup>3</sup>, Lennie B. Kyomuhangi<sup>2</sup>, Julie Buekens<sup>2</sup>, Jocelyn Razafindrakoto<sup>4</sup>, Catherine Dentinger<sup>5</sup>, Laurent Kapesa<sup>4</sup>, Stephane M. Rabearimanana<sup>6</sup>, Ralinoro Fanomezantsoa<sup>6</sup>, Tovonahary A. Rakotomanga<sup>6</sup>, Yves Marie Bernard<sup>2</sup>, Jehan Ahmed<sup>2</sup>, Arsane C. Ratsimbaoa<sup>7</sup>

<sup>1</sup>PMI Impact Malaria, Antananarivo, Madagascar, <sup>2</sup>PMI Impact Malaria, Washington, DC, United States, <sup>3</sup>Department of Parasitology and Mycology, Cheikh Anta Diop University, Dakar, Senegal, <sup>4</sup>US Presidential Malaria Initiative, Antananarivo, Madagascar, <sup>5</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>6</sup>National Malaria Control Program, Antananarivo, Madagascar, <sup>7</sup>Faculty of Science, University of Antananarivo, Antananarivo, Madagascar

High quality microscopy remains the reference method for malaria diagnosis and allows for parasite detection (PD), parasite species identification (ID), and parasite count (PC). In Madagascar, where *Plasmodium falciparum*, *vivax*, *ovale* and *malariae* all exist, microscopists have limited skills due to a lack of malaria microscopy (MM) training, validated malaria species slides for practicing, and adequate supervision. To improve MM quality, PMI Impact Malaria supported the Government of Madagascar to conduct ten, five-day basic malaria diagnostic refresher trainings (bMDRT) from August 2019 to March 2021. Trainings included didactic and practice sessions on microscope maintenance, slide preparation, staining and reading, and quality assurance. Improvement was measured by comparing pre- and post-test scores on a written exam and by assessing competency in reading validated malaria slides. In line with WHO-defined proficiency levels, we aimed for participants to achieve scores of at least 80% for PD and ID and at least 40% for PC. A total of 188 microscopists completed one five-day training; microscopists from all 22 regions of the country were represented. The mean written test score increased pre to post from 33% (range, 8-100%) to 57% (range, 8-100%). Slide reading average scores increased from 70% (range, 0-100%) to 88% (range, 29-100%) for PD, 43 (range, 0-91%) to 60% (range, 9-100%) for ID, and 15% (range, 0-100%) to 30% (range, 0-100%) for PC. A total of 149 (79%), 39 (21%), and 67 (36%) participants achieved a WHO proficiency score of at least level B in PD, ID and PC, respectively. Malagasy microscopists' diagnostic skills improved after a five-day training; nearly 80% demonstrated competence in PD; however, ID and PC will require additional practice and training. Cyclical training and supervision will be important to improve overall microscopy skill levels to meet WHO proficiency level B. In addition, supplying microscopists with validated slides of the four malaria species would allow them to continuously practice their MM skills.

### SERIOUS HAEMOLYSIS DURING PRIMAQUINE RADICAL CURE TREATMENT OF PLASMODIUM VIVAX MALARIA: A SYSTEMATIC REVIEW AND DESCRIPTIVE ANALYSIS

**Daniel Yilma**<sup>1</sup>, Emily Groves<sup>2</sup>, Rob Commons<sup>2</sup>, Nick Douglas<sup>2</sup>, Kamala Ley-Thriemer<sup>2</sup>, Wuelton M. Monteiro<sup>3</sup>, Jose Diego Brito-Sousa<sup>3</sup>, Cindy Chu<sup>4</sup>, Marcus V.G. Lacerda<sup>5</sup>, Ric Price<sup>2</sup>

<sup>1</sup>Jimma University, Jimma, Ethiopia, <sup>2</sup>Menzies School of Health Research, Darwin, Australia, <sup>3</sup>Universidade do Estado do Amazonas, Manaus, Brazil, <sup>4</sup>Shoklo Malaria Research Unit, Mae Sot, Thailand, <sup>5</sup>Fundaeco de Medicina Tropical Dr. Heitor Vieira Dourado, Manaus, Brazil

Primaquine (PQ) is the only widely available drug that kills *Plasmodium vivax* hypnozoites. It can cause serious drug induced haemolysis in individuals with glucose-6 phosphate dehydrogenase (G6PD) deficiency. We conducted a systematic review of all clinical trials, prospective cohorts, case-control studies and case reports published between 1900 and 2020 that included individual patient data reporting serious haemolysis associated with PQ radical cure of vivax malaria. Serious haemolysis was defined as a requirement for hospitalization, blood transfusion, renal replacement therapy or death thought to have been attributable to either haemolysis or anaemia. A total of 17 eligible studies with 157 patients from 11 countries were identified. Overall 79.6% (121/152) of cases were prescribed with a high dose of PQ (>0.5 mg/kg/day) for radical cure and, at the time of hospitalization, the median total dose of PQ received was 2 mg/kg (IQR 1.5-2.5; range 0.5-5). The most common clinical presentations were pallor (92.7%, 102/110), jaundice (90%, 126/140) and dark urine (89.1%, 98/110). Of 153 patients with a documented G6PD activity result, 94.7% (n=145) had G6PD deficiency. The first symptoms of haemolysis were reported within 5 days of initiation of treatment in 92.3% (96/104) of cases, with most reported on 3rd (24%, 25/104) and 4th day (24%, 25/104). All patients were hospitalized for serious haemolysis within 7 days of the first dose of PQ. Overall 57.8% (74/128) of patients required transfusion and 6.7% (8/119) were dialyzed. Of 157 patients, seven (4.5%) died. The remaining patients were discharged from hospital after a median of 4 days (IQR: 3-6). Even with G6PD testing, enhanced monitoring for severe haemolysis is warranted following PQ radical cure. Our findings suggest that clinical review within the first 5 days of treatment may facilitate early detection of haemolysis, reduce hospitalization and improve outcomes of patients who are prone to serious PQ-associated haemolysis.

### OPTIMIZATION OF OUTREACH TRAINING AND SUPPORTIVE SUPERVISION PLUS (OTSS+) TO IMPROVE MALARIA DIAGNOSTICS SERVICE DELIVERY IN SIERRA LEONE

**Fay Chalobah**<sup>1</sup>, Rogers Dena<sup>2</sup>, Doris Harding<sup>3</sup>, Zikan Koroma<sup>3</sup>, Emmanuel Yamo<sup>2</sup>, Julie Buekens<sup>2</sup>, Keith Esch<sup>2</sup>, Lennie Kyomuhangi<sup>2</sup>, Kwabena Larbi<sup>1</sup>, Temitayo Labor<sup>1</sup>, Ramlat Jose<sup>4</sup>, Anitta Kamara<sup>5</sup>

<sup>1</sup>PMI Impact Malaria, Freetown, Sierra Leone, <sup>2</sup>PMI Impact Malaria, Washington, DC, United States, <sup>3</sup>Directorate of Laboratory Diagnosis, Freetown, Sierra Leone, <sup>4</sup>President's Malaria Initiative, Freetown, Sierra Leone, <sup>5</sup>Sierra Leone National Malaria Control Program, Freetown, Sierra Leone

The WHO recommends that malaria treatment be based on a parasitological test (either microscopy or Rapid Diagnostic Tests) for rational use of drugs. Quality assured malaria microscopy (MM) is the gold standard used for the management of severe malaria. The President's Malaria Initiative Impact Malaria (IM) project supports the Sierra Leone National Malaria Control Program (NMCP) in the implementation of Outreach Training and Supportive Supervision Plus (OTSS+), an approach in which government laboratory (lab) supervisors use an electronic supervisory checklist to monitor and improve provider performance through quality supportive supervision at the health facility (HF) level. The first round of lab OTSS+ in Sierra Leone occurred Oct- Dec 2020

and reached a total of 53 health facilities. A total of 202 lab staff were mentored during this round of OTSS+. The number of lab staff in facilities ranged from 1 to 47, depending on level of HF. Although 78% of HFs had at least one functional microscope, none had a system in place for the repair and maintenance of microscopes nor had standard operating procedures available. Regarding key MM skills required for parasite detection, species identification and counting; 15%, 4% and 0% of HF met the WHO MM standards, respectively. None of the HFs had an internal or external quality control system. While OTSS+ results indicated that malaria lab diagnosis was available in all assessed HFs, the identified gaps jeopardize the quality and accessibility of malaria diagnostic services. Strong MM capacity of lab staff and quality assured diagnostic services along with access to needed equipment leads to improved quality malaria services. IM will work with the Ministry of Health and Sanitation through the NMCP to convert these findings into activities aimed at building in-country malaria diagnostic human resource capacity; expanding OTSS+; supporting malaria diagnostic refresher trainings; and liaising with supply chain partners to ensure the availability of commodities, such as buffer tablets of pH 7.2 and stock Giemsa staining solution as well as equipment such as functioning microscopes and pH meters.

0631

### DETECTION OF NUCLEIC ACIDS EXTRACTED FROM RAPID DIAGNOSTIC TESTS REVEALS A SIGNIFICANT PROPORTION OF FALSE POSITIVE TEST RESULTS ASSOCIATED WITH RECENT MALARIA TREATMENT

**Salome Hosch**<sup>1</sup>, Charlene Yoboue<sup>1</sup>, Olivier Tresor<sup>2</sup>, Etienne Guirou<sup>1</sup>, Jean-Pierre Danguy<sup>1</sup>, Maxmilian Mpina<sup>3</sup>, Elizabeth Nyakarungu<sup>3</sup>, Koranan Bloechliger<sup>1</sup>, Carlos A. Guerra<sup>2</sup>, Wonder P. Phiri<sup>2</sup>, Mitoha Ondo'o Ayekaba<sup>4</sup>, Guillermo A. Garcia<sup>2</sup>, Marcel Tanner<sup>1</sup>, Claudia Daubenberger<sup>1</sup>, Tobias Schindler<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>Medical Care Development International, Malabo, Equatorial Guinea, <sup>3</sup>Ifakara Health Institute, Bagamoyo, United Republic of Tanzania, <sup>4</sup>Ministry of Health and Social Welfare, Malabo, Equatorial Guinea

The diagnostic performance of field-deployed rapid diagnostic tests (RDTs) used for malaria surveys can be assessed by retrospective molecular analysis of the blood retained on the tests. Of the 2,865 RDTs that were collected in 2018 on Bioko Island and analysed in our study, 4.7% had a false-negative result. These false-negative RDTs were associated with low parasite density infections. No pfrp2 gene deletions and four pfrp3 gene deletions (11.1%) were found among 36 investigated RDTs. Masked pfrp2 and pfrp3 gene deletions due to a high proportion of multiclonal infections were found in 30.6% and 50.0% of samples, respectively. A proportion of 28.4% of positive RDTs were tested negative by qPCR and therefore considered to be false-positive. This could be explained by PfHRP2 antigen persistence after malaria treatment by analysing the questionnaire data collected from the participants. RDTs recording a false-positive result are likely to cause an underestimation of the potentially negative impact of asymptomatic malaria infections on the anaemia status of children under five years of age. Malaria surveillance depending solely on RDTs need well-integrated quality control procedures assessing the impact of reduced sensitivity and specificity of RDTs on the malaria control programs.

0632

### REINFORCING MICROSCOPY SKILLS DURING MALARIA DIAGNOSIS REFRESHER TRAININGS TO IMPROVE THE QUALITY OF MALARIA DIAGNOSIS IN THE DEMOCRATIC REPUBLIC OF CONGO (DRC)

**Ange Landela**<sup>1</sup>, Seraphine Kutumbakana Kimwesa<sup>1</sup>, Anselme Manyong Kapit<sup>1</sup>, Lennie Kyomuhangi<sup>2</sup>, Julie Buekens<sup>2</sup>, Jordan M. Smith<sup>2</sup>, Nicole Carbone<sup>3</sup>, Dieudonne Mumba Ngoyi<sup>4</sup>, Godefroid Tshiswaka Bondo<sup>5</sup>, Eric Mukomena Sompwe<sup>6</sup>, Renion Saye<sup>7</sup>

<sup>1</sup>PMI Impact Malaria, MCDI, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>PMI Impact Malaria, MCDI, Silver Spring, MD, United States, <sup>3</sup>PMI Impact Malaria, PSI, Washington, DC, United States, <sup>4</sup>Institut National de Recherche Biomedicale, Kinshasa, Democratic Republic of the Congo, <sup>5</sup>USAID, Kinshasa, Democratic Republic of the Congo, <sup>6</sup>National Malaria Control Program, MOH, Kinshasa, Democratic Republic of the Congo, <sup>7</sup>PMI Impact Malaria, MCDI, Bamako, Mali

Similar to many malaria endemic countries in sub-Saharan Africa, practicing laboratory (lab) technicians in the DRC often lack adequate malaria diagnostic skills, particularly in malaria microscopy (MM), due to limited training and reinforcement of skills following initial education. Malaria Diagnosis Refresher Trainings (MDRT) and Outreach Training and Supportive Supervision (OTSS+) aim to reinforce basic lab competencies with an emphasis on updated MM techniques through practical modules for technicians who have received pre-service malaria diagnostic training. MDRT is a five-day in person training that includes theory and practical microscopy modules. OTSS+ is a quality improvement approach aimed at enhancing the quality of malaria clinical and diagnostic service delivery during visits to health facilities (HF). A checklist together with on-site training are used to ensure that procedures follow national guidelines. PMI Impact Malaria supported nine provinces in the DRC to lead refresher trainings in 2019 and 2020 in order to improve the quality of MM among lab technicians in 51 HF. The aim of these trainings was to increase the percentage of HFs with lab technicians meeting the minimum WHO competency level at 90% for MM parasite detection (PD). The 2020 MDRT included 32 returning lab technicians from the 2019 training, along with 14 new participants. During the training, returning lab technicians improved their competencies in PD, in species identification, and parasite counting. Returning participants had an average PD score of 75% in pre-test and 86% in post-test during the first MDRT, followed by 81% in the pre-test and 90% in post-test in their second MDRT. During the 2020 MDRT training, new participants had an average PD score of 64% in the pre-test and 82% in their post-test. Results show that the continuity of training of lab technicians helps to improve MM competencies. We plan to measure the correlation between PD scores during MDRTs and OTSS+ in order to assess if MDRTs contributed to an increase in MM competencies. These skills are essential for lab technicians to diagnose malaria, and for clinicians to provide adequate treatment.

<sup>1</sup>Medicines for Malaria Venture, Geneva, Switzerland, <sup>2</sup>SGS Life Sciences, Antwerp, Belgium, <sup>3</sup>ICON Clinical Research GmbH, Langen, Germany, <sup>4</sup>Institute of Tropical Medicine, Antwerp, Belgium, <sup>5</sup>IntiQuan GmbH, Basel,

Switzerland, <sup>6</sup>University of Antwerp, Global Health Institute, Antwerp, Belgium, <sup>7</sup>University of Cape Town, Division of Clinical Pharmacology, Department of Medicine, Cape Town, South Africa

Malaria Volunteer Infection Studies (VIS) accelerate antimalarial drug development. The *Plasmodium falciparum* Sporozoite Direct Venous Injection (PfSPZ-DVI) VIS model is established for evaluating new antimalarials for chemoprotection but is not currently utilized for evaluating new antimalarials with blood stage activity. This single-center, open-label, phase Ib study in malaria-naive healthy adult volunteers evaluated if direct venous injection of 3200 *P. falciparum* (NF54 strain) sporozoites was safe and feasible for evaluating new antimalarials with blood stage activity. Sixteen healthy males and females with no prior history of malaria were enrolled in two sequential cohorts of 8 participants per cohort. Following PfSPZ-DVI, parasitemia was assessed from day 7 using quantitative PCR with artemether-lumefantrine administration (regimen approved for the treatment of acute uncomplicated *P. falciparum* malaria in adults) planned to commence at a target threshold of  $\geq 5000$  parasites/mL. A total of 31 adverse events (AEs) occurred in 15 participants with 29 AEs grade 1 (mild) or 2 (moderate), and 2 AEs (both transient neutropenia) grade 3 (severe). All 16 participants developed parasitemia  $\geq 250$  parasites/mL after a geometric mean of 9.68 days (95%CI: 9.06; 10.35). The target threshold of  $\geq 5000$  parasites/mL was reached in a median of 11.46 days (95%CI: 10.42; 12.42) when the geometric mean pre-treatment parasitemia was 15530 parasites/mL (95%CI: 10268; 23488). The pre-treatment parasitemia profile was characterized by an oscillating log-linear growth mixed effect model with an estimated parasite multiplication rate per 48 hours ( $\log_{10}$ PMR<sub>48</sub>) of 1.25 (95%CI: 1.25; 1.26). Artemether-lumefantrine rapidly cleared parasites with a geometric mean time to parasite clearance of 1.34 days (95%CI: 0.86; 2.09) and mean parasite reduction ratio per 48 hours ( $\log_{10}$ PRR<sub>48</sub>) of 3.56 (95%CI: 3.38; 3.74). The findings of our study successfully demonstrated the safety/ tolerability and feasibility of PfSPZ-DVI VIS model for evaluating new antimalarials with blood stage activity.

0634

#### COMPARISON OF DIFFERENT GENOTYPING TECHNIQUES TO DIFFERENTIATE PLASMODIUM FALCIPARUM RECRUDESCENCE FROM NEW INFECTIONS IN ANTIMALARIAL DRUG EFFICACY STUDIES

Annina Schnoz<sup>1</sup>, Liliana K. Rutaihwa<sup>1</sup>, Maura Concu<sup>1</sup>, Carla Beuret<sup>1</sup>, Salome Hosch<sup>1</sup>, Maria Gruenberg<sup>1</sup>, Anita Lerch<sup>2</sup>, Christian Nsanzabana<sup>1</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute, Basel, Switzerland, <sup>2</sup>University of Notre Dame, Notre Dame, IN, United States

The assessment of antimalarial drug efficacy for *Plasmodium falciparum* requires "PCR correction" to distinguish a true failure due to recrudescence parasites or a failure due to a new infection. New infections are defined as the presence of solely novel *P. falciparum* clones in post treatment samples compared to the pre-treatment samples. A recrudescence is present if the follow-up sample contains one or multiple identical *P. falciparum* clones as in the pre-treatment sample. The World Health Organization (WHO) recommends the genotyping of three highly polymorphic genes: merozoite surface protein 1 (*msp1*), merozoite surface protein 2 (*msp2*), and glutamate rich protein (*glurp*) by capillary electrophoresis for PCR correction. However, in practice, different genotyping methods are used, making it difficult to compare results from different studies. This work aimed at comparing different techniques, to assess their sensitivity in detecting minority clones, their robustness, workload and cost. The methods were assessed using four well-characterized *P. falciparum* lab-strains (3D7, K1, HB3 and FCB1), which were mixed in different ratios. The following techniques were compared: fast capillary electrophoresis, and high-resolution capillary electrophoresis using polymorphic length markers including *msp1*, *msp2*, *glurp* and four microsatellites. Targeted amplicon deep sequencing using single nucleotide polymorphism markers (*ama1-D3*, *cpmp*, *cpp*, *csp*, *msp7*), and high-resolution melting analysis using either length-polymorphic markers (*msp1* and *msp2*), or 24-SNP barcode were

also assessed. Overall, minority clones detection and robustness varied greatly between the different techniques, with high-resolution capillary electrophoresis using length-polymorphic markers and targeted amplicon deep sequencing using SNP-rich markers performing the best. However, they were associated with increased cost and workload. The two methods are more appropriate for genotyping in high-transmission settings; but would require substantial investment to establish reference laboratories in malaria endemic settings.

0635

#### MALARIA DURING PREGNANCY: EFFECTS OF INTERMITTENT PREVENTIVE TREATMENT (IPTP) WITH DP, DPAZ AND SP ON MATERNAL IMMUNE ACTIVATION AND PLASMODIUM FALCIPARUM CLEARANCE

Amaya Ortega<sup>1</sup>, Feiko ter Kuile<sup>2</sup>, Mwayi Madanitsa<sup>3</sup>, Victor Mwapasa<sup>4</sup>, Kenneth Maleta<sup>4</sup>, Kamija Phiri<sup>4</sup>, Stephen Rogerson<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases, The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia, <sup>2</sup>Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, <sup>3</sup>College of Medicine, University of Malawi Department of Community Health, Blantyre, Malawi, <sup>4</sup>University of Malawi, College of Medicine, Blantyre, Malawi

Intermittent Preventive Treatment (IPTP) is an important component of malaria prevention in pregnant women in malaria-endemic areas. But the emergence of resistance to sulphadoxine-pyrimethamine (SP), which is recommended by WHO, is compromising the efficacy of IPTP in countries like Malawi and alternative agents are needed. One such, DP (dihydroartemisinin-piperaquine), has entered human clinical trials. The IMPROVE\* trial (NCT03208179), has explored the feasibility of replacing SP with DP for IPTP, alone or combined with the antibiotic azithromycin. Our lab is currently exploring *in vitro* the effect of the different IPTP drugs (SP, DP and AZ) on the maternal immune response. We are measuring cytokine responses to *Plasmodium falciparum*-infected red blood cells (iRBCs) and other stimuli, and the ability of maternal immunocytes to take up iRBCs. To do that, we are using PBMCs collected at three-time points from Malawian women enrolled in the IMPROVE trial (who received different IPTP regimens during their pregnancy). We will examine paired cytokine responses and PBMCs activity using samples collected from the same patient before and after receiving IPTP, and/or at study enrolment and at delivery, using parametric and non-parametric tests as appropriate. Additionally, we are using PBMCs from Australian donors who have never been exposed to *P. falciparum* to examine whether *in vitro* exposure to these drugs alters their immune responses. We hypothesize that AZ will decrease cytokine secretion and that compared to SP, DP will be superior at inducing monocyte clearance of *P. falciparum* iRBCs.

0636

#### MALARIA POSITIVITY FOLLOWING A SINGLE ORAL DOSE OF AZITHROMYCIN AMONG CHILDREN IN BURKINA FASO: A RANDOMIZED CONTROLLED TRIAL

Jessica Brogdon<sup>1</sup>, Clarisse Dah<sup>2</sup>, Ali Sié<sup>2</sup>, Mamadou Bountogo<sup>2</sup>, Boubacar Coulibaly<sup>2</sup>, Idrissa Kouanda<sup>2</sup>, Mamadou Ouattara<sup>2</sup>, Guillaume Compaoré<sup>2</sup>, Eric Nebie<sup>2</sup>, Mariam Seynou<sup>2</sup>, Elodie Lebas<sup>1</sup>, Fanice Nyatigo<sup>1</sup>, Benjamin F. Arnold<sup>1</sup>, Thomas M. Lietman<sup>1</sup>, Catherine E. Oldenburg<sup>1</sup>

Azithromycin is a broad-spectrum antibiotic that has moderate antimalarial activity and has been shown to reduce all-cause mortality when biannually administered to children under five in high mortality settings in sub-Saharan Africa. One potential mechanism for this observed reduction in mortality is via a reduction in malaria transmission. We evaluated whether a single oral dose of azithromycin reduces malaria positivity by rapid diagnostic test (RDT). We conducted an individually randomized placebo-controlled trial in Burkina Faso during the high malaria transmission season

in August 2020. Children aged 8 days to 59 months old were randomized to a single oral dose of azithromycin (20 mg/kg) or matching placebo. At baseline and 14 days following treatment, we administered an OnSite™ rapid diagnostic test to detect *Pfalciparum* and measured tympanic temperature for all children. Caregiver-reported adverse events and clinic visits were also recorded. We enrolled 449 children with 221 randomized to azithromycin and 228 to placebo. The median age was 32 months and 48% were female. A total of 8% of children had a positive RDT for malaria at baseline and 11% had a fever (tympanic temperature  $\geq 37.5^\circ\text{C}$ ). In the azithromycin arm, 8% of children had a positive RDT for malaria at 14 days compared to 7% in the placebo arm ( $P=0.65$ ). Fifteen percent of children in the azithromycin arm had a fever compared to 21% in the placebo arm ( $P=0.12$ ). The day 14 positivity rate among those who had a fever was 3% in both arms ( $P=0.96$ ). However, caregivers of children in the azithromycin group had lower odds of reporting fever as an adverse event compared to children in the placebo group (OR 0.41, 95% CI 0.18-0.96,  $P=0.04$ ). Caregiver-reported clinic visits were uncommon, and there were no observed differences between arms ( $P=0.32$ ). We did not find evidence that a single oral dose of azithromycin reduced malaria positivity during the high transmission season. Caregiver-reported fever occurred less often in children receiving azithromycin compared to placebo, indicating that azithromycin may have some effect on non-malarial infections.

## A DIVERSE GLOBAL FUNGAL LIBRARY FOR DRUG DISCOVERY

Guodong Niu<sup>1</sup>, Thirunavukkarasu Annamalai<sup>1</sup>, Xiaohong Wang<sup>1</sup>, Sheng Li<sup>2</sup>, Stephen Munga<sup>3</sup>, Guomin Niu<sup>4</sup>, Yuk-Ching Tse-Dinh<sup>1</sup>, Jun Li<sup>1</sup>

<sup>1</sup>Florida International University, Miami, FL, United States, <sup>2</sup>City University of New York, New York, NY, United States, <sup>3</sup>Kenya Medical Research Institute, Kisumu, Kenya, <sup>4</sup>Southern Medical University Affiliated Nanhai Hospital, Foshan, China

Secondary fungal metabolites are important sources for new drugs against infectious diseases and cancers. To obtain a library with enough diversity, we collected about 2,395 soil samples and 2,324 plant samples from 36 regions in Africa, Asia, and North America. The collection areas covered various climate zones in the world. We examined the usability of the global fungal extract library (GFEL) against parasitic malaria transmission, Gram-positive and negative bacterial pathogens, and leukemia cells. Nearly ten thousand fungal strains were isolated. Sequences of nuclear ribosomal internal transcribed spacer (ITS) from 40 randomly selected strains showed that over 80% were unique. Screening GFEL, we found that the fungal extract from *Penicillium thomii* was able to block *Plasmodium falciparum* transmission to *Anopheles gambiae*, and the fungal extract from *Tolyposcladium album* was able to kill myelogenous leukemia cell line K562. We also identified a set of candidate fungal extracts against bacterial pathogens.

## POST-TREATMENT TRANSAMINASE ELEVATIONS IN MALARIA VOLUNTEER INFECTION STUDIES: DETERMINING WHAT IS CONSIDERED SIGNIFICANT

Anand A. Odedra<sup>1</sup>, Lachlan Webb<sup>2</sup>, Louise Marquart<sup>2</sup>, Laurence J. Britton<sup>3</sup>, Stephan Chalons<sup>4</sup>, Bridget E. Barber<sup>2</sup>, David G. Lalloo<sup>1</sup>, James S. McCarthy<sup>5</sup>

<sup>1</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom, <sup>2</sup>Queensland Institute of Medical Research Berghofer, Brisbane, Australia, <sup>3</sup>Princess Alexandra Hospital, Brisbane, Australia, <sup>4</sup>Medicines for Malaria Venture, Geneva, Switzerland, <sup>5</sup>The Peter Doherty Institute for Infection and Immunity, Melbourne, Australia

Transaminase elevations encountered during malaria volunteer infection studies (VIS) where investigational antimalarials are being evaluated raise concerns for the safety of healthy volunteers in these studies, and may lead to cessation of drug development due to concerns of drug induced liver injury (DILI). Hence, incorrect assignment, or lack of correct

assignment, of causality of these adverse events to a new clinical entity has serious implications. The threshold for grading severity of transaminase levels are typically assigned by WHO or by the Common Terminology Criteria for Adverse Events. To explore the effect of setting the thresholds in transaminase levels we investigated transaminase elevations from two human *Plasmodium vivax* VIS (n=32). An Alanine transaminase (ALT) cut off of  $\geq 2$  times  $\times$  upper limit of normal (ULN) was compared to that of  $\geq 2.5 \times$  ULN. Reducing the ALT cut off from  $\geq 2.5 \times$  ULN to  $\geq 2.0 \times$  ULN increased the number of volunteers with significant transaminase elevations from 11/32 (34%) to 14/32 (44%) and strengthened the associations between transaminase elevations and CRP (OR 1.43 [95% CI 1.10-1.86;  $p=0.008$ ] to 1.81 [1.21-2.71;  $p=0.004$ ] for every 1  $\times$  ULN increase in maximum CRP) and parasite clearance burden, defined as the log-fold reduction in parasitemia 24-hours post-treatment (OR 4.28 [95% CI 1.26-14.59;  $p=0.020$ ] to 5.09 [1.40-18.48;  $p=0.013$ ]). Peak parasitemia and maximum temperature were associated with an increased risk of having a peak ALT  $\geq 2.0 \times$  ULN (OR 5.86 [95% CI 1.17-29.43;  $p=0.032$ ] and OR 3.13 [95% CI 1.14-8.61;  $p=0.027$ ] respectively) but not ALT  $\geq 2.5 \times$  ULN (OR 3.72 [95% CI 0.77-18.03;  $p=0.10$ ] and OR 1.92 [95% CI 0.78-4.69;  $p=0.15$ ] respectively). We believe a peak ALT  $\geq 2.0 \times$  ULN is significant in healthy volunteers experimentally infected with *P. vivax* and should be used when assessing for associations. The mechanisms underlying these elevations remain unclear. We suggest that similar analyses should be conducted for *P. falciparum* VIS and our data illustrate the importance of further studies of mechanisms and time course of liver function abnormalities in antimalarial clinical trials where DILI is a concern.

## FIRST-IN-HUMAN EVALUATION OF A PLASMODIUM FALCIPARUM TRANSMISSION-BLOCKING MONOCLONAL ANTIBODY

Saskia C. van der Boor<sup>1</sup>, Merel J. Smit<sup>1</sup>, Stijn W. van Beek<sup>2</sup>, Jordache Ramjith<sup>1</sup>, Peter Pickkers<sup>3</sup>, Yimin Wu<sup>4</sup>, Emily Locke<sup>4</sup>, Kazutoyo Miura<sup>5</sup>, Robert W. Sauerwein<sup>1</sup>, Rob ter Heine<sup>2</sup>, Teun Bousema<sup>1</sup>, Christian F. Ockenhouse<sup>4</sup>, Matthijs M. Jore<sup>1</sup>, Matthew B. McCall<sup>1</sup>

<sup>1</sup>Medical Microbiology, Radboud University Medical Center, Nijmegen, Netherlands, <sup>2</sup>Clinical Pharmacology, Radboud University Medical Center, Nijmegen, Netherlands, <sup>3</sup>Intensive Care, Radboud University Medical Center, Nijmegen, Netherlands, <sup>4</sup>PATHs Center for Vaccine Innovation and Access, Seattle, WA, United States, <sup>5</sup>Laboratory of Malaria and Vector Research, National Institute of Allergy and Infectious Diseases, National Institute of Health, Bethesda, MD, United States

Novel transmission-blocking interventions (TBIs) are urgently required to reduce the global malaria burden. TB31F is a humanised version of monoclonal antibody (mAb) 45.1 that targets the Pfs48/45 protein on gametocytes and gametes of *Plasmodium falciparum* (Pf) and is the most potent Pf transmission-blocking mAb described to date. We here present the final results of the first-in-human trial assessing the safety, pharmacokinetics and transmission-reducing activity (TRA) of TB31F in adult malaria-naïve volunteers. Four groups of five healthy F/M subjects were administered a single intravenous (i.v.) dose of respectively 0.1, 1, 3 and 10 mg/kg TB31F and monitored until day (D) 84 post-administration. A fifth group of 5 volunteers was administered a single subcutaneous (s.c.) dose of 100mg mAb TB31F to explore bioavailability. Solicited local, solicited systemic and unsolicited adverse events were recorded until D7, D28, and D84, respectively. Titres of circulating TB31F mAb were measured by ELISA and TRA was assessed by standard membrane feeding assays using laboratory-reared *Anopheles stephensi* mosquitoes, cultured Pf gametocytes (NF54) and subjects' serum. Anti-drug antibodies were measured by sandwich ELISA using anti-id mAbs. TB31F administration was safe and well-tolerated at all administered i.v. and s.c. doses, including the highest dose of 10mg/kg i.v.. With a single dose of 1, 3 or 10 mg/kg i.v. or 100mg s.c., sufficient serum TB31F concentrations were obtained to achieve >80% TRA in 19/20 volunteers, which was maintained up to D28, D56, D84 and D28 after administration respectively. With an estimated TB31F half-life of 20.5 days, a single dose of 10mg/kg i.v. is predicted to

maintain >80% TRA for over four months. This makes TB31F a potent tool for deployment in areas of seasonal malaria transmission where effective transmission blockade may cover the entire season after a single administration. Future work will include testing TB31F in field settings to inform the potential of mAbs as a TBI and SMFA as a tool for efficacy assessment, and exploring Fc-modification of TB31F mAb to extend serum half-life.

### IMMUNIZATION OF WOMEN OF CHILDBEARING POTENTIAL WITH PFSPZ VACCINE PRIOR TO PREGNANCY IN OUELESSÉBOUGOU, MALI: SAFETY DURING SUBSEQUENT PREGNANCY, POSTPARTUM AND INFANCY PERIODS

Djibrilla Issiaka<sup>1</sup>, Halimatou Diawara<sup>1</sup>, Sara Healy<sup>2</sup>, Aye Sousa Diallo<sup>2</sup>

<sup>1</sup>Malaria Research & Training Center, Faculty of Medicine, Pharmacy and Dentistry, University of Bamako, Bamako, Mali, <sup>2</sup>Laboratory of Malaria Immunology and Vaccinology, NIAID/NIH, Washington, DC, United States, Bamako, Mali

Sanaria® PfSPZ Vaccine (radiation-attenuated, purified, cryopreserved *Plasmodium falciparum* (Pf) sporozoites (SPZ)) has been shown to be efficacious using condensed (4-week) regimens suitable for pregnancy. This double-blind, normal saline (NS) placebo-controlled trial in women of child-bearing potential (WOCBP) investigated safety and vaccine efficacy (VE) against naturally transmitted Pf malaria of two dosage regimens, 9x10<sup>5</sup> and 1.8x10<sup>6</sup> PfSPZ administered on days 1, 8 and 29, to women who planned to become pregnant after vaccination. An important objective was to evaluate safety during post-vaccination pregnancy, post-partum, and infancy follow up. 300 women were randomized to receive 9 x10<sup>5</sup> or 1.8x10<sup>6</sup> PfSPZ or NS via direct venous inoculation (DVI) (n=100/arm) and were followed for two years to assess safety by recording adverse events (AEs) and pregnancy/infancy outcomes. All received artemether lumefantrine 2 weeks prior to 1st and 3rd vaccination to clear any existing parasitemia. 180 pregnancies occurred post vaccination in 163 women, with 29 pregnancy losses in 27 women, rates comparable to those recorded in an independent Pregnancy Registry Study in the same community. The majority of AEs during the intrapartum and postpartum periods were Grade 1. Nine subjects experienced intrapartum or postpartum SAEs, 4 in the 1.8x10<sup>6</sup> arm, 1 in the 9x10<sup>5</sup> arm and 4 in the NS arm. Eight resolved without sequelae but 1 (puerperal sepsis) resulted in death 5 days post-partum. 104 infants were born, with the majority of AEs Grade 1 and related to neonatal infections; 22 SAEs occurred in infants, all considered unrelated to vaccination and the majority being hospitalization for neonatal infection. Two stillbirths occurred, one each in the 1.8x10<sup>6</sup> PfSPZ and NS arms. Two pre-term twin deliveries (1.8x10<sup>6</sup> PfSPZ Vaccine group) resulted in 4 early neonatal deaths. One infant death (1.8x10<sup>6</sup> PfSPZ Vaccine) occurred, at 1 month of life secondary to malaria and anemia. Detailed safety results in pregnant women (intrapartum and postpartum) as well as in their offspring will be presented.

0641

### EXTENDED DURATION ARTEMETHER-LUMEFANTRINE FOR THE TREATMENT OF PLASMODIUM FALCIPARUM MALARIA IN HIV-UNINFECTED CHILDREN IN UGANDA: A RANDOMIZED PK/PD CLINICAL TRIAL

Richard Kajubi<sup>1</sup>, Meghan Whalen<sup>2</sup>, Francis Orukan<sup>1</sup>, Justin Goodwin<sup>3</sup>, McKenzie Colt<sup>3</sup>, McKenzie Colt<sup>3</sup>, Kacey Richards<sup>3</sup>, Martina Wade<sup>3</sup>, Moses Were<sup>1</sup>, Florence Marzan<sup>2</sup>, Liusheng Huang<sup>2</sup>, Norah Mwebaza<sup>1</sup>, Francesca Aweeka<sup>2</sup>, Sunil Parikh<sup>3</sup>

<sup>1</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>2</sup>University of California - San Francisco, San Francisco, CA, United States, <sup>3</sup>Yale School of Public Health, New Haven, CT, United States

Artemether-lumefantrine (AL) is the most widely used artemisinin-based combination therapy in sub-Saharan Africa. Lumefantrine (LUM) exposure is lower in young children and is associated with differences

in treatment outcomes. Dose-limited absorption requires extending AL duration to improve LUM exposure. We conducted a prospective PK/PD study of extended duration AL in children ages 6 months to 17 years in a high transmission setting in Uganda. Children with uncomplicated *P. falciparum* malaria were randomized to 3-day (standard 6-dose) or 5-day (extended 10-dose) AL with intensive or population PK sampling for artemether, dihydroartemisinin (DHA), and LUM for 21 days and clinical follow-up for 42 days. 228 children were enrolled into 3-day (n=115) or 5-day (n=113) AL. Day 28 microscopy determined treatment outcomes for 3-day versus 5-day AL were: ACPR (48% vs 60%), LPF (40% vs 32%), and LCF (12% vs 8%). Day 42 microscopy determined treatment outcomes were: ACPR (25% vs 31%), LPF (55% vs 51%), and LCF (19% vs 18%). PCR genotyping of six microsatellites suggests that 10 microscopic recurrences represented recrudescence, with four in the 3-day arm and six in the 5-day arm. 100 children were enrolled into intensive 3-day (n=50) or 5-day (n=50) PK sampling. Terminal LUM concentrations were significantly increased in the 5-day versus 3-day regimen on days 8, 14, and 21 (822, 184, 80.7 ng/mL vs 330, 131, 58.6 ng/mL, respectively; all p-values <0.005). Total LUM exposure (area under the concentration versus time curve) measured from the time of the last dose over 21 days indicates a geometric mean AUC<sub>0-21d</sub> of 288 and 252 ug-hr/mL for the 5-day and 3-day AL regimens, respectively. Compared to 3-day AL, 5-day AL significantly enhances terminal LUM concentrations out to day 21. Increased exposure in the 5-day AL regimen appears to coincide with a modest reduction in the risk of recurrent malaria at 28 days, with risk reduction diminishing by 42 days in this high transmission setting. Data is preliminary but final statistical analysis of treatment outcomes with incorporated population PK data will be presented.

0642

### AN ADAPTIVE, RANDOMIZED, ACTIVE-CONTROLLED, OPEN-LABEL, SEQUENTIAL COHORT, MULTICENTER STUDY TO EVALUATE THE EFFICACY, SAFETY, TOLERABILITY, AND PHARMACOKINETICS OF INTRAVENOUS CIPARGAMIN (KAE609) IN ADULT AND PEDIATRIC PARTICIPANTS WITH SEVERE PLASMODIUM FALCIPARUM MALARIA (KARISMA - KAE609'S ROLE IN SEVERE MALARIA)

PAMAFRICA KAE609 Consortium

Novartis Pharma AG, MMV, University of Tubingen, Basel, Geneva, Tubingen, Switzerland

Severe malaria is a life-threatening disease, which predominantly affects children under 5 years in Africa. To date, intravenous artesunate is the recommended first-line parenteral therapy. However, increasing resistance threatens its efficacy. KAE609 is a PfATP4 inhibitor with potent and fast-acting schizonticidal activity. Oral KAE609 has been evaluated in ~190 patients with uncomplicated malaria. Rapid parasite clearance properties of KAE609 suggest a promising role in severe malaria. KARISMA is a Phase 2 adaptive, multicenter, randomized, open label, sequential cohort study to evaluate the efficacy, safety and PK of two different IV dose regimens (20mg once a day and 40 mg once a day) of KAE609. About 250 patients will be enrolled in an age descending (≥12 years old in Cohorts 1-2 and patients between <12 years to ≥6 months of age in Cohorts 3-5) and severity ascending manner (moderately severe malaria in Cohort 1 and severe malaria patients in Cohorts 2-5). Upon completion of Cohort 2, dose for patients <12 years old will be selected based on interim assessment of data from Cohorts 1-2. Traditionally, severe malaria studies used mortality as primary endpoint in thousands of patients. KARISMA will use proportion of patients with ≥90% parasite clearance as primary endpoint to enable dose selection and will also evaluate a novel composite clinical success endpoint (based on survival, absence of key symptoms of severe malaria and parasite clearance) as a key secondary endpoint. Clinical success after 48 hours will function as a surrogate for the survival and speed of recovery and is defined by absence of parasites, absence of key severe malaria symptoms (i.e. altered consciousness, renal impairment, lactic acidosis and respiratory distress) and death. Data collected from this study is expected to enable the use of clinical success as the primary endpoint for pivotal regulatory trials in severe malaria and thereby enable

an efficient development program. This program is an important step in the direction of finding an alternative to IV artesunate for management of severe malaria in the near future.

0643

### MECHANISM OF ACTION STUDIES OF PHENOTYPIC WHOLE CELL-ACTIVE ANTIMALARIAL LEADS; IDENTIFYING NOVEL TARGETS FOR THE TREATMENT OF MALARIA

Constance Mawunyo Korkor<sup>1</sup>, Kathryn Witch<sup>1</sup>, David Fidock<sup>2</sup>, Timothy Egan<sup>1</sup>, Kelly Chibale<sup>1</sup>

<sup>1</sup>University of Cape Town, Cape Town, South Africa, <sup>2</sup>Columbia University, New York, NY, United States

The 2020 WHO Malaria Report estimates 229 million cases of malaria worldwide with over 409,000 deaths. The disease continues to cause significant morbidity and mortality, globally, with children under five and pregnant women being the most groups affected. Contrary to popular belief, recent malaria figures suggest that the infection decline rate has stalled since 2014 and has even reversed in certain areas. The recrudescence in the disease burden may be due to factors, including the emergence of resistant parasite mutants to frontline treatments as observed in South-East Asia, as well as the development of resistance to insecticides from the mosquito vectors. Also, due to the recent impact of the deadly coronavirus, malaria morbidity is expected to be on the rise as most health facilities and health care systems in malaria-endemic regions are severely overwhelmed. These among other factors have made malaria elimination a more challenging venture than otherwise anticipated and thus calls for accelerated research efforts to identify safe and efficacious agents with novel modes of action, with activity across multiple stages of the parasite lifecycle, for the treatment of malaria. In this regard, we previously reported the antimalarial properties of pyrido[1,2-a]benzimidazole (PBI) compounds, identified via a phenotypic whole-cell screening approach. Although this approach has been successful in identifying new molecule entities to feed the drug discovery pipeline, mechanistic deconvolution of hits to leads has remained a very challenging aspect. Herein, we report a resistance selection, fluorescent drug localization, and chemical proteomics approaches to studying the mechanism of action of the PBIs and identifying their molecular targets.

0644

### NOVEL MULTIPLE-STAGE ACTIVE ANTIMALARIAL TAMBAMINES

Papireddy Kancharla<sup>1</sup>, Yuexin Li<sup>2</sup>, Brandon Pybus<sup>3</sup>, Alison Roth<sup>3</sup>, Mara Kreishman-Deitrick<sup>3</sup>, Chad Black<sup>3</sup>, Qigui Li<sup>3</sup>, Christina Nolan<sup>3</sup>, Jason Sousa<sup>3</sup>, Jane Kelly<sup>2</sup>, Kevin Reynolds<sup>1</sup>

<sup>1</sup>Portland State University, Portland, OR, United States, <sup>2</sup>Portland VA Medical Center, Portland, OR, United States, <sup>3</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States

The impact of malaria is staggering. Each year, malaria causes about 200 million clinical cases and claims nearly half a million lives, mostly children under the age of five and pregnant women. Drug resistance to current therapies, such as quinolines and artemisinin derivatives, is growing at an alarming rate. Therefore, the novel antimalarial chemotypes that can combat multiple stages of the parasite (blood stage, liver stage and gametocyte stage) through novel mechanism(s) of action are ideal and they are urgently needed to treatment and prevention of malaria. In this context, we present a novel antimalarial tambamine chemotype that demonstrates single oral dose efficacy against blood stage malaria, in addition to prevention of sporozoite-induced *Plasmodium* liver stage infection and potential for transmission blocking.

### MEASUREMENT OF OOCYST AND SPOOROZOITE INFECTION RATES IN ANOPHELES GAMBIAE S.L. UNDER NATURAL CONDITIONS IN BANCOUMANA, MALI

Daman Sylla<sup>1</sup>, Adama Sacko<sup>1</sup>, Jen C. Hume<sup>2</sup>, Abdrahamane Fofana<sup>1</sup>, Heather Goodman<sup>2</sup>, Boubacar Coulibaly<sup>1</sup>, Makan Camara<sup>1</sup>, Moussa Diallo<sup>1</sup>, Salifou M. Kone<sup>1</sup>, Gaoussou Fofana<sup>1</sup>, Sekou Goita<sup>1</sup>, Moridie Sidibe<sup>1</sup>, Sale Sidibe<sup>1</sup>, Yacouba Dembele<sup>1</sup>, Yacouba Diarra<sup>1</sup>, Chata Doumbia<sup>1</sup>, Boubacar Tembely<sup>1</sup>, Amadou Sekou Traore<sup>1</sup>, Issaka Sagara<sup>1</sup>, Patrick E. Duffy<sup>2</sup>, Mamadou B. Coulibaly<sup>1</sup>

<sup>1</sup>USTTB, Bamako, Mali, <sup>2</sup>LMV/INIAID/NIH, Bethesda, MD, United States

The dynamics of mosquito infections play a central role in *P. falciparum* transmission and human infection rates, and can be considered as an endpoint in trials of transmission-interruption interventions like vaccines. Here we measured natural oocyst and sporozoite infection rates in wild-caught *An. gambiae s.l.* Every month (Mar 2018-Jul 2019), a team collected mosquitoes in 63 households comprising 503 rooms, for 7,435 collections total (372-494 collections per month). Live mosquito collections using mouth aspiration were followed by pyrethrum spray collections of killed mosquitoes. Live *Anopheles* mosquitoes with recent bloodmeal were separated from unfed mosquitoes and kept seven days; midguts were dissected and oocyst infections were counted. Killed *Anopheles* mosquitoes were preserved in 80% ethanol and retained for ELISA-CSP (sporozoite infection rates) and PCR (*Anopheles* speciation). Collections yielded 4,089 live female *Anopheles* with an average density of 0.55 (SD = 0.84) per hut; 3,164 (77.4%) mosquitoes survived to dissection, of which 84 (2.7%) were infected with mean of 2.1 oocysts [range 1-15]. Among 3,143 killed mosquitoes identified morphologically as *An. gambiae s.l.* (mean 0.42 mosquitoes per hut), 25 (0.79%) were positive for CSP infection by ELISA. As expected, the highest number of infected mosquitoes (n=21) were collected during peak transmission season (Aug-Oct). A subset of mosquitoes underwent PCR analysis that identified two predominant species, *An. coluzzii* and *An. arabiensis*, at frequencies of 61.5% and 8.6% respectively. These large-scale collections provide an estimate of the incidence of malaria infection in circulating mosquito populations and can be a valuable tool to measure the impact of any malaria control measures tested or implemented in communities.

0646

### ANEMIA AND MALARIA INCIDENCE BETWEEN 2007-2018 IN UNSTABLE MALARIA TRANSMISSION SETTING OF WESTERN KENYA

Shehu S. Awandu<sup>1</sup>, Lindsey B. Turnbull<sup>2</sup>, Caitlin Bond<sup>2</sup>, George Ayodo<sup>1</sup>, Chandy C. John<sup>2</sup>

<sup>1</sup>Jaramogi Oginga Odinga University of Science and Technology, Bondo, Kenya, <sup>2</sup>Indiana University, Indianapolis, IN, United States

Malaria is a leading cause of anemia in many areas of sub-Saharan Africa. In high malaria transmission settings, children often have reduced hemoglobin levels, in contrast to low transmission settings where hemoglobin levels are not reduced. Our previous studies in the western Kenyan highland areas of Kipsamoite and Kapsisiywa, areas of low and unstable malaria transmission, showed that hemoglobin levels in asymptomatic individuals increased after 1 year of malaria interruption, 2007-2008. We hypothesized that during the subsequent years of low transmission, months with higher malaria incidence would be associated with a higher prevalence of anemia in the population. To test this hypothesis, we evaluated malaria incidence and hemoglobin concentrations in all individuals who presented to the local health centers with fever or headache from 2007-2018 (n=3852). We performed a time-series regression with negative binomial distribution to compare monthly malaria count to monthly anemia count, using a spline function of time with adjustments for seasonality and long-term trends. Anemia was defined as <11 g/dL in children <5 years; <11.5 g/dL in children 5-15 years; <12 g/dL in females >15 years; and <13 g/dL in males >15 years.

In month-based age-and sex-stratified time-series models, malaria was significantly associated with increased anemia in all ages when individuals with clinical malaria were included in anemia counts, and in children <5 years (incidence rate ratio [95% confidence interval], 1.13 [1.05, 1.23]) and males ≥15 years (1.18 [1.07, 1.31]) when individuals with clinical malaria were excluded from anemia counts. Over the 11-year study period, the proportion of malaria cases and anemia in children <5 years decreased, while the proportions in children 5-14 years and individuals ≥15 years increased. The study findings suggest that reduction or elimination of malaria would lead to a significant population-level decrease in anemia even in areas of low and unstable malaria transmission.

0647

### RISK FACTORS FOR BORDER MALARIA IN A LOW TRANSMISSION SETTING: A CASE-CONTROL STUDY IN JAZAN, SAUDI ARABIA

Shaymaa A. Abdalal<sup>1</sup>, Joseph Keating<sup>1</sup>, Hassan M. Ozayr<sup>2</sup>, Hussan A. Alkayri<sup>2</sup>

<sup>1</sup>Tulane School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>2</sup>Center of Vector Borne Disease, Public Health Department Ministry of Health, Jazan, Saudi Arabia

Saudi Arabia has successfully reduced the malaria incidence and is considered malaria-free, apart from Jazan and Aseer region in the south. Malaria remains a public health threat in the southern border of Saudi Arabia, especially among the high-risk population communities living along the border with Yemen. An unmatched case-control study was conducted to identify risk factors for border malaria in Jazan region. A total of 261 participants were recruited for the study, including 81 cases of confirmed malaria through the RDTs and microscopy, and 180 controls were residence of the same area but not the same household in the Baish Governorate in Jazan Provinces, Saudi Arabia. Using a web-based data management system; A questionnaire was administered, and the data were captured electronically. The study aimed to evaluate the demographic characteristics, livelihood activities, travel history, and preventive measures associated with malaria infection between December 2017 to January 2019. A logistical regression model was used to investigate factors associated with infection. After adjusting for several confounding factors, persons who reported traveling away from their home village in the last 30 days OR 11.5 (95% CI 4.43 - 29.9), those who attended a seasonal night spiritual gathering OR 3.04 (95% CI 1.10 - 8.42), involved in animal husbandry OR 2.52 (95% CI 1.09 - 5.82), and identified as male OR 4.57 (95% CI 1.43 - 14.7), were more likely to test positive for malaria infection. Eliminating malaria program might consider addressing social and behavioral practices within the border communities.

0648

### POPULATION SIZE ESTIMATION OF SEASONAL FOREST GOING POPULATIONS IN CHAMPASAK PROVINCE, SOUTHERN LAO PDR

Francois Rerolle<sup>1</sup>, Gerald Jacobson<sup>1</sup>, Paul Wesson<sup>1</sup>, Emily Dantzer<sup>1</sup>, Bouasy Hongvanthong<sup>2</sup>, Jennifer Smith<sup>1</sup>, John Marshall<sup>3</sup>, Hugh Sturrock<sup>1</sup>, Adam Bennett<sup>1</sup>

<sup>1</sup>UCSF, San Francisco, CA, United States, <sup>2</sup>CMPE, Vientiane, Lao People's Democratic Republic, <sup>3</sup>UC Berkeley, Berkeley, CA, United States

Forest-going populations are key to malaria transmission in the Greater Mekong Sub-region (GMS) and are therefore targeted for elimination efforts. Estimating the size of the population of forest-goers is essential for programs to assess, track and achieve their elimination goals. Forest-goers were defined as individuals spending a night outdoors for forest or agricultural activities. Leveraging data from three cross-sectional household surveys and one survey of participants in an intervention among forest-goers, the size of this high-risk population in a southern province of Lao PDR between December 2017 and November 2018 was estimated by two methods: individual household survey estimates and capture-recapture. During the first month of the dry season, the first month of the rainy

season, and the last month of the rainy season, respectively, 16.2% [14.7; 17.7], 9.3% [7.2; 11.3], and 5.3% [4.4; 6.1] of the household population 15 years or older were estimated to have engaged in forest-going activities. Cumulatively, the capture-recapture method estimated a total population size of 18,426 [16,529; 20,669] forest-goers, meaning 61.0% [54.2; 67.9] of the population 15 years or older had engaged in forest-going activities over the 12-month study period. This study in a historically epidemic-prone area demonstrates two feasible methods for developing population size estimates to inform malaria research and programming. The seasonality and turnover within this forest-going population provide unique opportunities and challenges for control programs across the GMS as they work towards malaria elimination.

### THE IMPACT OF THE COVID19 PANDEMIC ON CARE SEEKING AND IMPLICATIONS FOR THE PROCESS OF CERTIFYING MALARIA ELIMINATION IN CABO VERDE

Adilson De PINA<sup>1</sup>, Amanda Tiffany<sup>2</sup>, Gillian Stresman<sup>3</sup>

<sup>1</sup>National Malaria Program, Ministry of Health, Praia, Cape Verde, <sup>2</sup>Global Malaria Programme, World Health Organization, Geneva, Switzerland, <sup>3</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom

Cabo Verde, a nation with a population over 550,000 people, reported the first case of COVID-19 on March 19, 2020. Containment measures were quickly implemented and over 80,000 COVID tests were performed in 2020 with 11,840 confirmed infections (2% of the population) and 154 deaths. The COVID pandemic is expected to lead to a reduction in care-seeking for non-COVID health concerns. In a setting with the last locally acquired malaria case in January 2018, any interruptions to malaria care-seeking have the potential for transmission to re-establish. This work aims to determine whether there was any change in the number of people seeking care for malaria aligned with the progression of the COVID pandemic and determine whether the COVID interventions implemented had any impact on testing for malaria using an interrupted time series analysis. The routinely collected surveillance data for outpatient attendance, malaria, and COVID were aggregated per month for each facility (outpatient and malaria) and municipality (COVID) from 2017 to 2020. The timeline of COVID interventions was generated based on when and where official interventions were implemented. Preliminary results suggest that there was a marked shift in care-seeking in Cabo Verde. The mean outpatient attendance dropped from 1777 visits per month between January 2017 and March 2020 to 813 between April to December 2020. Malaria testing in Cabo Verde has generally declined since 2017, consistent with the reduction in malaria transmission. However, from April 2019 to March 2020 (pre-COVID, post malaria interruption) facilities tested a mean of 25 people per month compared to 15 tests per month between April to December 2020 (p=0.206). Therefore, results suggest that the pandemic has impacted both care-seeking and testing for malaria. However, with the cessation of international travel, the risk of imported infections seeding new transmission also declined likely contributing to the reduction in testing. It is important for countries to understand their specific malaria risks and vulnerabilities in order to ensure the achievements made to interrupt malaria transmission can be sustained.

College of Health Sciences, Moi University, Eldoret, Kenya, <sup>5</sup>School of Public Health, College of Health Sciences, Moi University, Eldoret, Kenya, <sup>6</sup>Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>7</sup>Duke Global Health Institute, Durham, NC, United States

With malaria case reductions stalling under current interventions, efficient reduction of *Plasmodium falciparum* human-to-mosquito transmission may be enhanced by identifying clinical and parasitologic factors associated with successful transmission to mosquitoes. Previous work has measured predictors through direct or membrane feeding of mosquitoes, which fail to fully capture transmission dynamics in a natural setting. We captured *P. falciparum* human-to-mosquito transmission using longitudinal sampling of people as well as naturally-collected mosquitoes from their households over 14 months in Western Kenya. We matched parasites in human and mosquito infections using amplicon deep sequencing and haplotype inference of the parasite gene *pfscsp*, and adapted a previously-published probabilistic modelling approach to identify predictors of successful transmission. Univariate multi-level logistic regression models compared the probability of transmission across people's sex, age, infection parasite density, infection type (asymptomatic or symptomatic), bed net usage, and transmission season. Covariates with *p*-values < 0.2 in univariate models were included in a multivariate model to estimate adjusted Odds Ratios (aORs). We identified 1,039 human and 203 mosquito infections, which comprised 229 unique parasite *pfscsp* haplotypes. We used these haplotypes to estimate transmission across 3727 human-mosquito pairs from 198 people and 182 mosquitoes collected in 37 households. A higher likelihood of successful transmission to caught mosquitoes was associated with lower parasite densities [aOR 1-200 p/μL vs. <1 p/μL: 0.63, 95% CI: 0.49, 0.82; aOR >200 p/μL vs. <1 p/μL: 0.23, 95% CI: 0.17, 0.31], irregular bed net usage [aOR 0.50, 95% CI: 0.38, 0.66], or occurrence in the high transmission season [aOR 1.46, 95% CI: 1.22, 1.74]. Further analyses investigated the influence of parasite density on transmission. These results suggest that future elimination efforts focus on reducing low density infections and increasing usage of insecticide-treated bed nets during the high transmission season to decrease malaria transmission.

#### DECLINES IN MODERATE AND SEVERE ANEMIA DURING A LONGITUDINAL STUDY IN HIGH MALARIA TRANSMISSION REGIONS OF KINSHASA, DEMOCRATIC REPUBLIC OF THE CONGO

Rachel Sendor<sup>1</sup>, Kristin Banek<sup>1</sup>, Melchior Kashamuka Mwandagalirwa<sup>2</sup>, Nono Mvuama<sup>2</sup>, Joseph A. Bala<sup>2</sup>, Marthe Nkalani<sup>2</sup>, Georges Kihuma<sup>2</sup>, Joseph Atibu<sup>2</sup>, Thwai Kyaw<sup>1</sup>, Varun Goel<sup>1</sup>, Jeffrey Bailey<sup>3</sup>, Jonathan J. Juliano<sup>1</sup>, Michael Emch<sup>1</sup>, Margaret Carrel<sup>4</sup>, Antoinette Tshetu<sup>2</sup>, Jonathan Parr<sup>1</sup>

<sup>1</sup>University of North Carolina Chapel Hill, Chapel Hill, NC, United States, <sup>2</sup>Kinshasa School of Public Health, Kinshasa, Democratic Republic of the Congo, <sup>3</sup>Brown University, Providence, RI, United States, <sup>4</sup>University of Iowa, Iowa City, IA, United States

Malaria-related anemia is a major public health concern in Sub-Saharan Africa. We aimed to quantify anemia burden during a longitudinal surveillance study across seven villages in Kinshasa Province, Democratic Republic of the Congo, from 2015-2017. Active malaria surveillance was performed at enrollment and biannual follow-ups using rapid diagnostic tests (RDTs), and detected cases were referred to study clinics for antimalarial treatment. Passive surveillance was carried out through symptomatic subject presentation to clinics, where RDTs and hemoglobin levels were measured and treatment was administered according to national guidelines. Anemia prevalence at passive clinic visits was estimated overall and by season (rainy/dry), and factors associated with anemia were evaluated. In total, 1,033 (64.9%) symptomatic subjects presented to clinics (2,991 visits). Anemia period prevalence was 62.2% (n=643), ranging from 47.4% (n=230) among subjects 15+ years to 82.4% (n=164) among subjects less than five. Overall, 38.7% (n=400), 36.4% (n=376), and 7.1% (n=73) of subjects presented to clinics at least

once with mild, moderate, and severe anemia, respectively, according to WHO age/sex strata. While total anemia prevalence remained stable during the study (season 1: 48.4% [95% CI: 34.2-62.5%] to season 7: 42.6% [95% CI: 33.3-51.9%]),  $p_{\text{trend}}=0.0496$ , moderate/severe anemia declined across seasons (36.6% [95% CI: 24.3-48.8%] to 18.4% [95% CI: 12.3-24.5%]),  $p_{\text{trend}}=0.0001$ , both overall and among subjects with concurrent RDT+ malaria (34.4% [95% CI: 22.5-46.3%] to 14.8% [95% CI: 9.3-20.3%]),  $p_{\text{trend}}<0.0001$ . Unadjusted odds of anemia were higher in subjects with ages <15 years, male gender, poorer wealth scores, and PCR+ and RDT+ malaria at visits. While results confirm anemia was common in this setting, a decreasing trend of moderate/severe anemia was observed over the course of the study. Key study interventions - routine surveillance, community sensitization and improved access to malaria diagnostic testing and treatment - deserve further evaluation in high-transmission settings.

#### INFECTIVITY OF CLINICAL AND ASYMPTOMATIC MALARIA CASES TO ANOPHELES FARAUTI S. S. MOSQUITOES IN PAPUA NEW GUINEA

Lincoln Timinao<sup>1</sup>, Rebecca Vinit<sup>1</sup>, Esther W. Jamea<sup>1</sup>, Elma Nate<sup>1</sup>, Henson Dima<sup>1</sup>, Clemencia Ibam<sup>1</sup>, Thomas R. Burkot<sup>2</sup>, Louis Schofield<sup>2</sup>, Moses Laman<sup>1</sup>, Ivo Mueller<sup>3</sup>, Leanne Robinson<sup>4</sup>, Stephan Karl<sup>2</sup>

<sup>1</sup>Papua New Guinea Institute of Medical Research, Madang, Papua New Guinea, <sup>2</sup>Australian Institute of Tropical Health and Medicine, Cairns, Australia, <sup>3</sup>Walter and Eliza Hall Institute of Medical Research, Melbourne, Australia, <sup>4</sup>Burnet Institute, Melbourne, Australia

Transmission of malaria parasites can arise from asymptomatic parasite carriers as well as from individuals with clinical symptoms. Understanding the infectiousness of these different sub-populations is important to target malaria control focusing on interrupting transmission. Using an *Anopheles farauti* colony, we performed direct skin feeding assays on 11 asymptomatic parasite carriers identified in a population of 103 individuals from a highly endemic village in Madang Province, Papua New Guinea using rapid diagnostic tests (RDT) and qPCR techniques. We also conducted membrane feeding assays with samples collected from 182 clinical patients from two local health facilities enrolled on the basis of positive rapid diagnostic tests. All samples were further characterized retrospectively using expert light microscopy and qPCR. In the population of asymptomatic individuals, 2/11 were diagnosed by qPCR as *Plasmodium vivax* carriers while 3/11 were diagnosed with *P. falciparum*. Only the two *P. vivax* positive individuals successfully infected *Anopheles farauti* colony mosquitoes. Microscopy diagnosis done retrospectively also confirmed that the two participants were *P. vivax* positive with one having detectable gametocyte stages. The remaining 6/11 were qPCR negative but RDT positive. Of the 182 clinical malaria samples 38 (21%) resulted in successful mosquito infections. While according to qPCR only 10% (8/80) of *P. falciparum* gave rise to mosquito infections, 44% (24/55) of *P. vivax* cases were infectious to mosquitoes. Interestingly, 7.4% (2/27) of samples from patients who were negative by qPCR resulted in successful mosquito infection. Similar results were obtained for light microscopy for *P. falciparum*, 11% (10/88) and for *P. vivax* 44% (23/52) with an increase in mosquito infection rate to 58% (14/24) for *P. vivax* gametocyte carriers. Overall, *P. vivax* seemed to be more infectious in both, clinical and asymptomatic populations. In further studies, we plan to test more asymptomatic parasite carriers in order to clearly understand the differences in infectiousness of clinical versus asymptomatic malaria parasite carriers in PNG.

<sup>1</sup>Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>2</sup>Royal Thai Army-Armed Forces Research Institute of Medical Sciences, Bangkok, Thailand, <sup>3</sup>Royal Thai Army, Yala, Thailand, <sup>4</sup>University of Maryland-Baltimore, Baltimore, MD, United States, <sup>5</sup>Thai Ministry of Public Health, Ubon Ratchathani, Thailand, <sup>6</sup>Thai Ministry of Public Health, Bangkok, Thailand

In 2019, AFRMS began conducting a malaria surveillance study in collaboration with Thai MoPH and the Royal Thai Army to characterize malaria isolates for in-depth *in vitro* and genetic studies of drug resistance. Data was analyzed from 129 malaria patients from four provinces, each along a different international border: 56 cases from Yala Province (bordering Malaysia), 45 in Sisaket Province (bordering Cambodia), 3 cases from Ratchaburi Province (Myanmar border) with and 25 cases in Ubon Ratchathani Province (Laos border). The majority enrolled were male (86%), with 40% reporting work at rubber plantations and 25% in the military. There is approximately a 12% rate of G6PD deficiency with 71% being the Viangchan variant. Only 14 cases were *Plasmodium falciparum*, and all but one patient came from Yala Province. Initial testing of isolates from Yala by PCR demonstrated wild type for resistance markers PfCRT, plasmepsin 2, Pfm-dr1 and cytochrome b. The Kelch13 mutation was wild-type by PCR, but deep amplicon sequencing called 580Y at low signals in five isolates, suggesting the presence of mixed population. This low level of molecular markers associated with anti-malarial resistance stands in stark contrast to the rest of Thailand, where numerous mutations have been reported. The drug sensitivity profiles for 21 *P. vivax* isolates showed an *ex vivo* IC<sub>50</sub> of 47.6 nM (29.9-71) against chloroquine, demonstrating continued sensitivity to the first-line treatment in Thailand. The low number of *P. falciparum* cases demonstrate the great strides Thailand has made in the recent years, but continued efforts must be maintained in order to eliminate *P. vivax*.

### BURDEN, DETECTABILITY AND CLINICAL IMPACT OF PLASMODIUM FALCIPARUM INFECTION ON PREGNANT MOZAMBICAN WOMEN IN TRANSITIONING EPIDEMIOLOGIES

**Jessica Brogdon**<sup>1</sup>, Clarisse Dah<sup>2</sup>, Ali Sié<sup>2</sup>, Mamadou Bountogo<sup>2</sup>, Boubacar Coulibaly<sup>2</sup>, Idrissa Kouanda<sup>2</sup>, Mamadou Ouattara<sup>2</sup>, Guillaume Compaoré<sup>2</sup>, Eric Nebie<sup>2</sup>, Mariam Seynou<sup>2</sup>, Elodie Lebas<sup>1</sup>, Fanice Nyatigo<sup>1</sup>, Benjamin F. Arnold<sup>1</sup>, Thomas M. Lietman<sup>1</sup>, Catherine E. Oldenburg<sup>1</sup>

<sup>1</sup>University of California, San Francisco FI Proctor Foundation, San Francisco, CA, United States, <sup>2</sup>Centre de Recherche en Santé de Nouna, Nouna, Burkina Faso

Understanding how transmission intensity determines the detectability and clinical progression of malaria in pregnancy is crucial to guide the most efficient control and elimination approaches. We conducted a three-year prospective observational study (from 2016 to 2019) at antenatal care (ANC) clinics and maternity wards in three areas with different intensities of malaria transmission in southern Mozambique (at Magude and Manhiça

districts). Finger-prick blood samples onto filter papers collected at first antenatal visit and delivery, were analyzed by real-time quantitative polymerase chain reaction (qPCR) to assess the presence of *Plasmodium falciparum* (Pf). The Pf positivity rate by qPCR (PfPrqPCR), which was higher in Ilha Josina (19% [255/1329]) than in Magude (4% [175/4907]) and Manhiça (4% [262/6199], p<0.001) and at first ANC visit (7% [483/6471]) than at delivery (4% [209/5964], p<0.001), decreased with time in the 3 sites. Parasite densities increased during the study period in Magude while remained constant in Manhiça. In Ilha Josina, densities decreased and increased with time in primigravidae and multigravidae women, respectively. Overall, 39% (271/692) of the qPCR detected infections were above 100 parasites/μL and therefore considered as detectable by conventional RDTs. The proportion of detectable infections was higher in first ANC visit than delivery for Magude (43% vs 27%; p=0.029) and Manhiça (47% vs 27%; p=0.002). While hemoglobin levels decreased with increases in parasite densities in women from the 3 areas, the newborn weight was affected by Pf infection only in women from Manhiça. These results provide evidence of the value of pregnant women to identify changes in transmission even in low transmission settings, as well as malaria hotspots. Increases in the densities and detectability of Pf infections in Magude suggest the potential adaptation of malaria parasites to elimination efforts. Finally, declines in malaria transmission in high transmission settings are associated with significant epidemiological changes that indicate the rapid loss of herd immunity during pregnancy.

### IDENTIFYING MALARIA ASSOCIATED RISK FACTORS AMONG ADOLESCENTS LIVING IN AREAS WITH RESIDUAL MALARIA TRANSMISSION IN SENEGAL: A CASE CONTROL STUDY

**Fassiattou Tairou**<sup>1</sup>, Abdoulaye Diallo<sup>2</sup>, Ousmane Sy<sup>1</sup>, Aminatou Kone<sup>3</sup>, Isaac Akhenaton Manga<sup>1</sup>, Souleye Lelo<sup>1</sup>, Cheikh Binetou Fall<sup>1</sup>, Khadim Sylla<sup>1</sup>, Doudou Sow<sup>1</sup>, Magatte Ndiaye<sup>1</sup>, Babacar Faye<sup>1</sup>, Roger C K Tine<sup>1</sup>

<sup>1</sup>University Cheikh Anta Diop of Dakar, Dakar, Senegal, <sup>2</sup>Ministry of Health and Social Action, Dakar, Senegal, <sup>3</sup>Malaria Research and Training Center, University of Bamako, Mali, Bamako, Mali

In Senegal, malaria morbidity has decreased over these past years but malaria epidemiology remains heterogeneous with persisting transmission in the southeastern part of the country and more important cases among older children and adolescents. However, little is known about factors associated with clinical malaria among this group. A better understanding of malaria transmission will guide future interventions targeting these key populations. This study aimed at identifying factors associated with clinical malaria among adolescents in Senegal. A case-control study was conducted from November to December 2020 in four health posts, in the Saraya health district. The case was adolescent of 10-19 years with uncomplicated malaria (fever, Temperature>37.5° or history of fever, with positive malaria RDT) according to the National Malaria Control Program (NMCP) guidelines. Control was a same age group person, living in the neighborhood of the case, with negative mRDT. A questionnaire was administered to each participant followed by home visit to assess the living conditions. Factors associated with clinical malaria was assessed using a Stepwise Logistic regression analysis. In total, 492 individuals were recruited; 246 cases and 246 controls. In a multivariate analysis, factors associated with clinical malaria included non-use of bed net (aOR=2.65; 95% CI=1.58-4.45), non-use of other preventive measures (aOR=2.51; 95% CI=1.53-4.11) and indoor sleeping (aOR=3.22; 95% CI=1.66-6.23). Protective factors included age of 15-19 years (aOR=0.38; 95% CI 0.23-0.62), absence of stagnant water around the house (aOR=0.27; 95% CI=0.16-0.44), having a female household head (aOR=0.47; 95% CI=0.25-0.90), occupation such as apprentice (OR=0.24; 95% CI=0.11-0.52). The study revealed that environmental factors and non-use of preventive measures are the main determinants of malaria among adolescents living in areas with persisting transmission in Senegal. Strategies aiming at improving disease awareness and access to health care interventions such as LLIN are thus needed to improve malaria control and prevention among these vulnerable groups.

## MALARIA DEATHS EVOLUTION FROM 2015 TO 2019 IN THE DEMOCRATIC REPUBLIC OF CONGO (DRC)

**Hyacinthe Kaseya Ilunga**<sup>1</sup>, Eric Mukomena Sompwe<sup>1</sup>, Xavier Mwema<sup>1</sup>, Meschac Mutombo<sup>1</sup>, Packy Mbayo<sup>1</sup>, Johanna Karemere Nzigire<sup>2</sup>

<sup>1</sup>DRC National Malaria Control Program, Kinshasa, Democratic Republic of the Congo, <sup>2</sup>U.S. President's Malaria Initiative Measure Malaria/ICF, Chapel Hill, NC, United States

Malaria remains one of the most widespread and deadly parasitic diseases in the world and constitutes a real public health problem in the Democratic Republic of Congo (DRC), it is the leading cause of morbidity and mortality for which children under 5 years of age pay the heavy price. Deaths from malaria are often the result of no treatment, late treatment, or inappropriate treatment. The objective is to determine the evolution of deaths due to malaria from 2015 to 2019. Data were collected from DHIS2 software and from the National Malaria Control Program (NMCP) database. Analyses were performed with Excel software. Between 2015 to 2019, a gradual decrease in deaths due to malaria was observed, 39,054 deaths were recorded in 2015, 33,997 deaths in 2016, 27,458 deaths in 2017, 18,030 deaths in 2018 and 13,072 deaths in 2019. The proportion of malaria deaths in children under 5 represents 77% of all malaria deaths in 2015, 73% in 2016, 69% in 2017, 75% in 2018 and 69% in 2019. It is noticed an average of 73% over the 5 years considered, so children under 5 die more from malaria. The proportion of severe malaria out of all malaria cases varied between 12% and 14% with an average of 12% from 2015 to 2019. The good results obtained in relation to the decline in deaths caused by malaria between 2015 and 2019, would probably be due to the combination of several interventions including the providers training in case management, the regular supervision of care providers and the availability of drugs for the management of severe cases of malaria in the health facilities, as well as free malaria treatment practiced in DRC. These gains should be preserved by strengthening the management of malaria cases, by improving the supply chain for antimalarial drugs and other commodities, also by stepping up training supervision in health facilities. Sustained and special efforts should be directed towards the cases management in children under 5 who are much more affected by deaths due to this terrible endemic.

## BOTTLENECKS TO INTERVENTION SCALE UP: SUPPLY AND DEMAND SIDE PERSPECTIVES FROM A LARGE, COMMUNITY-BASED TRIAL OF MALARIA TESTING IN WESTERN KENYA

**Joseph Kipkoach**<sup>1</sup>, Lucy Abel<sup>1</sup>, Edna Sang<sup>2</sup>, George Ambani<sup>1</sup>, Erick Naliany<sup>1</sup>, Jane Namae<sup>1</sup>, Diana Menya<sup>1</sup>, Josephine Malinga<sup>3</sup>, Wendy Prudhomme-O'Meara<sup>3</sup>

<sup>1</sup>Academic Model Providing Access to Healthcare, Eldoret, Kenya, <sup>2</sup>Duke Global Health Institute, Eldoret, Kenya, <sup>3</sup>Duke Global Health Institute, Durham, NC, United States

Prompt malaria diagnosis either by microscopy or rapid diagnostic tests is recommended for all patients with suspected malaria before treatment. In the Kenyan retail sector, RDTs are not always available, and most patients who purchase antimalarials are not diagnosed before treatment. We tested an intervention where CHWs provided free RDTs in the community. In this analysis, we sought to identify factors that influenced the demand for malaria testing in the community and supply of testing by CHWs. A community-based survey was conducted to collect individual study outcomes based on a population-based survey sampling strategy at 12- and 18-months post-implementation. Testing data was collected from all 244 CHWs and in-depth interviews conducted with a random sample of 70. Of all survey participants, 55% (n=948/1738) reported having a malaria test for their recent illness where 38% of those were tested by a CHW. Delayed seeking care beyond the first 24 hours (AoR=1.23, 95%CI:1.06-1.43), being aware of your local CHW (AoR=1.50, 95%CI: 1.10-2.04) and belonging to a wealthy household (AoR=1.53 95%CI:

1.14-2.06) was associated with high malaria testing uptake. Wealthier families (AoR=0.32, 95%CI:0.17-0.60), and delaying testing beyond two days reduced the odds of testing with a CHW (AoR=0.41, 95%CI:0.23-0.73). School-aged children between 5-17 years were more than twice as likely to be tested by a CHW (AoR =2.47, 95%CI: 1.47-4.14). Both confidence in AL treatment (AoR =3.27, 95% CI: 1.71-5.25) and accuracy of an RDT performed by a CHW (AoR =2.29, 95% CI: 1.01-5.22) were strongly and positively associated with testing at a CHW. CHWs who were formally employed performed on average 1.37 more tests per month (Adj coeff=1.37,95% CI: 0.05,2.70) and those serving areas with a high proportion of positive tests (proportion positive >25%) tested on average 2 more clients per month than those in lower prevalence areas (Adj coefficient= 2.14, 95%CI: 0.63,3.64). These results show that there is a high demand for malaria testing at the community and provision of rapid test by CHW is feasible.

## HIGH-RESOLUTION SUB-DISTRICT STRATIFICATION OF MALARIA RISK IN ZANZIBAR

**Shabbir Lalji**<sup>1</sup>, Donal Bisanzio<sup>2</sup>, Humphrey Mkali<sup>1</sup>, Abdulwahid Al-mafazy<sup>1</sup>, Joseph Joseph<sup>1</sup>, Ssanyu Nyinondi<sup>1</sup>, Faiza Abbas<sup>3</sup>, Mohamed Ali<sup>3</sup>, Wahida Hassan<sup>3</sup>, Chonge Kitojo<sup>4</sup>, Naomi Serbantez<sup>4</sup>, Erik Reaves<sup>5</sup>, Mike McKay<sup>2</sup>, Jeremiah Ngondi<sup>2</sup>, Richard Reithinger<sup>2</sup>, Erin Eckert<sup>2</sup>

<sup>1</sup>RTI International, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>RTI International, Washington, DC, United States, <sup>3</sup>Zanzibar Malaria Elimination Programme, Zanzibar, United Republic of Tanzania, <sup>4</sup>US President's Malaria Initiative, United States Agency for International Development, Dar es Salaam, United Republic of Tanzania, <sup>5</sup>US President's Malaria Initiative, US Centers for Disease Control and Prevention, Dar es Salaam, United Republic of Tanzania

To achieve their malaria elimination target, Zanzibar has decided to implement an intervention approach based on risk strata. This study describes a novel approach to create a shehia (sub-district) malaria stratification map for Zanzibar. Case-level malaria data were obtained from the Malaria Case Notification system from January 2017 to December 2019. Data were aggregated and used to estimate the number of cases, incidence, fraction of imported cases, and probability of finding new cases during follow-up investigation of primary index cases for all 388 shehias. For each selected malaria indicator, pre-determined thresholds were assigned to determine risk levels of each shehia. Malaria indicator risk levels were analyzed using a multiple correspondence analysis (MCA) to assign a score for each shehia. The quartiles of the scores were then used to divide 333 shehias in four strata (1<sup>st</sup>-4<sup>th</sup> stratum, from high to low burden, with approx. 80 shehia per stratum). The performance of the MCA in creating distinct groups was evaluated comparing the distribution of the indicators among the strata (Wilcoxon signed-rank test). An additional fifth stratum was also created for 55 shehias in Mjini (urban) district due to different approaches for targeted interventions. Two stratification maps were created by varying indicator thresholds, one for the whole archipelago and one for each district. Malaria indicators showed a significant difference among the 1<sup>st</sup>-4<sup>th</sup> strata (p<0.05, Wilcoxon's test), highlighting good performance of grouping shehias using MCA. The maps showed that most of the high malaria burden strata aggregated in southern Unguja and low burden strata aggregated in southern Pemba. The resulting stratification will rapidly be implemented in Zanzibar. Intervention packages for shehias in the 2<sup>nd</sup>, 3<sup>rd</sup>, and 4<sup>th</sup>, strata will be based on community-level interventions while the 1<sup>st</sup> stratum will adopt a shehia-level approach. Specific interventions will be implemented per each urban shehia. This stratified approach will improve intervention effectiveness and programmatic resource allocation to support Zanzibar's path to elimination.

0659

### SYMPTOMATIC MALARIA IS ASSOCIATED WITH REDUCED RISK OF REINFECTION WITH PLASMODIUM FALCIPARUM PARASITES HARBORING HOMOLOGOUS CIRCUMSPOROZOITE PROTEIN EPITOPES

Jens E. Petersen<sup>1</sup>, Kelsey Sumner<sup>2</sup>, Elizabeth Freedman<sup>1</sup>, Judith N. Mangeni<sup>3</sup>, Lucy Abel<sup>4</sup>, Andrew A. Obala<sup>3</sup>, Wendy Prudhomme-O'Meara<sup>1</sup>, Steve M. Taylor<sup>1</sup>

<sup>1</sup>Duke University, Durham, NC, United States, <sup>2</sup>University of North Carolina, Chapel Hill, NC, United States, <sup>3</sup>Moi University, Eldoret, Kenya, <sup>4</sup>Moi Teaching and Referral Hospital, Eldoret, Kenya

The antigenic diversity of *Plasmodium falciparum* is a major hurdle in understanding antiparasite immunity and developing efficacious vaccines against malaria. Even for well described parasite proteins, such as Circumsporozoite protein (CSP) and Apical Membrane Antigen 1 (AMA1), the effect of antigenic diversity on naturally acquired protection against infection remains incompletely understood. Using a 14-month longitudinal cohort of 239 people in a high-transmission setting in Western Kenya from 2017 to 2018, we analyzed the influence of CSP and AMA1 diversity on the risk of re-infection. Using reported CSP and AMA1 variants cataloged by amplicon deep sequencing, we analyzed 296 unique CSP and 449 unique AMA1 amino acid sequences from 861 *P. falciparum* positive samples. We used a random forest algorithm to identify the most important amino acid positions for predicting overall fragment diversity, and then used these informative positions to examine the risk of reinfection with similar CSP or AMA1 proteins with mixed effect cox proportional hazard models. For CSP, the most predictive amino acids were clustered in previously identified T-cell epitopes. To further investigate this, we grouped CSP into 27 types, which despite the lower number (27 types vs. 298 haplotypes), were closely correlated with overall CSP haplotype multiplicity of infection (MOI) in individual infections (slope = 0.95,  $R^2 = 0.99$ ). Compared to asymptomatic infections, exposure to a CSP variant in a symptomatic infection was significantly associated with a prolonged time to reinfection by parasites with homologous CSP type (Adjusted hazard ratio = 0.6,  $p = 0.0036$ ). For AMA1, defining types based on the most predictive amino acid positions was highly correlated with MOI (slope = 0.9,  $R^2 = .99$ ); however, there was no significant effect of symptomatology on time to homologous reinfection based on AMA1 types. These findings highlight the importance of immune responses to specific CSP epitopes in conferring protection against *P. falciparum* infection, as people with symptomatic compared to asymptomatic infections were less likely to be reinfected with homologous CSP types.

### IMPACT OF PROACTIVE COMMUNITY CASE MANAGEMENT ON MALARIA AND ANEMIA PREVALENCE AMONG PREGNANT WOMEN IN BANKASS, MALI

Kassoum Kayentao<sup>1</sup>, Saibou Doumbia<sup>1</sup>, Jane Yang<sup>1</sup>, Caroline Whidden<sup>1</sup>, Emily Treleaven<sup>2</sup>, Julie Thwing<sup>3</sup>, Ari Johnson<sup>1</sup>

<sup>1</sup>MUSO, Bamako, Mali, <sup>2</sup>Institute for Social Research, University of Michigan, Ann Arbor, MI, United States, <sup>3</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States

Malaria and anaemia in pregnancy remain common in Mali despite the availability of proven interventions for their control. We conducted a study to assess whether proactive community case management (ProCCM) is more effective than the conventional, passive, fixed site approach to integrated community case management (iCCM) in reducing the prevalence of malaria and anaemia among pregnant women in a rural area of Bankass, Mali, in 2020. This study was nested in a three-year cluster randomized controlled trial assessing the impact of proactive case detection in reducing under-5 mortality. The study was conducted in the catchment areas of seven primary health facilities in which all 137 village-clusters were randomized to ProCCM or control arms. In clusters assigned to the ProCCM arm, community health workers (CHWs) were trained and deployed to conduct at least two hours daily of door-to-door case-finding

home visits with the goal of visiting each household at least two times a month. CHWs provided health services in the home including screening for recent illness or symptoms and follow-up for sick patients. CHWs in the control arm provided the same services in their communities at a fixed location. CHWs in both arms offered: malaria rapid diagnostic tests (RDT); antimalarial treatment for those with positive tests; pregnancy testing; referral to facility-based ANC; and follow-up maternal and newborn services. Baseline and annual household surveys were conducted. At the endline survey, all pregnant women were administered RDTs for malaria and hemoglobin levels for assessment of anaemia. The endline survey prevalence of malaria among pregnant women ( $N = 1,848$ ) was 16.8% (14.9-19.7) and that of mild, moderate, and severe anaemia was 27.2% (95% CI 24.9-29.4), 37.1% (95% CI 34.4-39.8), and 2.7% (95% CI 0.4-3.5), respectively. The study will be unblinded in June 2021, and results will be presented by treatment arm to assess whether the prevalence of these outcomes varied by treatment arm to inform community health system design and malaria control programs.

### PEDIATRIC MALARIA DETERMINANTS AND RISK MAPPING WITHOUT CLINICAL DATA IN SUSSUNDENGA MUNICIPALITY, MOZAMBIQUE

João Luis Ferrão<sup>1</sup>, Dominique Earland<sup>2</sup>, Roberto Mendes<sup>3</sup>, Kelly M. Searle<sup>2</sup>

<sup>1</sup>Instituto Superior de Ciências e Educação a Distância, Beira, Mozambique, <sup>2</sup>University of Minnesota, Minneapolis, MN, United States, <sup>3</sup>Universidade Católica de Mocimboa, Beira, Mozambique

Malaria is a parasitic borne disease representing a large burden in poor countries' economies such as Mozambique. In Mozambique malaria is the main public health concern. Children and pregnant women are at higher risk for morbidity and mortality due to decreased acquired immunity to clinical symptoms. Malaria transmission has a strong association with weather, socio-demographic determinants and age. Few studies on pediatric malaria have been done in Mozambique. Malaria risk is rarely uniform between places and the knowledge of malaria determinants and the evaluation of local heterogeneity can improve the understanding of pediatric malaria incidence and spatial distribution. Two consecutive years (2018 and 2019) of pediatric malaria case data ( $N = 42,248$ ,  $n = 21,663$ ) and, climatic (precipitation, mean temperature and Relative humidity) monthly data for 2019 were extracted from Sussundenga Rural Hospital and, world weather online records respectively. Attributable factor of the disease, incidence, sex, pediatric age category and patient origin were investigated. The relationship between the malaria cases and climate was tested using regression and Pearson correlation. For risk mapping, ten malaria factors (sociodemographic, climatic and clinic) were used to produce two maps one using malaria incidence data and, other without. Bioclimatic, Diva GIS 7.4.0 and, Landsat 8 image were used to produce the maps. From the visiting patients, 51.2% tested positive for malaria with an incidence of 45.7%. There is a difference between neighborhood in malaria incidence ( $p < 0.05$ ). As per gender, the malaria positive patients were equally distributed. Age groups 5 to 14 years presented 45.6% of the malaria cases.  $R^2$  was implying that, 74.5% of the malaria cases can be explained by rainfall, temperature and humidity. Both maps showed a malaria risk in the northeast and southeast areas. The malaria high risk areas seem to be located in high populated areas and, close to water bodies. Relevant information is provided for effective planning in malaria intervention for pediatric malaria patients.

## EXPLORING DISCREPANCIES BETWEEN MALARIA TEST POSITIVITY RATES FROM AUTOMATED READERS AND ROUTINE SURVEILLANCE DATA IN THE DEMOCRATIC REPUBLIC OF CONGO

Michael Humes

USAID - PMI, Washington, DC, United States

Test positivity rate (TPR) can be a strong predictor of malaria transmission, provide estimates of temporal changes in malaria burden and display seasonal fluctuations, particularly in areas with unimodal rainfall patterns. TPR has a direct relationship with incidence but is comparatively less influenced by reporting rates or care seeking. TPR is important in assessing true burden of malaria, but it is vulnerable to provider misreporting of test results, which warrants exploration. From early 2016 to mid-2019 automated malaria rapid diagnostic test (RDT) readers, Deki Readers, were deployed in health facilities across two provinces in southern Democratic Republic of Congo (DRC). Previous research has shown that Deki Readers are as good at interpreting RDTs as trained healthcare workers. A retrospective review of malaria data was conducted, comparing TPRs reported from the Deki Readers against TPRs reported from the same facilities in the DRC Health Management Information System (HMIS). Data from 102 health facilities that regularly used the Deki Readers in 2017 and 2018 were extracted. Paired t-testing showed a statistically significant ( $p < 0.001$ ) difference in TPRs of 30.2 percentage points by source, with an average annual Deki Reader TPR of 23.6% (CI: 22.7 - 24.6), compared to 53.8% (CI: 52.6 - 55.0) from HMIS. TPRs from the Deki Readers correlated strongly with climate trends, whereas data from HMIS largely lacked the expected seasonality. The difference was more extreme during the low malaria transmission season (May - September), during which the Deki Readers reported a TPR of 16.3% (CI: 15.1 - 17.5) compared to 51.1% from DHIS2 (CI: 49.1 - 53.1). For the two-year period these data show the TPR from HMIS is 128% higher than the TPR from Deki Readers. In DRC, the majority of suspect malaria cases are tested by RDT and present at peripheral facilities where diagnostic capacity is limited, and healthcare workers may have less support and training than staff at larger hospitals. These data suggest that potential reporting biases in HMIS data may be substantial and have considerable implications for true measures of cases, incidence and treatments.

## SPATIO-TEMPORAL DYNAMICS OF MALARIA IN ZANZIBAR

Donal Bisanzio<sup>1</sup>, Shabbir Lalji<sup>2</sup>, Humphrey R. Mkali<sup>2</sup>, Abdulwahid Al-mafazy<sup>2</sup>, Joseph J. Joseph<sup>2</sup>, Ssanyu S. Nyinondi<sup>2</sup>, Faiza B. Abbas<sup>3</sup>, Mohamed H. Ali<sup>3</sup>, Wahida S. Hassan<sup>3</sup>, Chonge Kitojo<sup>4</sup>, Naomi Serbantez<sup>4</sup>, Mike McKay<sup>1</sup>, Erin Eckert<sup>1</sup>, Jeremiah Ngondi<sup>1</sup>, Richard Reithinger<sup>1</sup>

<sup>1</sup>RTI International, Washington, DC, United States, <sup>2</sup>RTI International, Dar es Salaam, United Republic of Tanzania, <sup>3</sup>Zanzibar Malaria Elimination Programme, Ministry of Health, Zanzibar, United Republic of Tanzania, <sup>4</sup>US President's Malaria Initiative, United States Agency for International Development, Dar es Salaam, United Republic of Tanzania

Since 2017, malaria incidence in Zanzibar has gradually been increasing, undermining efforts to reach malaria elimination. This study describes the spatio-temporal dynamics and rainfall effect on malaria cases in Zanzibar. Case-level malaria data were obtained from Zanzibar's Malaria Case Notification (MCN) system from January 2015 to April 2020. For each primary (index) case attending public or private health facilities and reported through the MCN system, the following additional data were recorded at index case households: sex, age, other household members tested and treated for malaria, and self-reported travel history outside or within Zanzibar during the previous month. Using data aggregated at shehia (subdistrict) level, we performed a statistical hot-spot analysis, spatio-temporal regression and Kendall's concordance test to describe the spatial distribution of cases and its correlation with seasonal rainfall.

During the study period, 27,046 index cases were reported through the MCN system, of which, 40% had a travel history outside of Zanzibar. The total number of index cases ranged from 3,745 in 2015 to 4,252 in 2017, but steadily increased after 2017 to 5,494 in 2018 and 6,766 in 2019. From 2017 to April 2020, precipitation increased in both the short (Nov-Jan) and long (March-May) rainy seasons. The number of reported cases was significantly correlated with the precipitation of the previous three months. The percentage of tested household members who were malaria positive (secondary cases) showed a declining trend from 2015 (5.1%) to 2018 (4.1%) and an increase in 2019 (5.8%). The identified hot spots of index cases showed similar spatial distribution over the years. In 2019 and 2020, the number of cases and their spatial distribution during both rainy seasons were similar (Kendall's  $W = 0.76$ ,  $p < 0.05$ ). Results show a correlation between the recent increase in malaria cases and precipitation in Zanzibar. Identified malaria hotspots will be used by the Zanzibar Malaria Elimination Program for more effective targeting of interventions and allocation of programmatic resources.

## COMPREHENSIVE ASSESSMENT OF HETEROGENEITY OF MALARIA PREVALENCE AMONG CHILDREN UNDER FIVE YEARS IN THREE MALARIA ENDEMIC SUB-REGIONS OF UGANDA

Anthony Nuwa<sup>1</sup>, Geoffrey Beinomugisha<sup>1</sup>, Geoffrey Magumba<sup>1</sup>, David Salandini<sup>1</sup>, Flavia Mpanga<sup>2</sup>, Francis Abwaimo<sup>1</sup>, Musa Odongo<sup>1</sup>, Maureen Amutuhaire<sup>1</sup>, Robinah Lukwago<sup>3</sup>, Fred Kagwire<sup>2</sup>, Shirah Karungi<sup>1</sup>, James Tibenderana<sup>4</sup>

<sup>1</sup>Malaria Consortium Uganda, Kampala, Uganda, <sup>2</sup>Unicef, Uganda, Kampala, Uganda, <sup>3</sup>Foreign, Commonwealth & Development Office, Uganda, Kampala, Uganda, <sup>4</sup>Malaria Consortium Uganda, London, United Kingdom

The current national malaria indicator surveys are conducted at regional level thus they don't provide district and sub-district malaria prevalence data. This study was conducted to provide district and sub-district specific malaria prevalence for timely localized malaria control decision making. A total of 6,350 children under five years of age (U5) from 7,684 Households with the consent of their caregivers/parents were tested for malaria using both microscopy and malaria Rapid Diagnostic Tests (mRDTs). Microscopy results were used to compare the heterogeneity of malaria prevalence. Analysis was conducted using STATA version 12 and significance levels done using Fisher's test at 5%. The overall U5 malaria prevalence in the three sub regions was 17.1%. Karamoja sub-region had the highest malaria prevalence of 36% followed by Acholi (9.8%) and Lango (7.9%). In Karamoja sub-region, Moroto and Amudat districts had the lowest prevalence of 1.9% and 2.3% respectively, while Kotido, Nabilatuk and Nakapiripirit had the highest at 55.4%, 50% and 42.1% respectively. In Acholi sub-region, Amuru and Lamwo districts had the lowest prevalence at 2.1% and 3.2%, while Nwoya, Kitgum and Gulu had the highest at 22.8%, 10.7% and 10.6% respectively. In Lango, Amolator and Alebtong had the lowest prevalence at 2.4% and 2.9% respectively, while Kole, Kwania and Otuke had the highest at 17.0%, 15.9% and 14.9% respectively. Malaria prevalence significantly (Fisher's value=0.005<5%) increased with age ranging from 8.4% for children 0-11 months to 22.1% for children 48-59 months. Study findings also showed that malaria prevalence significantly (Fisher's value=0.000<5%) decreased with increasing wealth status of the individuals from 31.6% (lowest quintile) to 15.2% (second lowest quintile), 14.8% (middle quintile), 11.3% (fourth quintile) and 10.1% (highest quintile). However, the prevalence did not significantly ( $p > 0.425 > 5%$ ) change with gender. i.e. 17.7% for males and 16.4% for females. The study confirmed that malaria prevalence across the three sub-regions is highly heterogeneous in terms of geographical, age and wealth quintile.

0665

## MULTIPLE ARTEMISININ-BASED COMBINATION THERAPIES REMAIN EFFECTIVE FOR PLASMODIUM FALCIPARUM MALARIA IN MALI: A SYSTEMATIC REVIEW AND META-ANALYSIS

Fatoumata O. Maiga<sup>1</sup>, Mamadou Wele<sup>1</sup>, Sounkou Toure<sup>1</sup>, Makan Keita<sup>1</sup>, Cheick Oumar Tangara<sup>1</sup>, Randi R. Refeld<sup>2</sup>, Oumar Thiero<sup>1</sup>, Kassoum Kayentao<sup>1</sup>, Mahamadou Diakite<sup>1</sup>, Antoine Dara<sup>1</sup>, Jian Li<sup>2</sup>, Mahamoudou Toure<sup>1</sup>, Issaka Sagara<sup>1</sup>, Abdoulaye Djimé<sup>1</sup>, Frances J. Mather<sup>2</sup>, Seydou O. Doumbia<sup>1</sup>, Jeffrey G. Shaffer<sup>2</sup>

<sup>1</sup>University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali, <sup>2</sup>Tulane University, New Orleans, LA, United States

Artemisinin-based combination therapies (ACTs) were deployed in 2005 as an alternative to chloroquine and are considered the most effective treatments for uncomplicated *Plasmodium* (*P.*) *falciparum* malaria. While widespread artemisinin resistance has not been reported to date in Africa, recent studies have reported artemisinin resistance in Southeast Asia. Review studies have recently been performed on a country-specific basis for Sudan, Ethiopia, and Cameroon. The purpose of this study is to complement these studies with a current review of ACT efficacy based on trials occurring at Mali study sites, where *P. falciparum* malaria is highly endemic. A systematic review of the literature was performed to identify randomized clinical trials on ACTs at Mali study sites. Selected studies included clinical trials occurring at Mali study sites with reported polymerase chain reaction (PCR)-corrected adequate clinical and parasite response rates (ACPRCs) at 28 days. Data were pooled and analyzed using random effects meta-analysis approaches. ACPRCs were pooled and compared between artemether-lumefantrine (AL; the first-line treatment for *P. falciparum* malaria in Mali) and non-AL treatment arms. Results A total of 10 studies met the inclusion criteria, and a risk of bias assessment carried out by two independent reviewers determined low risk of bias among all assessed criteria. The overall ACPRC for the first line AL ACT at Mali sites was 97.3% (95% CI: [95.9%, 98.8%]), while the ACPRC among non-AL treatment arms was 98.2% (95% CI: [97.2%, 99.3%]). The difference in ACPRCs between non-AL treatment arms and AL treatment arms statistically significant ( $p = .016$ ) suggesting that there are potential treatment alternatives beyond the first-line of AL in Mali. ACT remains highly effective in treating uncomplicated *P. falciparum* malaria in Mali. Country-specific meta-analyses on ACTs are needed on an ongoing basis for monitoring and evaluating drug efficacy patterns to detect drug resistance and guide local malaria treatment policies, particularly in the wake of observed artemisinin resistance in Southeast Asia.

0666

## IMPACTS OF SEVERE CYCLONES ON MALARIA RISK ALONG THE MOZAMBIQUE AND ZIMBABWE BORDER

Kelly M. Searle<sup>1</sup>, Dominique Earland<sup>1</sup>, Anísio Novela<sup>2</sup>, Albino Bibe<sup>3</sup>, João L. Ferrão<sup>4</sup>

<sup>1</sup>University of Minnesota, Minneapolis, MN, United States, <sup>2</sup>Direccao Distrital de Saúde de Sussundenga, Manica, Sussundenga, Mozambique, <sup>3</sup>Escola Secundária de Sussundenga, Sussundenga, Mozambique, <sup>4</sup>Instituto Superior de Ciências de Educação, Beira, Mozambique

Mozambique currently has the 5<sup>th</sup> highest malaria prevalence globally. While there is within country heterogeneity, the central region has high malaria incidence and prevalence. The central region is also prone to seasonal cyclones which have the potential to impact malaria transmission through increased rains and altered water tables. These cyclones also cause damage to property and infrastructure which can increase the risk of malaria and impact the effectiveness of intervention programs. Sussundenga District in Manica Province lies directly on the Zimbabwe border. A cross-sectional community survey was conducted from December 2019-February 2020 to determine the malaria prevalence, risk factors, and impacts of severe weather events. This study was conducted one year after Cyclone Idai, which was devastating to the central region of Mozambique and eastern Zimbabwe. *Plasmodium falciparum* community

prevalence was documented as 31% in 2019. The primary intervention available to the community is limited to insecticide treated nets (ITN), and coverage was 65%. 59% of households reported structural household damage related to the cyclone, with 21% reporting that their home was completely destroyed. Household damage done during the cyclone was also strongly associated with malaria positivity during the survey. Additionally, 21% of households reported that all of their ITNs were destroyed or lost during the cyclone. While ITN coverage is moderate in this area, they are protective against infection. Destruction of ITNs during the cyclone was also associated with malaria infection at the time of the survey. The impacts of this cyclone are still contributing to malaria risk in the long-term. With increased frequency of cyclones in this region, it is imperative that these long-term impacts are well understood to respond accordingly.

0667

## BULK SEGREGANT APPROACHES TO FINDING DRUG RESISTANCE LOCI IN PLASMODIUM FALCIPARUM

Katelyn M. Vendrely<sup>1</sup>, Katrina A. Button-Simons<sup>1</sup>, Xue Li<sup>2</sup>, Sudhir Kumar<sup>3</sup>, Lisa A. Checkley<sup>1</sup>, Haley Dahlhoff<sup>1</sup>, Marina McDew-White<sup>4</sup>, Nelly Camargo<sup>3</sup>, Ann Reyes<sup>2</sup>, Meseret T. Haile<sup>3</sup>, Spencer Y. Kennedy<sup>3</sup>, Douglas A. Shoue<sup>1</sup>, Abeer Sayeed<sup>2</sup>, François H. Nosten<sup>5</sup>, Stefan H. Kappe<sup>3</sup>, Ian H. Cheeseman<sup>6</sup>, Ashley M. Vaughan<sup>3</sup>, Timothy J.C. Anderson<sup>2</sup>, Michael T. Ferdig<sup>1</sup>

<sup>1</sup>Eck Institute for Global Health, Department of Biological Sciences, University of Notre Dame, Notre Dame, IN, United States, <sup>2</sup>Disease Intervention and Prevention Program, Texas Biomedical Research Institute, San Antonio, TX, United States, <sup>3</sup>Center for Global Infectious Disease Research, Seattle Children's Research Institute, Seattle, WA, United States, <sup>4</sup>Disease Intervention and Prevention Program, Texas Biomedical Research Institute, San Antonio, IN, United States, <sup>5</sup>Shoklo Malaria Research Unit, Mahidol-Oxford Tropical Medicine Research Unit, Mahidol University, Mae Sot, Thailand, <sup>6</sup>Host Pathogen Interactions Program, Texas Biomedical Research Institute, San Antonio, TX, United States

Understanding the genetic architecture of complex phenotypes, such as drug resistance, is critical to developing effective interventions. Resistance to the antimalarial artemisinin (associated with mutations in the *kelch13* gene), along with resistance to other partner drugs (such as piperaquine), has emerged and is spreading in Southeast Asia. We demonstrate that bulk selection of uncloned progeny from *Plasmodium falciparum* genetic crosses cause allele frequency shifts at drug resistance loci and these selection effects can depend on genetic background. Our human liver-chimeric mouse model was used to generate four genetic crosses: i) multi-drug resistant Cambodian (KH004-2-019) and drug-sensitive Malawian (Mal31), ii) drug-sensitive lab-line (NF54) and an artemisinin-resistant C580Y *kelch13* mutant from the Thai-Myanmar border (NHP1337), iii) drug-sensitive from the Thai-Myanmar border (MKK2835) and NHP1337, and iv) drug-sensitive from the Thai-Myanmar border (MKK2835) and NHP1337 Y580C (the natural C580Y *kelch13* was CRISPR-edited to Y580C and is artemisinin-sensitive). The bulk recombinant populations from these four crosses were cultured *in vitro* and treated with antimalarial drugs at various concentrations. To optimize selection protocols, we first determined IC<sub>50</sub> drug-dose responses and ring-stage survival (for DHA) for the six individual parents of these crosses and four of the bulk populations. Treatment of bulk populations with 100 nM of chloroquine identified a locus at *pfcr*, confirming the ability of this approach to pinpoint resistance loci. Using a synchronized bulk population treated with 50 nM of DHA, we selected a strong allele frequency shift at the *kelch13* locus, extending our approach to drugs with strong stage specificity. Bulk segregant analysis allows us to initially screen phenotypes in thousands of progeny to identify candidate loci to be further investigated by individual clonal phenotyping and/or CRISPR validation.

## WHOLE GENOME ANALYSIS OF FOUR KENYAN PLASMODIUM FALCIPARUM STRAINS AS A PROOF OF CONCEPT OF DOWNSELECTION FOR CONTROLLED HUMAN MALARIA INFECTION

Elgin Akin<sup>1</sup>, Janette Moch<sup>1</sup>, Saba Alemayehu<sup>1</sup>, Ben Andagalu<sup>2</sup>, Edwin Kamau<sup>3</sup>, Alexander Pichugin<sup>1</sup>

<sup>1</sup>Walter Reed Army Institute of Research, Silver Spring, MD, United States,

<sup>2</sup>United States Army Medical Research Directorate - Africa/Kenya, Nairobi, Kenya, <sup>3</sup>University of California Los Angeles Health, Los Angeles, CA, United States

Given its morbidity, mortality, and global distribution, malaria is a significant risk to human health worldwide. Despite efforts with chemotherapy, bed nets, and insecticides, additional drugs and a vaccine are sorely needed. The WRAIR model of Controlled Human Malaria Infection (CHMI) is an invaluable tool to test vaccine and drug efficacy in healthy volunteers. However, as of 2021, only 4 *Plasmodium falciparum* (*Pf*) strains have been optimized for use in CHMI studies, and they do not represent genetic diversity of *Pf* strains in the field. To help to fulfill this gap, identified by FDA as one of the major gaps preventing CHMI studies from aiding licensure of a malaria vaccine for immune-naïve adults, we recently started the project to select and develop a suite of GMP-vialled *Pf* that represents geographic, genomic, and antigenic diversity for use in pre-clinical and clinical experiments, particularly CHMI. As a proof of concept, we have developed and optimized the pipeline to downselect novel *Pf* strains using culture-adapted *Pf* strains previously collected in Kenya. We demonstrated that 4 out of 32 strains can be successfully propagated *in vitro*, produce healthy gametocytes and sporozoites that are able to infect primary human hepatocytes. In order to evaluate genetic diversity, we sequenced the genomes of 4 strains. An average of ~43,000 SNPs and ~44,000 indels were observed across the 4 strains. All 4 strains contained a substantial number of coding variants in a panel of 16+ immunologically relevant regions for *Pf* vaccine development such as CSP, AMA1, TRAP, and LSA1. To assess a full genomic profile of 4 strains, we compared SNP calls against publically available *Pf* genomes revealing a strong representation to other Kenyan parasites despite rigorous culture adaptation. All 4 strains were also genetically distant of laboratory strains currently used for CHMI. The genomic characterization of *P. falciparum* strains provides invaluable information critical to development of CHMI strains to support vaccine and drug strategies against malaria.

## DEVELOPMENT AND EVALUATION OF NEW MULTIPLEXED AMPLICON SEQUENCING ASSAYS FOR PLASMODIUM FALCIPARUM MOLECULAR SURVEILLANCE

Emily LaVerriere<sup>1</sup>, Philipp Schwabl<sup>1</sup>, Manuela Carrasquilla<sup>1</sup>, Aimee Taylor<sup>1</sup>, Angela Early<sup>2</sup>, Ruchit Panchal<sup>2</sup>, Timothy Straub<sup>2</sup>, Meg Shieh<sup>1</sup>, Zachary Johnson<sup>1</sup>, Bronwyn MacInnis<sup>2</sup>, Daniel Neafsey<sup>1</sup>

<sup>1</sup>Harvard T.H. Chan School of Public Health, Boston, MA, United States,

<sup>2</sup>Broad Institute of MIT and Harvard, Cambridge, MA, United States

Molecular surveillance of *Plasmodium falciparum* can aid in tracking drug resistance mutations, transmission intensity, and connectivity of parasite populations. Multiplexed amplicon sequencing of small, highly diverse genomic regions balances the information content of targeted deep sequencing with the feasibility necessary for surveillance at scale in disease-endemic regions. While the use and availability of *Plasmodium* amplicon panels are increasing, no previous study has rigorously assessed the need for customization based on geographic region and expected diversity. Here we describe two new amplicon panels and evaluate their performance across a range of geographies: a four-amplicon panel composed of highly heterozygous antigen targets that works on samples with parasitemia as low as 10 parasites/ul without a pre-amplification step, and a 128-amplicon panel that incorporates drug markers and benefits from selective whole genome amplification (sWGA) for samples

with parasitemia below 1000 parasites/ul. We evaluated the panels on mock samples of varying parasitemia level and polyclonality as well as clinical samples from a range of geographies. We find that the four-amplicon panel improves upon the current standard of AMA1 sequencing for estimating complexity of infection (COI), with no additional protocol complexity or cost, and can reliably distinguish clonal vs. unrelated parasites. The larger 128-amplicon panel performs well in detecting intermediate levels of relatedness, and supports geographic attribution at a level comparable to two other recently published amplicon panels of similar size. We demonstrate that panels designed to target highly diverse populations are also informative in low diversity populations, suggesting that custom panel design will not be needed in most cases. Our findings suggest that choice of panel should depend on the specific study questions, and support the use of amplicon panels as information-dense, cost-effective methods for COI estimation, geographic attribution, and relatedness inference.

## TRACKING PLASMODIUM VIVAX THROUGH THE GREATER MEKONG SUBREGION USING GENOMES

Awtum M. Brashear<sup>1</sup>, Yubing Hu<sup>2</sup>, Yuling Li<sup>3</sup>, Yan Zhao<sup>2</sup>, Yaming Cao<sup>2</sup>, Liwang Cui<sup>1</sup>

<sup>1</sup>University of South Florida, Tampa, FL, United States, <sup>2</sup>China Medical University, Shenyang, Liaoning, China, <sup>3</sup>The First Affiliated Hospital of Dalian Medical University, Dalian, Liaoning, China

The Greater Mekong Subregion (GMS) intends to eliminate malaria by 2030. Malaria incidence in the GMS is heterogeneous; some countries, such as China, are approaching elimination status, while others, such as Myanmar, still have a high malaria burden. Additionally, multiple species of *Plasmodium* cause malaria in the GMS, though *Plasmodium vivax* is present within the majority of the region's malaria infections. *P. vivax* predominance in recent years has become more staggering as *P. falciparum* incidence has decreased. Large asymptomatic reservoirs and a dormant hypnozoite stage that can re-emerge months or years later make elimination of *P. vivax* especially challenging. Crossing this hurdle towards elimination will require targeted studies of *P. vivax* within the GMS. Genomics can provide a wealth of information for understanding the evolution and transmission of *P. vivax* through the GMS. In our studies, *P. vivax* whole genome sequences from across the GMS revealed notable structure between the east and west. While the China-Myanmar border was quite distinct from its neighbors, substantial genetic similarity existed between samples from Thailand and Cambodia. Despite the high incidence and a unique genetic profile, obtaining high-quality parasite samples from Myanmar is difficult, and little information exists from this part of the region. Genetic barcodes can help discern genetic differentiation information from relatively low amounts of parasite DNA and increase our available data. Therefore, we tested differentiation with existing genetic barcodes in this region and found that many of the variables in existing barcodes are not differentiated enough between populations to be informative here. Using our prior genetic differentiation results, we propose a new barcode. Whole-genome quality parasite sample size from Myanmar was small and whole-genome variant calling may not fully predict the capability of genetic barcodes, so follow-up analysis with existing barcodes in the northern part of the GMS is underway to determine if existing barcodes are capable of predicting structure from practical field data.

## PARASITE DETERMINANTS OF DISEASE SEVERITY FROM INFECTION WITH PLASMODIUM FALCIPARUM

We present a statistical analysis of deep meta-transcriptomic sequencing directly from whole blood of 220 samples obtained from pediatric malaria patients admitted to the Siaya County Reference Hospital in Siaya, Kenya. Our study design enabled the correlation of genetic features (expression profiles, genome inventory, complexity of infection, and mutational patterns) with various disease attributes, including parasite level, hemoglobin level, day zero vs. day 14 changes, and white blood cell counts. Transcriptomic data were analyzed on a by-read basis using peptide signatures and the Sequedex metagenomics analysis software, and by read-mapping to the KE01 completed genome from the MalariaGen project with bowtie2. Mapped reads were visualized with the Integrated Genome Browser, with gene expression quantified with htseq and variants identified with samtools. We observed numerous highly expressed parasite genes significantly associated with severe infections, including numerous surface antigens, histidine-rich proteins, and a cluster of exported proteins at the end of chromosome 14. Proteins with expression levels associated with less severe disease were also observed, including a lactate dehydrogenase. Functional characterization with metagenomic signatures showed considerable variation of *Plasmodium* heat shock proteins and those associated with glycolysis, redox metabolism, and vitamin B6 biosynthesis. Examination of patterns of polymorphisms associated with highly expressed genes provided evidence for both multiple infections within specific individuals and the same strains infecting multiple individuals in our sample set.

### FREQUENCY AND EVOLUTION OF HISTIDINE-RICH PROTEIN 2 AND 3 DELETION AMONG GLOBAL PLASMODIUM FALCIPARUM STRAINS

**Thomas C. Stabler**<sup>1</sup>, Ankit Dwivedi<sup>2</sup>, Biraj Shrestha<sup>3</sup>, Sudhaunshu Joshi<sup>3</sup>, Tobias Schindler<sup>1</sup>, Guillermo A. García<sup>4</sup>, Claudia Daubenberger<sup>1</sup>, Joana C. Silva<sup>5</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute; University of Basel, Basel, Switzerland, <sup>2</sup>Institute for Genomic Sciences, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>3</sup>Malaria Research Program, Center for Vaccine Development and Global Health, University of Maryland Baltimore, Baltimore, MD, United States, <sup>4</sup>Medical Care Development International, Silver Spring, MD, United States, <sup>5</sup>Institute for Genomic Sciences, University of Maryland School of Medicine; Department of Microbiology and Immunology, University of Maryland School of Medicine, Baltimore, MD, United States

Rapid diagnostics tests (RDTs) are a user-friendly diagnostic tool for suspected malaria infections in clinical and epidemiological settings. The majority of RDTs detect for presence of circulating *Plasmodium falciparum* (Pf) histidine-rich protein 2 (HRP2) in peripheral blood. HRP2-detecting RDTs can also cross-react with histidine-rich protein 3 (HRP3) in high-density infections (>1000 p/ml). Of concern is an increase in the frequency of global Pf isolates with HRP2/3 deletions, compromising our capabilities to monitor malaria in limited resource settings. We developed a computational pipeline to analyze whole genome sequence (WGS) datasets, generated using the Illumina platform, of field isolates to detect for the presence of deletions in the loci region encoding HRP2 and HRP3. Present deletions are characterized by start and end coordinates, the extent of the deletion (whole vs. partial coding sequence deletion), and whether it involved flanking intergenic regions and flanking genes.

We are currently analyzing WGS data of ~1400 Pf isolates, collected in 24 countries in South America, Africa, Southeast Asia and Oceania. Samples identified as having deletions at either *hrp2* or *hrp3* will be stratified by deletion characteristics, to determine the minimum number of independent deletion events per country. When applicable, we will perform a longitudinal analysis of HRP2/3 gene characteristics between samples from the same region collected at different time points. The historical use of RDTs will be examined in countries with increase deletion events over time. Within the partial deletion group, further investigation will identify the extent of the deletion (exon 1, exon 2, and intron). Results will be validated using a HRP2/3 gene-specific deletion assay that is effective in single or mixed genotype infections to ensure the reliability of pipeline results. Our study will demonstrate the capability and feasibility to accurately investigate *hrp2/hrp3* gene modifications and its frequency, characteristics and evolution to better understand potential drivers of these modifications over time and on a global scale.

### PLASMODIUM FALCIPARUM POPULATION STRUCTURE IN SOUTHWESTERN AFRICA, BASED ON NEWLY GENERATED GENOME-WIDE SEQUENCE DATA

**Wilson Tavares**<sup>1</sup>, Ankit Dwivedi<sup>2</sup>, Fernanda Dias<sup>3</sup>, Ana P. Arez<sup>1</sup>, Joana C. Silva<sup>2</sup>

<sup>1</sup>Instituto de Higiene e Medicina Tropical, Universidade NOVA de Lisboa, Lisboa, Portugal, <sup>2</sup>Institute for Genome Sciences, University of Maryland School of Medicine, Maryland, MD, United States, <sup>3</sup>Hospital Américo Boavida, Luanda, Angola

Angola, seventh in Africa both in area and in estimated number of malaria deaths in 2020, encompasses the southwestern-most edge of the distribution of *Plasmodium falciparum* in the continent. It is surrounded by distinct *P. falciparum* subpopulations, one in central Africa (Cameroon/Gabon) to the north, and another in south-central Africa (Democratic Republic of the Congo) to the northeast. Due to the lack of *P. falciparum* population genomics studies in Angola, it is unknown how genetically distinct its parasite population is from those of its neighbours, or whether molecular markers specific to the Angolan *P. falciparum* population(s) can be identified, to inform on parasite migration within and between countries. To address these knowledge gaps, we will generate and analyze whole-genome sequence (WGS) data for ~150 *P. falciparum* samples from children ≤ 5 years old, obtained from several Angolan provinces. Blood samples collected between 2006-2009, by fingerprick on filter paper, will be used. For each sample, DNA was extracted within one year of collection and stored at -20°C. Initially, to determine if the DNA was still viable for genome-wide analysis, we used *P. falciparum* selective whole genome amplification on four samples. Genomic libraries were sequenced in an Illumina NovaSeq sequencer, to generate paired-end 150 bp-long reads, and average genome coverage >35X. The sequencing data was mapped against the canonical *P. falciparum* 3D7 reference genome, single nucleotide polymorphisms (SNPs) identified according to best practices, and a principal component analysis was done using the recovered high confidence SNP calls, together with SNP calls from ~400 publicly available *P. falciparum* samples from East, West and Central Africa. Preliminary results show that Angolan samples group with others from Central Africa, indicating that these decade-old samples have adequate quality for WGS studies. WGS data currently being generated for the remaining >100 samples will be used to identify Angola-specific molecular markers and to initiate a study of *P. falciparum* demography in southwestern Africa, with a focus in Angola.

### USING BULK SEGREGANT ANALYSIS TO PROBE THE NUTRITIONAL REQUIREMENTS OF PLASMODIUM FALCIPARUM BLOOD STAGE GROWTH

In efforts to find novel targets to combat the malaria causing parasite *Plasmodium falciparum*, scavenging of nutrients and metabolic biosynthetic pathways can be potent targets for drug design. To study the roles of genes involved in parasite fitness in different nutrient conditions, we conducted an allopatric experimental genetic cross between a parasite of African origin, NF54 and a parasite of Asian origin, NHP4026. After we transitioned the recombinant parasites from liver stage-to-blood stage, we used bulk segregant analysis to compare genome-wide allele frequency changes in biologically independent progeny populations. Populations were grown in human serum, mirroring *in vivo* conditions, or AlbuMAX, a commercial bovine serum formulation commonly used to maintain asexual blood stage parasites in the laboratory. Genome wide changes in allele frequency were then measured over 15 asexual cycles. This bulk segregant approach detected three quantitative trait loci linked with differential growth conditions that contained strong candidate genes: aspartate transaminase, *AST* (chromosome 2); cysteine protease, *ATG4* (chromosome 14) and *EBA-140* (chromosome 13). Alleles inherited from NF54 (chromosomes 2 and 14) and from NHP4026 (chromosome 13) were positively selected for in AlbuMAX, while the same alleles were selected against in serum. Selection driving differential growth was strong (the selection coefficient,  $s = 0.10-0.23$  per 48-hour lifecycle) and was observed in all biological replicates. These results demonstrate the effectiveness of using bulk segregant approaches to reveal nutritional polymorphisms in *Plasmodium falciparum*. In turn, this will allow for a systematic dissection of nutrient acquisition and metabolic pathways that are potential targets for intervention against *P. falciparum*. Ultimately, this technique is suitable, alongside classical progeny analyses for the genetic mapping of a wide range of selectable traits including host specificity, immune evasion, and drug resistance.

### COMPLEXITY OF INFECTION ESTIMATION WITH ALLELE FREQUENCIES

Aris Paschalidis<sup>1</sup>, Oliver J. Watson<sup>2</sup>, Robert J. Verity<sup>2</sup>, Jeffrey A. Bailey<sup>1</sup>

<sup>1</sup>Brown University, Providence, RI, United States, <sup>2</sup>Imperial College London, London, United Kingdom

Polyclonal or complex malarial infections can provide insight into the genetic diversity and population structure of parasites as well as their transmission and within-host dynamics. The proportion of complex infections and the complexity of infection (COI—the number of strains infecting an individual) have been shown to be the most informative for inferring transmission intensity. Current state-of-the-art methods to estimate the COI such as THE REAL McCOIL are computationally intensive when working with a large number of samples or numerous genetic loci. In this study, we determined two relationships that tie the population-level minor allele frequency and the within-sample frequency of the minor allele to estimate the COI. We derived easily calculable measures to directly estimate the COI from these parameters that are easily obtained from sequencing read depth data. Our methods are computationally efficient,

estimating the COI of samples in less than a second, and perform well on simulated data. Furthermore, we demonstrate that our methods are comparably accurate to current methods in the literature. We apply both THE REAL McCOIL and our new methods to estimate the COI for 5,970 *P. falciparum* samples from 28 malaria-endemic countries collected as part of Pf3k (release 6). We explore the global heterogeneity of the COI and characterize the relationship between malaria prevalence at the time of sample collection and the COI. Lastly, we detail how our methods can be used to explore further within-sample parasite information, including the relatedness of parasites within mixed infections.

### NEXT-GENERATION-SEQUENCING-BASED ANALYSIS OF THE POLYMORPHISM OF MALARIA GENES IN AN ENDOGENOUS POPULATION OF PALAWAN ISLAND

Gnamian Nouveau Kanzin Alain, Taeko Naruse, Mahamoud Sama Cherif, Eleonor Avenido-Cervantes, Peterson Gitonga Mathenge, Chisato Narahara, Mario Jiz, Awet Teklemichael, Shusaku Mizukami, Kenji Hirayama

Institute of Tropical Medicine, Nagasaki University, Nagasaki, Japan

Genetic polymorphism of *Plasmodium falciparum* gene is a major concern for malaria control strategy. Host immune evasion, as well as genemutation, are known to be two important factors underlying the mechanism of resistance. Genetic analysis is one of the best ways used to identify mutant alleles in a local population parasite. In this study, we applied Next Generation Sequencing method to analyze 11 nominal genes obtained from an endogenous population of Palawan Island for their genetic polymorphisms. This study revealed the habitation of a variety of *Pf* strains in this region. 72 peripheral blood samples were collected from confirmed malaria cases. After DNA extraction and amplification by PCR, the PCR product was sequenced following Illumina miseq NGS protocol. GENETYX VER.15 application was utilized to make a multiple sequence alignment of those consensus sequences in each gene. The phylogenetic tree helped to categorize the different alleles present in those genes. NGS succeeded in sequence around 87.8% of the sample. 46.38% of successful sequences showed high-quality coverage. Newly identified SNPs were obtained from 5 vaccine candidate genes and 3 antimalarial drug target genes. The identified alleles varied between examined. B-cell epitope and T-cell epitope areas were analyzed for their SNPs distribution. SNPs in all the immunogenic genes were mainly targeted to the B-cell areas. 40% of our sample presented *PfDHFR* a resistant gene associated with a mutation at C59R. We didn't get enough PCR product explaining the low number of sequences observed in certain genes. *PfDHFR* and *GLURP* show very much different allele frequency due to the functional difference. Conclusion NGS-based analysis can be applicable to population genetics study.

### ELUCIDATING GENETIC DIVERSITY IN MALARIA DRUG RESISTANCE GENES IN AFRICA FOR THEIR IMPACT ON DRUG DEPLOYMENT AND TO MODEL EFFICACIOUS DRUGS

Rita A. Boateng<sup>1</sup>, Anita Ghansah<sup>2</sup>, Nigel Dolling<sup>3</sup>, James Myers-Hansen<sup>1</sup>

<sup>1</sup>Student, Noguchi Memorial Institute for Medical Research, Ghana,

<sup>2</sup>Researcher, Noguchi Memorial Institute for Medical Research, Ghana,

<sup>3</sup>Student, Noguchi Memorial Institute for Medical Research, Ghana

Malaria continues to plague the world, particularly sub-Saharan Africa. The gradual spread of resistance to artemisinin-based combination therapies in South East Asia is a clarion call for malaria-endemic regions, including Ghana. Heterogeneity in artemisinin resistance markers in Africa most likely. A preemptive approach to drug resistance monitoring will ensure a better control than how chloroquine and sulphadoxine-pyrimethamine resistance were handled. Additionally, the mechanism of action of resistant drugs is fully not understood. We, therefore, hypothesized that new mutations could be one of the driving forces of resistance across

Africa. The aim of this study is to identify putative and novel resistant variants, estimate their prevalence across Africa and the impact a variant or haplotype may have on protein structure, function and phenotypic associations of proteins encoded by *Pfcr1*, *Pfdhfr* and *Pfmdr1*. This study was carried out using 2596 African genome variations in *Pfcr1*, *Pfmdr1* and *Pfdhfr* from the MalariaGEN database. The retrieved variants comprise samples from Ethiopia, Gambia, Ghana, Kenya, Malawi, Mali, and Tanzania per each gene. Data pre-processing, sequence translation, sequence alignment and phylogenetic analyses were done. Mutability and high-quality structures of *Pfcr1*, *Pfmdr1* and *Pfdhfr* were generated for downstream analyses. Mapping of mutations and their effect on structural properties were done via Chimera. We expect to identify a novel set of mutations and haplotypes in *Pfcr1* and *Pfmdr1*, *Pfdhfr* and *Pfmdr1* across the African continents which could potentially drive ACT partner and SP drug resistance respectively in Africa, and relate these mutations to protein structure and function to elucidate the possible mechanism of action. This may form the basis for designing better novel antimalarial drugs.

### AGE-RELATED DIFFERENCES IN MONOCYTE DNA METHYLATION AND IMMUNE FUNCTION IN HEALTHY ADULTS AND CHILDREN LIVING IN AN AREA WITH INTENSE MALARIA TRANSMISSION

Katherine R. Dobbs<sup>1</sup>, Paula Embury<sup>1</sup>, Emmily Koech<sup>2</sup>, Sidney Ogolla<sup>2</sup>, Stephen Munga<sup>2</sup>, James W. Kazura<sup>1</sup>, Arlene E. Dent<sup>1</sup>

Age-related changes in adaptive and innate immune cells have been associated with a decline in effective immunity and chronic, low-grade inflammation. Epigenetic, transcriptional, and functional changes in monocytes occur with aging, though most studies to date have focused on differences between young adults and the elderly in populations with European ancestry; few data exist regarding changes that occur in circulating monocytes during the first few decades of life or in African populations. Such changes in innate immune cells early in life are likely to have a substantial impact on immunity to pathogens that disproportionately affect young children, most notably malaria. We analyzed DNA methylation profiles, cytokine production, and inflammatory gene expression profiles in negatively selected monocytes from healthy young adults (aged 19-35 years) and children (aged 1-9 years) from Kisumu County, Kenya, an area with perennially high malaria transmission. We identified several hypo- and hyper-methylated CpG sites in monocytes from young adults vs. children that replicated findings in the current literature of differential DNA methylation in monocytes from elderly persons vs. young adults across diverse populations. Differentially methylated CpG sites were also noted in gene regions important to inflammation and innate immune responses. Monocytes from young adults vs. children displayed increased production of IL-8, IL-10, and IL-12p70 in response to TLR4 and TLR2/1 stimulation as well as distinct inflammatory gene expression profiles. These findings complement previous reports of age-related methylation changes in isolated monocytes and provide novel insights into the role of age-associated changes in innate immune functions, which may be relevant to the acquisition and maintenance of clinical immunity to malaria.

### DISSECTING ANTIBODY MEDIATED FUNCTIONAL RESPONSES ASSOCIATED WITH PROTECTIVE IMMUNITY IN MALARIA INFECTED INDIVIDUALS USING A RAPID, WHOLE BLOOD FLOW CYTOMETRY ASSAY

Dilini Rathnayake<sup>1</sup>, Elizabeth H. Aitken<sup>1</sup>, Agersew A. Mengist<sup>1</sup>, Holger Unger<sup>2</sup>, Maria Ome-Kaius<sup>3</sup>, Stephen J. Rogerson<sup>1</sup>

<sup>1</sup>Department of Infectious Diseases, The Peter Doherty Institute of Infection & Immunity, University of Melbourne, Victoria 3010, Australia, <sup>2</sup>Menzies

School of Research, Royal Darwin Hospital Campus, Darwin, Northern Territory, Australia, <sup>3</sup>Papua New Guinea Institute of Medical Research, Madang Province, Madang, Papua New Guinea

Naturally acquired antibodies against *Plasmodium falciparum* malaria are key to protection, but their functional mechanisms remain poorly understood. Antibody dependent phagocytosis (ADP) of *P. falciparum*-infected erythrocytes (IEs) by neutrophils and monocytes is an important potential mechanism of pathogen clearance. To produce a more physiological model to measure ADP of *P. falciparum*-IEs, we devised a rapid flow cytometry assay using human whole blood without cell isolation. IEs opsonised with heat-inactivated plasma from malaria-exposed pregnant women were subjected to phagocytosis by neutrophils and monocytes in prediluted whole blood from malaria naïve volunteers. Fluorescently labelled antibodies against CD16 and CD66b, CD14, and CD45 were used to identify neutrophils, monocytes, and all leukocytes, respectively. Neutrophil and monocyte ADP of opsonised IEs is exposure-specific, and lysis of erythrocytes followed by fixation increase assay throughput without altering ADP of opsonised IEs. We observed good intra-donor and inter-donor correlation when assays were repeated among different donors (n=3) for both neutrophils (Spearman r=0.69-0.92) and monocytes (Spearman r=0.6-0.69) representing high reproducibility. In plasma collected in mid pregnancy from 77 women, we observed significantly more phagocytosis of IEs opsonised with plasma from pregnant women who progressed to placental infection at delivery compared to women who did not have placental infection, by both neutrophils (Mann-Whitney U test, P<0.0001) and monocytes (P=0.0007). A comparison ADP assay conducted with isolated neutrophils using IEs opsonised with the 77 plasma samples and correlated with neutrophil phagocytosis in whole blood showed a moderate correlation (Spearman r=0.5) between the assays. This assay can simultaneously quantitate exposure-specific opsonic phagocytosis of IEs by neutrophils and monocytes in human malaria. ADP was increased in pregnant women protected from placental malaria compared to those with placental malaria, indicating the assay's potential to measure protective immunity in malaria.

0680

### EXPANDED NATURAL REGULATORY T CELLS IN PREGNANCY-ASSOCIATED MALARIA ALTER DENDRITIC CELL FUNCTION INDIRECTLY THROUGH EFFECTOR T CELLS

Gullit Meinnafo Tasse

University of Dschang, Dschang, Cameroon

In malaria endemic area where pregnancy modulates malaria-specific responses in women, we sought to determine whether expanded populations of natural regulatory T cells (nTregs) directly modulate the production of malaria-induced cytokines by antigen presenting cells (APCs). We first used flow cytometry to phenotype nTregs in malaria-infected and malaria-uninfected pregnant women. We found that the frequencies of nTreg expressing CTLA-4, GITR, LAG-3, and IL-10 were significantly higher in malaria positive compared to malaria negative pregnant women. Depletion of CD25+ cells from PBMCs or antibody blockade of GITR, LAG3, PD1, CTLA-4 and IL-10R in PBMCs from malaria positive women significantly increased the production of malaria-specific IL-12p70 (p = 0.02), CXCL-10 (p=0.04) and CXCL-9 (p = 0.02) by APCs. However, co-culturing nTregs and APCs purified from malaria positive women did not affect malaria-specific cytokine production compared to APCs alone (p > 0.05), nor did blockade of GITR, LAG3, PD1, and CTLA-4. Antibody blockade of IL-10R, in contrast, did up-regulate APC production of malaria-specific CXCL-9 (p= 0.02), CXCL-10 (p = 0.0078) and IL-12p70 (p= 0.0049) when APCs were co-cultured with nTregs

### MALIAN CHILDREN DEVELOP ACUTE BUT NOT DURABLE ANTI-PFEMP1 SEROLOGIC RESPONSES TO CLINICAL MALARIA INFECTION

<sup>3</sup>University of California, Irvine, Irvine, CA, United States

*Plasmodium falciparum* erythrocyte membrane protein-1s (PfEMP1s) comprise a diverse family of proteins expressed on the surface of infected red blood cells. Each *P. falciparum* genome encodes dozens of antigenically distinct PfEMP1s. These parasite proteins adhere to host vasculature, aiding in replication and immune evasion. Host anti-PfEMP1 immune responses may play a role in protecting against clinical illness, particularly severe malaria. Using a custom protein microarray, we measured the serologic responses of children (n=40, 1-6 years old) in Bandiagara, a rural Malian town, over the course of a malaria transmission season. We hypothesized that at the start of the malaria transmission season, children who did not develop clinical infection have greater serologic responses to extracellular PfEMP1 fragments than children who developed clinical infection, that children who developed clinical infection have an increase in responses at peak transmission season compared to season start, and that these responses persist through end of season. We defined a fragment as serorecognized if a group's mean fluorescence intensity (MFI) to the fragment was significantly greater (Kolmogorov-Smirnov test, p<0.05) than naïve North American control's. At the start of the season, children who did not develop clinical infection serorecognized a similar number of fragments as children who developed clinical infection (28/138 extracellular PfEMP1 fragments and 25/138, respectively). Also at the start, they had similar (115/138) and lower (22/138) MFIs than children who developed clinical infection. Children who developed clinical infection gained serorecognition (40/138) and had higher MFIs (18/138) at peak-season than they did at the start. These increased responses waned quickly: serorecognition was lost (18/138) between peak and end of season, and MFIs to all PfEMP1 fragments did not differ between season start and end. Further studies of PfEMP1 serologic responses in a wider age range of Malian children over multiple malaria transmission seasons may provide insight into their role in protective immunity.

### CYTOKINE PROFILE IN PREGNANT WOMEN WITH PREECLAMPSIA AND PLACENTAL MALARIA

Dorotheah Obiri<sup>1</sup>, Daniel Oduro<sup>2</sup>, Isaac Joe Erskine<sup>3</sup>, Thomas Addison<sup>1</sup>, Kwame Adu-Bonsaffoh<sup>4</sup>, Kwadwo Asamoah Kusi<sup>1</sup>, Michael Fokuo Ofori<sup>1</sup>, Ben Gyan<sup>1</sup>

<sup>3</sup>Department of Pathology, Korle-Bu Teaching Hospital, Accra, Ghana,

<sup>4</sup>Department of Obstetrics and Gynaecology, University of Ghana Medical School, Accra, Ghana

Placental malaria and preeclampsia are independently known to alter the inflammatory/angiogenic pathways and are associated with poor pregnancy outcomes. However, it is unknown if the inflammatory/angiogenic pathways during PM precipitate or aggravate the syndrome of PE. We studied how markers of inflammation and angiogenesis compare in cases of preeclampsia comorbid with placental malaria. Our study sampled peripheral and placental plasma from 74 pregnant women (30 with Normal pregnancy and 44 diagnosed with preeclampsia) at delivery. We measured levels of twenty-six inflammatory and angiogenic markers

using a multiplex bead-based ELISA assay. Placental malaria was diagnosed by the histological examination of placental biopsies. Biomarker levels were mostly elevated in placental plasma compared to the periphery except C-Reactive Protein (CRP) which showed an inverse trend. In the peripheral plasma of preeclampsia diagnosed women with placental malaria, most biomarkers associated with inflammation/anti-angiogenesis such as CRP, CXCL8 showed higher concentrations. Preeclampsia diagnosed women with past placental malaria had lower concentrations of regulatory markers such as IL10 compared to normal pregnant women. The pattern was quite similar in the placental plasma. Correlation analysis was used to explore association between same markers from peripheral and placental plasma. The markers in peripheral plasma were distinct from those from placental plasma across the groups with and without placental malaria or preeclampsia. This study has generally shown that placental malaria further dysregulates inflammation/angiogenesis in preeclampsia. This knowledge should be expounded to inform clinical management.

### ANTIBODIES TO PFEMP1 EPCR-BINDING ANTIGENS BUT NOT CD36-BINDING ANTIGENS REMAIN ELEVATED FOR TWELVE MONTHS IN CHILDREN HOSPITALIZED WITH SEVERE MALARIA

Elizabeth Fernander<sup>1</sup>, Louise Turner<sup>2</sup>, Dibadyuti Datta<sup>1</sup>, Robert Opoka<sup>3</sup>, Ruth Namazzi<sup>3</sup>, Thomas Lavstsen<sup>2</sup>, Chandy John<sup>1</sup>

<sup>1</sup>Indiana University School of Medicine, Indianapolis, IN, United States,

<sup>2</sup>University of Copenhagen, Copenhagen, Denmark, <sup>3</sup>Makerere University,

Kampala, Uganda

Antibodies to *P. falciparum* erythrocyte membrane protein 1 (PfEMP1) are naturally acquired over time in people living in malaria-endemic countries and contribute to malaria immunity. Antibodies to endothelial protein C receptor (EPCR)-binding domains, which are frequently expressed in children with severe malaria (SM), are typically acquired before antibodies to other PfEMP1 domains, such as CD36-binding domains, which are more often expressed in uncomplicated malaria. The ordered acquisition of antibodies is believed to contribute to clinical immunity to severe malaria in early childhood in highly malaria endemic areas. To understand the role of PfEMP1 antibody mediated protection in SM, we measured IgG antibodies to 18 PfEMP1 domains in cohort of Ugandan children with SM (n=116) or asymptomatic community control children (n=22, 8 of whom had *P. falciparum* parasitemia) at enrollment and 12-month follow-up, using a multiplex cytometric bead assay. 83.6% of children with SM had antibodies to ≥1 of nine EPCR-binding antigens tested and 82.8% had antibodies to ≥1 of 6 CD36-binding antigens. 68.2% of CC group had antibodies to EPCR-binding antigens (p=0.09 compared to SM), and 68.2% of CC group had antibodies to CD36 antigens (p=0.11 compared to SM). At 12-month follow-up, prevalence of antibodies to EPCR-binding antigens among children with SM was similar to baseline (87.9%), but the prevalence of antibodies to CD36 antigens decreased significantly (58.6%, p<0.001 compared to enrollment). However, among CC, there was no significant reduction in prevalence of antibodies to EPCR- or CD36-binding antigens from enrollment to 12-month follow-up. In this study, children with SM had persistent antibodies to PfEMP1 EPCR-binding antigens, but decreased antibodies to CD36-binding antigens over time, while asymptomatic community control children had persistence of antibodies to both antigens over time. Ongoing analysis is being performed to determine if antibodies to either PfEMP1 antigen family were associated with protection from recurrent severe or uncomplicated malaria.

0684

### CELLULAR AND HUMORAL RESPONSES TO THE HIGHLY IMMUNOGENIC PLASMODIUM VIVAX PROTEIN VIR14

Anne D. Berhe<sup>1</sup>, Raianna F. Fantin<sup>2</sup>, Camila H. Coelho<sup>1</sup>, Dhelio Pereira<sup>2</sup>, Antonio Campos-Neto<sup>3</sup>, Daniella Bartholomeu<sup>2</sup>, Ricardo Fujiwara<sup>2</sup>, Lilian L. Bueno<sup>2</sup>, Patrick E. Duffy<sup>1</sup>

<sup>1</sup>NIH, Bethesda, MD, United States, <sup>2</sup>UFMG, Belo Horizonte, Brazil, <sup>3</sup>Tufts University, North Grafton, MA, United States

While *Plasmodium vivax* is the most widely distributed malaria parasite, tools to prevent, diagnose, and treat *vivax* infections are lacking. The *P. vivax* superfamily of VIR proteins can localize to the surface of infected red blood cells and is targeted by naturally acquired immunity which could aid in the development of new tools. In a proteomic survey, we identified a peptide identified to be from VIR14 in the urine of 2/4 infected Brazilian subjects. We then assessed VIR14 immune responses in diverse malaria-endemic populations, including residents of *vivax*-endemic Rondonia (Brazil) and Pursat province (Cambodia) and *falciparum*-endemic Mali. By ELISA, we detected VIR14-IgG in 74/121 (61%) adults in Brazil and 19/55 (34.5%) adults and children in Cambodia during *vivax* infections. IgG subclass profiling of Brazilian subjects revealed the response is dominated by IgG1 (detected in 42.9%) and IgG3 (in 36.1%). None of the 28 Malian adult *falciparum*-infected subjects showed detectable VIR14 reactivity, implying the absence of a cross-reactive *P. falciparum* antigen. Immune cell profiling via flow cytometry revealed that subjects with the highest VIR14-IgG levels had higher proportions of monocytes in PBMCs, as well as higher CD8+ T cells and lower CD4+ T cells measured as percent of CD3+ T cells. Considering the prevalence of VIR14 antigen and antibody in affected populations, further studies of VIR14 as a target for vaccines or diagnostic tools for *P. vivax* are warranted.

### CELLULAR CORRELATES FOR PROTECTION AGAINST MALARIA ACQUIRED ACROSS MULTIPLE PREGNANCIES

Adam Kiro Singh<sup>1</sup>, Lauren De La Parte<sup>1</sup>, Maureen Ty<sup>1</sup>, Abel Kakuru<sup>2</sup>, Mary K. Muhindo<sup>3</sup>, Mary K. Muhindo<sup>3</sup>, Nathalie Thulin<sup>1</sup>, Moses Kamya<sup>2</sup>, Margaret Feeney<sup>3</sup>, Grant Dorsey<sup>3</sup>, Taia Wang<sup>1</sup>, Prasanna Jagannathan<sup>1</sup>

<sup>1</sup>Stanford University, Palo Alto, CA, United States, <sup>2</sup>Infectious Diseases Research Collaboration, Kampala, Uganda, <sup>3</sup>University of California San Francisco, San Francisco, CA, United States

Malaria during pregnancy remains a significant cause of morbidity and mortality for both pregnant women and their infants, although with successive pregnancies, women eventually develop immunity against these adverse outcomes. To identify cellular correlations of malaria protection in pregnancy, we obtained cryopreserved peripheral blood mononuclear cells both at enrollment (2nd trimester) and delivery among 100 pregnant women. Cellular phenotypes and intracellular cytokine production following stimulation with 3D7 and CS2-infected red blood cells were assessed by flow cytometry. We found that women in their first pregnancies have a malaria-specific CD4+ T cell response characterized by high IL-10, and that multigravida women have a malaria-specific response that is more TNF-producing (P=0.009). Higher malaria-specific IL-10 producing CD4+ T cells at enrolment were associated with an increased likelihood of malaria parasitemia during pregnancy (P<0.0001). Furthermore, women with placental malaria had a malaria-specific CD4+ T cell response characterized by increased IL-10, whereas women without placental malaria had a malaria-specific response characterized by increased TNF. To further characterize these cytokine-producing populations we are performing RNA sequencing on sort-purified cells expressing TNFA or IL10/IFNg. Also, correlations between cellular responses and malaria-specific antibody repertoires are ongoing. Identification of correlates of protection against malaria in pregnancy will guide mechanistic studies and assist in prevention efforts, including chemoprevention and vaccines.

### INDUCTION OF HIGH ANTIBODY LEVELS AND PROTECTIVE IMMUNITY BY MRNA-LNP VACCINES BASED ON PRE-ERYTHROCYTIC AND TRANSMISSION-BLOCKING ANTIGENS IN PLASMODIUM FALCIPARUM

Clifford Hayashi<sup>1</sup>, Yi Cao<sup>1</sup>, Drew Weissman<sup>2</sup>, Fidel Zavala<sup>3</sup>, Jacob Van Parys<sup>1</sup>, Nirbhay Kumar<sup>1</sup>

<sup>1</sup>Department of Global Health, Milken Institute School of Public Health, George Washington University, Washington, DC, United States, <sup>2</sup>Department of Infectious Diseases, University of Pennsylvania, Philadelphia, PA, United States, <sup>3</sup>Johns Hopkins Malaria Research Institute, Baltimore, MD, United States

The mRNA based vaccination represents a new promising alternative to conventional vaccine approaches against infectious diseases because of its high potency and rapid development. Whether mRNA vaccines may elicit potent immune responses and effective protection against human malaria parasites is still elusive. In this study, mRNAs encoding *P. falciparum* circumsporozoite protein (PfCSP) and P25 (Pfs25) were optimized with appropriate UTRs and nucleoside modifications and complexed with lipid nanoparticles (LNPs). mRNA-LNPs were administered intramuscularly to female Balb/c mice (three doses at 4 week interval). Groups of mice (N=5) received various doses (3, 10, 30 ug) of either PfCSP or Pfs25 mRNA-LNPs as well as combination of both mRNAs (10ug each). In parallel, groups of mice were immunized with DNA vaccines encoding PfCSP, Pfs25 or a combination of both via *in vivo* electroporation for comparison of immunogenicity differences. Antigen specific antibodies were analyzed by ELISA. Immune protection against sporozoite challenge was evaluated by microscopic evaluation of blood stage parasitemia, and transmission blocking activity was evaluated in standard membrane feeding assays. All the mRNA-LNP immunized mice generated much higher antigen specific antibody titers than those in DNA vaccine immune mice. Elevated specific antibodies were detected after the primary dose of mRNA-LNPs, increasing dramatically to much higher levels after subsequent immunizations in all mRNA-LNP groups. Similar antibody levels were observed for both PfCSP and Pfs25 between the single mRNA groups (10ug/dose) and combined mRNA group (10ug each/dose), suggesting no interference of immunogenicity. After sporozoite challenge, all the mice in the groups receiving 10 and 30 ug PfCSP mRNA-LNPs were fully protected, whereas in the group receiving 3 ug mRNA-LNP only 1 out of 5 mice was fully protected. Also, 4 out of 5 mice in the combined mRNA-LNP group were fully protected. Our studies strongly support further studies on the development of mRNA-LNP formulations for vaccines targeting multiple stages in multiple *Plasmodium* species.

### ANTIBODIES TO PLASMODIUM FALCIPARUM CIRCUMSPOROZOITE PROTEIN: A NON-MECHANISTIC CORRELATE OF PROTECTIVE EFFICACY OF PFS25 VACCINE IN THE FIELD

Natasha KC<sup>1</sup>, Kayla McLeod<sup>1</sup>, Sumana Chakravarty<sup>1</sup>, Tooba Murshedkar<sup>1</sup>, Mahamadou S. Sissoko<sup>2</sup>, Sara Healy<sup>3</sup>, Patrick E. Duffy<sup>3</sup>, Sodiomon B. Sirima<sup>4</sup>, Matthew B. Laurens<sup>5</sup>, Martina Oneko<sup>6</sup>, Laura Steinhart<sup>7</sup>, Robert A. Seder<sup>8</sup>, LW Preston Church<sup>1</sup>, B. Kim Lee Sim<sup>1</sup>, Peter F. Billingsley<sup>1</sup>, Thomas L. Richie<sup>1</sup>, Stephen L. Hoffman<sup>1</sup>

<sup>1</sup>Sanaria Inc, Rockville, MD, United States, <sup>2</sup>Malaria Research and Training Center (MRTC), Bamako, Mali, <sup>3</sup>LMIVINIAID/NIH, Rockville, MD, United States, <sup>4</sup>Groupe de Recherche Action en Santé, Ouagadougou, Burkina Faso, <sup>5</sup>Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>6</sup>Kenya Medical Research Institute, Centre for Global Health Research, Kisumu, Kenya, <sup>7</sup>Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>8</sup>National Institute of Health, Bethesda, MD, United States

*Plasmodium falciparum* (Pf) sporozoite (SPZ) vaccine (PFS25 Vaccine) has been assessed in 1,726 5-month to 61-year-olds in Africa, Europe, and

the US. Vaccine efficacy (VE) has been assessed against controlled human malaria infection (CHMI) and field exposure to heterogeneous, intensely transmitted Pf. VE against CHMI has been > 90% in 5 trials in the US, Europe, Tanzania, and Mali, and durable for at least 14 months. Best VEs against naturally transmitted Pf infection in Mali and Burkina Faso have ranged from 48% to 56% and been shown to last for at least 18 months. Vaccine development and implementation would be enhanced by having an assay that predicts protection, a correlate. VE is thought to be mediated by tissue (liver) resident CD8+ cells, which cannot be assayed, and assessment of peripheral blood mononuclear cells does not correlate with protection. We have extensively studied antibodies to PfSPZ and the major surface protein on PfSPZ, the Pf circumsporozoite protein (CSP) for an association with protection in the field. The results of 3 studies in 18-50 year olds (MLSPZV1, N=42 vaccinees, 5 doses of  $2.7 \times 10^5$  PfSPZ), (MLSPZV2, N=54, 3 doses of  $1.8 \times 10^6$  PfSPZ), (BFSPZV1, N=39, 3 doses of  $2.7 \times 10^6$  PfSPZ) and one study in 5-12 month olds (KSPV1, N=67, 3 doses of  $1.8 \times 10^6$  PfSPZ) show that IgG antibodies to PfCSP 2 weeks after last vaccine dose were significantly higher in subjects who did not become infected (protected) as compared to those who became infected (unprotected) in follow up; serum dilution at which the OD was 1.0: 1,742 vs 231 ( $p=0.044$ ), 3,790 vs 978 ( $p=0.001$ ), 5,550 vs 1,410 ( $p=0.01$ ), and 10,138 vs 3,724 ( $p=0.007$ ) in the 4 trials respectively. Assessment of IgM antibodies to PfCSP and IgG antibodies to PfSPZ by IFA showed similar results. However, results of a functional assay, inhibition of sporozoite invasion assay, did not show an association with VE. These data suggest that the antibodies are not mediating VE, but are a non-mechanistic correlate (biomarker) of VE of PfSPZ Vaccine in the field at the group, but, because of extensive overlap in the ranges, not at the individual level. These data as well as data from CHMI studies will be presented.

#### MAXIMIZING THE POTENTIAL WINDOW OF OPPORTUNITY FOR MALARIA ELIMINATION VIA GENE DRIVES AND CHEMICAL VECTOR CONTROL

**Prashanth Selvaraj**, Shirley Leung, Caitlin Bever

*Institute for Disease Modeling, Seattle, WA, United States*

Gene drives result in select genes spreading through a population at a higher than normal inheritance rate leading to phenotypes associated with these genes dominating a population faster than random genetic drift. Phenotypes that have been considered for mosquitoes carrying a gene drive include among others mosquitoes that are rendered refractory to malaria transmission as well as ones that distort the sex of the progeny to bias the male-female ratio to suppress a population. Given rising levels of insecticide resistance across sub-Saharan Africa, gene drives are being developed as a solution to decreased chemical intervention efficacy. However, populations of mosquitoes that experience gene drive introductions eventually develop resistance to the drives as well either through natural mutations or due to incorrect cleaving and copying of the drive components at the target site. This would eventually lead to drive failure in the population and the loss of desirable phenotypes. Additionally, uncertainty in future climate cycles as well as heterogeneity of mosquito migration and behavior patterns over large geographies would necessitate continued chemical insecticide pressure on regional vector populations to drive transmission to zero within a specific window of opportunity. Here, we investigate which gene drive strategies offer the most optimal path to malaria elimination in a range of transmission settings by leveraging a large scale individual-based model of malaria transmission, EMOD, in combination with a multi-locus, agent-based model of vector genetics that accounts for mutations and many-to-many mappings of genotypes to phenotypes. We also evaluate release conditions that will maximize the efficacy of gene drive propagation as well as chemical intervention rotation strategies that offer the largest window of opportunity for elimination than either method deployed individually in a range of transmission settings.

#### EVALUATING THE ROLE OF COVERAGE, CAMPAIGN TIMING, AND ADHERENCE ON THE PROGRAMMATIC IMPACT OF SEASONAL MALARIA CHEMOPREVENTION: A MODELING STUDY

**Erin Zwick**<sup>1</sup>, Kamaldeen Okuneye<sup>1</sup>, Caitlin Bever<sup>2</sup>, Monique Ambrose<sup>2</sup>, Jaline Gerardin<sup>1</sup>

<sup>1</sup>*Northwestern University, Chicago, IL, United States*, <sup>2</sup>*Institute for Disease Modeling, Seattle, WA, United States*

The WHO recommends seasonal malaria chemoprevention (SMC) with sulfadoxine-pyrimethamine plus amodiaquine (SP+AQ) for children in regions where malaria is highly seasonal and drug resistance is low. While SP+AQ is highly effective at reducing uncomplicated malaria incidence in clinical trials, its effectiveness declines during programmatic SMC deployment. This study implemented simulation modeling to identify and quantify factors that affect the programmatic performance of SMC. We modeled malaria transmission with EMOD, an established individual-based simulation modeling software, and extended the model to include the pharmacokinetics and pharmacodynamics of SP and AQ. We incorporated an SMC campaign by distributing four cycles of SMC monthly throughout the rainy season. The population of eligible children was divided into two groups: high or low SMC accessibility. Children in the high-access group received all four rounds of SMC while those in the low-access group had variable chance of receiving SMC each cycle. We validated the model against study data from a programmatic SMC deployment in Kaya District, Burkina Faso then simulated the effect of SMC after varying coverage level, campaign timing relative to the transmission season, or adherence to doses 2 and 3 of AQ. We found that coverage has the greatest effect on reducing clinical incidence followed by timing. Increasing coverage to 95% of children resulted in a 77% greater reduction in clinical incidence compared to the baseline coverage level of 58% of children and starting the first SMC cycle any time in the month before peak transmission season decreased clinical incidence 10% more than starting SMC during peak transmission season. We find no evidence that adherence rate affects clinical incidence. Our results suggest that the decay in SMC impact during programmatic deployment is more likely attributable to insufficient coverage and suboptimal timing rather than poor adherence. We plan explore the role of drug resistance in future model iterations. The results of our model provide supportive data for optimizing future SMC deployments.

#### MODELING PLASMODIUM FALCIPARUM PARASITE GENETICS INSIDE AN AGENT-BASED, SPATIAL MODEL

**Daniel Bridenbecker**, Jonathan Russell, Albert Lee, Jessica Ribado, Svetlana Titova, Edward Wenger, Joshua L. Proctor, Caitlin Bever

*Institute for Disease Modeling, Seattle, WA, United States*

The genetics of *Plasmodium falciparum* is playing an increasingly important role in the understanding of malaria transmission and guiding the use of interventions. A model of the parasite's genetics has been integrated into IDM's open source Epidemiological MODELing software. EMOD is a stochastic, mechanistic, agent-based model that simulates the actions and interactions of individuals within geographic areas in order to understand the disease dynamics in a population over time. The new parasite genetics module takes the existing model from sporozoites to gametocytes in the human and extends it with a detailed model in the mosquito of the parasite progressing from gametocyte to oocyst to sporozoite. This enables us to more easily model parasite genome changes due to mutation and recombination. We will explain how this is modeled as well as demonstrate how different intervention strategies - such as ITN, IRS, and MDA - impact the complexity of infection as a metric of changing transmission intensity.

### EVALUATING THERAPEUTIC EFFICACY STUDY METHODOLOGIES WITHIN AN AGENT-BASED MODEL OF MALARIA WITH EXPLICIT PARASITE GENETICS

Jonathan R. Russell<sup>1</sup>, Daniel Bridenbecker<sup>1</sup>, Jessica Ribado<sup>1</sup>, Albert Lee<sup>1</sup>, Sam Jones<sup>2</sup>, Ian Hastings<sup>3</sup>, Joshua L. Proctor<sup>1</sup>, Caitlin A. Bever<sup>1</sup>

<sup>1</sup>Institute of Disease Modeling, Seattle, WA, United States, <sup>2</sup>Medicines for Malaria Venture, Geneva, Switzerland, <sup>3</sup>Liverpool School of Tropical Medicine, Liverpool, United Kingdom

Therapeutic Efficacy Studies (TES) are a critical tool in the surveillance for drug resistance to antimalarials. The ability to genotype parasites observed in treatment failures during these drug trials is necessary to distinguish true drug failures (recrudescences) from reinfections as individuals in endemic settings continue to be exposed to infectious bites. As WHO guidelines for molecular correction of TES have not been revisited in over a decade, and diverse approaches are used to evaluate parasite genotypes, mathematical models of malaria offer the capability to test the robustness of both molecular techniques and algorithms against simulations of drug treatment trials. Here we demonstrate the accuracy of novel and traditional methods for molecular correction of TES results within the context of EMOD, a calibrated individual based model of malaria epidemiology with explicit parasite genetics. Using simulation, we explore the sensitivity of molecular correction methods as a function of drug type and failure rate, sequencing technology, ranges of transmission intensity, seasonality, and within-host immunity. We demonstrate the relative impact of these sensitivities on the resolving power of commonly used genotyping methodologies and classification algorithms. These results add to a growing body of evidence that updated methods are needed for obtaining accurate failure rate estimates that can be compared across transmission settings.

### A SYSTEMS-LEVEL GENE REGULATORY NETWORK MODEL FOR PLASMODIUM FALCIPARUM REVEALS ELEVATED TRANSCRIPTIONAL VARIATION IS ASSOCIATED WITH REDUCED ARTEMISININ SENSITIVITY

Ling Wei<sup>1</sup>, Maxwell L. Neal<sup>1</sup>, Kamalakannan Vijayan<sup>1</sup>, Sruthi Sravanam<sup>2</sup>, Eliza Peterson<sup>3</sup>, Mario L. Arrieta-Ortiz<sup>3</sup>, Samuel A. Danziger<sup>4</sup>, Nitin S. Baliga<sup>3</sup>, John D. Aitchison<sup>1</sup>, Alexis Kaushansky<sup>1</sup>

<sup>1</sup>Seattle Children's Research Institute, Seattle, WA, United States, <sup>2</sup>University of Washington, Seattle, WA, United States, <sup>3</sup>Institute for Systems Biology, Seattle, WA, United States, <sup>4</sup>Bristol Myers Squibb, Seattle, WA, United States

Malaria is a life-threatening disease caused by *Plasmodium* parasites that are transmitted to humans through the bites of infected female *Anopheles* mosquitoes. Unfortunately, reduced sensitivity of even highly effective artemisinin-based combination therapies has been observed in the field. Here, we aim to understand the gene regulatory programs that govern the sensitivity of *P. falciparum* to artemisinin. We built a systems-level gene regulatory network for *P. falciparum* upon the transcriptomic data of parasite isolates from patients with acute malaria, using a well-validated, machine-learning approach. To build the inference network, co-regulated genes were first identified based on the coherence of their transcriptomic profiles across multiple samples and the presence of common upstream binding motifs. With a compiled list of transcriptional regulators, we then implemented a linear regression-based statistical modeling method to determine the directed and weighted gene regulatory interactions. The resulting network accurately predicts expression levels of transcriptionally coherent gene regulatory programs in independent transcriptomic datasets generated in geographically diverse settings by multiple research groups. The model serves as a hypothesis-generating tool for illuminating clinically relevant gene regulatory mechanisms. We found that reduced artemisinin sensitivity is associated with incoherent gene expression across many regulatory programs, including antigenic variation and erythrocyte-host

interactions. The association between increased transcriptional variation and reduced artemisinin sensitivity could be explained by the parasite utilizing bet-hedging strategies to diversify the population and help ensure the survival of the population as a whole under drug pressure. Our work demonstrates the importance of transcriptional heterogeneity in promoting the likelihood of survival for certain subpopulations of *P. falciparum* in the context of environmental stresses.

### IMPROVING MALARIA SURVEILLANCE THROUGH ROBUST FACILITY CATCHMENT POPULATION ESTIMATION

Justin Millar<sup>1</sup>, Rohan Arambepola<sup>2</sup>, John Miller<sup>3</sup>, Adam Bennett<sup>1</sup>, Chris Lungu<sup>3</sup>, Marie-Reine Rutagwera<sup>3</sup>, Busiku Hamainza<sup>4</sup>, Ewan Cameron<sup>5</sup>, Hannah Slater<sup>1</sup>

<sup>1</sup>PATH, Seattle, WA, United States, <sup>2</sup>Department of Epidemiology, Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>3</sup>PATH, Lusaka, Zambia, <sup>4</sup>National Malaria Elimination Centre, Zambia Ministry of Health, Lusaka, Zambia, <sup>5</sup>Malaria Atlas Project, Telethon Kids Institute, Curtin University, Perth, Australia

Malaria surveillance systems are critically important for local-scale monitoring and evaluation, supporting evidence-based decision making, and ultimately pushing towards elimination. However, their overall utility is undermined when facility catchment populations are either unknown or poorly described. Without accurate population denominators, it is difficult or impossible to determine comparable rates of malaria incidence or intervention and commodity coverage. In the Zambian HMIS DHIS2, 818 out of 2,338 geolocated health facilities are missing population denominators. We developed a geospatial modelling framework for estimating catchment populations, which integrates patient travel times and attributes from individual facilities (e.g., facility type, total outpatient records). This approach produces catchments that account for inherent differences between facilities, incorporate meaningful distance measures, and overlap geographically. This method was used to estimate catchment populations for all geolocated malaria-treating health facilities in Zambia. Population estimates were validated using facility headcount (where available) and household field surveys, and compared to "nearest facility" Voronoi estimates. The catchment model had a higher overall correlation ( $R = 0.39$ ) with the HMIS populations compared to the Voronoi estimates ( $R = 0.30$ ), and had equal or higher correlations in 9 of the 10 individual provinces. The purpose of this model is to support national monitoring, intervention targeting and commodity distribution. We also developed tools to apply this framework to other geographies, and incorporated additional information such as treatment seeking rates and seasonal dynamics. These robust estimates for catchment populations will fill existing gaps and improve the utility of malaria surveillance systems.

0694

### USING ROUTINE CASE DATA TO QUANTIFY THE EFFECTIVENESS OF SEASONAL MALARIA CHEMOPREVENTION UNDER PROGRAMMATIC IMPLEMENTATION: A QUASI-EXPERIMENTAL STUDY IN BURKINA FASO

Sebastian Rodriguez<sup>1</sup>, Cheick Compaore<sup>2</sup>, Boulaye Dao<sup>2</sup>, Beatriz Galatas<sup>3</sup>, Abdisalan Noor<sup>4</sup>, Jaline Gerardin<sup>5</sup>, Jaline Samia<sup>1</sup>

<sup>1</sup>Northwestern University, Evanston, IL, United States, <sup>2</sup>National Program for the Fight Against Malaria, Ouagadougou, Burkina Faso, <sup>3</sup>World Health Organization, Geneva, Switzerland, <sup>4</sup>World Health Organization, Swaziland, <sup>5</sup>Northwestern University, Chicago, IL, United States

Seasonal malaria chemoprevention (SMC) was first recommended by the WHO in 2012 to prevent uncomplicated malaria in children, with 21.5 million children under 5 years old receiving at least one dose in 2019. Systematic assessment of the impact of national SMC campaigns requires data with high temporal resolution and spatial coverage over several years. Using routine health facility data from 2015 to 2018 from Burkina Faso, we quantify the effectiveness of SMC against symptomatic malaria with

generalized linear mixed models in a difference-in-differences framework. We group health districts into SMC rollout groups, defined as the group of districts receiving SMC for the first time in the same year. We quantify the effectiveness of SMC in reducing the incidence of confirmed malaria cases, hospitalizations, and the malaria proportion of outpatient visits for each group. SMC showed a weak protective effect on reducing the malaria proportion of outpatient visits in children under 5: 7.13% [95%CI 1.99%, 12.00%] reduction for the 2016 SMC rollout group, 16.94% [10.69%, 22.75%] reduction for the 2017 group, and no significant effect for the 2018 group. SMC reduced reported incidence in children under 5 by 38.53% [32.31%, 44.18%], 45.20% [37.05%, 52.30%], and 25.36% [13.12%, 35.87%] in the 2016-2018 SMC groups, respectively. SMC was also associated with a reduction in malaria hospitalizations in children under 5 by 36.68% [26.97%, 45.10%] in the 2016 SMC rollout group and 23.51% [4.31%, 38.85%] in the 2017 group. SMC was not associated with a significant reduction in any of the three indicators for individuals over 5. Reporting quality and treatment-seeking behavior increased in Burkina Faso concurrent with SMC rollout, potentially introducing trends in routine surveillance data independent of changes in the underlying risk of clinical disease. Analyses of crude incidence can be complemented by analyses on other variables such as the malaria proportion of outpatient visits, which can control for changing surveillance quality, to create a more complete understanding of intervention efficacy.

0695

#### CONVERSION RULES BETWEEN HAEMOGLOBIN AND HAEMATOCRIT IN PATIENTS WITH UNCOMPLICATED PLASMODIUM FALCIPARUM OR PLASMODIUM VIVAX MALARIA: INDIVIDUAL PATIENT DATA META-ANALYSIS USING WORLDWIDE ANTIMALARIAL RESISTANCE NETWORK DATA REPOSITORY (WWARN)

**Prabin Dahal**, On Behalf of WWARN Haemoglobin-Haematocrit Study Group

*University of Oxford, OX3 7FZ, United Kingdom*

Worldwide Antimalarial Resistance Network (WWARN) promotes data sharing and data re-use for generating new evidence to improve health and understanding of the diseases. We used data from the WWARN repository to assess the accuracy of conversion algorithms for haemoglobin (Hb) and haematocrit (Hct) measurements in patients with uncomplicated *Plasmodium falciparum* (Pf) and *P. vivax* (Pv) malaria. Studies in the WWARN repository with concurrent measurements of Hb and Hct at enrolment into clinical trials were identified and individual patient data was requested through WWARNs Independent Data Access Committee. The accuracy of two conversion rules were assessed: Rule 1 -  $Hct (\%) = 3 \times Hb (g/dL)$  and Rule 2 -  $Hct (\%) = 5.62 + 2.60 \times Hb (g/dL)$ . The proportion of derived Hb values that fell within  $\pm 1$  g/dL of the true measurements and the sensitivity [95% confidence interval (CI)] of the conversion rules in identifying anaemic patients ( $Hb < 11$  g/dL) were presented separately for Pf and Pv malaria. Forty-five studies enrolling 11,680 Pf patients and 13 studies enrolling 1,588 Pv patients contributed to the analysis. In Pf patients, Rule 1 led to derived Hb values within  $\pm 1$  g/dL of true Hb in 72% (2604/3624) of children <5 years, 82% (3780/4640) among aged  $\geq 15$  years, 81% (4704/5838) of non-anaemic and 74% (341/463) of severely anaemic ( $Hb < 7$  g/dL) patients. The corresponding estimates using Rule 2 were 62%, 76%, 75% and 58%. In Pv patients, Rule 1 led to derived Hb within  $\pm 1$  g/dL of true Hb in 53% (42/80) of children <5 years, 85% (1096/1297) of  $\geq 15$  years, 85% (1067/1254) of non-anaemic and 69% (229/330) of mild/moderate anaemic ( $Hb \geq 7$  and  $Hb < 11$  g/dL) patients. The corresponding estimates for Rule 2 were 66%, 82%, 83% and 81%. The sensitivity of Rule 1 in identifying anaemic patients was 86% [95% CI: 82-89] in Pf and 77% [95% CI: 65-86] in Pv; the corresponding estimates for Rule 2 were 94% [95% CI: 91-95] and 88% [95% CI: 80-94]. Overall Rule 2 appeared better for identifying anaemic patients, but both rules had lower accuracy in young children and anaemic patients. Modelling is ongoing to explore alternative rules.

0696

#### IMPROVEMENTS TO GENEPI: INCREASING THE BIOLOGICAL REALISM AND COMPUTATIONAL EFFICIENCY FOR SIMULATING MALARIA PARASITE GENETICS FROM A TRANSMISSION HISTORY

**Albert Lee**<sup>1</sup>, Jessica V. Ribado<sup>1</sup>, Jonathan Russell<sup>1</sup>, Daniel Bridenbecker<sup>1</sup>, Sharon Chen<sup>1</sup>, Tony Ting<sup>1</sup>, Christopher Lorton<sup>1</sup>, Wesley Wong<sup>2</sup>, Edward Wenger<sup>1</sup>, Caitlin Bever<sup>1</sup>, Joshua L. Proctor<sup>1</sup>

<sup>1</sup>*Institute for Disease Modeling, Seattle, WA, United States*, <sup>2</sup>*Harvard T.H. Chan School of Public Health, Boston, MA, United States*

As malaria control programs expand their genomic surveillance efforts with new collection methods and sequencing technologies, genetic models with flexible internal representations can be valuable for analyzing the wide variety of data. We present recent extensions to GenEpi, a layered and modular framework for interfacing simulations of parasite genetics with transmission records from epidemiological models. GenEpi has been developed as a Python package and is part of comprehensive effort to build an end-to-end pipeline that can connect detailed simulations to genomic data and support the application of the data towards genomic use-cases. Here, we describe updates to the model designed to improve its mechanistic accuracy for evaluating parasite genetic diversity and multiplicity of infection in a population. We incorporate the recombination of gametocytes as they are transmitted from the mosquito vector and construct the evolving population of parasites through a series of transmission chains. With these updates, the model has a self-consistent internal representation that is easy to interpret and can be used to distinguish between the effects of superinfection or cotransmission. We discuss some simplifying reductions in the model's representation of parasites, which make simulations tractable while maintaining the fidelity of critical mechanistic components. GenEpi is intended to be an open source tool that can be adopted by collaborators and the broader scientific community. We demonstrate simulation outputs that can in turn be processed by a sampling and sequencing model, and we conclude with current and future use cases of the model for furthering our understanding and increasing the interpretability of parasite sequences.

0697

#### IMPROVED ESTIMATES OF MULTIPLICITY OF INFECTION IN MALARIA AND RELATED INFECTIOUS DISEASES

**Meraj Hashemi**, Henri Christian Junior Tsoungui Obama, Kristan Alexander Schneider

*Hochschule Mittweida, Mittweida, Germany*

The UN's Sustainable Development Goals commit to eradicate several infectious diseases, including malaria, to achieve global well-being. These efforts require monitoring disease transmission at a level that differentiates between pathogen variants at the genetic/molecular level. In fact, the advantages of genetic (molecular) measures like multiplicity of infection (MOI) over traditional metrics, e.g., basic reproduction number, are being increasingly recognized. MOI refers to the presence of multiple pathogen variants within an infection due to multiple infective contacts. Maximum-likelihood (ML) methods have been proposed to derive MOI and pathogen-lineage frequency estimates from molecular data. These estimates can be substantially biased for small sample sizes, as they often occur in practice. Considering a single molecular marker, we derive a bias-corrected ML estimator for MOI and pathogen-lineage frequencies. The bias of the estimates substantially reduced. A further bias reduction can be achieved by heuristical adjustments. This results in (almost) unbiased estimates, whose variance coincides with the theoretical minimum among all unbiased estimators (Cramér-Rao lower bound). This suggests that no further improvements are possible unless additional information is provided. Such information can be obtained by combining data from several molecular markers. By averaging MOI estimates from several molecular markers (with desirable properties), the variance of the MOI estimates can be substantially reduced. This heuristic variance reduction is a potent alternative to deriving MOI estimates from combined information

of several molecular markers if missing values are common in the data. Based on a simulation study, we investigate under which situations the heuristic variance reduction should be applied. As an example, we apply and compare different estimates, including the bias-corrected and variance-reduced ones, to several malaria molecular datasets from Africa and South America.

0698

### MATHEMATICAL MODELING TRANSMISSION OF WOLBACHIA AMONG ANOPHELES ALBIMANUS MOSQUITO POPULATIONS IN HAITI

Alyssa J. Young<sup>1</sup>, Benjamin P. Stager<sup>2</sup>, Kerly Bernabe<sup>1</sup>, Daniela A. Florez<sup>2</sup>, Zhuolin Qu<sup>3</sup>, James M. Hyman<sup>2</sup>

<sup>1</sup>Tulane University School of Public Health and Tropical Medicine, New Orleans, LA, United States, <sup>2</sup>Tulane University School of Science and Engineering, New Orleans, LA, United States, <sup>3</sup>University of Texas San Antonio Department of Mathematics, San Antonio, TX, United States

Malaria elimination is possible in Haiti. Preliminary studies of *Anopheles* (*An.*) mosquitoes infected with *wAlbB* *Wolbachia* bacterium have shown that the infected mosquitoes are less capable of spreading malaria. The infection induces a cytoplasmic incompatibility that disrupts the infection cycle through population suppression, inhibiting within-vector replication of the *Plasmodium falciparum* parasite, and reducing vector competence. *Wolbachia* is widespread among arthropods, and there are ongoing trials for sustaining wild populations of *Wolbachia*-infected *Aedes aegypti* to prevent the spread of dengue fever. We create and analyze a model to evaluate different approaches for maintaining *wAlbB* infection within *An. albimanus* mosquitoes and apply it to assess its potential as a malaria control strategy in Haiti. Our nine non-linear differential equation model divides the population based on the mosquito's sex, infection status, pregnancy status and includes an aquatic stage. The model simulates the combination of traditional malaria vector control strategies of insecticide-treated net (ITN) distribution and indoor residual spraying (IRS) with different release scenarios of *wAlbB*-infected mosquitoes, and it evaluates the impact that seasonality can have on the releasing time and strategies for reaching a stable high-infection (90%) among wild *An. albimanus* mosquitoes. Our preliminary results indicate that the use of IRS at baseline and release of infected pregnant female mosquitoes during the rainy season lead to the fastest establishment of endemic *wAlbB* transmission. Consequently, acquiring endemic *wAlbB* infection can reduce malaria transmission in *Anopheles* mosquitoes and thereby be a potentially useful measure for preventing and controlling malaria transmission.

0699

### A MICROPLANNING MODEL TO IMPROVE DOOR-TO-DOOR HEALTH SERVICE DELIVERY: THE CASE OF SEASONAL MALARIA CHEMOPREVENTION IN SUB-SAHARAN AFRICAN VILLAGES

Andre Lin Ouedraogo

BMGF, Bellevue, WA, United States

Malaria incidence has plateaued in Sub-Saharan Africa despite Seasonal Malaria Chemoprevention's (SMC) introduction. Community health workers (CHW) use a door-to-door delivery strategy to treat children with SMC drugs, but for SMC to be as effective as in clinical trials, coverage must be high over successive seasons. We developed and used a microplanning model that utilizes population raster to estimate population size, generates optimal households visit itinerary, and quantifies SMC coverage based on CHWs' time investment for treatment and walking. CHWs' performance under current SMC deployment mode was assessed using CHWs' tracking data and compared to microplanning in villages with varying demographics and geographies. Estimates showed that microplanning significantly reduces CHWs' walking distance by 25%, increases the number of visited households by 36% ( $p < 0.001$ ) and increases SMC coverage by 21% from 37.3% under current SMC deployment mode up to 58.3% under microplanning ( $p < 0.001$ ). Optimal

visit itinerary alone increased SMC coverage up to 100% in small villages whereas in larger or hard-to-reach villages, filling the gap additionally needed an optimization of the CHW ratio. We estimate that for a pair of CHWs, the daily optimal number of visited children (assuming 8.5mn spent per child) and walking distance should not exceed 45 (95% CI 27-62) and 5 km (95% CI 3.2-6.2) respectively. Our work contributes to extend SMC coverage by 21-63% and may have broader applicability for other community health programs.

### ASSESSMENT OF INTEGRATED COMMUNITY MALARIA VOLUNTEER KNOWLEDGE AND JOB PERFORMANCE IN MYANMAR, 2018-2020

May Oo Khin<sup>1</sup>, Aung Mon<sup>2</sup>, Wint Phyto Than<sup>2</sup>, Thiha Myint Soe<sup>1</sup>, Khin Thant Zin<sup>1</sup>, Aung Ko Ko Zaw<sup>1</sup>, Ni Ni Aye<sup>1</sup>, Khant Maung Maung<sup>3</sup>, Kaung Myat Thbu<sup>3</sup>, Khun Aung Thant<sup>4</sup>, Tun Zaw Lat<sup>5</sup>, Su Hlaing Than<sup>6</sup>

<sup>1</sup>Jhpiego, Myanmar, U.S. President's Malaria Initiative (PMI) Defeat Malaria Project, Yangon, Myanmar, <sup>2</sup>National Malaria Control Program, Nay Pyi Taw, Myanmar, <sup>3</sup>University Research Co., Myanmar, U.S. President's Malaria Initiative (PMI) Defeat Malaria project, Yangon, Myanmar, <sup>4</sup>American Refugee Committee, U.S. President's Malaria Initiative (PMI) Defeat Malaria Project, Hlaingbwe, Myanmar, <sup>5</sup>Myanmar Health Assistant Association, U.S. President's Malaria Initiative (PMI) Defeat Malaria Project, Sittwe, Myanmar, <sup>6</sup>Myanmar Nurse and Midwife Association, U.S. President's Malaria Initiative (PMI) Defeat Malaria Project, Yangon, Myanmar

The PMI-funded Defeat Malaria Project contributes to Myanmar's goal of eliminating malaria by 2030. As an implementing partner, Jhpiego supports capacity development for the National Malaria Control Program (NMCP) and health providers at all levels of service provision. As malaria cases are decreasing, NMCP adopted a policy on integrated community malaria volunteers (ICMV) in 2017 and trained village malaria workers (VMW) as ICMVs to sustain their knowledge and skills in malaria and 5 other infectious diseases to augment their impact in communities and to provide health education and referral of suspected cases among patients with negative mRDTs. From October 2018 to March 2020, 400 ICMVs in 12 States/Regions received a 5-day training followed by refresher training and regular supportive supervision. Defeat Malaria Project partners and the NMCP collaborated to assess the knowledge and skills of 384 ICMVs of the 400 trained from June - December 2020 (at 5 - 6 months and 9 - 12 months post-training). Due to COVID19 restrictions, assessments were conducted via phone interview using standardized knowledge questionnaires and skills assessment forms. 90% of ICMVs achieved scores of  $\geq 80\%$  on knowledge of malaria and 64% on non-malaria diseases (passing score is  $\geq 80\%$ ). 73% knew mRDT testing criteria and 99% correctly performed mRDTs. 99.5% followed national treatment guidelines for malaria and 96% knew referral criteria. Due to lack of confidence only 53% correctly identified, and 34% referred, suspected cases of non-malaria diseases mentioned above to health facilities. Per self-reports, 81% supported LLIN distribution and 58% supported prevention of non-malaria diseases. 97% had stocks of mRDT and anti-malaria drugs; 99% regularly reported on malaria and 90% on non-malaria diseases. 96% advocated to village administrators and the community and 11% received support from the community for referral. ICMV knowledge and skills are influenced by regular training and follow up. The findings will be utilized by NMCP to guide further implementation to achieve malaria elimination and community health care.

## TRENDS IN FEVER CASE MANAGEMENT FOR FEBRILE INPATIENTS IN A LOW MALARIA INCIDENCE SETTING OF TANZANIA

**Deng B. Madut**<sup>1</sup>, Matthew P. Rubach<sup>1</sup>, John P. Bonnewell<sup>1</sup>, Elena R. Cutting<sup>1</sup>, Nathaniel Kalengo<sup>2</sup>, Manuela Carugati<sup>1</sup>, Michael J. Maze<sup>3</sup>, Anne B. Morrissey<sup>1</sup>, Blandina T. Mmbaga<sup>2</sup>, Bingileki F. Lwezaula<sup>4</sup>, Grace Kinabo<sup>2</sup>, Ronald Mbwasi<sup>2</sup>, Kajiru G. Kilonzo<sup>2</sup>, Venance P. Maro<sup>2</sup>, John A. Crump<sup>3</sup>

<sup>1</sup>Duke University Medical Center, Durham, NC, United States, <sup>2</sup>Kilimanjaro Christian Medical Centre, Moshi, United Republic of Tanzania, <sup>3</sup>University of Otago, Dunedin, New Zealand, <sup>4</sup>Mawenzi Regional Referral Hospital, Moshi, United Republic of Tanzania

In 2010, the World Health Organization (WHO) recommended parasitological confirmation for all patients with suspected malaria prior to antimalarial initiation. We present data on changes in fever case management following the 2010 WHO policy shift among febrile inpatients in a low malaria transmission setting in northern Tanzania. We analyzed data from 2,098 children and adults enrolled in two hospital-based prospective cohort studies, cohort 1 (2011-2014) and cohort 2 (2016-2019). All patients underwent malaria blood smear microscopy. We compared diagnoses, treatments, and outcomes between the two study periods. Participants who had a negative malaria blood smear microscopy but received a diagnosis of malaria or received an antimalarial were categorized as malaria over-diagnosis and over-treatment, respectively. Of participants, the median (IQR) age was 27 (3-43) years and 1,047 (50.0%) were female. Malaria was detected by blood smear microscopy in 23 (2.3%) participants in cohort 1 and 42 (3.8%) in cohort 2, ( $P = 0.059$ ). Malaria over-diagnosis occurred in 334 (35.0%) participants in cohort 1 and 190 (17.7%) in cohort 2, ( $P < 0.001$ ). Malaria over-treatment occurred in 528 (55.1%) participants in cohort 1 and 196 (18.3%) in cohort 2, ( $P < 0.001$ ). There were 30 (3.1%) deaths in cohort 1 and 60 (5.4%) in cohort 2, ( $P = 0.007$ ). All deaths in both cohorts occurred among participants with a negative malaria blood smear microscopy. In summary, we observed a substantial decline in malaria over-diagnosis and over-treatment among febrile inpatients in northern Tanzania between two time periods after 2010. Despite changes, some smear-negative participants were still diagnosed and treated for malaria. Our results highlight the need for continued monitoring of fever case management across different malaria epidemiologic settings in sub-Saharan Africa and the need to concentrate efforts towards improving outcomes for patients with a negative malaria diagnostic test.

## IMPROVING INTERMITTENT PREVENTIVE TREATMENT IN PREGNANCY UPTAKE IN TERTIARY REFERRAL HOSPITALS IN GHANA THROUGH FACILITY-BASED PREVENTION OF MALARIA IN PREGNANCY (MIP) AND QUALITY IMPROVEMENT TRAINING

**James Sarkodie**<sup>1</sup>, Mildred Kommey<sup>2</sup>, Felicia Babanawo<sup>1</sup>, Munkaila Mohammed<sup>1</sup>, Raphael Ntummy<sup>1</sup>, Amos Asiedu<sup>1</sup>, Keziah Malm<sup>3</sup>, Lolade Oseni<sup>3</sup>, Gladys Tetteh<sup>3</sup>

<sup>1</sup>US President's Malaria Initiative, Impact Malaria project, Accra, Ghana,

<sup>2</sup>National Malaria Control Programme, Accra, Ghana, <sup>3</sup>US President's Malaria Initiative, Impact Malaria project, Baltimore, MD, United States

Regional and teaching hospitals in Ghana serve as tertiary referral hospitals (RHs) with high antenatal care utilization and provide vital access to intermittent preventive treatment in pregnancy (IPTp) for pregnant women. In RHs, the National Malaria Control Programme (NMCP) supports capacity building for IPTp services through classroom-type (CT) trainings in malaria in pregnancy (MIP). Review of Health Management Information System (HMIS) data from 2015-2020 revealed low IPTp coverage and poor data quality at these RHs. In 2019, IPTp-3 coverage ranged from 0% for Komfo Anokye Teaching Hospital to a notably high coverage of 181% for Bono Regional Hospital attributable to poor data quality. To improve IPTp

coverage and data quality, PMI Impact Malaria (IM) supported NMCP to implement facility-based (FB) trainings in MIP and quality improvement (QI) in six RHs. A total of 183 health workers (HWs) (about 30 per RH) were trained through the FB trainings in November 2020. Training participants included midwives, clinicians, health information officers, store managers, laboratory technologists and pharmacists involved in MIP service delivery. The training aimed to build a team with knowledge on the updated MIP guidelines, logistics and data management skills and competence for quality service delivery and QI methods. To ensure ownership, training facilitators were selected from a pool of clinicians at the RH, and all RHs developed action plans (APs) and established teams to implement them. APs listed priorities through QI to address challenges across departments in knowledge in MIP, health commodity availability and data quality. Post-training supervision occurred two months after training. The average pre-test score was 46% and average post-test score was 75%. Post-training, no RH has experienced stock outs of MIP-related commodities and all show improved MIP data quality. The average IPTp-3 coverage for 5 of the 6 RHs improved from 49% to 100% while MIP data inconsistencies decreased from 83% to 50%. Facility-based MIP training with QI methods complements CT training and improves IPTp coverage and data quality in a sustainable manner.

## THE ROLE OF NEEDS ASSESSMENT OF THE COMMUNITY HEALTH PROGRAM IN IMPROVING COMMUNITY MALARIA CASE MANAGEMENT, RWANDA

**Jean Modeste Harerimana**<sup>1</sup>, Aimable Mbituyumuremyi<sup>2</sup>, Beatrice Mukamana<sup>3</sup>, Noella Umulisa<sup>1</sup>, Katherine Wolf<sup>4</sup>, Anastase Muhashyi<sup>2</sup>, Jean Damascene Niyonzima<sup>2</sup>, Eliab Mwiseneza<sup>1</sup>

<sup>1</sup>US President's Malaria Initiative, Impact Malaria project, Kigali, Rwanda,

<sup>2</sup>Malaria and Other Parasitic Diseases Division/Rwanda Biomedical Center, Kigali, Rwanda, <sup>3</sup>Maternal, Child and Community Health Division/Rwanda Biomedical Center, Kigali, Rwanda, <sup>4</sup>US President's Malaria Initiative,

Impact Malaria project, Jhpiego, Baltimore, MD, United States

Rwanda's community health program is a home-grown solution to address 2 key health challenges: access to health services and a shortage of health providers. Each village has 4 community health workers (CHWs), including a male-female pair providing basic care and the integrated community case management (iCCM) package for childhood illness. Over the past 15 years, the integrated CHW program has helped decrease all causes <5 mortality from 152 to 45 deaths/1000 live births. The Ministry of Health started a community health program needs assessment (NA) to understand program effectiveness and identify challenges. NAs provide information and guide decision-making and resource allocation. Based on community health indicators and reports, in Sept 2020, the Malaria Division and PMI Impact Malaria (IM) conducted a baseline NA on iCCM and home-based management of malaria (HBm) packages in two new IM-supported districts served by 2360 CHWs. The NA revealed that among 2360 CHWs assessed, 82% were trained on iCCM and HBm packages; 62.5% reported receiving supervision every quarter from the health center, and 75% from the CHW cell coordinator. The NA flagged unreported stockouts and outdated job aids and materials as challenges. Among the CHWs assessed, 81% had updated registers, 43% completed correctly the iCCM registers, 100% had a malaria treatment algorithm, while only 62% had drug storage boxes. NA results showed that 81% of CHWs were trained in the past two years but there was no plan for refresher training. Findings led to the design and implementation of a Training of Trainers program where 40 nurses and 40 community health environment officers were trained to conduct quarterly supportive supervision, enable all CHWs to provide the iCCM package and train 426 new CHWs. As a result, 83% of CHWs received supportive supervision (SS), updated materials and regular medical supplies. This study showed that NAs conducted jointly with regular SS can generate data which are critical to identifying gaps and challenges that inform the design and adaptation of high-impact solutions. NA recommendations must be well formulated and practical to be effective.

### SCALE UP OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY (IPTP) BY COMMUNITY HEALTH WORKERS FOLLOWING THE RESULTS OF A FEASIBILITY PILOT IN PO DISTRICT, BURKINA FASO

Ousmane Badolo<sup>1</sup>, Justin Tiendrebeogo<sup>1</sup>, Youssouf Sawadogo<sup>1</sup>, Thierry Ouedraogo<sup>1</sup>, Moumouni Bonkougou<sup>1</sup>, Gauthier Tougri<sup>2</sup>, Gladys Tetteh<sup>3</sup>, Lolade Oseni<sup>3</sup>, Edward Kenyi<sup>3</sup>

<sup>1</sup>Improving Malaria Care (IMC) Project / Jhpiego, Ouagadougou, Burkina Faso, <sup>2</sup>National Malaria Control Program, Ouagadougou, Burkina Faso, <sup>3</sup>Improving Malaria Care (IMC) Project / Jhpiego, Baltimore, MD, United States

Malaria in pregnancy remains a major concern in sub-Saharan Africa. Since 2012, the World Health Organization has recommended that all pregnant women receive a minimum of three doses of intermittent preventive treatment of malaria in pregnancy (IPTp) with sulfadoxine-pyrimethamine (SP) starting in the 13th week of pregnancy. In Burkina Faso, the attendance rate for at least 1 antenatal care (ANC) visit is satisfactory (92%). According to the Multiple Indicator Demographic and Health Survey only 42.8% of women in rural areas attended ANC in their 1<sup>st</sup> trimester of pregnancy in 2015. In 2017, the Improving Malaria Care project (IMC) supported the Ministry of Health to carry out a feasibility study on community level provision of IPTp in three districts (Batie, Ouargaye and Po). This pilot showed that community-based health workers (CHWs) were able to work with facility-based health workers to provide IPTp at the community level (C-IPTp), thereby improving ANC attendance and IPTp coverage among pregnant women. IPTp4 coverage increased from 22% to 47% during baseline April 2017 versus end-line July 2018 in intervention sites while ANC4 attendance went from 62% to 77%. In 2019, following the successful implementation of this pilot, the NMCP—supported by IMC—extended the C-IPTp intervention from 2 to 22 health facilities (and catchment areas) in Po district. The main objective of this extension was to test the effectiveness of the intervention over a larger population. Thus, after cascade training of health care providers and their respective CHWs, the CHWs received commodities for C-IPTp delivery, and technical supervision. Due to COVID-19 restrictions, monitoring of this extension was achieved through telephone calls and analysis of Health Information Management System data. Analysis of the data from January to September 2020 showed an increase of IPTp4 from 33% in 2018 to 55% in 2020, where CHWs contributed 55% of the IPTp 4<sup>th</sup> dose administration. Additionally, ANC4 visit coverage increased from 37.5% in 2018 to 41.3% in 2020. Skilled CHWs can contribute to increasing IPTp coverage as well as ANC attendance.

0705

### DOOR TO DOOR AND FOCUS GROUP COMMUNICATION BY COMMUNITY HEALTH WORKERS: FUNDAMENTAL FACTORS IN IMPROVING COMMUNITY-BASED MALARIA INTERVENTIONS IN BURKINA FASO

Thierry Damien Ouedraogo<sup>1</sup>, Ousmane Badolo<sup>1</sup>, Moumouni Bonkougou<sup>1</sup>, Youssouf Sawadogo<sup>1</sup>, Gauthier Tougri<sup>2</sup>, Gladys Tetteh<sup>3</sup>, Karine Nankam<sup>3</sup>, Lolade Oseni<sup>3</sup>, Edward Kenyi<sup>3</sup>

<sup>1</sup>Improving Malaria Care (IMC) Project / Jhpiego, Ouagadougou, Burkina Faso, <sup>2</sup>National Malaria Control Program, Ouagadougou, Burkina Faso, <sup>3</sup>Improving Malaria Care (IMC) Project / Jhpiego, Baltimore, MD, United States

The Ministry of Health in Burkina Faso provides free care for children under five and pregnant women, but attendance at health facilities by these vulnerable groups remains low. The Improving Malaria Care (IMC) project, in collaboration with the National Malaria Control Program, has developed a community-based information approach to raise malaria awareness and improve attendance at health facilities. Four regions: Centre (Ce), Centre-Ouest (CO), Hauts Bassins (HB) and South-Ouest (SO) received a pilot intervention aimed at improving attendance at health facilities through communication. IMC held meetings with 416 Community Health

Workers (CHWs) from the 19 health districts covered by the project in 2018. These meetings provided an opportunity to examine sensitization activities that took place in 2018. CHWs conducted 17,872 sensitization sessions that reached 238,136 people, including 149,870 women, on the appropriate use of Insecticide Treated Nets, the importance of antenatal care for Intermittent Preventive Treatment of Malaria in Pregnancy and early consultation for early diagnosis of fever and appropriate malaria treatment. CHW-led sessions took place through educational talks, home visits, individual interviews, film screenings and theater forms. CHWs assessed referred 6,817 pregnant women to the Primary Health Care Center (PHCC); per their referral cards, 4,829 (70.8%) were specifically referred for IPTp. 16,149 children under 5 years were referred for malaria treatment. Of these, 60% were seen at the PHCC, as indicated on their referral cards. There was an overall increase in the Intermittent Preventive Treatment of malaria in pregnancy 3<sup>rd</sup> dose (IPTp3) uptake in these regions between 2017 and 2018: CO from 46.4% to 64.5; Ce from 38.9% to 43.6%; HB from 39.3% to 53.7%; SO from 38.9% to 55.7%. This intervention contributed to a decrease of under-5 malaria case fatality rate in 3 regions: CO from 1.2% to 0.8%; Ce from 1% to 0.6%; and SO from 1.2% to 1%; the rate stayed stable in the HB at 1.7%. The CHW-led pilot intervention ensured knowledge of and access to available prevention and treatment services by vulnerable groups.

### SURVEILLANCE, MONITORING, AND EVALUATION TRAINING IMPROVES PRACTICES: RESULTS FROM A FOLLOW-UP SURVEY OF MALARIA PROGRAM STAFF TRAINING, MADAGASCAR, 2020

Maurice Ye<sup>1</sup>, Sabas Rabesahala<sup>2</sup>, Jean Marie N'Gbichi<sup>3</sup>, Urbain Rabibizaka<sup>2</sup>, Saraha Rabehisoa<sup>2</sup>, Brune Ramiranirina<sup>2</sup>, Fanomezana V. Andriamamonjy<sup>2</sup>, Celestin Razafinjato<sup>2</sup>, Lova A. Ralijaona<sup>4</sup>, Laurent Kapesa<sup>4</sup>, Catherine Dentinger<sup>5</sup>, Brittany Iskarpatyoti S. Iskarpatyoti<sup>6</sup>, Yazoume Ye<sup>3</sup>

<sup>1</sup>U.S. President's Malaria Initiative Measure Malaria, University of North Carolina at Chapel Hill/ICF, Antananarivo, Madagascar, <sup>2</sup>National Malaria Control Program, Antananarivo, Madagascar, <sup>3</sup>U.S. President's Malaria Initiative Measure Malaria, University of North Carolina at Chapel Hill/ICF, Chapel Hill, NC, United States, <sup>4</sup>U.S. President's Malaria Initiative, Antananarivo, Madagascar, Antananarivo, Madagascar, <sup>5</sup>U.S. Centers for Disease Control and Prevention, Antananarivo, Madagascar, <sup>6</sup>U.S. President's Malaria Initiative Measure Malaria, University of North Carolina at Chapel Hill, Chapel Hill, NC, United States

In 2018, the U.S. President's Malaria Initiative (PMI), under the MEASURE Evaluation project, supported the Ministry of Health to train 113 malaria program managers during a seven-day workshop that included content on malaria epidemiology; surveillance, monitoring, and evaluation (SME); developing district M&E plans; assuring data quality and practice with data analysis and use. Mean post-training test scores were 37% higher than pre-training scores. In March 2020, the PMI Measure Malaria, (follow-on to MEASURE Evaluation) conducted an online survey of the trainees to collect demographic information and understand their data analysis, use, dissemination and reporting practices and challenges. Of the 113 contacted, 75 (66%) completed the survey, of whom 16 (21%) were female. Respondents included physicians (49 [65%]), nurses (20 [27%]), and midwives (6 [8%]). 47 (63%) reported leading the development of their district's malaria SME plan, and 70 (93%) reported validating malaria data before entry in the District Health Information System (DHIS2) for management and analysis. 59 (79%) had developed at least one malaria bulletin over the previous 12 months, and 72 (96%) reported that their district was using data for decision making, including identifying malaria outbreaks based on weekly reports, monitoring testing and treatment supplies, and summarizing uptake of intermittent preventative treatment during pregnancy for discussions with health staff and community members. Respondents also listed factors affecting low reporting timeliness such as geographic inaccessibility to health centers (29 [39%]), health staff shortages (28 [37%]), weak internet connectivity (20 [27%]), and shortages of phone/text credit (17 [23%]). Overall, nearly all the

respondents reported validating district data, sharing malaria data via bulletins, and using data for decision making. Although the SME training contributed to improvements in data analysis and use, issues remain with staff shortages and increasing access to communication networks.

0707

### STRENGTHENING MALARIA SURVEILLANCE THROUGH FRONTLINE FIELD EPIDEMIOLOGY TRAINING IN THE NORTH REGION OF CAMEROON

**Olivier Kakesa**

*Measure Malaria, Chapel Hill, CA, United States*

To improve health care providers' capacity in malaria epidemiological surveillance, the U.S. President's Malaria Initiative Measure Malaria project supported by the National Malaria Control Program provided the Frontline Field Epidemiology Training Program (FFETP), a 3-month in-service training based on a core curriculum from the U.S. Centers for Disease Control and Prevention that aims to strengthen epidemiologic capacity at the district level of the health system by improving staff's ability to detect, investigate, and respond to diseases of public health importance. The goal was to improve malaria case detection, data collection and reporting, data analysis and interpretation, and dissemination at the operational level. The training targeted Malaria Focal Points (MFPs) working at health facilities (HF) reporting a high number of malaria cases and deaths in the North Region. Training included three weeks of didactic sessions and 9 weeks of field work. Trainees were assessed with pre and post training questionnaires; mastery was assessed using a 5-point Likert scale (no, low, fair, good, or very good knowledge). Trainees produced weekly and monthly surveillance reports, and an analysis report of an identified surveillance problem. Of 25 MFPs enrolled from five health districts, 24 successfully completed the training. Good mastery of key surveillance interventions (case detection, data collection, analysis, interpretation, and communication) increased from 2 of 24 to 21. Prior to the training, no MFP had plotted a graph of malaria cases, but after the training this increased to 22. Furthermore, trainees' report submission timeliness assessed from DHIS2 increased to 94%, compared to the previous year (74%). The training significantly improved frontline staff knowledge on malaria surveillance. Improved analytical and interpretative skills will contribute to early and effective detection of increased malaria cases at the operational level. Expanding the training to more cohorts in addition to post-training follow-up will further strengthen malaria surveillance at the service delivery point.

0708

### IMPROVING HEALTH CARE WORKER COMPETENCIES AND ADHERENCE TO GUIDELINES FOR MALARIA CASE MANAGEMENT BY USE OF A BLENDED CAPACITY BUILDING MODEL: KENYA EXPERIENCE

**Dickson Mtungu Mwakangalu**<sup>1</sup>, Maureen Mabiria<sup>1</sup>, Sarah Ballard<sup>2</sup>, Hellen Gatakaa<sup>1</sup>, Augustine Ngindu<sup>1</sup>, Mildred Shieshia<sup>3</sup>, Gladys Tetteh<sup>4</sup>, Lolade Oseni<sup>4</sup>, Daniel Wacira<sup>3</sup>

<sup>1</sup>PMI Impact Malaria Project, Nairobi, Kenya, <sup>2</sup>US President's Malaria Initiative, US Centers for Disease Control and Prevention, Nairobi, Kenya, <sup>3</sup>US President's Malaria Initiative, United States Agency for International Development, Nairobi, Kenya, <sup>4</sup>PMI Impact Malaria Project, Baltimore, MD, United States

Current national guidelines for diagnosis, treatment, and prevention of malaria in Kenya aim at improving patient outcomes through case management (CM). Newly recruited health care workers (HCWs) have CM knowledge gaps because pre-service curricula are not always updated with current malaria CM guidelines. The 2019 PMI Impact Malaria (IM) baseline assessment conducted in 186 facilities from the malaria lake endemic counties and 2019 Quality of Care (QoC) survey indicated that many HCWs were not adhering to malaria CM guidelines. While the April 2019 cross-sectional IM baseline assessment found treatment of uncomplicated malaria cases near 100% (range 105-116%), and relatively infrequent

presumptive treatment of malaria-negative diagnoses with antimalarials (8%), the QoC survey's composite malaria CM indicator demonstrated only 60% adherence to Kenya's "test and treat" policy, signaling a need for HCW training in the diagnosis and classification components of CM while continuing to promote proper treatment. IM supported 8 malaria-endemic counties to implement a cascade approach to in-service, with frequent, brief facility-based trainings, frequent mentorship, and targeted supportive supervision of new and never-trained HCWs in malaria diagnosis, classification, and treatment. From April 2019 to December 2020, IM trained 60 trainers of trainers (TOTs), supported the TOTs to train 347 subcounty mentors who trained 1,468 HCWs, and mentored 1,826 HCWs in malaria CM. Supportive supervision was conducted for 693 HCWs in 208 targeted health facilities. This blended capacity building approach was associated with an improvement of HCW competency scores in correctly diagnosing and classifying case severity from 88% to 96%, correctly managing uncomplicated malaria from 74% to 87%, correctly treating positive test results from 73% to 88%, and avoiding presumptive treatment of negative test results from 80% to 92%. This capacity building model enables counties and sub counties to have a core team of trainers, mentors, supervisors and competent HCWs who continuously address knowledge gaps for provision of quality malaria CM.

### ADDRESSING DATA QUALITY ISSUES OF ROUTINE HEALTH FACILITY MALARIA DATA

**Sumaiyya G. Thawer**<sup>1</sup>, Ally Mohamed<sup>2</sup>, Samwel Lazaro<sup>2</sup>, Sijenunu Aaron<sup>2</sup>, Frank Chacky<sup>2</sup>, Khalifa Munisi<sup>2</sup>, Noela Kisoka<sup>1</sup>, Christian Lengeler<sup>3</sup>, Amanda Ross<sup>3</sup>, Fabrizio Molteni<sup>1</sup>, Emilie Pothin<sup>4</sup>

<sup>1</sup>Swiss Tropical and Public Health Institute/ University of Basel, Dar es Salaam, United Republic of Tanzania, <sup>2</sup>National Malaria Control Program, Ministry of Health, Community Development, Gender, Elderly and Children, Dodoma, Tanzania, Dodoma, United Republic of Tanzania, <sup>3</sup>Swiss Tropical and Public Health Institute/ University of Basel, Basel, Switzerland, <sup>4</sup>Swiss Tropical and Public Health Institute/ University of Basel/Clinion Health Access Initiative, Basel, Switzerland

The availability and access to malaria parasitological diagnosis at health facilities (HF), coupled with the adoption of the district health information system (DHIS2), has greatly strengthened the value of routine data. The emphasis in the World Health Organization's Global Technical Strategy 2016-2020 and the High Burden High Impact initiative for the increased usage of quality routine data to support tailored malaria control approach, is likely to further increase its usage. This demands the need to conduct data quality checks for a reliable analysis. In mainland Tanzania, the completeness and consistency of malaria indicators for 7,878 HF were assessed for the period 2017-2019. Essentially, the reporting rate (RR) completeness and missingness, presence of outliers and internal consistency between reports and trends were analysed. 1,208 HF with <50% RR and >5 consecutive months of missing reports were excluded. An algorithm from *anomalize* R package was used to systematically detect outliers and a further 0.1% of monthly reports were excluded. The type and extent of quality checks should be seen at two levels: (i) HF level for the purpose of improving data capturing and reporting; (ii) central level for the purpose of analysis. While detailed guidelines exist for the former, this is not the case for how to process and systematically handle aggregated routine data biases such as inconsistencies, outliers and missing values. A mini-survey was thus conducted amongst various partners between July-September 2020 to understand the current approaches taken for HF data processing and cleaning, and assess whether a harmonized approach was needed to address common challenges. The survey highlighted varying methodological approaches being undertaken, depending on the objectives of the analysis and recommended the need for developing guidelines addressing gaps in routine data and for handling such data in a systematic manner. This is essential for increasing confidence in the data, increase the use of routine data for decision making, and generally enhanced harmonization in the approaches taken.

0710

### ACCURACY OF CAREGIVER RECALL OF CHILDHOOD VACCINATIONS: IMPLICATIONS FOR THE RTS,S/AS01 COVERAGE ESTIMATES IN THE CONTEXT OF THE PILOT INTRODUCTION IN WESTERN KENYA

**Nelli Westercamp**<sup>1</sup>, Dorcas Akach<sup>2</sup>, Brian Seda<sup>2</sup>, Irene Okanda<sup>2</sup>, Elizabeth Marube<sup>2</sup>, Isabella Nyangau<sup>2</sup>, Titus Kwambai<sup>3</sup>, Simon Kariuki<sup>2</sup>, Aaron Samuels<sup>3</sup>

<sup>1</sup>U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>2</sup>KEMRI, Kisumu, Kenya, <sup>3</sup>U.S. Centers for Disease Control and Prevention, Kisumu, Kenya

The RTS,S/AS01 malaria vaccine is being piloted by the Kenya Ministry of Health in 46 sub-counties of western Kenya after a recommendation by the World Health Organization. Feasibility of integrating the 4-dose malaria vaccine into the Expanded Program on Immunization (EPI) schedule is being evaluated through a series of household vaccine coverage surveys. A population representative baseline survey was conducted in July–October 2019 to assess EPI vaccine coverage in 1,338 children 12–23 months of age. Home-based vaccination records (HBR) were available for 1,151 (86%) children; caregiver recall alone was available for the remaining 14% of children. To evaluate the accuracy of recall, vaccination data were collected from HBR and recall for any vaccine dose received, and for each vaccine dose (HBR: dates; recall: number of doses). Agreement between HBR and recall was measured by Gwet's agreement coefficient (agreement). Vaccine coverage estimates from HBR for any dose were high at 95% (95% CI: 92–97) for Bacillus Calmette-Guérin (BCG), 99% (95% CI: 98–99) oral poliovirus (OPV), 98% (95% CI: 98–99) pneumococcal (PCV), 99% (95% CI: 99–100) diphtheria-tetanus-pertussis (DTP), 98% (95% CI: 97–99) rotavirus (RV), and 88% (95% CI: 85–91) measles-containing vaccine (MCV). HBR and recall agreement for any dose was good at 0.94 (95% CI: 0.93–0.96) for BCG, 0.97 (95% CI: 0.96–0.98) for OPV, 0.78 (95% CI: 0.75–0.81) for PCV, 0.95 (95% CI: 0.93–0.96) for DTP, 0.76 (95% CI: 0.73–0.79) for RV, and 0.89 (95% CI: 0.87–0.91) for MCV. Agreement was markedly lower when evaluating specific doses. For example, agreement for DTP dose-1 was 0.93 (95% CI: 0.91–0.95), but only 0.64 (95% CI: 0.59–0.68) for DTP-3. Caregiver's age, education, and number of children were not associated with level of agreement, however agreement was higher when the respondent was the child's mother compared to other caregivers (i.e., fathers, grandmothers, or other relatives,  $p < 0.05$ ). The high HBR and recall agreement for EPI vaccines has good implications for receipt of any RTS,S/AS01 doses, though recall may be less reliable for specific vaccine doses. RTS,S/AS01 results are forthcoming.

### ARTEMETHER-LUMEFANTRINE ANTIMALARIAL EFFICACY AMONG ADULTS ON ANTIRETROVIRAL THERAPY IN MALAWI

**Jernelle C. Miller**<sup>1</sup>, Wongani Nyangulu<sup>2</sup>, Randy G. Mungwira<sup>3</sup>, Titus H. Divala<sup>3</sup>, Ngina Nampota<sup>3</sup>, Sunil Parikh<sup>4</sup>, Joep J. Oosterhout<sup>5</sup>, Matthew B. Laurens<sup>6</sup>, Miriam K. Laufer<sup>6</sup>

<sup>1</sup>University of Maryland, School of Medicine, Baltimore, MD, United States, <sup>2</sup>Dignitas International, Zomba, Malawi, <sup>3</sup>Blantyre Malaria Project, University of Malawi, College of Medicine, Blantyre, Malawi, <sup>4</sup>Yale School of Public Health, Laboratory of Epidemiology and Public Health, New Haven, CT, United States, <sup>5</sup>Dignitas International and University of Malawi, College of Medicine, Blantyre, Malawi, <sup>6</sup>Malaria Research Program, Center for Vaccine Development and Global Health, University of Maryland, School of Medicine, Baltimore, MD, United States

We conducted a randomized, controlled trial of daily trimethoprim-sulfamethoxazole compared to weekly chloroquine or no prophylaxis among adults on antiretroviral therapy (ART) in southern Malawi. We evaluated artemether-lumefantrine (AL) treatment efficacy in this population, with 81% of participants on efavirenz (EFV)-based ART. Because EFV reduces lumefantrine levels, we hypothesized EFV use may

impair treatment efficacy. We conducted a 28-day therapeutic efficacy study among participants with clinical malaria confirmed by blood smear and classified outcomes according to the World Health Organization protocol. We analyzed samples from recurrent malaria infections using PCR for three polymorphic genes: merozoite surface protein 1 and 2, and glutamate-rich protein. Pre- and post-treatment genotypes were compared via gel electrophoresis to distinguish recrudescence from reinfection. Any single difference was classified as a new infection. Plasma lumefantrine levels were determined using LC/MS/MS. From December 2012 to July 2018, 411 malaria episodes were followed with 84.2% (346/411) having an adequate clinical and parasitological response. Treatment failures included 8 early clinical failures, 35 late clinical failures (LCF) and 22 late parasitological failures (LPF). Of 57 participants with recurrent parasitemia (LCF and LPF), we successfully genotyped 42. We identified 12 recrudescence infections and 30 reinfections. PCR-corrected treatment efficacy, assuming unevaluable specimens were recrudescence, was 91.5% (376/411). Mean day 7 lumefantrine levels among 85 samples were 146 ng/mL (97), and mean day 7 desbutyl-lumefantrine levels were 23 ng/mL (9.5). AL efficacy in this population remains above the minimum 90% threshold. However, lumefantrine levels with most below 200 ng/mL, the current recommended dose, suggests increased treatment failure risk due to subtherapeutic drug concentrations. Drug-drug interactions are an important consideration for ART and other drugs with the same metabolic pathway. In addition, the possibility that HIV infection impacts antimalarial drug efficacy should be explored.

### PROCESS EVALUATION FOR THE IMPLEMENTATION OF ARTESUNATE RECTAL CAPSULES AS PRE-REFERRAL INTERVENTION FOR SEVERE MALARIA PATIENTS AT COMMUNITY LEVEL IN MADAGASCAR

**Arsene C. Ratsimbaoa**<sup>1</sup>, Mamy Razafimahatratra<sup>2</sup>, Michael Nomenjanahary<sup>3</sup>, Solotiana Ravelonarivo<sup>1</sup>, Ny Ako R.<sup>4</sup>, Mauricette Andriamananjara<sup>5</sup>

<sup>1</sup>Faculty of Medicine - University of Fianarantsoa, Fianarantsoa, Madagascar, <sup>2</sup>National Institute of Public Health - Faculty of Medicine, Antananarivo, Madagascar, <sup>3</sup>National Institute of Public Health, Antananarivo, Madagascar, <sup>4</sup>Faculty of Medicine, Antananarivo, Madagascar, <sup>5</sup>National Malaria Control Program, Antananarivo, Madagascar

Artesunate rectal capsule (ARC) is a pre-referral intervention recommended by WHO since 2015 for children under 6 years of age living in remote areas, to reduce the mortality rate of severe malaria. In 2015, Madagascar National Malaria Control Programme (NMCP) conducted a training to implement this new initiative but the quality assured medicines were not in stock. In 2019, when the commodities were finally procured, a cascade training in 8 regions was coordinated by the NMCP to support the ARC introduction. A process evaluation was conducted to assess the implementation of this intervention at the community level, including the assessment of inputs, activities performed and the short-term impact, to inform the NMCP for a nationwide scaling up. The following approaches were adopted: (a) collection and analysis of existing data (b) two-pronged knowledge, attitude and practice (KAP) survey targeting healthcare providers (CHWs, CSB Heads, central level) as well as the population, to assess health care-seeking behaviour and perception of ARC. A large majority of the population (87%) was in favor of the ARC pre-referral intervention. The majority of CHWs did not have the required management tools and resources to follow the protocol and manage severe malaria cases optimally. Most CHWs (85%) declared having a problem with ARC availability, mainly due to stock out issues in ordering sites.

## INTRODUCTION OF RECTAL ARTESUNATE FOR PRE-REFERRAL TREATMENT OF SEVERE MALARIA AMONG CHILDREN UNDER FIVE YEARS OF AGE AT THE COMMUNITY LEVEL IN MADAGASCAR, 2019-2020

**Andritiana Tsarafihavy**<sup>1</sup>, Serge Raharison<sup>1</sup>, Riana Ramanantsoa<sup>1</sup>, Feno Rakotoarimanana<sup>1</sup>, John Yanulis<sup>2</sup>, Aishling Thurow<sup>2</sup>, Laurence Laumonier-Ickx<sup>2</sup>, Thomas Hall<sup>3</sup>, Louise Rahantanirina<sup>4</sup>, Brian Mulligan<sup>4</sup>, Yvette Ribaira<sup>5</sup>, Laurent Kapesa<sup>6</sup>, Jocelyn Razafindrakoto<sup>6</sup>, Catherine Dentinger<sup>7</sup>, Solofo Razakamiadana<sup>6</sup>, Voahangy Razanakotomalala<sup>8</sup>, Celestin Razafinjato<sup>8</sup>, Mauricette Andriamanjara<sup>8</sup>

<sup>1</sup>Management Sciences for Health, Antananarivo, Madagascar,

<sup>2</sup>Management Sciences for Health, Medford, MA, United States,

<sup>3</sup>Management Sciences for Health, Arlington, VA, United States, <sup>4</sup>JSI Research and Training Institute Inc, Antananarivo, Madagascar, <sup>5</sup>JSI Research & Training Institute Inc, Antananarivo, Madagascar, <sup>6</sup>President's Malaria Initiative/United States Agency for International Development, Antananarivo, Madagascar, <sup>7</sup>US Centers for Disease Control and Prevention, Antananarivo, Madagascar, <sup>8</sup>National Malaria Control Program, Madagascar, Antananarivo, Madagascar

An estimated 9% of children under five years of age (CU5) in remote Madagascar who present to community health volunteers (CHV) or health centers (CSB) with malaria have signs of severe disease. To reduce mortality in this population, the United States Agency for International Development (USAID)- and the U.S. President's Malaria Initiative (PMI)-funded Accessible Continuum of Care and Essential Services Sustained (ACCESS) and Community Capacity for Health (CCH)/Mahefa Miaraka Programs worked with the Ministry of Health to introduce pre-referral rectal artesunate (RA) treatment. For rollout, we prioritized PMI-supported communities with the highest malaria incidence in CU5 and designed a distribution and monitoring plan; developed job aids and conducted provider training; made communication tools for providers and community members; modified patient tracking tools; and analyzed preliminary data from CHVs and CSBs. From August-December 2019, 13,943 RA capsules were distributed to 44 districts (population 8.8 million, 18% of whom were CU5); 11,578 (83%) to CHVs and 2,365 (17%) to CSBs. A total of 11,672 CHVs and 1,056 CSB staff in these districts were trained in RA use. During January-December 2020, 9,535 cases of severe malaria in CU5 were reported, 3,445 (36%) of whom benefited from pre-referral RA treatment (2,067 [60%] treated by CHVs and 1,378 [40%] at CSBs). Of these, 1,360 (39%) cases had outcome data reported via project tracking tools, and all CU5 had received post-referral treatment with an injectable antimalarial. For the remaining 61% of cases, no follow-up data was available. Furthermore, of 23 deaths in CU5 reported via CSBs and the tracking tool during this time, no details regarding treatment were available. In targeted districts, about one-third of intended CU5 received RA therapy in the first year after the launch of the program. To improve, additional investigation will be necessary to describe missed opportunities for RA use in these districts, and tracking of RA recipients must be more comprehensive to understand if CU5 are properly referred and treated.

## DETERMINANTS OF HEALTH WORKERS' COMPLIANCE WITH OUTPATIENT MALARIA 'TEST AND TREAT' GUIDELINES DURING THE PLATEAUING PERFORMANCE PHASE IN KENYA, 2014-2016

**Beatrice Amboko**<sup>1</sup>, Kasia Stepniewska<sup>2</sup>, Lucas Malla<sup>1</sup>, Beatrice Machini<sup>3</sup>, Philip Bejon<sup>4</sup>, Robert W. Snow<sup>1</sup>, Dejan Zurovac<sup>1</sup>

<sup>1</sup>KEMRI-Wellcome Trust Research Programme, Nairobi, Kenya, <sup>2</sup>WorldWide Antimalarial Resistance Network, Oxford, United Kingdom, <sup>3</sup>Division of National Malaria Programme, Ministry of Health, Kenya, <sup>4</sup>KEMRI-Wellcome Trust Research Programme, Kilifi, Kenya

Health workers' compliance with outpatient malaria 'test and treat' guidelines has improved but plateaued at the highest yet suboptimal levels

in Kenya. We examined the determinants of compliance at the high levels of performance. Association between 31 determinants and three 'test and treat' outcomes were examined using multilevel logistic regression models. A total of 2,752 febrile patients seen by 594 health workers at 486 health facilities were analysed. Higher odds of composite 'test and treat' performance was associated with lake endemic (aOR=8.61; 95% CI: 4.29-17.30), coast endemic (aOR=2.16; 95% CI: 1.02-4.59), highland epidemic (aOR=3.15; 95% CI: 1.81-5.47) and semi-arid seasonal (aOR=1.81; 95% CI: 1.09-3.01) compared to low risk areas; health workers' perception of malaria endemicity as high-risk (aOR=1.85; 95% CI: 1.16-2.94); in-service training (aOR=1.63; 95% CI: 1.19-2.23); correct knowledge about the 'test and treat' policy (aOR=1.64; 95% CI: 1.13-2.39); older patients compared to infants, higher temperature measurements and main complaints of fever, diarrhoea, headache, vomiting and chills. Lower odds of compliance was associated with government-owned (aOR=0.28; 95% CI: 0.17-0.46) compared to FBO/NGO-owned facilities; male (aOR=0.64; 95% CI: 0.47-0.88) compared to female health workers; and for patients having main complaints of a rash (aOR=0.46; 95% CI: 0.23-0.93) and a running nose (aOR=0.67; 95% CI: 0.47-0.94). Other factors associated with malaria testing or antimalarial compliance for test negative patients included supervision with feedback, access to guidelines, health workers age, and a cough complaint. To optimize 'test and treat' case-management, quality improvement interventions should focus on compliance within low malaria risk areas; target male, older and government health workers; disseminate updated guidelines; continue with in-service training and supportive supervision with feedback, and generally improve health workers' knowledge about malaria testing criteria considering their perceptions of endemicity.

## RELIABILITY OF REPORTED FEVER IN CHILDREN UNDER AGE FIVE AMONG HOUSEHOLD MEMBERS: AN EXAMINATION OF HOUSEHOLD SURVEY DATA FROM NIGERIA AND MOZAMBIQUE

**Cameron Taylor**<sup>1</sup>, Trevor Croft<sup>1</sup>, Mahmoud Elkasabi<sup>1</sup>, Livia Montana<sup>1</sup>, Yazoume Ye<sup>2</sup>

<sup>1</sup>The DHS Program-ICF, Rockville, MD, United States, <sup>2</sup>PMI Measure Malaria-ICF, Rockville, MD, United States

Fever among children under age five is the most common symptom household members use as criteria for initiating treatment-seeking. It also used as a screening measure in household surveys for collecting additional health-related information on children. Most surveys have relied on mothers to provide information on their child's fever. However, it is unclear if other household members could provide similarly reliable information. This analysis uses data from three Malaria Indicator Surveys (MIS) in Nigeria (2015 and 2010) and Mozambique (2018) with information on recall of fever among children under age five in the two weeks before the survey. To validate the recall of fever in children under five by household members, the recall of fever as reported by the head of household was compared to the mother's recall using sensitivity, specificity, and kappa coefficients. Across the three surveys, the sensitivity of the head of household's recall of fever ranged from 74.9% in the 2010 Nigeria MIS to 84.4% in the 2015 Nigeria MIS. The proportion of the heads of households correctly reporting that the child did not have fever as compared to the mother's report ranged from 84.7% in the 2010 Nigeria MIS to 94.8% in the 2018 Mozambique MIS. The agreement between the household respondent's report of fever and mother's report of fever, as measured by kappa scores, ranged from 0.59-0.79. Across all three surveys, if the household head was the child's father, the agreement was slightly stronger than if the child was a grandchild or other relative of the household head. This analysis shows that there is a strong collective memory of fever within a household. While a mother should always be the "gold standard" this analysis shows that other household members can potentially provide accurate responses for fostered children or others living in a household without a mother/caregiver.

## INTERMITTENT PREVENTIVE TREATMENT OF MALARIA IN PREGNANCY COVERAGE ESTIMATES FROM POPULATION-BASED SURVEYS: RELIABILITY OF WOMEN'S RECALL AMONG WOMEN WITH ANC CARDS

Natasha Hansen<sup>1</sup>, Susan Youll<sup>2</sup>, Lia Florey<sup>2</sup>, Cameron Taylor<sup>3</sup>

<sup>1</sup>National Cancer Institute, Bethesda, MD, United States, <sup>2</sup>President's Malaria Initiative, USAID, Washington, DC, United States, <sup>3</sup>The DHS Program-ICF, Rockville, MD, United States

Large household surveys depend on recall to estimate coverage rates for various health interventions, including intermittent preventive treatment in pregnancy (IPTp). Many studies call into question the validity of recalled data, and for vaccine coverage rates it is standard practice to validate responses with medical history cards. For malaria in pregnancy interventions, large survey data is important to assess programmatic success and coverage. Sulphadoxine-Pyrimethamine (SP), is recommended by the WHO at least 3 times during pregnancy for IPTp. Key indicators for assessing optimal IPTp coverage are the percentage of women receiving at least one dose (IPTp1+) and the percentage of women receiving at least 3 doses (IPTp3+). To validate intermittent preventive treatment in pregnancy coverage rates in large household surveys, recalled coverage rates were compared to antenatal care cards using sensitivity, specificity, and kappa coefficients from four Demographic in Health data sets from the 2017 Malawi MIS, the 2017-2018 Benin DHS, the 2011-2012 Tanzania HIV and Malaria Indicator Survey (THMIS), and the 2014 Ghana DHS. Across surveys, sensitivity for women's ability to correctly report IPTp coverage ranged from 79%-92% for IPTp1, from 79% to 96% for IPTp2, and from 73% to 100% for IPTp3+. The proportion of women correctly reporting that they did not receive IPTp (specificity) ranged from 88%-99.6% for IPTp1, from 87%-96% for IPTp2, and from 83% to 98% for IPTp3+. The results found that the recall was comparable to the coverage rates on the antenatal care cards. These findings suggest that intermittent preventive treatment coverage rates from large household surveys based on recalled data are valid without the use of the antenatal card, which is a time consuming additional step to data collection. The results of this study support the validity of recall for IPTp indicators in large household surveys suggesting that national malaria control programs can reliably assess their IPTp intervention coverage and make programmatic decisions based on survey data.

## GENDER DETERMINANTS OF INTERMITTENT PREVENTIVE TREATMENT IN PREGNANCY (IPTP) UPTAKE WITHIN MALARIA IN PREGNANCY (MIP) SERVICES IN CAMEROON AND KENYA

Elizabeth Arlotti-Parish<sup>1</sup>, Eric Meli Tchinda<sup>2</sup>, Caroline Teh Monteh Sofa<sup>2</sup>, Jean Yves Mukamba<sup>2</sup>, Dickson Mwakangalu<sup>1</sup>, James Andati<sup>1</sup>, James Andati<sup>1</sup>, George Githuka<sup>3</sup>, Dorothy Achu<sup>4</sup>

<sup>1</sup>US President's Malaria Initiative Impact Malaria (IM) project, Nairobi, Kenya, <sup>2</sup>US President's Malaria Initiative Impact Malaria (IM) project, Yaounde, Cameroon, <sup>3</sup>Ministry of Health, Division of National Malaria Programme, Nairobi, Kenya, <sup>4</sup>National Malaria Control Programme, Yaounde, Cameroon

PMI Impact Malaria (IM) conducts MiP activities in Kenya and Cameroon, where IPTp use falls from the 1<sup>st</sup> to the 3<sup>rd</sup> dose (77% to 38% in Kenya; 75% to 32% in Cameroon). This may be due to late ANC attendance: median months pregnant at ANC initiation is 5.4 in Kenya and 4.5 in Cameroon. Evidence linking gender barriers to early ANC and IPTp uptake is limited. IM examined gender determinants of IPTp use in Kenya and Cameroon using focus group discussions and interviews with parents of children under five, older women, providers, and community health workers. IM Kenya engaged 132 participants in two counties, while IM Cameroon engaged 144 participants in the North and Far North regions. Findings show that women and their partners in both countries know how, when, and why to attend ANC (and in Kenya, use IPTp). In Kenya,

those with influence (e.g. friends) and decision-making power (male partners, mothers-in-law) over women determine when she will begin care, and if she will attend ANC or traditional care. Male partners are the key decision-makers in Cameroon. In both countries, men control funds for transport to ANC. Kenyan partners worry about provider abuse, while in Cameroon men hesitate to send their wives to predominantly male ANC providers. Engaging decision-makers is critical to support early ANC uptake. Once a woman begins ANC, decision-making influence shifts from the partner to the provider. If a woman starts ANC she is likely to continue, if the provider treats her with respect. (Respectful care is a gender determinant due to provider attitudes about female clients and inequitable power dynamics between providers and clients.) Cameroonian participants were generally unfamiliar with IPTp, but did note women's lack of financial control to be a barrier, as IPTp is often stocked out at facilities and must be purchased elsewhere. In Kenya, providers counsel clients on the benefits of IPTp, while women are concerned with its smell and taste. Providers can improve IPTp continuation by allowing women to voice their concerns; listening with empathy; and addressing questions. This further supports a positive experience of care, encouraging women to return to ANC.

<sup>1</sup>London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>2</sup>Maferinyah National Research Center, Ministry of Health, Guinea, <sup>3</sup>Programme Nationale Lutte contre le Paludisme, Conakry, Guinea, <sup>4</sup>Programme Nationale Lutte contre le Paludisme, Cotonou, Benin, <sup>5</sup>Programme Nationale Lutte contre le Paludisme, Ouagadougou, Burkina Faso, <sup>6</sup>National Malaria Control Programme, Yaounde, Cameroon, <sup>7</sup>Programme Nationale Lutte contre le Paludisme, N'Djamena, Chad, <sup>8</sup>National Malaria Control Programme, Accra, Ghana, <sup>9</sup>Programa Nacional de Luta contra o Paludismo, Bissau, Guinea-Bissau, <sup>10</sup>Programme Nationale Lutte contre le Paludisme, Bamako, Mali, <sup>11</sup>Programme Nationale Lutte contre le Paludisme, Niamey, Niger, <sup>12</sup>National Malaria Elimination Programme, Abuja, Nigeria, <sup>13</sup>Programme Nationale Lutte contre le Paludisme, Dakar, Senegal, <sup>14</sup>National Malaria Control Programme, Banjul, Gambia, <sup>15</sup>Programme Nationale Lutte contre le Paludisme, Lome, Togo, <sup>16</sup>Universite Gamal Abdel Nasser, Conakry, Guinea, <sup>17</sup>La Cooperativa Humanitaria, Barcelona, Spain, <sup>18</sup>Medicines for Malaria Venture, Geneva, Switzerland, <sup>19</sup>Universite de Thiès, Thiès, Senegal, <sup>20</sup>UNDP/UNICEF/World Bank/WHO Special Programme for Research and Training in Tropical Diseases (TDR)/ World Health Organization (WHO), Geneva, Switzerland, <sup>21</sup>Liz Thomas Associates Ltd, UK, London, United Kingdom

We investigated the use of video job-aids to improve the quality of SMC delivery. The study was prompted by the need for training tools that could be used in a socially-distanced manner, and which would familiarise distributors with drug administration procedures to minimise the risk of spreading COVID-19. Videos were developed in French, English, Portuguese and Hausa, illustrating key steps to follow to administer SMC, including wearing masks, washing hands, and keeping a safe distance. A consultative group comprising representatives of Malaria Programmes of The Gambia, Guinea, Guinea Bissau, Nigeria, Senegal and Togo reviewed successive versions of the videos to ensure accurate and relevant content. A case study in Guinea to evaluate the use of the video, used focus

groups, indepth interviews, and direct observation of SMC distribution. Distributors said the video covered all steps they had been taught during their training, but they found the video easier to understand. But messages were not always followed. Though supplied with face masks, some distributors did not use them, a distributor wearing a mask was perceived as a spreader of coronavirus, and some parents refused SMC saying they did not recognise them with the mask. One distributor said "it is difficult to observe social distancing; if you distance yourself from them, they will feel offended". During the SMC campaign the video reinforces messages and can be viewed many times. Used during training, the video provides a focus of discussion and support for trainers. Audio-visuals help retain messages. Limitations were that not all distributors use android phones, and local language versions were requested. Although ownership of smartphones in sub-Saharan Africa is limited (33% in 2017, Pew Research Center 2018), it is increasing, and android devices are used by drug distributors in some countries to record SMC administration. Community health workers increasingly have access to devices that can display video job-aids that can improve quality of delivery of SMC and other primary health care interventions. The videos from the OPT-SMC project are at <https://tinyurl.com/35uhf3fh>.

### THE RELATIONSHIP BETWEEN GENDER EQUALITY AND INSECTICIDE-TREATED NET USE IN UGANDA

**Bolanle Olapeju**<sup>1</sup>, Anna Passaniti<sup>1</sup>, Judith Nalukwago<sup>1</sup>, Isaac Musoke<sup>1</sup>, Musa Kimbowa<sup>1</sup>, Pearl Kobusingye<sup>1</sup>, Emmanuel Kayongo<sup>1</sup>, Ruth Musekura<sup>1</sup>, Lyndsey Mitchum<sup>1</sup>, Arzum Ciloglu<sup>1</sup>, Leanne Wolfe<sup>1</sup>, Glory Mkandawire<sup>1</sup>, Richard Kabanda<sup>2</sup>, Joel Kisubi<sup>3</sup>, Sheila Nyakwezi<sup>3</sup>, Douglas Storey<sup>1</sup>, Mariam Nabukenya<sup>2</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Ministry of Health, Uganda, Kampala, Uganda, <sup>3</sup>US President's Malaria Initiative, United States Agency for International Development (USAID), Uganda, Kampala, Uganda

Background: The Ministry of Health with support from the United States Agency for International Development (USAID) funded Social and Behavior Change Activity (SBCA) aims to use innovative social and behavior change (SBC) approaches to improve gender equality norms and healthy behaviors to prevent malaria among other diseases. This study explored insights on the effects of gender equality norms on insecticide-treated net (ITN) use in Uganda. Methodology: A nationally representative mobile phone survey was conducted among 1,400 men and women aged 18-49 years. Gender equality was assessed using four parameters of political, economic, religious, and social gender equality, which was also condensed into a composite variable. Multivariable regressions explored the relationship between ITN use and perceptions on gender equality norms, controlling for socio-demographics. Results: In this mostly rural (70%) population, most respondents slept under an ITN the previous night (83%) and supported political (94%), economic (82%), religious (83%) and social equality (64%). Overall, 80% of respondents reported having equitable gender norms, and ITN use was 5% higher among those who reported equitable gender norms. People with equitable gender norms had a 1.2 higher odds of ITN use after accounting for respondents' region, residence, age, gender, parity, and education level. Discussion: Promoting gender equality at the interpersonal and household levels may improve ITN use through use of gender transformative interventions to address gender determinants of malaria prevention and treatment behaviors. Interventions should involve communities in the co-design of SBC activities and message development, increase partner communication and dialogue about gender norms at individual, household and community levels so as to promote ITN use among all household members.

0720

### EVALUATION OF A HAEMOZOIN BASED DIAGNOSTIC TEST FOR MALARIA DIAGNOSIS IN SRI LANKA

**Sumadhyia Deepika Fernando**<sup>1</sup>, Priyaleela Thota<sup>2</sup>, Saveen Semage<sup>3</sup>, Rahuman Booso<sup>4</sup>, Kumudunayana T. de A.W. Gunasekera<sup>5</sup>, David Bell<sup>2</sup>, Prasad Ranaweera<sup>5</sup>

<sup>1</sup>University of Colombo, Colombo, Sri Lanka, <sup>2</sup>Hemex Health, Portland, OR, United States, <sup>3</sup>Army Headquarters, Colombo, Sri Lanka, <sup>4</sup>Directorate of Health Services, Sri Lanka Air Force, Colombo, Sri Lanka, <sup>5</sup>Anti Malaria Campaign, Colombo, Sri Lanka

Although malaria was eliminated from Sri Lanka in 2012, in recent years, approximately 50 imported malaria infections per year have been reported. Parasitological surveillance is one of the key strategies to prevent reintroduction of malaria in Sri Lanka. Early diagnosis and treatment of malaria infected individuals can prevent onward transmission of disease. Microscopy remains the traditional gold standard for malaria diagnosis. Rapid Diagnostic Tests (RDTs) are used as a supplementary diagnostic method. Molecular detection techniques have a much higher sensitivity and can detect malaria in cases wherein the parasite densities are below the detection threshold of either microscopy or RDTs, however, these are not cost-effective to use on a large scale. This study aimed to compare the diagnostic capability of a new haemozoin- detecting test (Gazelle™) with microscopy, Carestart RDT and PCR. Blood samples were collected from individuals referred for confirmation of malaria by a clinician (passive case detection; PCD) as well as individuals at high risk of malaria (proactive case detection; PACD). Overall, 305 individuals were screened for malaria between October 2020 and April 2021 as a part of the study. This included 27 individuals by PCD and 278 by PACD. Ten malaria positive patients (2 each of *Plasmodium vivax* and *P. falciparum*, 5 *Plasmodium falciparum* and 1 *P. malariae* infections), were diagnosed by microscopy and PCR. Gazelle identified the *P. vivax*, *P. ovale* and *P. malariae* infections accurately. Gazelle gave false negative results in 2 patients with *P. falciparum* infection in whom the parasitaemia levels were 96/μl and 1188/μl, respectively. This is the first-of-its-kind study wherein haemozoin was tested as a biomarker for malaria diagnosis in Sri Lanka. Gazelle required low level of user training to perform the test and a large volume of samples were screened within a short period of time (~60 samples per device in a day). Use of Gazelle has the potential to benefit the malaria surveillance program and contribute to the goal of preventing reintroduction of malaria in Sri Lanka by providing rapid screening of high-risk population.

0721

### ASSESSING THE ROLL OUT OF ARTESUNATE RECTAL CAPSULES AS PRE-REFERRAL INTERVENTION IN FIVE DISTRICTS IN SIERRA LEONE

**Anitta R.Y. Kamara**<sup>1</sup>, Keith Esch<sup>2</sup>, Kwabena Larbi<sup>3</sup>, Dr. Temitayo Labor<sup>3</sup>, Nelson Fofana<sup>3</sup>, Jibba Bowah<sup>3</sup>, Ramlat Jose<sup>4</sup>, Nicole Carbone<sup>2</sup>, Jadmin Mostel<sup>2</sup>, Adam Nothem<sup>2</sup>

<sup>1</sup>Sierra Leone National Malaria Control Program, Freetown, Sierra Leone, <sup>2</sup>PMI Impact Malaria Project (PSI), Washington, DC, United States, <sup>3</sup>PMI Impact Malaria Project-Sierra Leone (PSI), Freetown, Sierra Leone, <sup>4</sup>President's Malaria Initiative, Freetown, Sierra Leone

An estimated two percent of the global malaria deaths occurred in Sierra Leone in 2019. The progression of uncomplicated malaria to severe malaria is generally attributable to failures and delays in healthcare delivery and health-seeking behavior. To reduce severe malaria deaths, PMI Impact Malaria (IM) supported the National Malaria Control Program (NMCP) to roll out artesunate rectal capsules (ARC) as a pre-referral intervention to peripheral health units (PHUs) in 14 districts. In 2020, IM supported NMCP to train providers in ARC administration and referral across 14 districts reaching 2,452 PHU health providers. Average pre/post-test scores increased from 53% to 86%. In 2021, NMCP and IM conducted a follow-up record review of a convenience sample of 106 PHUs- selected by urbanicity, facility type and proximity to district capital and referral facilities in 5 districts to quantify appropriate ARC administration and referral

practices, and to document health outcomes of patients receiving ARC. All 109 patients who met severe malaria case criteria were administered ARC and were referred. However, 11% of family members/guardians refused the referral. Record review data did not indicate reasons for refusal. Of the 65 patients who were admitted to a referral facility, 5 (8%) died in hospital and 52 (80%) were discharged. Records for 7 patients were not located. Ambulances were used as the transportation method in 75% of referrals. While 72% of ARC administration took place in Community Health Posts or Maternal and Child Health Posts, which are often remote and offer basic care, 92% of patient deaths occurred in patients who were referred from these facilities. ARC rollout in Sierra Leone successfully improved quality severe malaria care to the PHU level. IM will continue to employ its Outreach, Training and Supportive Supervision Plus (OTSS+) quality improvement efforts to provide on-the-job training and mentorship at targeted facilities to maintain high quality of care. NMCP and IM will collaborate with social behavior change stakeholders to understand and address caretaker refusal of referral.

### FOCI INVESTIGATION OF A CLUSTER OF MALARIA CASES IN A SINGLE VILLAGE IN COASTAL MYANMAR

**Khin Mon Mon**<sup>1</sup>, Wint Phyo Than<sup>2</sup>, Alexandra Fischer<sup>3</sup>, Sway Minn Htet<sup>4</sup>, Kaung Myat Min<sup>4</sup>, Aung Zaw Moe<sup>4</sup>, Khin Than Win<sup>1</sup>, May Aung Lin<sup>1</sup>, Kyaw Myint Tun<sup>1</sup>

<sup>1</sup>University Research Co., LLC, Yangon, Myanmar, <sup>2</sup>National Malaria Control Programme, Ministry of Health and Sports, Nay Pyi Taw, Myanmar, <sup>3</sup>University Research Co., LLC, Chevy Chase, MD, United States, <sup>4</sup>University Research Co., LLC, Toungup, Myanmar

Pyin Boke, the outermost village of Pumpkin Island of Rakhine State, has 55 households and a population of 232. The village is surrounded by paddy fields and streams and is close to the forested mountain. The U.S. President's Malaria Initiative funded Defeat Malaria Project supported and supervised the Village Malaria Worker (VMW) since 2017. Annual Blood Examination Rates were more than 10% for four consecutive years. There had not been any malaria cases detected since 2017 but entomological assessment revealed primary and secondary vectors including *Anopheles minimus*, *An. annularis*, *An. sudaicus* and *An. aconitus*. Although the first case had mild fever on 2<sup>nd</sup> November 2020, he did not seek care for fever from the VMW until 2nd December 2020. An additional 30 cases including his wife and neighbors were identified by reactive case detection conducted in December 2020 and January 2021. The last case was diagnosed on 25<sup>th</sup> January 2021. All cases were tested with malaria Rapid Diagnostic Test and some cases were confirmed with microscopy. All cases were treated according to the National Malaria Treatment Guideline. Case investigation results revealed that no cases had a history of travel within the previous month. The first case was diagnosed with *Plasmodium vivax* and had migrated from a higher malarious area of Rathedaung Township in the last year. However as past malaria history was unclear, it could not be conclusively classified as "relapsed" and identified it as the index case. Qualitative interviews of key informants revealed that 15 internally displaced people temporarily stayed in the village from June to August 2020. Long-lasting insecticidal treated nets (LLINs) had not been distributed as the village was classified as low risk by the national malaria risk stratification. Amalgamation of high receptivity and little or no immunity of residents against malaria triggered occurrence of cases. Socio-behavior change communication to encourage early care seeking at the onset of fever, to sleep under LLINs, and mobility monitoring are integral to prevent the reintroduction of malaria in receptive areas such as Pyin Boke.

0723

### MALARIA AND INTERANNUAL CLIMATE MODES: MECHANISMS AND PREDICTABILITY

**Shirley Leung**, Prashanth Selvaraj

*Institute for Disease Modeling, Seattle, WA, United States*

Seasonal predictions of transmission and epidemics can allow public health officials to target malaria interventions more efficiently. Much current work on seasonal predictions of malaria utilize complicated weather forecasts, but predictions based on these detailed forecasts may be difficult and impractical for public health officials to use. Simpler and more practical predictions can potentially be generated by better understanding how interannual climate variability, as represented by large-scale climate modes such as ENSO (El Niño-Southern Oscillation) and IOD (Indian Ocean Dipole), affects malaria transmission. Climate variability is also often disregarded when evaluating the efficacy of past interventions, sometimes leading to overoptimism and a lack of preparedness for future resurgences. Better understanding the effects of different climate modes on malaria transmission can thus allow for more accurate intervention efficacy assessments. Here we compile and summarize peer-reviewed studies conducted throughout the African continent that examine the effects of ENSO, IOD, and other relevant climate modes on malaria transmission. We map these effects over different regions and denote the most important climate mode-associated environmental factors, such as minimum or maximum daily temperature, rainfall, humidity, and vegetation indices, that drive malaria transmission in each studied locale. Based on these findings and the timescales of predictability associated with each climate mode, we make inferences about which climate mode(s) may be best suited for use with early warning systems in each region. We conclude by suggesting high priority pathways for future research on climate mode-driven malaria forecasts, informed by a review of the processes that currently generate the largest uncertainties and complexities in the use of seasonal predictions.

0724

### UNDERSTANDING MALARIA IN PREGNANCY SERVICE DELIVERY QUALITY IN SEVEN AFRICAN COUNTRIES

**Katherine Wolf**<sup>1</sup>, Lolade Oseni<sup>1</sup>, Patricia Gomez<sup>1</sup>, Gladys Tetteh<sup>1</sup>, Jadmin Mostel<sup>2</sup>, Nicole B. Carbone<sup>2</sup>, Tabitha Kibuka<sup>2</sup>

<sup>1</sup>Jhpiego/PMI Impact Malaria, Washington, DC, United States, <sup>2</sup>PSI/PMI Impact Malaria, Washington, DC, United States

Coverage of malaria in pregnancy (MiP) interventions, in particular, intermittent preventive treatment of malaria in pregnancy (IPTp), lags behind other key malaria indicators. In 2019, only 34% of eligible pregnant women received at least 3 doses of IPTp across sub-Saharan Africa although antenatal care (ANC) attendance in the region is relatively high. In order to better understand barriers to achieving global MiP targets, we reviewed MiP supportive supervision checklist data collected by the PMI Impact Malaria project and malaria control programs in 7 countries to explore the quality of care (QoC) for MiP prevention and treatment services as measured by a standard checklist as part of Outreach Training and Supportive Supervision Plus (OTSS+) activities. OTSS+ visits took place between October 2019 and March 2021 in Cameroon, Cote d'Ivoire, Ghana, Kenya, Mali, Niger and Sierra Leone. The data collected during these visits was analyzed and included provider training and behavior, elements of respectful care, facility readiness including MiP commodity stock status, and record keeping. Competency scores were calculated based on observations recorded in the supervision checklist. Average competency scores in MiP prevention range from 67% to 91% at baseline and 68-97% at follow up measurement, with five countries improving by an average of 6 percentage points. Average competency scores in MiP treatment range from 50% to 89% at baseline and 73% to 93% at follow up, with 5 countries improving by an average of 11 percentage points. Initial findings highlight the impact of known stock-outs on competency scores and inconsistent application of respectful maternity care principles on MiP QoC. The full analysis to be presented

will explore variations in and implications of individual elements of MiP service delivery on the overall QoC to identify notable successes and key challenges in implementing quality MiP service delivery. This review will generate targeted recommendations for improving MiP service QoC based on trends in MiP service delivery seen across countries, thereby contributing to potential improvements in MiP intervention coverage.

0725

### SEX-SPECIFIC EFFECT OF INTERMITTENT PREVENTIVE TREATMENT OF MALARIA WITH ARTEMISININ COMBINATION THERAPIES AMONG SCHOOL CHILDREN IN MALI: A THREE-ARM OPEN LABEL RANDOMISED CONTROLLED TRIAL

**Hamma Maiga**<sup>1</sup>, Charles Opondo<sup>2</sup>, R. Matthew Chico<sup>3</sup>, Lauren M. Cohee<sup>4</sup>, Issaka Sagara<sup>5</sup>, Oumar B. Traore<sup>5</sup>, Mamadou Tekete<sup>5</sup>, Antoine Dara<sup>5</sup>, Zoumana I. Traore<sup>5</sup>, Modibo Diarra<sup>5</sup>, Samba Coumare<sup>5</sup>, Aly Kodio<sup>5</sup>, Amadou Bamadio<sup>5</sup>, Bouran Sidibe<sup>5</sup>, Ogobara K. Doumbo<sup>5</sup>, Aboudaye A. Djimde<sup>5</sup>

<sup>1</sup>Institut National de Sante Publique, Bamako, Mali, <sup>2</sup>Department of Medical Statistics, Faculty of Epidemiology and Population Health, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>3</sup>Department of Disease Control, Faculty of Infectious and Tropical Diseases, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Center for Vaccine Development and Global Health, University of Maryland School of Medicine, Baltimore, MD, United States, <sup>5</sup>Malaria Research and Training Center, Department of Epidemiology of Parasitic Diseases, Faculty of Medicine and Dentistry, Faculty of Pharmacy, University of Sciences, Techniques and Technologies of Bamako, Bamako, Mali

Single or multiple courses of intermittent preventive treatment in schoolchildren (IPTsc) has been shown to reduce clinic visits, asymptomatic parasitaemia, and anaemia. To our knowledge, the differential effects of IPTsc by sex have not been the subject of a longitudinal study in Africa. In this analysis, we investigate the overall efficacy of IPTsc and explore differences by sex. We conducted an open-label, rolling cohort randomized controlled trial among schoolchildren aged 6–13 years between September 2007 and February 2013 in Kollé, Mali. Students were randomized into three groups: sulfadoxine-pyrimethamine plus artesunate (SP+AS), amodiaquine plus artesunate (AQ+AS), and control (C). All students received two full treatment courses every two months while age-eligible and for the duration of the study period. We investigated overall effect and sex-specific effect of treatment on *Plasmodium falciparum* infection, haemoglobin and standardized grade-point average (SGPA). Over a six-year period, there were 4,564 observations from the 296 students who were randomised. Antimalarial treatment reduced the odds of *P. falciparum* infection in SP+AS and AQ+AS compared to C (OR 0.33, 95%CI 0.26-0.43, and OR 0.46, 95%CI 0.36-0.59). Strong evidence of increased haemoglobin level (g/dL) was observed in the SP+AS compared to C (difference +0.37, 95%CI 0.13-0.58), although AQ+AS produced similar protection to C (+0.15, 95%CI -0.08-0.37). There was evidence of improved SGPA in the AQ+AS compared to control (difference +0.36, 95%CI 0.02 to 0.69) and evidence of sex-specific difference in treatment effect on SGPA: in the SP+AS the difference in SGPA relative to control was -0.27, 95%CI -0.71-0.16 in boys versus +0.50, 95%CI -0.02-1.02 in girls, whereas in the AQ+AS the difference in SGPA was +0.33, 95%CI -0.12-0.78 in boys versus +0.40, 95%CI -0.10-0.90 in girls, relative to C. IPTsc with SP+AS reduced *P. falciparum* malaria and anaemia among school children and increased the SGPA among girls relative to boys. This evidence supports a more regular investigation of sex-specific effects of malaria interventions in children in sub-Saharan Africa.

### INSIGHTS ON FOREST GOER'S EXPERIENCE AND KNOWLEDGE OF MOSQUITO REPELLENT IN CAMBODIA USING RESPONDENT-DRIVEN SAMPLING

**Po Ly**<sup>1</sup>, Boukheng Thavrin<sup>1</sup>, Sochea Phok<sup>2</sup>, Mahesh Paudel<sup>3</sup>, Shwetha Srinivasan<sup>4</sup>, Huy Rekol<sup>1</sup>, Siv Sovannaroth<sup>1</sup>, Saad Hassan<sup>5</sup>, Stephen Poyer<sup>3</sup>, Andy Tompsett<sup>3</sup>, Jim Malster<sup>3</sup>

<sup>1</sup>National Center for Malaria Control, Parasitology and Entomology, Phnom Penh, Cambodia, <sup>2</sup>Population Services International Cambodia, Phnom Penh, Cambodia, <sup>3</sup>Population Services International, Washington DC, MD, United States, <sup>4</sup>Population Services International Laos, Vientiane, Lao People's Democratic Republic, <sup>5</sup>U.S. President's Malaria Initiative/United States Agency for International Development, Phnom Penh, Cambodia

Despite Cambodia's significant progress in reducing the prevalence of malaria over the past decade, some populations like forest goers are at higher risk of malaria infection due to their occupational profile. In August-September 2020, a representative survey of 654 forest goers was conducted using respondent-driven sampling to understand the experiences of repellent use among forest goers. One seed from each of 16 villages in Kampong Chhnang and Pursat provinces was recruited and referred up to three forest-goer contacts. Eligible participants reported spending at least one night in the forest in the past month. Recruitment continued until the required sample was reached, with up to 9 waves for some seeds. There is limited knowledge and awareness on repellents among all forest-goers. Only 25% of all forest-goers have previously heard about repellents before and only 17% of them reported using repellents recently or within the last three months. Among forest goers who have heard about repellents, less than half of them (48%) know where they can get them. Of those who have been exposed to or heard about repellents, 63% think it is very effective while 36% think it is only somewhat effective. Almost half of all forest goers (46%) expressed concerns about repellent use while the rest were not concerned or were unsure about repellents. Main concerns about repellent use revolve around worry about health effects (83%), skin reactions (30%) and possible side effects (18%). Although many forest goers express an intention to use repellents (85%), they think ITN is more suitable for forest goers (70%) over repellents (55%) for prevention purposes. Preventive behaviors are critical to achieve malaria elimination objectives. Repellents remain little known and used among forest goers in Cambodia; many believe they are effective and portable but many also have concerns about side effects. Repellents are not yet a WHO recommended intervention and further studies are required to explore effectiveness of repellents in this context, thus social and behavior change activities for improving prevention behaviors should remain focused on ITN use.

0727

### FINDINGS FROM A RESPONDENT DRIVEN SAMPLING SURVEY EXPLORING CARE-SEEKING BEHAVIORS FOR FEBRILE ILLNESS AMONG FOREST GOERS IN CAMBODIA

**Boukheng Thavrin**<sup>1</sup>, Po Ly<sup>1</sup>, Sochea Phok<sup>2</sup>, Mahesh Paudel<sup>3</sup>, Shwetha Srinivasan<sup>4</sup>, Huy Rekol<sup>1</sup>, Siv Sovannaroth<sup>1</sup>, Saad Hassan<sup>5</sup>, Stephen Poyer<sup>3</sup>, Andy Tompsett<sup>3</sup>, Jim Malster<sup>3</sup>

<sup>1</sup>National Center for Malaria Control, Parasitology and Entomology, Phnom Penh, Cambodia, <sup>2</sup>Population Services International Cambodia, Phnom Penh, Cambodia, <sup>3</sup>Population Services International, Washington, DC, United States, <sup>4</sup>Population Services International Laos, Vientiane, Lao People's Democratic Republic, <sup>5</sup>U.S. President's Malaria Initiative/United States Agency for International Development, Phnom Penh, Cambodia

Malaria continues to disproportionately affect Cambodian forest workers and migrants. Due to forest goers' hard-to-reach and mobile nature, novel data collection methods are required to gain behavioral insights to inform appropriate malaria elimination interventions. In 2020, PSI conducted a survey of forest goers using respondent driven sampling (RDS) to understand determinants of care-seeking behaviors, with a total of 654 forest goers identified and included in the study. Only 57% of forest

goers reported seeking care for fever outside the home during their last febrile illness. Among those who sought care, 39% reported receiving care within 24 hours. Forest goers' care-seeking behavior was generally influenced by previous experience of febrile illness, provider preference, and social norms. Forest goers who suspected their last febrile illness was malaria were twice as likely to seek treatment within 24 hours (48% vs 31%). Forest goers who chose to go to a public sector provider were more likely to seek care within 24 hours than who chose a non-public provider (73% vs 34%). Additionally, forest goers who believe members of their community seek care within 24 hours were more likely to do so. Choice of provider is mainly influenced by perception of effective treatment (52.1%), proximity (49.4%), and trust in provider (43.6%). Main reasons for not seeking care were perceptions that the illness was not serious (50.9%) and being present in forest during symptom onset (38%). These findings show levels of care-seeking behavior significantly below targets required to achieve malaria elimination by 2025. Malaria interventions should capitalize on factors that promote prompt care seeking amongst forest goers, including building social norms, and enhancing treatment access for forest goers while in the forest. In particular, targeted social behavior change interventions that focus on improving timely care-seeking amongst forest goers is urgently required in order to meet malaria elimination goals in Cambodia.

0728

### NET USE BEHAVIOURS AND HIGH PREVALENCE OF MALARIA PARASITEMIA AMONG CHILDREN UNDER FIVE IN ZAMFARA STATE, NIGERIA

**Adefisoye Oluwaseun Adewole**<sup>1</sup>, Ndadilnasiya Waziri<sup>1</sup>, Saheed Gidado<sup>1</sup>, Amina Umar<sup>1</sup>, Usaini Bala<sup>1</sup>, Simple Edwin<sup>1</sup>, Gideon Ugbenyo<sup>1</sup>, Adam Attahiru<sup>1</sup>, Isaac Igbaver<sup>1</sup>, Shelby Cash<sup>2</sup>, Kwame Asamoah<sup>2</sup>

<sup>1</sup>African Field Epidemiology Network, Abuja, Nigeria, <sup>2</sup>Malaria Branch, Centers for Disease Control and Prevention, Atlanta, GA, United States

In Zamfara state, Nigeria's 2015 National Malaria Indicator Survey found ownership of at least one long-lasting insecticidal net (LLIN) of 88.6%, LLIN use of 56.3%, and malaria parasitemia among children under five (U5) of 69.9%. We assessed LLIN use, and perceived risk factors associated with this high level of parasitemia. A cross-sectional household (HH) survey was conducted in August 2018 in 60 HHs each in six local government areas (LGA) to assess LLIN ownership and use. Data on LLIN ownership and use for HHs were obtained through interviews with household heads. Each LGA conducted six focus group discussions (FGDs) of U5 caregivers (36 FGDs) and one FGD of facility healthcare workers (HCWs). Each FGD included 6-12 participants. Individual discussions were held with five state malaria program officers and six LGA malaria program officers. Semi-structured questionnaires guided the FGD discussions; these were audio-recorded, transcribed, and translated into English. Frequencies and proportions were calculated for HH data; FGD findings were analyzed for themes. A total of 358 HHs (99.4%) of those targeted were surveyed; 333 (93.0%) had at least one LLIN and 181 (50.6%) had at least one LLIN for every 2 persons. 2,134 (73.3%) persons slept under an LLIN the night before the survey. Caregivers attributed the high rate of parasitemia to rains, U5s staying outdoors late (watching films, attending night Arabic schools) without protective clothes, and improper use of LLIN (e.g., use of torn nets). HCWs reported staying outdoors late without wearing protective clothing, proximity of houses to irrigation projects, and inadequate supply of LLIN. LLIN access and use in Zamfara should be improved; behavioral change communication on use of protective clothing for children during evenings and public sensitization on the effectiveness and use of LLINs may be beneficial to reducing high levels of parasitemia in Zamfara.

0729

### A NEW COLLABORATION PLATFORM TO SUPPORT THE DEVELOPMENT OF NEXT-GENERATION MEDICAL INTERVENTIONS FOR MALARIA PREVENTION

Lydia Burgert, Narimane Nekkab, Josephine Malinga, Monica Golumbeanu, Nadja Cereghetti, **Melissa A. Penny**  
Swiss Tropical and Public Health Institute, Basel, Switzerland

A gap remains in providing personal protection for preventing infections in children and other vulnerable populations experiencing the highest burden of malaria. The development of next-generation medical interventions and immune therapies is guided by Target Product Profile documents that support decisions to prioritize candidates and ensure unmet health needs and targets are reached. Mathematical modelling can provide quantitative evidence to support identifying minimum necessary product requirements to reach a desired health goal. Potential impact is estimated by capturing the interaction of new interventions, malaria transmission dynamics, and health system properties in models of malaria transmission and control. Together with key stakeholders, the Bill & Melinda Gates Foundation and Swiss Tropical and Public Health Institute developed a collaboration platform to foster effective communication between stakeholder groups and align product requirements with health targets throughout the research and development (R&D) process. Within this ongoing collaboration platform, we aim to shape key performance characteristics guiding future R&D efforts. Quantitative evidence to support priority questions on use cases, intervention characteristics and implementation specifics is provided by combining malaria modelling and simulation experiments with machine learning approaches. This allows us to map a large parameter-space of candidate properties and investigate their potential public-health impact. Here, we present conclusions from a first stakeholder convening including a roadmap towards consensus decision making between stakeholder groups. Additionally, we report results from a modelling exercise in which we evaluated the product characteristics of a novel anti-infective intervention over varying age eligibility, seasonal patterns, deployments, and health system accessibilities. Subsequently, we carved out the trade-offs between further optimisation of intervention characteristics through further research and delay in implementation of new interventions.

0730

### SMARTNET INITIATIVE: HARNESSING MOBILE TECHNOLOGY TO ANSWER KEY QUESTIONS ABOUT INSECTICIDE-TREATED NETS (ITN) USAGE AND MALARIA ILLNESSES IN MALAWI

**Michael Kayange - Malawi SmartNet Initiative**<sup>1</sup>, Akuzike Banda - Malawi SmartNet Initiative<sup>1</sup>, Austin Gumbo - Malawi SmartNet Initiative<sup>1</sup>, Taonga Mafuleka - Malawi SmartNet Initiative<sup>1</sup>, Monica Bautista - Malawi SmartNet Initiative<sup>2</sup>, Maurizio Beccherle - Malawi SmartNet Initiative<sup>3</sup>, Mariela Chacaltana - Malawi SmartNet Initiative<sup>4</sup>, Sabyasachi Das - Malawi SmartNet Initiative<sup>3</sup>, Edson Dembo - Malawi SmartNet Initiative<sup>2</sup>, Caroline Desrousseaux - Malawi SmartNet Initiative<sup>4</sup>, Edward Dzanjalimodzie - Malawi SmartNet Initiative<sup>4</sup>, Emmie Francaoise - Malawi SmartNet Initiative<sup>4</sup>, Lilia Gerberg - Malawi SmartNet Initiative<sup>5</sup>, Reuben Granich - Malawi SmartNet Initiative<sup>4</sup>, Shannon Harmon - Malawi SmartNet Initiative<sup>5</sup>, Collins Kwizombe - Malawi SmartNet Initiative<sup>2</sup>, Joseph Maisano - Malawi SmartNet Initiative<sup>4</sup>, Isaac Manda - Malawi SmartNet Initiative<sup>6</sup>, Pius Masache - Malawi SmartNet Initiative<sup>2</sup>, Elias Mwalabu - Malawi SmartNet Initiative<sup>7</sup>, Manoj Prabhu - Malawi SmartNet Initiative<sup>3</sup>, Joseph Raji - Malawi SmartNet Initiative<sup>7</sup>, Patrick Sieyes - Malawi SmartNet Initiative<sup>4</sup>, Harkirat Singh - Malawi SmartNet Initiative<sup>4</sup>, Harsha Thirumurthy - Malawi SmartNet Initiative<sup>8</sup>, Vipin Yadav - Malawi SmartNet Initiative<sup>3</sup>

<sup>1</sup>National Malaria Control Program - Ministry of Health and Population of Malawi, Lilongwe, Malawi, <sup>2</sup>U.S. President's Malaria Initiative, Lilongwe, Malawi, <sup>3</sup>Dure Technologies, Geneva, Switzerland, <sup>4</sup>Vestergaard, Lausanne,

Switzerland, <sup>5</sup>U.S. President's Malaria Initiative, Washington, DC, United States, <sup>6</sup>FHI360, Durham, NC, United States, <sup>7</sup>Global Health Supply Chain Program - Procurement and Supply Management Malawi, Lilongwe, Malawi, <sup>8</sup>University of Pennsylvania, Philadelphia, PA, United States

Malaria remains a leading cause of morbidity and mortality in Malawi, with over 5 million confirmed cases in 2019. As the country targets elimination of malaria by 2030, increasing the distribution and use of insecticide-treated mosquito nets (ITNs) could help to reduce malaria incidence. To obtain real-time data on ITN ownership, use, and malaria cases, the Malawi SmartNet Initiative used 2/3/4G mobile technology to reach ITN owners across Malawi. Of the 300,000 recipients of ITNs at antenatal clinics in March 2020, 54,682 subsequently voluntarily dialed a short code and of those 18,555 (34%) completed an Unstructured Supplementary Service Data (USSD) mobile phone survey; 14,947 (80%) respondents completing surveys also provided the unique ITN code. Of the respondents between March 2020 and March 2021, 12,671 (68%) were male and 38% were 15-24 years old. Respondents reported owning an average of 1.9 ITNs per household. The total number of household members was reported as 71,694 (average 4) of whom an average of 75% members reported as sleeping under a net the previous night. Nearly 2,561 (17%) respondents reported a household member had malaria in the past three months. Limitations include potential lack of representativity of this sentinel sampling approach; biases include increased response from those who are literate and have mobile phones. Although generalizability of these data remains to be determined, through future surveys, this sentinel engagement with 21,434 individuals is one of the largest conducted in African malaria control and provides opportunities to both disseminate and collect information in real time.

#### 0731

### ACCESS, ACCEPTABILITY AND UPTAKE OF AN EXTENDED MALARIA SERVICE PACKAGE FOR REACHING UNDERSERVED POPULATIONS OF FOREST GOERS

**Khin Lin**<sup>1</sup>, Kyawt Mon Win<sup>2</sup>, Feliaciano Monti<sup>3</sup>, William Hawley<sup>4</sup>, Jimee Hwang<sup>5</sup>, John Gimnig<sup>4</sup>, Mark Maire<sup>6</sup>, Alexander Moran<sup>7</sup>, Hsu Thadar<sup>8</sup>, Kyaw Myint Tun<sup>1</sup>

<sup>1</sup>University Research Co., LLC, Yangon, Myanmar, <sup>2</sup>National Malaria Control Programme, Ministry of Health and Sports, Nay Pyi Taw, Myanmar, <sup>3</sup>PMII USAID, Yangon, Myanmar, <sup>4</sup>Entomology Branch, Division of Parasitic Diseases and Malaria, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>5</sup>U.S. President's Malaria Initiative, Malaria Branch, Division of Parasitic Diseases and Malaria, U.S. Centers for Disease Control and Prevention, Atlanta, GA, United States, <sup>6</sup>U.S. President's Malaria Initiative, U.S. Centers for Disease Control and Prevention, Yangon, Myanmar, <sup>7</sup>University Research Co., LLC, Chevy Chase, MD, United States, <sup>8</sup>University Research Co., LLC, Palaw, Myanmar

Reported malaria cases in Myanmar declined 88% from 2012-2019. However, the declining trend has stabilized over the past 3 years, particularly among forest goers. Conventional malaria services are often not accessible among forest goers. A mixed method was applied to assess the access, acceptability and uptake of an extended malaria service package including topical mosquito repellent, a long-lasting insecticidal net, and health messaging. A voucher system was introduced to identified eligible forest goers through Village Malaria Workers (VMW) and Mobile Malaria Workers, allowing participants with vouchers to access the continuum of malaria service packages including replenishment of topical repellents, and malaria diagnosis and treatment. The study was conducted in 38 villages of Tanintharyi Region and Rakhine State where there were stable malaria transmission and presence of a VMW. Forest goers ≥5 years of age were screened, and 2,624 participants (69% male) were enrolled and provided vouchers for enhanced and ongoing malaria services during March to August 2020. Participant ages ranged from 5-9 years with a mean and standard deviation of 36±14 years. Most were of the Kayin (50%) and Bamar (43%) ethnics. A total of 2,624 tubes of repellents were distributed at enrollment while 2,601 tubes were replenished until February 2021. Of the participants returning from the forest, 54%

reported consistent use of repellents while in the forest. Over half of the participants (51%) accessed malaria testing with 2,210 rapid diagnostic tests conducted resulting in 30 (1.4%) malaria positives. Key informants revealed that the vouchers created the social bond between VMWs and forest goers for providing and accepting continuum of malaria service packages over 1 year of field survey period. Forest goers accepted the vouchers as tokens for their right to receive free care services from VMWs. Vouchers were kept by VMWs who used them as a tool for tracking the malaria services provided to every voucher holder. This client-oriented voucher mechanism represents an innovative approach to deliver malaria services packages to reach underserved forest goers.

#### 0732

### EVALUATING INDIVIDUAL AND COMMUNITY-LEVEL FACTORS ASSOCIATED WITH MALARIA KNOWLEDGE, ATTITUDES, AND PRACTICES USING BASELINE DATA FROM A COMMUNITY-RANDOMIZED TRIAL ASSESSING THE EFFECTIVENESS OF TARGETED ACTIVE MALARIA CASE DETECTION AMONG HIGH-RISK POPULATIONS IN SOUTHERN LAO PDR

**Teah R. Snyder**<sup>1</sup>, Emily Dantzer<sup>2</sup>, Bouasy Hongvanthong<sup>3</sup>, Francois Rerolle<sup>2</sup>, Ratanaxay Phetsouvanh<sup>4</sup>, Adam Bennett<sup>2</sup>, Andrew A. Lover<sup>1</sup>

<sup>1</sup>University of Massachusetts Amherst, Amherst, MA, United States, <sup>2</sup>University of California, San Francisco, San Francisco, CA, United States, <sup>3</sup>Center for Malariology, Parasitology and Entomology, Ministry of Health, Vientiane, Lao People's Democratic Republic, <sup>4</sup>Department of Communicable Disease Control, Ministry of Health, Vientiane, Lao People's Democratic Republic

Despite great global progress towards malaria elimination, it remains a substantial source of morbidity and mortality in many regions. The Health Belief Model suggests that an individual's knowledge and perception of disease risk can influence the likelihood of prevention behaviors. However, few studies have investigated the relationship between socioeconomic factors (SES) and knowledge, attitudes, and practices (KAP) regarding malaria in Asia. The literature regarding malaria-specific KAP in the Greater Mekong Subregion of Southeast Asia, including Laos, is particularly sparse. We evaluated associations using baseline cross-sectional data from the population-based ACME-Lao study, a randomized trial among 1313 households in Laos from 2017 - 2018. Heads of households completed a questionnaire including questions on SES and malaria-specific KAP. Socioeconomic variables include highest level of education, primary occupation, and owned assets as a proxy for income. Composite variables were derived separately for knowledge, attitudes, and prevention practices. Knowledge was evaluated with six questions regarding malaria signs, symptoms, and transmission. Attitudes were evaluated with six questions regarding the acceptability of malaria testing and treatment for themselves and their children. Prevention practices were assessed with a single question that asked about a variety of practices; outcomes were recorded as the total number of behaviors utilized. Non-composite variables for treatment-seeking behavior, including type of treatment sought and time to treatment, were evaluated for the overall study population and for those who reported illness in the previous two weeks using ordinal logistic regression models with adjustment for potential confounders. Analyses are ongoing with results anticipated in August 2021. This study is innovative in being the first to study the relationship between SES and malaria-specific KAP among a general population sample in the Lao People's Democratic Republic to support evidence-based programming to address residual malaria transmission.

### PROTECTING ADOLESCENT GIRLS AGAINST MALARIA: THE NEED FOR ADAPTED POLICIES AND HEALTH SYSTEMS TO BENEFIT AN UNDERSERVED NEGLECTED POPULATION

**Abena Poku-Awuku**<sup>1</sup>, Silvia Ferazzi<sup>1</sup>, Valentina Buj<sup>2</sup>, Clara Menendez<sup>3</sup>, Marcy Levy<sup>4</sup>, Clara Pons-Duran<sup>3</sup>, Joanna Lai<sup>4</sup>, Raquel Gonzalez<sup>3</sup>, Katya Halil<sup>1</sup>, Maud Majeres-Lugand<sup>1</sup>

<sup>1</sup>Medicines for Malaria Venture, Vernier, Switzerland, <sup>2</sup>UNICEF, Geneva, Switzerland, <sup>3</sup>ISGlobal, Barcelona, Spain, <sup>4</sup>UNICEF, New York, NY, United States

Malaria is a largely unrecognized and under-investigated, but significant, cause of death in adolescent girls. However, a review of the literature reveals limited evidence on the specific impact of malaria on adolescent girls. Lack of recent age and sex-disaggregated data leaves policymakers without solid evidence to develop sound policies and programmes to reduce the burden of malaria in adolescent girls. This policy paper, developed by ISGlobal, MMV and UNICEF, presents the socio-cultural, socio-economic and biological factors that make adolescents girls more vulnerable to malaria. Regional mortality and morbidity estimates from the World Health Organization's data portal for adolescents living in sub-Saharan Africa and South-East Asia were assessed to understand whether adolescent girls are at higher risk of malaria in comparison to adolescent boys. Adolescent girls (aged 10-19) in sub-Saharan Africa have a higher risk (7%) of dying from malaria than adolescent boys. This is slightly more pronounced in younger adolescent girls (aged 10-14) who have a 12% higher mortality rate than younger adolescent boys and a 36% higher mortality rate than older adolescent girls (aged 15-19). Adolescent girls also have higher malaria morbidity rates (9% more DALYs) than adolescent boys. Younger adolescent girls have 11% more DALYs than younger adolescent boys and 40% more DALYs than older adolescent girls. In South-East Asia, adolescent girls have a 36% higher malaria mortality rate than adolescent boys. Younger adolescent girls have a 28% higher mortality than younger adolescent boys and a 46% higher mortality rate than older adolescent girls. Although some progress has been made, malaria mortality rates among adolescents, especially girls, have stagnated. The authors advocate for a revision of malaria policies and plans to include strategies tailored for adolescent girls to accelerate towards malaria elimination targets. They call for the generation of in-depth evidence on the impact of malaria on adolescent girls, increased political commitment, and community mobilization.

<sup>1</sup>Department of Medical Microbiology, Radboud university medical center, Nijmegen, Netherlands, <sup>2</sup>Centre National de Recherche et de Formation sur le Paludisme, Ouagadougou, Burkina Faso, <sup>3</sup>MRC Tropical Epidemiology Group, London School of Hygiene & Tropical Medicine, London, United Kingdom, <sup>4</sup>Institute for Disease Modeling, Bellevue, WA, United States, <sup>5</sup>Department of Preventive Medicine, Northwestern University, Chicago, IL, United States, <sup>6</sup>Department of Immunology and Infection, London School of Hygiene & Tropical Medicine, Faculty of Infectious and Tropical Diseases, London, United Kingdom

Many malaria-infected individuals in endemic countries do not experience symptoms that prompt treatment-seeking and can remain infectious to mosquitoes for many months. These asymptomatic infections are a major obstacle in the path to malaria elimination, and reductions in malaria burden could be achieved by detecting and treating them early. In a

cluster-randomized trial in Burkina Faso, in an area of intense, seasonal malaria, we assessed the impact of two interventions on the prevalence and transmissibility of malaria infections. The interventions included (i) enhanced community case management (CCM), comprising active weekly screening for fever, with treatment of rapid diagnostic test positive febrile individuals, or (ii) monthly screening and treatment (MSAT) using standard rapid diagnostic tests. 180 compounds with 906 subjects were randomized to: Arm 1 - control; Arm 2 - enhanced CCM; or Arm 3 - enhanced CCM combined with MSAT. Interventions were implemented over 16 months, with parasitemia and gametocytemia monitored in 4 start/end season cross-sectional surveys and a rolling survey. At the start of the study, parasite prevalence by qPCR was 64%, and 61% of these infections carried gametocytes. Most infections in cross-sectional surveys were asymptomatic (98.6% [1336/1355]), and asymptomatic infections were as transmissible to mosquitoes in membrane feeding assays (4.5% [35/771]) as symptomatic infections (5.7% [7/123]). A total of 1159 clinical malaria episodes were passively detected at local health facilities; 108 infections detected by CCM; and 629 infections detected by MSAT. In each cross-sectional survey there was a significant impact of CCM plus MSAT. Notably, at the end of the dry season, qPCR parasite prevalence was reduced to 7.6% in Arm 3 compared to 36.6% in Arm 1, and transmissible gametocyte prevalence (>1000p/mL) was reduced to 1.1% in Arm 3 compared to 17.2% in Arm 1. This study could pave the way for a simple yet effective method to control malaria burden in areas of high transmission by abrogating infections before clinical presentation and the development of transmissible gametocytemia.

### FROM CONTROL TO ELIMINATION: A SPATIAL-TEMPORAL ANALYSIS OF MALARIA ALONG THE CHINA-MYANMAR BORDER

**Fang Huang**<sup>1</sup>, Li Zhang<sup>1</sup>, Jing-Bo Xue<sup>1</sup>, Hong-Ning Zhou<sup>2</sup>, Aung Thi<sup>3</sup>, Shui-Sen Zhou<sup>1</sup>, Jun Zhang<sup>4</sup>, Zhi-Gui Xia<sup>1</sup>, Xiao-Nong Zhou<sup>1</sup>

<sup>1</sup>National Institute of Parasitic Diseases, China CDC, Shanghai, China, <sup>2</sup>Yunnan Institute of Parasitic Diseases, Puer, China, <sup>3</sup>Department of Public Health, Ministry of Health and Sports, Myanmar, Nay Pyi Taw, Myanmar, <sup>4</sup>Health Poverty Action East Asia Programme Office, Kunming, China

Malaria cases have declined significantly along the China-Myanmar border in the past 10 years and China has achieved elimination. The aim of this study is to investigate the epidemiology of malaria along the border, will identify challenges in the progress from control to elimination. National reported malaria cases from China and Myanmar, along with the data of 18 Chinese border counties and 23 townships in Myanmar were obtained from a web-based diseases information reporting system in China and the national malaria control program of Myanmar, respectively. Epidemiological data was analyzed, including the number of reported cases, annual parasite index and proportion of vivax infection. Spatial mapping of the annual parasite index at county or township level in 2014 and 2018 was performed by ArcGIS. The relationship of malaria endemicity on both sides of the border was evaluated by regression analysis. The number of reported malaria cases and API declined in the border counties or townships. In 2014, 392 malaria cases were reported from 18 Chinese border counties, including 8.4% indigenous cases and 91.6% imported cases, while the highest API (0.11) was occurred in Yingjiang County. There have been no indigenous cases reported since 2017, but 164 imported cases were reported in 2018 and 97.6% were imported from Myanmar. The average API in 2014 in 23 Myanmar townships was significantly greater than that of 18 Chinese counties ( $P < 0.01$ ). However, the API decreased significantly in Myanmar side from 2014 to 2018 ( $P < 0.01$ ). The number of townships with an API between 0-1 increased to 15 in 2018, compared to only five in 2014, while still four townships had API > 10. *Plasmodium vivax* was the predominant species along the border. The number of reported malaria cases and the proportion of vivax infection in the 18 Chinese counties were strongly correlated with those of the 23 Myanmar townships ( $P < 0.05$ ). In order

to sustain the elimination along the China-Myanmar border and prevent the malaria re-establishment, continued political, financial and scientific commitment is required.

### UNDERSTANDING MALARIA KNOWLEDGE, PREVENTIVE PRACTICES, AND CARE-SEEKING BEHAVIOR AMONG COMMUNITIES IN THE SHARED BORDER AREAS OF ANGOLA, NAMIBIA, AND ZAMBIA, AND IDENTIFYING OPPORTUNITIES FOR IMPROVEMENT

**Alyse Maglior**<sup>1</sup>, Alexandra Gordon<sup>1</sup>, Rebecca J. Vander Meulen<sup>1</sup>, Jesse Heitner<sup>2</sup>, Constance Njovu<sup>3</sup>, João Lino Rafael<sup>4</sup>, Stefanus Nangombe<sup>5</sup>, José Franco Martins<sup>6</sup>, Petrina Uusiku<sup>7</sup>, Busiku Hamainza<sup>8</sup>

<sup>1</sup>Isdell:Flowers Cross Border Malaria Initiative, J.C. Flowers Foundation, New York, NY, United States, <sup>2</sup>Aceso Global, Washington, DC, United States, <sup>3</sup>Isdell:Flowers Cross Border Malaria Initiative, Anglican Diocese of Lusaka, Lusaka, Zambia, <sup>4</sup>Isdell:Flowers Cross Border Malaria Initiative, Anglican Diocese of Angola, Luanda, Angola, <sup>5</sup>Isdell:Flowers Cross Border Malaria Initiative, Namibia Anglican Community Development Organization, Windhoek, Namibia, <sup>6</sup>National Malaria Control Program, Angola Ministry of Health, Luanda, Angola, <sup>7</sup>National Vector-borne Diseases Control Programme, Namibia Ministry of Health and Social Services, Windhoek, Namibia, <sup>8</sup>National Malaria Elimination Centre, Zambia Ministry of Health, Lusaka, Zambia

A cross-sectional survey of 10,143 households assessed malaria knowledge, insecticide treated net (ITN) use and access, indoor residual spraying (IRS) acceptance, and care-seeking behavior among communities in six Provinces/Regions of the Isdell:Flowers Cross Border Malaria Initiative program areas along the shared borders of Angola, Namibia, and Zambia—countries collaborating through the Elimination Eight Initiative to eliminate malaria in the region by 2030. The survey, conducted from June - September 2020 using a structured questionnaire on the KoboCollect platform, established baseline indicators that will be tracked annually for five years and indicated areas for further attention. To reduce malaria incidence, there is need for increased ITN access: though reported population ITN use (average of each household's percentage) was low: 36.5% (Angola), 56.4% (Namibia), and 59.6% (Zambia), the ITN use:access ratio was high: 0.85 (Angola), 0.74 (Namibia), and 1.04 (Zambia, indicating that mean users per net exceed 2), showing the gap in ITN use can be largely attributed to lack of access. IRS coverage must increase in areas where it is indicated and be well announced (the primary reason for not receiving IRS was that it was not offered, and the secondary was not being home at time of spraying), and in some regions, demand generation should increase (IRS refusals were low [ $<1.0\%$ ] in Angola and Namibia, but considerably higher [15.0%] in Zambia). In addition, to reduce malaria deaths, treatment seeking must be more prompt: among respondents whose child  $<5$  years had a fever in the past two weeks, 91.6% sought care from a health facility or community health worker, though only 57.1% did so within 24 hours of fever onset. To eliminate malaria, there is need for increased knowledge about low-density infections; though knowledge of the cause and symptoms of malaria was high in most areas ( $\geq 80.0\%$ ), only 63.0% in Namibia, an area nearing elimination, knew of the possibility of infections without symptoms. These findings can inform strategic planning and behavior change messaging that is targeted and tailored to this key cross-border area.

### IMPACT OF SPATIAL VARIATION IN ACCESS TO COMMUNITY HEALTH WORKERS ON MALARIA OUTCOMES AMONG CHILDREN IN A HIGH TRANSMISSION REGION IN ZAMBIA

**Molly Mantus**<sup>1</sup>, Jean-Bertin Kabuya<sup>2</sup>, Dickson Phiri<sup>3</sup>, Enock Banda<sup>4</sup>, Mulakwa Kamuliwo<sup>5</sup>, James Sichivula<sup>2</sup>, Timothy Shields<sup>1</sup>, Gershon Chongwe<sup>2</sup>, William Moss<sup>1</sup>, Matthew Ippolito<sup>6</sup>

<sup>1</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, United States, <sup>2</sup>Tropical Diseases Research Centre, Ndola, Zambia, <sup>3</sup>Department of Health Management Information Systems, Saint Pauls General Hospital, Nchelenge, Zambia, <sup>4</sup>PATH, Lusaka, Zambia, <sup>5</sup>Program for the Advancement of Malaria Outcomes, Lusaka, Zambia, <sup>6</sup>Johns Hopkins University School of Medicine, Baltimore, MD, United States

Integrated community case management (iCCM) was implemented in Nchelenge District in northern Zambia where malaria parasite prevalence is greater than 50 percent and malaria cases make up 35 percent of all pediatric hospital admissions. The iCCM program in Nchelenge District deployed 386 community health workers (CHWs) trained to diagnose and treat malaria in the community and refer patients who require hospital level care, with the aim to facilitate earlier treatment of malaria and prevent malaria deaths. Geolocations were available for 332 of the 386 CHWs. We assessed the impact of iCCM-expanded access to care in a 1:2 time-matched case-control study (n=159 cases). Access to care was approximated by the density of CHWs within 1 km of a patient's village, and the association between CHW density and in-hospital mortality was examined using adjusted conditional logistic regression models. Secondary analyses were conducted to assess the potential impact of CHW access on mortality in subgroups of patients. In sensitivity analyses, we examined larger (2 km) and smaller (0.5 km) radii and limited the analysis to an 8-month period during which CHWs were verified to be active. Access to CHWs was not associated with in-hospital mortality and this was seen across all subgroups and sensitivity analyses. The negative finding may be explained by saturation—almost 100 percent of patients came from villages with 1 or more CHWs within a 1 km radius—or the presence of other barriers to access that have not been surmounted by the current CHW deployment, such as the low availability of emergency transport systems and pre-referral therapies.

Malaria elimination faces the challenge of taking into account a specifically vulnerable category: isolated and mobile (often cross-border) populations, usually linked to clandestine activities. We previously developed an innovative approach for improved management of malaria attacks in these situations: the Malakit project. Implemented among illegal gold miners, reached at their staging areas at French Guiana's borders, its strategy consists in distributing kits for self-testing and self-treatment following specific training. The last challenge to meet is the radical cure of latent *Plasmodium vivax* infections, which otherwise lead to spontaneous recurrences and fuel vector-borne transmission. CUREMA will be a mixed-methods interventional multicentric study based on a pragmatic design. Our purpose is to test an intervention model that addresses malaria elimination in a mobile and isolated population, producing results that can be transferred to many contexts facing the same challenges around the world. Our target is the hard-to-reach, mobile population working

in informal gold mining in the Amazon forest of the Guiana Shield. Our innovative approach is to combine several new tools for malaria case management and offer them at strategic cross-border staging areas. Our intervention will have an effect on asymptomatic carriage of *Plasmodium vivax* hypnozoites (radical cure of individuals at risk, Module A) and on malaria episodes occurring in extremely remote areas (distribution of Malakits, Module B). With this study we will: (1) assess the effectiveness of the overall intervention on malaria transmission among the target population; (2) identify the best medication (primaquine or tafenoquine) for Module A in terms of acceptability and compliance; (3) assess levers and obstacles to carrying out this intervention in a pre-elimination setting. The intervention evaluation will be conducted by remote longitudinal follow-up of participants and by quantitative (pre/post) and qualitative surveys.

Spatial and temporal malaria distribution and the progress towards malaria elimination is known to be heterogenous in countries that have transitioned their malaria strategies from control to elimination. A malaria stratification exercise can categorise the levels of transmission intensities in districts and their potential to reach and maintain zero malaria status. The Southern African Development Community Malaria Elimination 8 (E8) sought to use the WHO subnational verification criteria to identify districts that reach and maintain zero malaria for a period of three years. Border districts are of particular interest since border malaria often impedes progress towards elimination in low burden countries. The E8 subregion collects monthly malaria data from border districts from its member countries to track progress towards elimination at district level. A criterion for subnational elimination, modelled from the WHO malaria elimination certification toolkit was used. Malaria receptive border districts which reported zero local malaria for three consecutive years were identified and evidence of receptivity and the interruption of transmission verified by a sub-national verification committee. Subnational elimination of malaria can provide an incentive to intensify efforts, particularly at local level, and pave the way towards national elimination and WHO malaria free certification in a country. Districts that reduce malaria and ultimately reach zero will require sustained resources to prevent the reestablishment of malaria in a context where country priorities may shift to medium or high transmission districts.
